Introduction

Because of increasing interest in methods for controlling nonpoint sources of water pollution, the Environmental Law Institute (ELI) has been identifying and collecting *enforceable* provisions in state laws that bear on, or that could be brought to bear on, discharges from these sources. Nonpoint source discharges, which consist generally of polluted runoff from farms, forests, land development and other activities, are not regulated under the federal Clean Water Act's National Pollutant Discharge Elimination System permitting program.[1] Instead they are addressed primarily through nonregulatory means, such as planning, incentive and cost-share mechanisms, voluntary Best Management Practices (BMPs), and other approaches.[2]

Yet, increasingly, states are finding it necessary to deal with nonpoint source discharges that cannot be prevented, controlled, or abated adequately by these means. A broad summary of existing enforceable state laws was published by ELI in late 1997 as *Enforceable State Mechanisms for the Control of Nonpoint Source Water Pollution* (available on the Institute's website - www.eli.org). That study identified the types of enforcement-based state laws that apply to nonpoint source discharges, and the opportunities and obstacles affecting their use.[3] This new study builds upon the prior study. It provides a state-by-state summary of enforcement-based laws that are potentially applicable to nonpoint source water pollution.

Scope of Study

This study consists of 52 summary reports for the states, the District of Columbia, and the Commonwealth of Puerto Rico. The laws identified for each state do not represent the totality of that state's efforts to control nonpoint source water pollution – such as the voluntary, technical assistance, cost-share and other provisions that typically serve as the core of most state programs. Rather, the summary reports identify only the *enforceable* provisions that can apply to nonpoint source discharges in each state.

For purposes of this study, enforceability is defined as the ability of the state to impose a sanction upon an unwilling person or entity. This definition excludes provisions that simply prescribe the withholding of a benefit – such as the many forest and agricultural tax laws that require repayment of back taxes if a management plan is violated, or laws that allow a state agency to condition receipt of cost-share moneys upon compliance by the recipient.

The reader should note that the state laws identified are ones that *could* be used to address nonpoint source pollution. The summaries are not limited to state laws that are currently being used in this way. State laws written at various times and for various purposes can often be applied in new ways. Knowledge of existing enforceable laws is becoming increasingly important as many states attempt to deal with large inventories of waters that are impaired, in whole or in part, by nonpoint sources. States that must prepare load allocations for nonpoint sources under Total Maximum Daily Loads (TMDL) requirements, for example, will need such enforceable mechanisms to assure that the load allocation targets can be met.[4] Coastal states also need to demonstrate their ability to use enforceable mechanisms in order to continue to receive coastal zone

R0017022

and nonpoint source financial assistance from the federal government under the terms of the Coastal Zone Act Reauthorization Amendments of 1990.[5]

The state reports are, in essence, inventories of provisions that could be pressed into service to deal with nonpoint source water pollution discharges or activities that frequently cause such pollution. Because they are available without new legislation, these provisions present state agencies, governors, attorneys general, and citizen groups with potential tools that can be used in improving water quality.

Organization of State Reports

The enforcement-based provisions described in each state report are grouped under six headings for purposes of easy reference and to facilitate comparison among states. States with lengthy summary reports do not necessarily have stronger or more comprehensive laws than those with shorter reports. Nor do the summaries show how the state is using its array of tools.

The first three headings appear under the general category "Discharge Prohibitions." They are intended to identify enforceable state provisions that apply to nonpoint source discharges without regard to the type of source or activity creating the discharge:

> *Water Pollution Control Law* is intended to identify provisions in the state's primary water pollution law or environmental code that can be used as a basis for enforcement against some (or any) discharges from nonpoint sources. This section includes provisions in these laws that are broad enough to cover nonpoint sources even when, to date, they have been used only to address point source discharges. The reader should note applicable limitations, such as laws that cover only discharges of "waste," or laws that require the government to prove that the discharge caused impairment of the receiving waters.
>
> *Other Discharge Limitations* is intended to identify nuisance-type enforceable provisions, laws that protect public water supplies from impairment, public health laws, and other miscellaneous (often older) laws that apply to nonpoint source discharges. Often these provisions are usable only where there is a demonstrated harm, or where particular listed substances are discharged into the state's waters.
>
> *Fish/Fisheries Laws* is intended to identify provisions in state fish and game laws that impose discharge prohibitions or limitations, and provisions that may be used to take enforcement action when a nonpoint discharge results in taking, death, or injury to fish or other aquatic life.

The next three headings are grouped under the general category "Operational Requirements." This category is intended to identify laws that impose enforceable *operating* requirements -- not just discharge prohibitions -- for *three* particular kinds of activities that often result in nonpoint source water pollution discharges:

> *Forestry Requirements* is intended to identify enforceable regulatory requirements applicable to silviculture activities, including the harvesting of timber. If forestry

enforcement is only under the water pollution control law, however, this section may indicate that no specific operating requirements apply. For example, forestry best management practices that are not themselves enforceable are not listed here, even though the state may take enforcement action under its water pollution law if forestry operations cause water pollution incidents.

Agriculture Requirements is intended to identify enforceable regulatory requirements applicable to agricultural activities. It may include limits on soil erosion, pesticide use, fertilizer use, manure spreading, and regulation of animal operations with respect to nonpoint source discharges. This section does not report on state *point source* regulation of concentrated animal feeding operations (CAFOs) required under the federal Clean Water Act, but may identify state programs that address a wider universe of animal feeding operations than do federal CAFO requirements, or state programs that impose specific licensing, setback, manure management, or other requirements particularly relevant to nonpoint source pollution.

Development and Other Earth-Disturbing Activities is intended to identify enforceable state requirements applicable to excavation and land-clearing activities. In general, it does not include provisions that simply implement the urban stormwater *point source* requirements of the federal Clean Water Act.

Enforceable requirements applicable to some other kinds of nonpoint sources are not directly addressed in this compendium, such as laws addressing on-lot sewage systems, dams and hydromodification projects, marinas, and mineral development.

Conclusions

This review of the laws in 50 states, Puerto Rico, and the District of Columbia indicates that most states have a number of enforceable authorities that can be used to address various nonpoint source discharges, but that legal coverage of all nonpoint sources is often incomplete. The laws contain numerous exemptions, especially for agriculture and forestry. Much regulation under state laws is left up to local entities. These include conservation districts (only some of which have regulatory and enforcement powers) and municipal governments (which may or may not address nonpoint sources under their zoning and regulatory powers). The implications of the many exemptions and limitations are discussed in detail in ELI's 1997 study.

This almanac of enforceable state laws is intended to raise the level of visibility of these enforceable mechanisms, and to serve as a resource to state and federal legislators and policy makers seeking to control nonpoint source water pollution in the years ahead. The array of existing enforceable state laws that can be brought to bear on nonpoint source discharges is both impressive and discouraging. Impressive because of the diversity and ubiquity of state legal mechanisms. Discouraging because of the inconsistent treatment of similar problems from one state to the next, and because of the significant gaps in coverage that still exist in many states.

Endnotes

1. 33 U.S.C. § 1342; *see* definitions of "discharge of a pollutant" and "point source" at 33 U.S.C. § 1362(12), (14).
2. 33 U.S.C. § 1329, added to the Clean Water Act in 1987, provides a federal basis for planning and federal funding of state nonpoint source control programs using these tools.
3. *See also*, James M. McElfish, Jr., "State Enforcement Authorities for Polluted Runoff," 28 Envtl. L. Rep. (Envtl. L. Inst.) 10181 (April 1998).
4. *See* 33 U.S.C. § 1313(d).
5. 16 U.S.C. § 1455(d)(16). All submitted state programs were conditionally approved by the Environmental Protection Agency and the National Oceanic and Atmospheric Administration, but most need to demonstrate their ability to use the enforceable mechanisms identified in their submittals and/or to develop additional mechanisms. *See* http://www.nos.noaa.gov/ocrm/czm/6217/findings.html.

ALABAMA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Alabama's water pollution control law, which requires a permit for discharge of "pollution," provides a basis for enforcement against some nonpoint source discharges, but regulations exclude nonpoint source discharges from agriculture and silviculture from the permit requirement. The state also maintains that it may directly enforce against nonpoint sources, if they cause violation of water quality standards. In addition, the law provides two general authorities which allow the state to take enforcement action to deal with any type of water pollution resulting from negligence, or any water pollution that produces a health hazard.

- "Every person, prior to discharging any new or increased pollution into any waters of this state, shall apply to the commission [now the Alabama Department of Environmental Management (ADEM)] in writing for a permit and must obtain such permit before discharging such pollution."[1] But although Alabama's permit requirement is not limited to point sources,[2] nevertheless a permit is not required for discharges "from non-point source agricultural and silvicultural activities."[3]

- Enforceable provisions may include water quality standards.[4] In addition to setting standards, the regulations only require specifically, however, that "nonpoint source discharges shall use best management practices adequate to protect water quality consistent with the Department's nonpoint source control program" with respect to antidegradation of waters meeting water quality criteria and outstanding state and national waters.[5] The referenced program, however, appears to be largely based on cost-shares and technical assistance.[6]

Enforcement of these provisions follows this procedure: "Whenever the commission [ADEM] determines that any person is violating, or is about to violate, any of the provisions of this chapter, or any rule or regulation or order or permit...thereunder, [ADEM] may notify such person of such determination... Within such time as may be specified in such notice, such person shall file with the commission [ADEM] a full report showing steps that have been taken and are being taken to control such pollution. Thereupon, the commission [ADEM] may make such orders as in its opinion are reasonable."[7] Enforcement includes orders, injunctions, civil actions for damages for pollution (including "any reasonable costs to prevent, minimize, or clean up any damage," costs for restocking of fish killed, civil penalties of $100 to $25,000 per day, and criminal penalties for willful violation or grossly negligent violations.[8]

- The law also provides that ADEM, the attorney general or any district attorney "may commence a civil action for damages for pollution of the waters of the state including, but not limited to, any reasonable costs to prevent, minimize or clean up any damage resulting from the wrongful act, omission or negligence of a person."[9]

• Furthermore, "Any and all pollution is...declared to be a public nuisance and, if it creates, or is about to create, a health hazard, shall be subject to immediate control of the commission [ADEM] by order or injunction. Any order issued under this subsection shall be deemed to be final and conclusive for the purposes of this chapter."[10]

Other Discharge Limitations

• Nuisance liability is noted above.

• Alabama law gives some rulemaking powers with respect to pollution discharges to the department of conservation and natural resources.[11] But the department cannot make "any rules or regulations which will hamper industry or which will interfere with the operation of any industrial plant or plants or any industrial operation...[or] which will hamper or interfere with the construction of dams built for impounding private waters...[or] which will in any way hamper or interfere with the maximum development of private waters as a source of food, farm income and recreation in the state of Alabama..."[12]

Fish/Fisheries Laws

• The taking or killing of any fish by depositing in any public stream or body of water "any poison, poisonous substance...or other deleterious or poisonous matter" is an offense.[13] The taking or killing of any fish by any means other than those expressly allowed by law or regulation of the department of conservation and natural resources is an offense.[14] These are punishable as misdemeanors, with a fine of $50 to $200.

OPERATIONAL REQUIREMENTS

Forestry Requirements

• The State Forestry Commission has power to operate state forests and to administer all laws relating to timber and forestry.[15] "The commission shall have the power to adopt and promulgate rules and regulations pertaining to all phases of forestry within this state, which rules and regulations when adopted shall have the force and effect of law."[16] However, the commission has not adopted enforceable nonpoint source regulations, relying instead on voluntary BMPs. The commission has adopted licensing requirement for foresters.[17] There are no enforcement provisions in the regulations apart from the licensing requirements. The state reports that it relies on its water pollution control act for enforcement.

• State law provides for the establishment of soil and water conservation districts;[18] the districts have the power to carry out preventive and control measures and to provide assistance, to develop comprehensive plans, and "to make and, from time to time, amend and repeal rules and regulations not inconsistent with this article to carry into effect its purposes and powers."[19] Specifically, the supervisors of a district have authority to "formulate regulations governing the use of lands within the district in the interest of conserving soil and soil resources and preventing and controlling soil erosion."[20] Such regulations may only go into effect after a referendum results in their approval by 4/5 of the votes cast; and the supervisors are not required to adopt the regulations even if the referendum is favorable.[21]

• A separate law provides that "any management guidelines developed by watershed management authorities [a special form of authority within some soil and water conservation districts] to protect forested watersheds shall follow the best management practices established by the Alabama Forestry Commission as they pertain to forested watersheds."[22] Enforcement of soil and water conservation district land use regulations is by injunction sought by the supervisors in the circuit court; or the supervisors may perform the work and recover the expenses thereof.[23]

Agriculture Requirements

• Enforceable land use regulation by soil and water conservation districts is described above.

• The Alabama Pesticide Act provides for pesticide registrations, for permitting of commercial applicators by the Dept. of Agriculture and Industry.[24] "Before any person is authorized to purchase and use restricted-use pesticides for application or use thereof, such person shall meet certain qualifications to be prescribed pursuant to rules and regulations...designed to satisfy the requirements of the Federal [FIFRA]...and to determine whether the user or applicator...can use and apply such products in a manner that will not endanger or be injurious to human health and nontarget animals, wildlife, vegetation, crops, and water or be detrimental to the general environment..."[25] The statute provides for penalties and injunctive relief.[26]

Development and Other Earth-Disturbing Activities

No operating requirements are set forth apart from any that may be contained in urban stormwater programs under the Clean Water Act or that may be authorized by general land use regulation such as zoning. Control of pollution from development activities is limited to stormwater permitting for activities over 5 acres.

State law does provide for the formation of watershed management authorities, which include contiguous watershed lands which may lie within one or more soil and water conservation districts.[27] The land included in the authority must be in a single watershed and must encompass at least 50 square miles. The purposes include plans and programs relating to, among other things, "water pollution control...erosion prevention and control of erosion, floodwater and sediment damages."[28] Authority to make and enforce rules and regulations is not clearly among the enumerated powers of these watershed management authorities.[29] Individual local government jurisdictions, particularly in the coastal zone, also have some authorities over runoff and sediment under their general land use powers or the coastal zone program.[30]

Endnotes

ALASKA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Alaska's water pollution control law includes some provisions that may be used to take enforcement action against nonpoint source discharges that pollute the waters of the state.

• Alaska law prohibits a person from "pollut[ing] or add[ing] to the pollution of the air, land, subsurface land, or water of the state."[1] The Alaska Department of Environmental Conservation (DEC) has broad authority to adopt pollution standards and "to determine what qualities and properties of water indicate a polluted condition..."[2]

If an activity presents "an imminent or present danger" to the people of the state or would result in or be likely to result in "irreversible or irreparable damage" to the environment, the DEC may issue an emergency abatement order without a hearing. The affected party may present proof to the contrary or prove that the order would impose "substantial private hardship."[3] In the ordinary case, if the DEC has reason to believe that a violation has occurred or is about to occur, then it may notify the person involved and require a report stating the measures that have been or will be taken to correct or control the conditions. The DEC may issue a compliance order after the time period specified for filing the report.[4] Superior court may also enjoin violations of statute, regulations, orders or permits.[5] Sanctions imposed include civil penalties of between $500 and $10,000 for the initial violation and not more than $5000 for each subsequent day of the violation. The court will determine the amount of the penalty based upon the characteristics of the substance discharged, the "sensitivity of the receiving environment," and the "degree" of environmental degradation. Costs to the state and the economic savings of the violator shall also be considered.[6] If the violation occurs with criminal negligence, then it is a Class A misdemeanor.[7]

Other Discharge Limitations

• A person is guilty of nuisance under Alaska state law if the person puts a "dead animal...excrement, or a putrid, nauseous, noisome, decaying, deleterious, or offensive substance into, or in any other manner ...pollutes...a spring, brook, creek, branch, well or pond of water that is or may be used for domestic purposes." It is a misdemeanor to neglect or refuse to abate a nuisance under this statute.[8] The court may assess damages for costs of abatement.[9] There is a similar nuisance provision for placement of "obnoxious" matter or things on land.[10]

• A discharge limitation is imposed whereby before beginning "to construct a hydraulic project, or use, divert, obstruct, *pollute*, or change the natural flow or bed of a specified river, lake, or stream, the person or governmental agency shall notify the commissioner..."[11] Proceeding without approval is a misdemeanor,[12] and sanctions are calculated based on the cost of restoring a river, lake or stream to its original condition in addition to court penalties.[13]

Fish/Fisheries Laws

• A person is generally liable to the state if the person "violates or disregards an order, permit, or other determination" of the DEC under the Water, Air, Energy, and Environmental Conservation Code and "thereby causes the death of fish, animals or vegetation or otherwise injures or degrades the environment of the state..."[14] The attorney general may recover damages under this provision, and liability includes costs recovered for the restocking of injured land or waters or to replenish a damaged or degraded resource or to otherwise restore the environment to its condition before the injury.[15] It is a class A misdemeanor if criminal negligence is found.[16]

• Obstruction, diversion or pollution of "water of the state, either fresh or salt, utilized by salmon in the propagation of species, by ...casting, passing, throwing, or dumping tree limbs or foliage, underbrush, stumps, rubbish earth, stones, rock or other debris, or passing or dumping sawdust, planer shavings, or *other waste or refuse of any kind in those waters*" is prohibited without a permit.[17] Also a permit is required to render the waters described above "inaccessible or *uninhabitable* for salmon for spawning or propagation."[18] A violation of these provisions is a misdemeanor punishable by a fine of between $100 and $500.[19] The permit may be granted if the purpose is "to develop power, obtain water for civic, domestic, irrigation, manufacturing, mining, or other purposes tending to develop the natural resources of the state."[20]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• With respect to forest resources and practices, the state, with the DEC as lead agency, "should exercise its full responsibility and authority for control of *nonpoint source pollution* with respect to the Federal Water Pollution Control Act."[21] While this policy is not itself an enforceable mechanism, the law further provides that the Commissioner of Natural Resources ("Commissioner") may issue nonpoint source pollution regulations subject to DEC approval.[22]

• On state, municipal, and private forest land, state law provides that "environmentally sensitive areas" shall be recognized "in the development of regulations and best management practices that are designed to implement *nonpoint source pollution* control measures authorized under this chapter."[23] Also "significant adverse effects of soil erosion and mass wasting on water quality and fish habitat shall be prevented or minimized."[24]

• Before operations begin on municipal or private forest land or on state land not managed by the division of forestry, the operator must submit to the state forester (who heads the division of forestry) a "detailed plan of operations" which must be reviewed within thirty days. Unless a stop-work order is issued or the agency extends the review period, the operator may commence work, at the latest, thirty days after submission of the plan.[25] The plan must be renewed annually. The state forester may grant a variance from the statute or regulations if "the harm intended to be avoided by the requirement is not likely to occur because of site-specific circumstances relating to the particular activity and is not likely to cause harm to fish habitat or water quality."[26] Also small commercial operations and primarily noncommercial operations are exempt.[27] The Commissioner may assess civil fines and request that the attorney general seek an injunction for violations of directives or stop-work orders.[28] Upon making a determination that an activity violates this chapter, the state forester may issue a directive ordering the person to cease the violation or repair any resulting damage. If the person requests a hearing, then the activity may continue unless the state forester issues a stop-work order.[29] Where a person violates a directive requiring repair or correction of damage, the Commissioner may proceed with the repair and the violator is liable for the cost.[30] Violation of statute, regulation, directive or stop-work order can result in a maximum civil fine of $10,000.[31] If criminal negligence is found, then the violation is a Class A misdemeanor.[32]

• For each state forest, the Commissioner is required to prepare a forest management plan that considers and permits various forest uses, as well as "soil characteristics, water quality and watershed management."[33] Under the Alaska Lands Act, regardless of whether a forest management plan has been prepared, before the Department of Natural Resources ("DNR") can authorize timber harvest (except for harvests of ten acres or less or timber salvaged from land cleared for nonforest use), the DNR must adopt a forest land use plan that considers, among other factors, fish and wildlife habitat, including retention of riparian, wetland and ocean-shoreline vegetation; water quality and watershed management.[34] Finally, the Commissioner is to adopt regulations to protect riparian areas that provide higher standards of protection for lands managed by the DNR than other public or private land.[35] Specifically, for state lands managed by the DNR, no harvest is permitted within 100 feet of the water body, subject to certain exceptions and depending upon whether the land is located north or south of the Alaska range.[36] Whereas the timber harvest riparian standards for private land located in a coastal spruce or hemlock forest vary depending upon the water classification, distance of the activity from the water body and slope stability standards. For other private forest land, riparian standards are established by regulation.[37] The same exemptions, enforcement mechanisms and sanctions apply here that are discussed above with respect to the general forestry provisions.

Agriculture Requirements

• Generally, Alaska state law regulates the licensing of pesticides.[38] More specifically, "a person may not spray or apply...pesticide or broadcast chemical in a manner that may cause damage to or endanger the health, welfare, or property of another person, or *in a manner that is likely to pollute the air, soil, or water of the state* without prior authorization of the [DEC]."[39] Enforcement and sanctions follow same provisions as outlined above under general discharge limitations.

Development and Other Earth-Disturbing Activities

• Alaska law provides for local land use regulation, planning and zoning, but state law does not prescribe specific nonpoint source duties in this context.

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Arizona's water pollution law has provisions that authorize development of a program for nonpoint source discharges, which may include, but does not require, development of enforceable mechanisms. It also has a general discharge prohibition applicable to intentional or grossly negligent discharges. Arizona also provides for aquifer protection permits that address some nonpoint source discharges to groundwater.

- Arizona law requires the Department of Environmental Quality (DEQ) to adopt not only permit requirements for point sources and for certain facilities likely to pollute aquifers, but also to adopt a "program to control nonpoint source discharges of any pollutant or combination of pollutants into navigable waters."[1] Thus, enforceable mechanisms could be created by regulation. Enforcement mechanisms available under the law generally include orders, injunctions, and court actions to recover civil penalties not to exceed $25,000 per day.[2]

- Arizona's general discharge prohibition makes it a criminal offense to discharge, with intent or gross negligence, any substance to waters without a required permit or other "appropriate authority," or to violate a water quality standard.[3]

- Arizona has a regulatory program for aquifer protection permits that has some bearing on nonpoint discharges. Facilities that may produce discharges to groundwater require an aquifer protection permit.[4] Some of these include nonpoint source activities, such as mines. The DEQ is further authorized to issue general permits under the aquifer protection program, including general permits requiring use of best management practices and addressing urban runoff, silviculture, and certain other activities.[5]

Other Discharge Limitations

- Nuisance authorities provides some additional enforcement authority where specific health or environmental hazards can be shown. Arizona defines an environmental nuisance as "creation or maintenance of a condition in the soil, air or water that causes harm to the public health or the environment and that is not otherwise subject to regulation under this title."[6] Examples include: "6. the pollution or contamination of any domestic waters" and "7. use of cesspools, septic tanks, or sewage for fertilizing or irrigation without approval."[7] The director of DEQ may serve an abatement order, which becomes final in 30 days. Failure or refusal to comply with order enables DEQ to abate the nuisance itself and recover costs.[8] DEQ may also file an action in superior court for enjoin further violation, compel compliance, or for abatement.[9] Other nuisances, including some water-pollution related actions, are specified by law.[10] Arizona also has a savings clause that preserves other causes of action, including public and private nuisance law.[11]

• Another law provides that "No person shall dump, deposit, place, throw or leave refuse, rubbish, debris, filthy or odoriferous objects, substances or other trash on any waterways or the shorelines of any waterways of the state."[12] Violation is a misdemeanor, and the violator may be ordered to "correct any unlawful condition, issued a written warning or written repair order, or issued a citation."[13]

• The crime of criminal littering or polluting is committed if a person unlawfully "1. Throws, places, drops or permits to be dropped on public property or property of another which is not a lawful dump any litter, destructive or injurious material which he does not immediately remove. 2. Discharges or permits to be discharged any sewage, oil products or other harmful substances into any waters or onto any shorelines within the state..."[14] The offense is a felony if it is a knowing violation, if the material exceeds 300 lbs. or 100 cu.ft., or if it is done for a commercial purpose. It is a misdemeanor if it is not a felony and "involves placing any destructive or injurious material on or within fifty feet of a highway, beach or shoreline of any body of water used by the public."[15]

Fish/Fisheries Laws

• The game and fish commission may bring an action against "any person, corporation, or government agency, to restrain or enjoin the person, corporation, or government agency from discharging or dumping into a stream or body of water in the state any deleterious substance which is injurious to wildlife."[16] It is also unlawful to take a fish by any means other than angling unless otherwise provided by the commission, subject to fine of $10 and misdemeanor penalty.[17] Because there is no intent requirement, this may provide some recourse for fish kills.

OPERATIONAL REQUIREMENTS

Forestry Requirements

State law does not appear to specify operational requirements related to nonpoint source water pollution from forestry activities.

Agriculture Requirements

• Arizona law provides that the director of DEQ shall adopt rules for agricultural general permits consisting of BMPs for "regulated agricultural activities" defined as "application of nitrogen fertilizer or a concentrated animal feeding operation."[18] The agricultural general permits are not subject to the general legal criteria for general permits or BMPs.[19] Individual permits for regulated agricultural activities are generally not required.[20] Agricultural BMPs are those that DEQ has determined "to be the most practical and effective means of reducing or preventing the discharge of pollutants by regulated agricultural activities."[21] The Director shall require "application of all economically feasible" BMPs that are the "most practical and effective means of reducing or preventing the discharge of pollutants by regulated agricultural activities but shall not require application of more stringent practices if such a requirement would result in cessation of the regulated activity."[22] Advisory committees were established to develop appropriate BMPs and recommend them to DEQ. Representatives from DEQ, the state department of agriculture, Dept. of Water

Resources, and college of agriculture at University of Arizona are on the committees.[23] Use of BMPs may be waived in a specific region if DEQ determines that existing regulated agricultural activities will not cause or contribute to violations of water quality standards.[24] Violation of the BMPs can result in revocation of the general permit after notice and opportunity for hearing and a requirement that the operation obtain an individual permit.[25]

• Arizona law also directs the director of DEQ to adopt, by rule, a "surface water quality general grazing permit consisting of *voluntary* best management practices for grazing activities".[26] The rule must be adopted within 180 days after receiving the recommendations of a grazing best management committee.[27] The committee includes representatives of DEQ, the state Dept. of Agriculture, the Dept. of Water Resources, the dean of the University of Arizona College of Agriculture, and 3 cattle ranchers and 1 sheep rancher appointed by the governor. Although the director shall require the application of economically feasible VBMPs that are "the most practical and effective means" of reducing or preventing discharge of pollutants by grazing activities, the director "shall not require application of more stringent practices if such a requirement would result in cessation or significant reduction of grazing activity." "The director may waive the use of voluntary best management practices in a designated region if he determines that existing grazing activities will not cause a violation of the adopted water quality standards for navigable waters."[28] Because the law requires development of and issuance of a permit, it is arguably an enforceable mechanism, but the term "voluntary" may pose impediments to actions beyond simply requiring the permit.

• Arizona regulates pesticides and provides for permits, licensing, and certifications, including training requirements and reporting, buffer zones, pesticide management areas, and enforcement.[29] Registration requirements designed to protect water quality are enforceable.[30] Continued registration, sale, or use of a pesticide is not allowed if it would cause a "violation of water quality standards at the applicable point of compliance."[31]

Development and Other Earth-Disturbing Activities

No operating requirements are set forth, apart from any that may be contained in urban stormwater programs under the federal Clean Water Act or that may be authorized by general land use regulation such as zoning. Boards of supervisors may adopt and enforce standards for excavation, landfill and grading to prevent unnecessary loss from erosion, flooding and landslides.[32]

ARKANSAS

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Arkansas' water pollution control law contains a general discharge prohibition that may be used to take enforcement against nonpoint source discharges that cause water pollution or against the placement of wastes that are likely to cause water pollution.

• The Arkansas Water and Air Pollution Control Act[1] makes it unlawful to "cause pollution ... of any of the waters of this state," or to "place or cause to be placed any sewage, industrial waste, or other wastes in a location where it is likely to cause pollution of any waters of this state."[2] "Pollution" is defined as "such contamination or other alteration of the physical, chemical, or biological properties of any waters of the state, or such discharge of any liquid, gaseous, or solid substance in any waters of the state as will, or is likely to, render the waters harmful, detrimental, or injurious to public health, safety, or welfare; to domestic, commercial, industrial, agricultural, recreational, or other legitimate beneficial uses; or to livestock, wild animals, birds, fish, or other aquatic life."[3]

The Arkansas Pollution and Ecology Commission enforces the Act, and is authorized to conduct investigations to determine the existence of violations. The Commission may conduct administrative proceedings, and also may institute civil enforcement actions in the proper court. Except in emergencies, no administrative penalty may be assessed without the opportunity for a hearing, and the Commission must provide public notice and an opportunity to comment. Parties may request an appeal to the court without a jury. Administrative penalties may be no greater than $10,000 per day of violation; civil actions may result in penalties not over $10,000 per day of violation, an order to enjoin violations and/or compel compliance, an order for remedial measures, and recovery of all costs, expenses, and damages.[4]

Any violation of the Act also is a criminal misdemeanor, punishable by imprisonment for not more than one year, a fine of not more than $25,000, or both. A purposeful, knowing, or reckless violation that "creates a substantial likelihood of adversely affecting" human health or the environment is a felony, punishable by imprisonment for not more than 5 years, a fine of not more than $50,000, or both; a purposeful, knowing, or reckless violation that "places another person in imminent danger of death or serious bodily injury" is punishable by imprisonment of not more than 20 years, a fine of not more than $250,000, or both. Further, if pecuniary gains are made from the commission of the offense, the state may seek an additional fine of double the amount of the gain.[5]

Other Discharge Limitations

• In addition to the prohibition under the Water and Air Pollution Control Act, Arkansas' Solid Waste Management Act makes it unlawful to "sort, collect, transport, process, or dispose of solid waste ... in such a manner or place as to cause or be likely to cause water pollution within the meaning of the Arkansas Water and Air Pollution Control Act.[6] Enforcement and penalties are the same as for the process enumerated in the Water Pollution Control Act, above.[7]

• The Litter Control Act makes it unlawful to drop [or] discard ... litter ... into any river, lake, pond, or other stream or body of water within this state."[8] There is no violation of the Act if the property is designated as a permitted disposal site, if the litter is deposited in such a manner as to prevent it from being carried away or deposited by the elements in waters of the state, or if the person is the owner or tenant in lawful possession of the property and the litter does not create a public nuisance, health or fire hazard. Violation of the Act is a misdemeanor; first-time offenses are subject to a $100 fine or 100 hours of community service.[9]

• Various sections of the code refer to nuisance law, but none specifically define "nuisance" or nuisance standards in the context of water pollution.[10] The Department of Pollution and Ecology is among the agencies authorized to pursue legal actions for public nuisance,[11] as is the State Board of Health, which may investigate and report on potential nuisances, order their abatement, or order the local sheriff to compel compliance.[12] Arkansas caselaw reflects instances where water pollution was held to be an actionable nuisance.[13] In addition, the zoning law provides that "every structure, fill, development ... placed within a flood prone area in violation of measures enacted under the authority of this section is a public nuisance."[14]

The Right to Farm Act prevents pre-existing farms from being sued for nuisance, stating that "agricultural facilities running for one year without nuisance will not be held liable for nuisance due to changes in the surrounding locality."[15] However, unlike similar laws in other states, Arkansas' Act makes an exception for pollution, and allows nuisance suits for pollution to be brought even against pre-existing farms:"damages sustained by pollution will not be limited by this section."[16]

. Fish/Fisheries Laws

The Arkansas code contains two separate provisions applicable to protection of fish that may provide enforceable mechanisms for some nonpoint source discharges.

• "Any person who shall poison any lake or stream of water for the purpose of killing fish, stock, *or for any other purpose* shall be deemed guilty of a misdemeanor and upon conviction shall be fined in any sum not less than one hundred dollars ($100) nor more than five hundred dollars ($500)."[17]

• In addition, "it shall be unlawful for any person to deposit, throw, drop, or discharge in any manner in any of the waters of this state any substance, liquid, or gas or anything else that will or does intoxicate or stupefy or in any manner injure any fish therein, whether done for the purpose of catching or taking fish or not."[18] For purposes of this provision, "waters of this state" are defined as "all streams, lakes, ponds, sloughs, bayous, marshes, or other waters, wholly or in part within this state."[19] "Any person violating this section shall be deemed guilty of a felony. Upon conviction, he shall be confined in the state penitentiary for a term of not less than one (1) month nor more than twelve (12) months."[20]

OPERATIONAL REQUIREMENTS

Forestry Requirements

State forestry laws do not appear to contain enforceable provisions directly relating to nonpoint source discharges. There is a single restriction on tree-cutting near river beds.

• "It is unlawful to remove any trees growing below the normal high watermark on any river or stream in this state which has been designated as a navigable river or stream. ... Any person violating the provisions of this section shall be guilty of a misdemeanor and upon conviction shall be punished by a fine of not less than ten dollars ($10.00) nor more than one thousand dollars ($1,000).[21]

Agriculture Requirements

• Soil Conservation Districts are authorized to make regulations to control erosion.[22] If the regulations are violated, directors of the local soil district may bring an action in chancery court, which may order the person to comply or take abatement measures, or authorize the directors of the district to enter the land to abate the violation. If the directors abate the violation, they may apply to the court to order the offender to reimburse the costs of abatement.

• The Arkansas Pesticide Control Act[23] makes it unlawful for any person to "dispose of, discard, or store pesticides or pesticide containers in a manner as to ... pollute any water supply or waterway.[24] Enforcement is handled by the State Plant Board,[25] which may make inspections to determine if violations exist and bring an action in the appropriate court for an injunction.[26] Violations are a misdemeanor, punishable on the first offense by a fine of $100 - $1000, and on subsequent offenses by a fine of $500 - $2000.[27]

• The Arkansas Pesticide Use and Application Act primarily prohibits use of pesticides without a license. However, it also authorizes the State Plant Board to "issue regulations relating to the conditions under which pesticides may be applied and ... restrict or prohibit use of pesticides to prevent unreasonable adverse effects" to plants, wildlife, fish, humans, animals, or beneficial insects.[28] Use of pesticides without a license or violation of the regulations is a misdemeanor, subject to a fine of $100-$2000 for "commercial parties" and $100-$500 for "private parties."[29]

Development and Other Earth-Disturbing Activities

Apart from any programs for the control of urban stormwater under the federal Clean Water Act, or that may be authorized under general land use regulation such as zoning, Arkansas has minimal authority potentially applicable to nonpoint sources.

• The zoning law declares that "every structure, fill, development. . . placed within a flood prone area in violation of measures enacted under the authority of this section is a public nuisance."[30] Thus, where municipalities have promulgated zoning ordinances restricting development in floodplains, violators can be prosecuted under nuisance law.

30. Ark. Code Ann. § 14-268-101.

CALIFORNIA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

California's Porter-Cologne Water Quality Control Act contains enforceable permitting provisions that may be applied to nonpoint source discharges. The law also empowers regional water quality control boards to order the abatement of discharges, including nonpoint source discharges, that create or threaten to create pollution.

• The Porter-Cologne Act requires "[a]ny person discharging waste, or proposing to discharge waste, within any region that could affect the quality of the waters of the state..." to file a "report of waste discharge" with the regional water quality control board.[1] The regional board must then issue waste discharge requirements (WDRs) – essentially a permit -- implementing "any relevant water quality control plans" and taking into consideration the beneficial uses to be protected, the water quality objectives reasonably required for that purpose, other waste discharges, and the need to prevent nuisances.[2] The law prohibits any discharge prior to filing of the report and the issuance of WDRs, or the expiration of prescribed decision times after filing the report, or receipt of a waiver.[3] The law allows regional boards to "conditional[ly]" waive the report of waste discharge and WDRs for specific discharges or types of discharges "where the waiver is not against the public interest." The waiver may be terminated at any time by the board.[4] California uses these provisions in the nonpoint context as a backup to voluntary and incentive based mechanisms, using the regional boards' power to require a report of waste discharge or to grant a conditional waiver. Timber operations conducted under the state's Z-Berg-Nejedly Forest Practices Act are exempt from the waste discharge requirements if the Act's requirements are certified as best management practices (BMP) by EPA, unless the State Water Resources Board makes a finding that compliance by forestry operations is not protecting water quality, or the forestry board requests issuance of WDRs.[5]

• A second provision includes general abatement authority. "Any person who has discharged or discharges waste into the waters of this state in violation of any waste discharge requirement or other order or prohibition issued by a regional board or the state board, *or who has caused or permitted, causes or permits, or threatens to cause or permit any waste to be discharged or deposited where it is, or probably will be, discharged into the waters of the state and creates, or threatens to create, a condition of pollution or nuisance*, shall upon order of the regional board, cleanup the waste or abate the effects of the waste, or in the case of threatened pollution or nuisance, take another necessary remedial action, including, but not limited to, overseeing cleanup and abatement efforts."[6]

Enforcement under Porter-Cologne is by order, injunction, or remedial action with cost recovery.[7] Other sections of the law provide for civil penalties, injunctions, misdemeanor prosecutions, and administrative orders.[8]

• Another provision, with some bearing on enforceable requirements, requires the state Water Resources Board to "establish fees applicable to all point and nonpoint dischargers who discharge to enclosed bays, estuaries, or any adjacent waters in the contiguous zone or the ocean...The fees shaDecember 14, 1998ll create incentives to reduce discharges to the ocean, bays, and estuaries and shall be based on the relative threat to water quality from point and nonpoint dischargers."[9] However, "[n]o fee may be imposed pursuant to this section on any agricultural nonpoint source discharger."[10]

Other Discharge Limitations

California has numerous nuisance law authorities potentially applicable to nonpoint source water pollution, in addition to "nuisance" as defined in Porter-Cologne itself.[11] The remedies against a public nuisance are: criminal "indictment or information...; [a] civil action; or... Abatement."[12]

• "Anything which is injurious to health, or is indecent, or offensive to the senses, or an obstruction to the free use of property, so as to interfere with the comfortable enjoyment of life or property by an entire community or neighborhood, or by any considerable number of persons, or unlawfullly obstructs the free passage or use, in the customary manner, of any navigable lake, or river, bay, stream, canal, or basin...is a public nuisance."[13]

• "Anything which is injurious to health..or is indecent or offensive to the senses, or an obstruction to the free use of property, so as to interfere with the comfortable enjoyment of life or property, or unlawfully obstructs the free passage or use, in the customary manner, of any navigable lake, or river, bay, stream, canal, or basin..is a nuisance."[14]

• "Every person who litters or causes to be littered, or dumps or causes to be dumped, any waste matter into any bay, lagoon, channel, river, creek, slough, canal, lake, or reservoir, or other stream or body of water, or upon a bank, beach, or shore within 150 feet of the high water mark of any stream or body of water, is guilty of a misdemeanor."[15] For purposes of this offense, littering means the "willful or negligent throwing, dropping, placing, depositing, or sweeping, or causing any such acts, of any waste matter on land or water in other than appropriate storage containers or areas designated for such purposes."[16] "Waste matter" means "discarded, used, or leftover substance including, but not limited to...any garbage, trash, refuse, paper, container, packaging or construction material, carcass of a dead animal, any nauseous or offensive matter of any kind, or any object likely to injure any person..."[17] This offense is punishable by a fine of $100 to $1,000.

• The Health and Safety Code contains other specific prohibitions: "no person shall put the carcass of any dead animal, or the offal from any slaughter pen, corral, or butcher shop, into any river, creek, pond, reservoir, or stream."[18] "No person shall put any water closet, privy, cesspool or septic tank, or the carcass of any dead animal, or offal of any kind, in, or upon the borders of any stream, pond, lake, or reservoir from which water is drawn for the supply of any portion of the inhabitants of this state..."[19] "No person shall allow any ....[of same] to remain in or upon the borders of any stream, pond, lake or reservoir...."[20] contamination of water supply by live stock.[21] It is also unlawful to dump "garbage" "in or upon the navigable waters of this state."[22] Violations

R0017043

of these provisions are punishable as misdemeanors.[23] In addition, "Anything done, maintained, or suffered, in violation of any of the provisions of this article is a public nuisance, dangerous to health, and may be summarily abated as such."[24] Nevertheless, "Nothing which is done or maintained under the express authority of a statute can be a nuisance."[25]

However, "No agricultural activity, operation, or facility, or appurtenances thereof, conducted or maintained for commercial purposes, and in a manner consistent with proper and accepted customs and standards, as established and followed by similar agricultural operations in the same locality, shall be or become a nuisance, private or public, due to any changed condition in or about the locality, after it has been in operation from more than three years if it was not a nuisance at the time it began."[26] But the right-to-farm nuisance exemption "shall not invalidate" applicability of provisions of the state's Health and Safety Code, Fish & Game Code, Food & Agriculture Code, or Porter-Cologne-Act, if the activity constitutes a nuisance "specifically defined or described in any of those provisions."[27] The Health & Safety Code further provides that none of its prohibitions "shall be held to prevent the grazing of livestock in areas embracing any stream or watershed where the grazing would not tend to render the waters unwholesome of injurious to the public health."[28]

Fish/Fisheries Laws

• A provision of the Porter-Cologne law is designed to protect commercial shellfish harvesting "from the effects of point and nonpoint pollution sources."[29] Regulation is authorized once an area is "threatened." This is defined as an area that has been downgraded or restricted by the state's Department of Health Services, subjected to closure for more than 30 days per year for 3 previous years, or formally determined by a regional water quality control board, the Department of Fish & Game, or the California Coastal Commission to be threatened.[30] "Once the nature, sources, scope, and degree of the pollution affecting a commercial shellfish growing area have been determined, the regional board, with the advice of the local technical advisory committee, shall *order* appropriate remedial action, including the adoption of best management practices to abate the pollution affecting that area."[31] However, the law further provides that "if *agricultural* sources of pollution have been identified as contributing to the degradation of shellfish growing areas, the regional board shall *invite* members of the local agricultural community representing the type of agricultural discharge affecting the local shellfish growing area, the local resource conserve district, the local soil conservation service.....and affected shellfish growers to develop and implement appropriate short- and long-term remediation strategies that will lead to a reduction in the pollution affecting the commercial shellfish growing area."[32]

• The Fish and Game Code contains several provisions that appear to create enforceable prohibitions applicable to nonpoint discharges. "Except [as authorized by a permit, license or waiver issued by the state water resources control board, a regional board, or federal permit for which a state water quality certification has been issued]..., it is unlawful to deposit in, permit to pass into, or place where it can pass into the waters of this state any of the following: (1) Any petroleum, acid....or residuary product of petroleum, or carbonaceous material or substance. (2) Any refuse, liquid or solid, from any...factory of any kind. (3) Any sawdust, shavings, slabs, edgings. (4) Any factory refuse, lime, or slag. (5) Any cocculus indicus. (6) Any substance or material deleterious to fish, plant life, or bird life."[33]

• A separate provision makes it "unlawful to deposit, permit to pass into, or place where it can pass into the waters of the state, or to abandon, dispose of, or throw away, within 150 feet of the high-water mark of the waters of the state, any cans, bottles, garbage, motor vehicle or parts thereof, rubbish, or the viscera or carcass of any dead mammal, or the carcass of any dead bird."[34]

These Fish & Game Code provisions are enforced as misdemeanors, although the first is also punishable by civil penalty of up to $25,000.[35] Another provision of the Code allows the state to recover damages for unlawful destruction of wildlife or fish.[36]

• The Fish & Game Code requires stream alteration permits; this may be applicable in some instances to some nonpoint source pollution, as it applies where debris, waste or other material may pass into the waters of any river, stream or lake. It is "unlawful for any person to substantially divert or obstruct the natural flow or substantially change the bed, channel, or bank of any river, stream, or lake designated by the department, or use any material from the streambeds, without first notifying the department" and obtaining the agreement of the Department (or pursuant to arbitrators' decision if another state agency is involved and agreement is not reached).[37]

OPERATIONAL REQUIREMENTS

Forestry Requirements

The Z'Berg-Nejedly Forest Practices Act contains numerous provisions addression nonpoint source pollution in the operating context of timber practices and harvests.[38] The law provides for the division of the state into 3 districts (coast forest, northern forest, southern forest), with distinct rules established by the state board of forestry.[39]

• The rules must "protect the soil, air, fish, and wildlife, and water resources, including, but not limited to, streams, lakes, and estuaries."[40] The rules must include measures for "soil erosion control, for site preparation that involves disturbance of soil or burning of vegetation following timber harvesting activities..., for water quality and watershed control, for flood control....[etc]." The rules must set forth tree stocking standards.[41] Soil erosion must be controlled, and the board must conduct research and "promulgate regulations for each district to govern timber operations that may cause significant soil disturbance."[42] In addition to these rules, "the board shall adopt rules for control of timber opeartion which will result or threaten to result in unreasonable effects on the benficial uses of the waters of the state" including rules for disposal of petroleum products, refuse, and sanitary wastes, construction of stream crossings to protect free passage of water and fish, minimizing damage to unmerchantable streamside vegetation, minimizing damage to streambeds or banks, control of slash, debris, fill, and side cast earth which may be carried into streams, and minimizing the effects of erosion on watercourses and lakes by installation and maintenance of certain drainage facilities, soil stabilization treatments, and planned abandonment of roads and landings.[43]

• Provisions are implemented through requirements for licensing of foresters and for filing and approval of timber harvest plans. "[N]o person shall engage in timber operations until that person has obtained a license from the board."[44] The license requirements include for first time applicants, completion of an education program and completion of work experience (with the exception of owners operating on their own lands), and liability insurance.[45] Licenses may be denied for misrepresentation, conviction within 1 year of application of unlawfully operating without a license, failure to comply with law and rules within three years prior to date of application, railure to pay a judgment or reimburse state for expenses resulting from violation of law or rules, failure to maintain insurance.[46]

• "No person shall conduct timber operations unless a timber harvesting plan prepared by a registered professional forester has been submitted for such operations to the department [of forestry] pursuant to this article."[47] The plan must include, among other provisions, "An outline of the methods to be used to avoid excessive accelerated erosion from timber operations to be conducted within the proximity of a stream" as well as measures to protect unique areas and information required to meet the rules.[48] The law provides for public comments and review by other agencies.[49] The promulgated rules are the "sole criteria" for review of the timber harvesting plans. [50] Reports of completion of work must be filed within one month after completion of the activity described in the plan, and operations must be inspected within six months.[51]

• California also regulates nonindustrial timberlands, defined as owners with less than 2500 acres and not primarily engaged in manufacture of forest products.[52] The law allows nonindustrial "timber management plans," which are reviewed but then remove the board's discretion to disapprove individual nonindustrial timber harvest notices submitted pursuant to th approved plans. The plan must include "(d) An outline of the methods to be used to avoid excessive accelerated erosion from timber operations to be conducted within the proximity of a stream" as well as measures to protect unique areas and information to meet the rules.[53] The plan is subject to public inspection, is reviewed and approved.

Enforcement measures include license actions, misdemeanor prosecutions (with fines of not more than $1000 per day nor imprisonment for more than 6 months), civil injunction actions, and departmental corrective actions with cost recoveries.[54] As noted above, timber operations conducted pursuant to the Forest Practices Act are, in most instances, exempt from the waste discharge provisions of Porter-Cologne.

• Although local government regulation of forestry is largely preempted,[55] the California Tahoe Regional Planning Agency may adopt rules that are stricter than those provided under the law or Board of Forestry regulations.[56]

Agriculture Requirements

• As noted above, waste discharge requirements may be applied to some agricultural nonpoint discharges. In addition, California's regional water quality control boards specifically require WDRs for confined animal facilities and "may impose additional requirements, if such additional requirements are necessary to prevent degradation of water quality or impairment of beneficial uses of waters of the state"[57]

Regulations include management of manure application, animal contact with surface waters, and other conditions.[58]

• California has a fertilizer law, which like those of many states, is aimed primarily at assuring efficacy and appropriate labeling of the fertilizer; the law includes licensing of manufacturers and distributors, and registration of products.[59] However, registration may be cancelled or refused if the substance is "detrimental or injurious to plants, animals, public safety, or the environment when it is applied as directed..."[60] The law is enforced as a petty criminal infraction, by cancellation of registration, and/or by injunction.[61]

• The Health & Safety Code provides that "No person shall keep any horses, mules, cattle, swine, sheep, or live stock of any kind, penned, corralled, or housed on, over, or on the borders of any stream, pond, lake, or reservoir, in a manner that the waters become polluted, if water is drawn therfrom for the supply of any portion of the inhabitants of this state."[62] In addition, "No person shall cause or permit any horses, cattle, sheep, swine, poultry, or any kind of live stock or domestic animals, to pollute the waters, or tributaries of waters, used or intended for drinking purposes by any portion of the inhabitants of this state."[63] Violation is punishable as a misdmeanor.[64] However, "Nothing in this article shall be held to prevent the grazing of livestock in areas embracing any stream or watershed where the grazing would not tend to render the waters unwholesome or injurious to the public health."[65]

• California has detailed laws governing the use of pesticides, including licensing of applicators and registration for pesticides. A pesticide registration may be cancelled where the material "has demonstrated serious uncontrollable adverse effects either within or outside the agricultural environment", "is of less public value or greater detriment to the environment than the benefit received by its use", or that "when properly used, is detrimental to vegetation, except weed, to domestic animals, or to the public health and safety."[66] The state also may regulate possession and use of restricted use material "injurious to the environment or to any person, animal, crop, or other property".[67] Criteria include "hazard to the environment from drift onto streams, lakes, and wildlife sanctuaries...[or] persistent residues in the soil resulting ultimately in contamination of the..waterways, estuaries or lakes, with consequent damage to fish, wild birds, and other wildlife."[68] A full panoply of license and registration actions, orders, injunctions, civil penalties, and criminal penalties exist under these laws.[69]

California's resource conservation districts do not exercise regulatory enforcement authority over nonpoint source pollution; but may only impose and enforce conditions for the receipt of funding and technical assistance.[70]

Development and Other Earth-Disturbing Activities

• California's land use laws to some extent provide enforceable mechanisms relevant to nonpoint source pollution from the built environment. California provides for comprehensive local land use regulation. Counties and cities must adopt comprehensive plans.[71] Such plans must include a "conservation element" for the conservation, development, and utilization of waters, forests, soils, rivers, harbors, fisheries, etc. "The conservation element may also cover (1) The reclamation of lands and waters. (2) Prevention and control of the pollution of streams and other waters. (3)

Regulation of the use of land in stream channels and other areas required for the accomplishment of the conservation plan. (4) Prevention, control, anc correction of the erosion of soils, beaches, and shores. (5) Protection of watersheds. (6) The location, quantity and quality of the rock, sand and gravel resources. (7) Flood control."[72] Also see the Coastal Act, discussed below, which requires local governments to prepare local coastal programs consistent with Coastal Act policies, and Coastal Commission certification.

Land use plans are implemented through zoning regulations and ordinances.[73] And further regulation is applied through subdivision ordinances. "The ordinance shall specifically provide for proper grading and erosion control, including the prevention of sedimentation or damage to offsite property."[74] A subdivision map must be disapproved if inconsistent with the applicable plans, or if "the design of the subdivision or the proposed improvements are likely to cause substantial environmental damage or substantially and avoidably injure fish or wildlife or their habitat."[75] Local governmental land use planning and zoning, as well as state agency decisions, are subject to the California Environmental Quality Act (CEQA),[76] which provides for the preparation of Environmental Impact Reports, alternatives analysis, mitigation, etc. Enforcement of zoning and subdivision requirements is through local authority, while CEQA is enforceable in court.

• California law addresses enforcement of urban stormwater requirements, technically a point source, but relevant to nonpoint source activities.[77]

• California's Coastal Act[78] regulates many activities in the coastal area. Provisions include the goal of biological productivity and water quality,[79] limits on diking, filling, or dredging of coastal waters, wetlands, estuaries, and lakes, [80] and limits on channelization, dams, alteration of rivers and streams.[81] A specific provision provides "(a) Environmentally sensitive habitat area shall be protected against any significant disruption of habitat values, and only uses dependent on those resources shall be allowed within those areas. (b) Development in areas adjacent to environmentally sensitive habitat areas and parks and recreation areas shall be sited and designed to prevent impacts which would significantly degrade those areas, and shall be compatible with the continuance of those habitat and recreation areas."[82] And detailed portions of the law establish provisions for development in the coastal zone,[83] including industrial development.[84] The law provides for preparation of local coastal plans by local governments, and for designation of sensitive coastal resource areas; as well as for submission and approval of local coastal plans, land use plans, zoning ordinances.[85] A coastal development permit must be obtained from a certified local government or from the California Coastal Commission.[86] Enforcement includes orders, injunctions, and civil penalties.

• The McAteer-Petris Act provides for the San Francisco Bay Conservation and Development Commission.[87] A permit is required for fill activities.[88] Enforcement is by order, injunction, and civil penalty.

• The State Lands Commission does permitting for depositing material or removing material from wetlands or other waters owned by the state.[89] Violation is a misdemeanor.

- Stream alteration permits are discussed above under "Fish/Fisheries Laws."

COLORADO

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Colorado's Water Quality Control Act[1] contains a general policy declaration in favor of preventing the discharge of untreated pollutants. However, the law does not have a general enforceable prohibition that directly applies to nonpoint sources. Instead, the Act confers authority on the water quality control commission to adopt regulations, which may include nonpoint source regulations. The Act specifically requires the use of non-regulatory mechanisms before regulatory approaches may be used for agricultural nonpoint sources. It also places express limitations on the use of permits or other control regulations against agricultural nonpoint source discharges.

• Under the Act, the state water quality control commission may classify state waters,[2] and must set water quality standards.[3] The commission *may* also promulgate "precautionary measures, both mandatory and prohibitory, that must be taken by any person owning, operating, conducting, or maintaining any facility, process, activity, or waste pile that does cause or could reasonably be expected to cause pollution of any state waters in violation of control regulations or...any applicable water quality standard."[4] The Act further declares the public policy of the state "to provide that no pollutant be released into any state waters without first receiving the treatment or other corrective action necessary to reasonably protect the legitimate and beneficial uses of such waters."[5] "Pollutant" is defined as "dredged spoil, dirt, slurry, solid waste, incinerator residue, sewage, sewage sludge, garbage, trash, chemical waste, biological nutrient, biological material, radioactive material, heat, wrecked or discarded equipment, rock, sand, or any industrial, municipal, or agricultural waste."[6] The Act expressly makes this policy enforceable against point sources, prohibiting pollutant discharges from point sources without a permit.[7] It allows, but does not require, adoption of such measures for nonpoint sources of pollution. The Act expressly exempts agriculture return flows and runoff from any permitting requirement except as required by federal law.[8]

• For specific basins not meeting water quality standards, the commission has promulgated special control regulations. For example, special regulations for the Chatfield Reservoir basin[9] allocate phosphorus emission limits to major point sources in the basin and authorize the local basin authority and Water Quality Control Division "to approve phosphorus poundage credits to point source allocations if nonpoint source phosphorus reductions can be verified," and require a two-to-one ratio of actual nonpoint source reduction to point source credit.[10] The regulations also mandate that "counties, municipalities, districts, corporations, proprietorships, agencies, or other entities with responsibility for activities or facilities that cause or could reasonably be expected to cause nonpoint source pollution ... shall implement best management practices for control of erosion and sediments" and that the same entities "which have responsibility for stormwater management shall implement nonpoint source control programs."[11]

• The Act provides that "with regard to nonpoint source water pollution control related to agricultural practices, the commission and division shall pursue incentive, grant, and cooperative programs in preference to the promulgation of control regulations.... Control regulations related to agricultural practices shall be promulgated only if incentive, grant, and cooperative programs are determined by the commission to be inadequate and such regulations are necessary to meet state law or the federal act."[12] The Act further declares that "the commission shall not adopt control regulations which require agricultural nonpoint source dischargers to utilize treatment techniques which require additional consumptive or evaporative use which would cause material injury to water rights."[13]

Enforcement of control regulations or standards includes a written notice of violation, which may include a cease-and-desist order or proposed corrective action.[14] Violators are entitled to a hearing.[15] Administrative sanctions include cease-and-desist orders and clean-up orders.[16] Civil penalties involve administrative and judicial processes. The state agency requests the penalty and sets the initial level up to $10,000 per day of violation, and the penalty determination is subject to administrative appeal; however, the ultimate imposition and collection is through judicial action, and the court may review the amount of the penalty.[17] The state may also ask the district attorney to seek injunctions.[18] Reckless, knowing, intentional, or criminally negligent violations are subject to a criminal fine. Maximum fines are $12,000 for reckless or criminally negligent acts; $25,000 for knowing or intentional acts; and double those amounts for second violations within a two-year period.[19]

Other Discharge Limitations

• Under Colorado's health code, the state department of public health and environment has the power and duty "to abate nuisances when necessary for the purpose of eliminating sources of epidemic and communicable diseases affecting the public health."[20] County and district health departments have similar powers.[21] The department and county and local boards of health are responsible for enforcement. They may order abatement, assess a $100 penalty for failure to act upon a nuisance abatement order within 24 hours, and recoup costs for abatement actions.[22] The health code also empowers courts to order abatement by public authorities at the defendant's expense "whenever any person is convicted of maintaining a nuisance injurious to the public health and safety."[23]

• Another title states that municipalities have the power "to declare what is a nuisance and abate the same".[24] Municipalities also have the power "to provide for the cleansing and purification of water, watercourses, and canals ... when necessary to prevent or abate nuisances."[25] Moreover, the water quality act states "nor shall any provision of this article or anything done by virtue of this article be construed as estopping individuals, cities, towns, counties, cities and counties, or duly constituted political subdivisions of the state from the exercise of their respective rights to suppress nuisances."[26] Municipalities have abatement authority for municipally-declared nuisances, and can impose fines of up to $1000.[27]

• Another law declares "any unlawful pollution or contamination of any surface or subsurface waters" to be a class 3 public nuisance, but provides that "no action shall be brought under this paragraph ... if the state department of public health and environment or any other agencies of state or local government charged by and acting pursuant to statute or duly adopted regulation has assumed jurisdiction by the institution of proceeding on that pollution or contamination."[28] Actions for abatement may be brought by the district attorney or, with the consent of the district attorney, by the attorney general.[29] The sanction is an injunction to abate the nuisance or an order for the sheriff to abate the nuisance at the expense of the owner or operator of the nuisance.[30]

With respect to nuisance actions, evidence of compliance with a state water quality permit "shall constitute a prima facie case that the activity to which the permit pertains is not a public or private nuisance."[31] Further, agricultural operations are exempt from common law nuisance actions and local nuisance ordinances where the operation has been in existence for at least one year, is not being operated negligently, and has not increased substantially in size.[32]

Fish/Fisheries Laws

• The fish and wildlife code appears not to provide enforceable authority against nonpoint source discharges, except as noted below under "Development and Other Earth-Disturbing Activities." However, it provides that "all wildlife within this state not lawfully acquired and held by private ownership is declared to be the property of the state."[33] Such a declaration arguably might serve as the foundation for a tort claim for property damage for fish kills. Violations of the wildlife code are misdemeanors punishable by fines of $50 and "points" in a hunting and fishing license suspension system.[34] Items used in committing a violation are subject to seizure as public nuisances.[35]

OPERATIONAL REQUIREMENTS

Forestry Requirements

The state board of agriculture has the power and duty "to foster and promote the control of soil erosion on ... forest lands."[36] The state forestry laws do not appear to contain enforceable provisions in this area.

Agriculture Requirements

• The soil conservation code creates soil conservation districts, but apparently does not vest them with regulatory powers.[37] However, the Soil Erosion-Dust Blowing Act makes it "the duty of the owner or occupier of any land in this state to prevent soil blowing therefrom, as nearly as can be done."[38] The act gives a right of action to individuals and governments for property damage due to blowing dust.[39] However, it does not apply to any land less than one acre in area.[40] There are two options for enforcement of the act: a civil suit for damages, or in emergency situations, an appeal for administrative action by the county.[41] A written complaint to the county board is a prerequisite to both civil suit and administrative relief. Upon receiving a written complaint, a county board may inspect lands and, if necessary, serve a citation or take corrective action and bill the land owner for costs.[42]

• A 1929 law declares it "the policy of this state to preserve the grasses and vegetation on the public domain ... and to prevent erosion of the soil and thereby conserve the waters and water supply originating on the public domain ranges of this state."[43] It creates a cause of action to seek an injunction reducing use of public range lands when "any such range is overstocked or ... said range is about to be overstocked with the kind of livestock which may be lawfully herded or grazed thereon and ... vegetation is being permanently destroyed or is about to be permanently destroyed and the water supply upon which any person is dependent is about to be diminished or impaired."[44] "[A]ny person using such range and any person having the right to use water from any stream or source of supply fed from the watersheds in any such range may apply to the court," and "all persons using said range shall be made parties defendant."[45] In the court hearing, "if it is fully and satisfactorily established that such range is overstocked or is about to be overstocked, the court may determine the number of livestock that said range or portion of said range is capable of supporting for a period not exceeding two years, enjoining all persons from willfully or intentionally grazing or herding any greater number."[46] The court is to give preference in its order to those who have used the land continuously and customarily for grazing and to neighboring property owners.[47]

• Colorado has promulgated feedlot rules under the rulemaking authority in the water quality control act.[48] Under these rules, "concentrated animal feeding operations are required to operated as no-discharge facilities."[49] The rules set out best management practices, which are enforceable using the department's authority in the water quality act.[50] In addition, the department has extensive rules on the use of sewage sludge ("biosolids") as fertilizer, which were also promulgated under the water quality act.[51] In 1998, Colorado voters adopted further controls on animal feeding operations by referendum.

• A targeted amendment to the water quality act directs the commissioner of agriculture to address groundwater pollution from agricultural chemicals.[52] It requires the commissioner to promulgate rules governing bulk storage and mixing of fertilizers and pesticides.[53] The agriculture department enforces the standards, may issue cease and desist orders against violators, and may also bring a civil suit.[54] It may seek civil penalties of up to $1000 per violation, and in court may seek the same penalties plus attorneys fees.[55]

The same amendment also empowers the commissioner to develop best management practices for "any other activity relating to the use of any agricultural chemical."[56] However, this authority is to some extent undercut by the water quality act, which defines "best management practices," to be "any *voluntary* activity, procedure, or practice established by the department of agriculture" to address pollution.[57] If voluntary practices do not work, the commissioner then can require agricultural management plans.[58] Further, "if continued monitoring reveals that rules and regulations adopted by the commissioner ... are not preventing or mitigating the presence of the subject agricultural chemical to the extent necessary," the water quality control commission effectively has authority to promulgate additional regulations.[59]

• The general state pesticide law gives the commissioner of agriculture the authority to promulgate rules "adopting a list of restricted use pesticides or limited use pesticides for the state or designating areas within the state if the commissioner determines that such pesticides require rules restricting their distribution or use."[60] The department also regulates handling, transportation, storage, display, and disposal of pesticides and their containers.[61] It is unlawful "to use or cause to be used any pesticide contrary to the rules or regulations."[62] The commissioner may issue compliance orders, may bring a civil suit seeking injunctive enforcement of administrative orders, or may bring a civil enforcement suit without prior administrative action.[63] The commissioner also may suspend, revoke, or deny registrations and licenses of violators,[64] and may also assess a civil penalty of up to $5000 per violation, with each day a separate violation.[65]

• The Colorado Chemigation Act governs the addition of agricultural chemicals to irrigation water.[66] This practice requires a permit from the department of agriculture.[67] The commissioner of agriculture can deny, suspend, or revoke permits if the operation does not meet equipment and installation requirements, has contaminated ground or surface water, or has operated in violation of procedural requirements of the law.[68] Chemigating without a permit is a class 6 felony, punishable by a fine of up to $1000, and an additional civil penalty of between $100 and $1000 dollars.[69] The department may also seek an injunction against the violator.[70]

Development and Other Earth-Disturbing Activities

Apart from any programs for the control of urban stormwater under the federal Clean Water Act or that may be authorized by general land use regulations such as zoning, state law provides the following authorities potentially applicable to nonpoint source discharges.

• The Colorado Land Use Act provides that "local governments shall be encouraged to designate areas and activities of state interest and, after such designation, shall administer such areas and activities of state interest and promulgate guidelines for the administration thereof"; state agencies are directed to assist local governments in designating areas and developing guidelines for their administration.[71] Potential areas of state interest include "natural hazard areas," which include floodplains, as well as "areas containing, or having a significant impact upon, historical, natural, or archeological resources of statewide importance."[72] As part of the designation process, the local government must adopt local guidelines for administration of the area.[73] Development in areas of state interest is subject to a permit system, and the standard for approving a permit is compliance with the local guidelines and regulations.[74] Local governments designate areas, adopt guidelines, and issue permits.[75] Either the local government or the Colorado Land Use Commission may take action against "any person desiring to engage in development in an area of state interest ... who does not obtain a permit," and violators may be enjoined from engaging in the development.[76]

As applied to floodplains, the Act requires these areas to be "administered so as to minimize significant hazards to public health and safety or to property. ... Activities shall be discouraged which, in time of flooding, would create significant hazards to public health and safety or to property. Shallow wells, solid waste disposal sites, and septic tanks and sewage disposal systems shall be protected from the inundation of floodwaters."[77] Similarly, the Act may extend to other kinds of ecologically sensitive areas, such as wetlands or endangered species habitat.[78] However, the Act may not be construed to affect constitutionally guaranteed property rights or "existing laws or court decrees with respect to the determination and administration of water rights."[79]

• The wildlife code requires state agencies to give notice to the wildlife commission 90 days before any action which would "obstruct, damage, diminish, destroy, change, modify, or vary the existing shape or form of any stream or its banks or tributaries by any type of construction."[80] If the project will "adversely affect" the stream, particularly as fishing waters, the commission can request modifications to the project and ultimately elevate decision on the project to the governor.[81] There are no sanctions beyond the elevation of inter-agency disputes to the governor.

CONNECTICUT

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Connecticut's water pollution law includes several provisions that may be used to take enforcement action against nonpoint source discharges.

• The law makes it a violation to discharge any substance to the waters of the state without a permit. "No person or municipality shall initiate, create, originate, or maintain any discharge of water, substance or material into the waters of the state without a permit for such discharge issued by the commissioner [of environmental protection]."[1] "Discharge" means "the emission of any water, substance or material into the waters of the state, whether or not such substance causes pollution."[2] And it is not limited to point sources. In setting standards for permits, the commissioner must consider "best management practices," defined as "practices which reduce the discharge of waste into the waters of the state and which have been determined by the commissioner to be acceptable based on, but not limited to, technical, economic and institutional feasibility."[3]

• It is also a violation to cause water pollution, regardless of the source. "No person or municipality shall cause pollution of any of the waters of the state or maintain a discharge of any treated or untreated wastes in violation of any provision of this chapter."[4] Pollution is defined as "the contamination or rendering unclean or impure or prejudicial to public health of any waters of the state by reason of any wastes or other material discharged or deposited therein by any public or private sewer or otherwise so as directly or indirectly to come in contact with any waters..."[5]

• Connecticut law also authorizes the commissioner to issue an order whenever any person has created or is maintaining a condition "which reasonably can be expected to create a source of pollution to the waters of the state."[6] A separate provision authorizes the commissioner "to investigate or order the person who caused or reasonably may be expected to cause the pollution to investigate all points of existing or potential waste discharge which may directly or indirectly result in pollution of the waters of the state."[7]

Enforcement authorities include orders prohibiting or abating pollution and orders to correct potential sources of pollution.[8] Orders may be issued to the landowner where different from the discharger.[9] Orders may be enforced by injunction.[10] Civil penalties are available up to $25,000 per day.[11] Criminal actions may be brought for willful violations or those with criminal negligence with a sanction of up to $25,000 per day and/or 1 year imprisonment.[12] Water pollution inspection and enforcement is delegable to political subdivisions of the state, subject to retained authority of the commissioner.[13]

Other Discharge Limitations

Connecticut law provides some enforceable mechanisms directed at pollution of sources of water supply, or creation of nuisances.

• The Department of Public Health may investigate any "source of water or ice supply from which water or ice used by the public is obtained, and, if it finds any pollution or threatened pollution which in its judgment is prejudicial to public health, it shall notify the owner or operator of such water company or system of ice supply, or the person or corporation causing or permitting such pollution or threatened pollution, and the Commissioner of Environmental Protection, of its findings and shall make such orders as it deems necessary to protect such water or ice supply and render such water or ice safe for domestic use."[14] Enforcement is by administrative order, which may be enforced by injunction; violation of an order leads to a fine of up to $500 per day.[15]

• "Whenever any land...is so used..that it is a source of pollution to any lake, pond or water from which ice is procured for domestic use or....to the water stored in a reservoir used for supplying residents of a town, city or borough with water or ice, or to any source of supply to such reservoir, or when such water or ice is liable to pollution in consequence of the same, the authorities of such town, city or borough, or the town director of health, or the person, firm or corporation having charge of such reservoir or the right to procure ice therefrom, may apply for relief to the superior court...and said court may make any order...which, in its judgment, may be necessary to preserve the purity of such water or ice." This provision also allows such persons to enter and abate any "nuisance likely to pollute such water or ice" after notice to the owners and upon their refusal to do so.[16]

• "The discharge or exposure of sewage, garbage or any other organic filth into or upon any public place in such a way that transmission of infective material may result thereby..." is a statutory public nuisance.[17]

• "No materials or waste products from any mill, factory, slaughterhouse, rendering or fertilizing works, junk establishment, common carrier or other industry or utility shall be stored or deposited so as to cause the surrounding atmosphere, land or water to be contaminated or polluted in such a manner as to injure the public health or create offensive conditions."[18]

• "Any person who wilfully deposits material in any watercourse where it will naturally be carried to the land of another to his injury shall pay to the party injured thereby double damages and costs, unless, within a reasonable time after notice of the injury, he removes such material from such land."[19]

• "Any person who places, collects or allows to remain upon the surface of land owned or occupied by him, or discharges or allows to be discharged from his premises upon the land of another or upon any public land, any filthy water, garbage or other filthy or noxious matter, whereby the owner or occupant of land in the vicinity thereof is injured or annoyed, or discharges or deposits upon the watershed of any stream or reservoir used to supply water to any community filthy or noxious matter...shall be fined not more than fifty dollars [and charged with any cost of removal, if not removed within three days]."[20]

It is the duty of local health directors to abate "all nuisances and sources of filth injurious to the public health." Abatement orders are issued and are enforceable by injunctive relief, and a civil penalty of $250 per day may be assessed for each day the nuisance is maintained after the time fixed for abatement, and recovery of damages for abatement or removal.[21]

However, farming operations are exempt from nuisance actions under some circumstances: "no agricultural or farming operation...shall be deemed to constitute a nuisance, either public or private, due to alleged objectionable.....(4) use of chemicals, provided such chemicals and the method of their application conform to practices approved by the commissioner of environmental protection or, where applicable, the commissioner of public health, or (5) water pollution from livestock or crop production activities, except the pollution of public or private drinking water supplies, provided such activities conform to accepted management practices for pollution control approved by the commissioner of environmental protection;" provided that the farm has been in operation for one or more years and not substantially changed "and such operation follows generally accepted agricultural practices." "Inspection and approval of the agricultural or farming operation...by the commissioner of agriculture or his designee shall be prima facie evidence that such operation follows generally accepted agricultural practices." The exemption from nuisance liability does not apply "whenever a nuisance results from negligence or wilful or reckless misconduct in the operation...."[22]

Fish/Fisheries Laws

Connecticut does not have a broad prohibition related to fisheries that may serve as an enforceable mechanism, but has some laws of limited utility in this context.

- The law provides that "No person shall place in any lake, pond or stream any lime, creosote or cocculus indicus or any other drug or poison injurious to fish" and imposes a fine of not more than $100 per fish taken.[23] The law does not require an intent to take fish; however, the types of substances listed, coupled with the need to show intent to place the injurious substances, limit this section's potential usefulness in the nonpoint context.

- State law also allows the state to recoup restoration costs and damages, such as damage to fish and habitat, resulting from knowing or negligent violation of environmental laws, including the water pollution laws.[24]

OPERATIONAL REQUIREMENTS

Forestry Requirements

- Connecticut law requires any person engaged in commercial forest practices to obtain and maintain a state certificate. There are three classes of certificate: forester, supervising forest products harvester, and forest products harvester. Examinations are required, and the certificate is valid for not more than five years; there is a requirement of continuing education biennially to maintain certificate.[25] Certified foresters, supervisors, and harvesters are required to file annual reports of their activities and continuing education.[26] These laws can provide a basis for assuring that commercial forest practices are conducted in accordance with the prevention of nonpoint source water pollution.

• State law authorizes the Commissioner of Environmental Protection to adopt regulations "governing the conduct of forest practices including, but not limited to, the harvest of commercial forest products and other such matters as the commissioner deems necessary to carry out the provisions [of this chapter]." "Such regulations shall provide for a comprehensive statewide system of laws and forest practices regulations which will achieve the following purposes and policies: (1) Afford protection to and improvement of air and water quality..."[27] The law also authorizes municipalities to regulate forest practices in a manner consistent with the state law; municipal regulations are effective only if they are approved by the Commissioner.[28] In addition, zoning regulations may restrict clear-cutting in areas with a "traprock ridge."[29] Enforcement tools include civil penalties of up to $5,000 per day per offense, compliance orders, injunctions, and denial, suspension, or revocation of a certificate.[30]

Agriculture Requirements

In addition to the exemption from nuisance liability the use of accepted agricultural practices provides under Connecticut law, state law also contains some other enforceable requirements.

• The Commissioner of Agriculture must adopt regulations "concerning acceptable management practices of intensive poultry farming," defined as more than 20,000 fowl confined within pens or buildings, and may issue "such orders as he deems necessary" to correct noncompliance.[31] The Commissioner may take action where intensive poultry operation is "causing, engaging in or maintaining, or is about to cause, engage in or maintain, any condition or activity which in his judgment may result in the introduction or spread of an environmental or health hazard" including issuance of an immediately effective abatement order without prior hearing. A hearing must be held within ten days. The Commissioner may also expend funds to abate an activity and recover such funds via a lien on the property.[32] Civil penalties are available for violations.[33]

• "No pigsty shall be built or maintained on marshy ground or land subject to overflow..."[34]

• State pesticide laws provide authority to prescribe regulations concerning the time, place, manner, methods, materials, amounts, and concentrations of application of pesticides to prevent damage to plants, wildlife, fish and other aquatic life, beneficial insects, animals, and humans.[35]

Development and Other Earth-Disturbing Activities

• The Soil Erosion and Sediment Control Act[36] declares state policy to establish a "state-wide coordinated erosion and sediment control program which shall reduce the danger from storm water runoff, minimize nonpoint sediment pollution from land being developed and conserve and protect the land, water, air and other environmental resources of the state."[37] The statewide Council on Soil and Water Conservation develops guidelines for soil erosion and sediment control and land being developed, including model regulations that may be used by municipalities.[38] The zoning and subdivision regulations[39] adopted and enforceable by a municipality must require that "(1) Proper provision be made for soil erosion and sediment control; (2) a soil erosion and sediment control plan be submitted with any application for development when the disturbed area of such development is more than one-half acre; and (3) the municipality or the soil and water conservation district shall certify that the plan complies with regulations adopted pursuant to said sections."[40] However, a single family dwelling that is not part of a subdivision of land is exempt from soil erosion and sediment control regulations.[41]

• Certain targeted conservation and development planning requirements,[42] including protection of Long Island Sound from "hypoxia, pathogens, toxic contaminants and floatable debris,"[43] and conservation zones along the Connecticut and Niantic Rivers,[44] provide zoning standards that can allow local governments to establish enforceable practices relevant to nonpoint source pollution. Coastal management law also provides for regulation of earth-disturbing activities by municipalities subject to state policies.[45] Connecticut also provides for additional municipal regulation along protected river corridors and multiple use river corridors.[46]

DELAWARE

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Delaware's water pollution law prohibits discharge of a pollutant to the waters of the state without a permit. This provision may be used to address pollution events caused by nonpoint source discharges; however, the regulations exempt certain agricultural and other activities.

• "No person shall, without first having obtained a permit from the Secretary [of Natural Resources and Environmental Control] undertake any activity...(2) In a way which may cause or contribute to discharge of a pollutant into any surface or ground water..."[1] The adopted permitting regulations are aimed at point sources, but the state also can use this statutory authority to deal with nonpoint source pollution events.[2] Regulations provide that numerous nonpoint activities do not require a permit, however. These include activities involving existing drainage ditches; uncontaminated stormwater discharges; application of fertilizer "using recognized methods"; transportation of fertilizers; application of herbicides, pesticides and plant growth regulators; plowing or cultivating for agricultural or horticultural purposes; irrigation practices utilizing uncontaminated water; snow and ice removal; movement of earth for building excavations; regrading of earth "unless otherwise regulated"; and salting and sanding of roadways for the express purpose of snow and ice control.[3] Enforcement includes civil penalties, orders, and injunctions.[4]

Other Discharge Limitations

• A separate law addresses pollution of public water supplies. "No person shall cast, put, place, discharge in or permit or suffer to be cast, put, discharged in or to escape into any running stream of water within the limits of this State, from which stream the inhabitants of any borough, town or city within this State are supplied wholly or in part with water for and as drink or beverage, any dye-stuffs, drugs, chemicals or other substance or matter of any kind whatsoever whereby the water so supplied...becomes noxious to the health or disagreeable to the senses of smell or taste."[5] This offense is punishable by a fine of $1000-$5000.

• Under nuisance-type legislation, Delaware law provides that a local board of health may abate "noisome matter."[6] And "a person is guilty of criminal nuisance when...[b]y conduct either unlawful in itself or unreasonable under all the circumstances, the person knowingly or recklessly creates or maintains a condition which endangers the safety or health of others." Criminal nuisance is punishable by fine of up to $575 and up to 30 days in jail.[7] However, with respect to nuisances, "No agricultural or forestal operation within this State which has been in operation for a period of more than 1 year shall be considered a nuisance, either public or private, as the result of a changed condition in or about the locality where such agricultural or forestal operation is located. This section shall not apply when the nuisance is determined to exist as the result of the negligent or improper operation of any agricultural or forestal operation or when such operation is being operated in violation of state or federal law or any local or county ordinance."[8]

• Littering legislation may also be usable to address pollution resulting from waste material or other discarded materials. It is unlawful to "dump, deposit, throw or leave, or cause or permit the dumping, depositing, placing, throwing or leaving of litter on any public or private property of this State, or any waters in this State."[9] "Litter" includes "all rubbish, waste material, refuse, cans, bottles, garbage, trash, debris, dead animals or other discarded materials of every kind and description."[10] This is a petty offense punishable by fine of $25-$50.[11]

Fish/Fisheries Laws

The state laws directed at fish and fisheries do not appear to provide independent enforcement mechanisms for nonpoint source pollution.

OPERATIONAL REQUIREMENTS

Forestry Activities

Delaware has a detailed enforcement order authority, or "bad actor" authority, to address nonpoint sediment pollution from forestry operations.

• "The Forestry Administrator shall provide for the protection of the waters of the State from pollution by sediment deposits resulting from silvicultural activities."[12] "Pollution" is defined as "such alteration of the physical, chemical or biological properties of any waters of the State resulting from *sediment deposition* that will or is likely to create a nuisance or render such waters (a) harmful or detrimental or injurious to the public health, safety or welfare, or to the health of animals, fish or aquatic life; (b) unsuitable with reasonable treatment for use as present or possible future source of public water supply; or (c) unsuitable for recreational, commercial, industrial, agricultural or other reasonable uses."[13]

The statute contemplates informal attempts to abate the problem initially. "If the Forestry Administrator...determines that an owner or operator is conducting or allowing the conduct of any silvicultural activity in a manner which is causing or is likely to cause pollution, the Forestry Administrator ...may advise the owner or operator of corrective measures needed to prevent or cease the pollution. Failure of the Forestry Administrator...to advise an owner or operator of such corrective measures shall not impair the Forestry Administrator's authority to issue special orders."[14]

The enforcement mechanism is the special order. "Special orders can be issued if the Forestry Administrator...finds that any owner or operator is conducting any silvicultural activity in a manner which is causing or is likely to cause alteration of physical, chemical or biological properties of any state water, resulting from sediment deposition presenting an *imminent and substantial danger* to (a) the public health, safety or welfare, or the health of animals, fish or aquatic life; (b) a public water supply; or (c) recreational, commercial, industrial, agricultural or other reasonable uses." The order may direct the owner or operator "to cease immediately all or part of the silvicultural activities on the site and to implement specified corrective measures within a stated period of time."[15] However, "[t]he Forestry Administrator shall not issue a special order to any owner or operator who has incorporated generally acceptable sediment control and stormwater management techniques and guidelines developed by the Forestry Administrator, which techniques have failed to prevent pollution, if the Forestry Administrator determines that the pollution is the direct result of unusual weather events which could not have been reasonably anticipated."[16]

Special orders are issued after notice and hearing and are effective not less than 5 days after service, except for emergency special orders which may be issued immediately provided there is a rapid post-issuance hearing. Sanctions are civil penalties of $200 to $2,000 per violation per day; but intentional and knowing violations of orders after written notice to comply are subject to fines of $500 to $10,000 per violation per day.[17]

Agricultural Activities

Delaware appears to have few enforceable nonpoint source provisions directed at agricultural practices, apart from manure management provisions for CAFOs.

• An older public health provision provides that "No person shall put or place, or permit to be put, place or used, any...hogpen or slaughterhouse over or so near that the excrement or offal therefrom shall escape or run into any stream of running water within the limits of this State from which the inhabitants of any town, borough or city are wholly or in part furnished with water as a drink or beverage."[18] This offense is punishable by a $100 fine.

• The state also has pesticide applicator regulations.[19] The law provides that the Department of Agriculture "may prescribe the methods to be used in application of pesticides, and may relate to the time, place, manner, materials and amounts and concentrations, in connection with the application of the pesticides, and may restrict or prohibit use of pesticides in designated areas during specified periods of time and shall encompass all reasonable factors which the Department deems necessary to prevent damage or injury by drift or misapplication to...plants...or adjacent or nearby lands...fish and other aquatic life in waters in reasonable proximity to the areas to be treated..."[20]

Development and Other Earth-Disturbing Activities

• Delaware's law on erosion and sedimentation control addresses some nonpoint issues in addition to the basic urban stormwater program.[21] "[U]nless exempted, no person shall engage in land disturbing activities without submitting a sediment and stormwater management plan to the appropriate plan approval authority and obtaining a permit to proceed."[22] "Projects which do not alter stormwater runoff characteristics may be required to provide water quality enhancement even if the predevelopment runoff characteristics are unchanged. Criteria will be detailed in the regulations regarding level of water quality control and variance procedures."[23] Local governments are authorized to adopt their own programs for DNREC approval.[24]

"Land disturbing activity" means "any land change or construction activity for residential, commercial, industrial and institutional land use which may result in soil erosion from water or wind or movement of sediments or pollutants into state waters or onto lands in the State, or which may result in accelerated stormwater runoff, including, but not limited to, clearing, grading, excavating, transporting and filling of land...."[25] Regulations exempt construction or development that disturbs less than 5,000 square feet.[26] The law also "does not apply to commercial forestry practices."[27] This exemption, and the deletion of "silvicultural" from the list of regulated activities occurred in 1994. Also, "The provisions of this chapter shall not apply to agricultural land management practices unless the conservation district or the Department determines that the land requires a new or updated soil and water conservation plan, and the owner or operator of the land has refused either to apply to a conservation district for the development of a plan, or to implement a plan developed by a conservation district."[28]

Standards are set by DNREC, providing minimum standards for delegation to local governments, and establishing required provisions and regulations.[29] Regulations require all plans to comply with the Delaware Erosion and Sediment Control Handbook dated 1989 and all supplements (subject to public review and comment prior to adoption of supplements).[30] Regulations identify other specifics of plans.[31] General permits apply for certain structures - such as certain individual residences with disturbed area less than 1 acre, highway shoulder and swale maintenance, commercial and industrial projects when disturbed area is less than ½ acre, modification of tax ditch when no change in water quantity, quality.[32] Based on certain criteria, the person engaged in the activity may be required to provide for construction review by a state-certified construction reviewer; the reviewer is responsible for weekly review of site activities, informing of violations, and referral to DNREC if person fails to correct items identified in review report.[33]

The law further provides that watersheds or subwatersheds proposed by a conservation district, county, municipality, or state agency and approved as "designated" shall have "regulatory requirements clearly specified through a watershed approach to nonpoint pollution control or flood control. The watershed approach shall result in a specific plan, developed or approved by the Department..." "Upon approval of the designated watershed or subwatershed plan, all projects...shall have stormwater requirements placed upon them that are consistent with the...plan."[34]

Enforcement provisions include local enforcement and/or referral to DNREC; also the law provides for DNREC cease and desist orders, and requests by DNREC to local authorities to deny any further building or grading permits until a violation is corrected.[35] Injunctions,[36] and criminal fines are also available.[37]

• The Delaware Land Protection Act also provides some possible basis for local enforceable mechanisms.[38] It requires each county government to adopt "overlay zoning ordinances, guidelines and specific technically based environmental performance standards, design, criteria and mitigation requirements, where appropriate" to protect open space. The guidelines shall include but not be limited to setback and design requirements, and the establishment of technically based specific environmental performance standards and design criteria that shall apply in and may apply adjacent to state resource areas in order to protect the values of said lands.[39] However, the law does not apply to lands producing agricultural commodities. Enforcement is under local laws and ordinances.

• The state's Wetlands Act applies to tidal and connected wetlands.[40] It requires a permit for any "activity in the wetlands" unless exempted by law; the secretary must consider environmental impacts including "impact of the site preparation and proposed activity on land erosion; effect of site preparation and proposed activity on the quality and quantity of tidal waters, surface, ground and subsurface water resources and other resources..."[41] No permit may be granted unless local government has first approved it by local zoning procedures. Fines and civil penalties apply; and enforcement includes orders, injunctions, and prosecutions.[42]

• A permit from DNREC is also required to deposit material upon or remove materials from, or construct or modify structures or facilities on, submerged lands or tidelands.[43] The regulations provide that no "project which may potentially...contribute to water pollution...shall be undertaken on public or private subaqueous lands unless approval has been obtained from the Department."[44] Enforcement is via orders, injunctions, civil and criminal penalties.[45]

DISTRICT OF COLUMBIA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

District water pollution control laws contain some provisions that may allow enforcement against nonpoint discharges if the mayor chooses to imposes limits, or in cases where there is an imminent and substantial danger. Another provision prohibits discharges that create a detrimental effect on receiving waters.

• "Except as provided in § 6-926, no person shall discharge a pollutant to the waters of the District."[1] "Discharge" is defined as "the spilling, leaking, releasing, pumping, pouring, emitting, emptying, or dumping of any pollutant or hazardous substance, including a discharge from a storm sewer, into or so that it may enter District of Columbia waters."[2] The cross-referenced provision states that: "(a) the Mayor may:...(2) Limit pollution from nonpoint sources to a feasible degree."[3] It further provides that "If the Mayor limits pollution from nonpoint sources under subsection (a)(2) of this section, then the regulation of the nonpoint sources shall apply to real estate construction and development."[4] The requirements for such permitting, if adopted, are spelled out: "Before any real estate construction takes place, the person performing the construction or the development shall obtain a permit for controlling pollution from the nonpoint source."[5] Enforcement mechanisms include administrative orders, civil penalties of up to $50,000, injunctive relief; and criminal prosecution for willful or negligent violations.[6]

• There is also a general authority to protect the public health and welfare that is applicable to nonpoint source discharges. "Whenever there is a discharge or a substantial threat of discharge into the waters of the District of a hazardous substance, or...of a pollutant which may present an imminent and substantial danger to the public health or welfare...the Mayor is authorized to act to remove or arrange for the removal of the pollutant and the Corporation Counsel of the District may bring suit ...to restrain immediately any person causing or contributing to a discharge or threat of discharge, to recover any costs or removal incurred by the District, to impose civil penalties or to seek any other relief as the public interest may require."[7]

• Finally, District laws prohibit certain discharges to sewers or via natural outlets to receiving waters including, apparently nonpoint discharges.[8] For example, one provision states that "discharge of any waters into any storm or combined sewer or to a natural outlet is prohibited if the discharge will create a detrimental effect upon the receiving water."[9] This provision is enforceable by order, injunction, civil penalty of up to $1,000 per day, and criminal prosecution.[10]

Other Discharge Limitations

• "For purposes of this chapter [which imposes liability and defines remedies], the term 'nuisance' means a condition or circumstance violative of the provisions listed in §6-2902(a)."[11] The referenced section lists local laws and rules relating to litter and discarded material, such as "No person shall deposit, throw or place...any solid waste in any alley, street, catch basin, or other public space, or into the Potomac River or other waters in the District, or onto any premise under the control of others."[12] The provision is enforced by notices of violation, civil fines, and abatement orders.[13]

• It is unlawful for any person to "cast, throw, drop, or deposit any stone, gravel, sand, ballast, dirt, oyster shells, or ashes in the water in any part of the Potomac River or its tributaries in the District of Columbia, or on the shores of said river below highwater mark," or to deposit into the river or its tributaries any dead fish, dead animals, shavings, straw or "filth of any kind whatsoever."[14] Violation is a misdemeanor punishable by a fine up to $100 and/or imprisonment up to 6 months.[15]

• It is also unlawful to allow "any waste product whatever of any mechanical, chemical, manufacturing, or refining establishment to flow into" Rock Creek, the Potomac River or its tributaries, or any pipe or conduit leading to the same. Violation is punishable by a fine of up to $300 and/or imprisonment up to 90 days.[16]

• The existence of "miscellaneous materials or debris of any kind" on a parcel of land, including substances accumulated as a result of repairs to yards of buildings, is a nuisance "insofar as they affect the public health, comfort, safety and welfare." These conditions are subject to orders to abate, fines of up to $50 per day after issuance of an order, or summary abatement by the District with recovery of twice the costs incurred.[17]

Fish/Fisheries Laws

District laws relating to fish or fisheries do not appear to contain enforceable provisions relating to nonpoint source discharges.

OPERATIONAL REQUIREMENTS

Forestry Requirements

None.

Agriculture Requirements

• Pesticide application must be made "in a manner to prevent harmful effects to the environment."[18] And no person shall "transport, store, discard, or dispose of any pesticide...in a manner that...pollutes any waterway in a way harmful to any wildlife in the waterway," nor "handle...any pesticide in a manner that endangers man and the environment."[19] Enforcement is via injunction, criminal prosecution with fine of not more than $300 and up to 90 days imprisonment, suspension of applicator's certificate, stop sale/use/removal orders.[20]

Development and Other Earth-Disturbing Activities

• As noted above, the city has power to regulate nonpoint sources, and if such regulation is imposed it "shall apply to real estate construction and development," including permitting.[21] Erosion control regulations require permit for land disturbing activities contingent upon submission and approval of erosion and sedimentation plan.[22] "In instances where erosion is occurring as a result of natural forces or past land disturbing activities, but in the absence of current land disturbing activities, the Department [of Community and Regulatory Affairs] shall have the authority to inspect the site and to order the property owner to correct the erosion problem."[23] Failure by a permittee to comply with a plan results in a notice and then permit revocation, denial of occupancy permit, injunctive relief, or misdemeanor sanction of up to $300 and/or ten days imprisonment.[24]

FLORIDA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Florida's water pollution control laws include provisions that may be used to take enforcement action against nonpoint source discharges resulting in pollution that harms human health or welfare or biological resources or property; and against certain unpermitted nonpoint source discharges that contribute to violation of water quality standards.

• Florida's water pollution control law, administered by the Department of Environmental Protection (DEP) has a general prohibition on pollution that is applicable to nonpoint sources: "It shall be a violation of this chapter, and it shall be prohibited for any person...[t]o cause pollution, except as otherwise provided in this chapter, so as to harm or injure human health or welfare, animal, plant, or aquatic life or property.[1]

• It is also a violation "[t]o fail to obtain any permit required by this chapter or by rule or regulation, or to violate or fail to comply with any rule, regulation, order, permit or certification adopted or issued by the department pursuant to its lawful authority..."[2] This provision may apply to some nonpoint source discharges because permits are required for discharges of materials that contribute to violations of water quality standards: "No person, without written authorization of the department, shall discharge into waters within the state any waste which, by itself or in combination with the wastes of other sources, reduces the quality of the receiving waters below the classification established for them...."[3] "Waste" means "sewage, industrial wastes, and all other liquid, gaseous, solid, radioactive, or other substances which may pollute or tend to pollute any waters of the state."[4] This permit requirement is not limited to point sources. However, agricultural activities (including all "normal and customary" farming and forestry operations) and agricultural water management systems do not require permits.[5]

• A separate law defines violations and provides similar enforcement authorities for Florida's five water management districts (WMDs).[6] Like the law referenced above, the law they administer defines a violation as "To cause pollution, as defined in [the law referenced above], except as otherwise provided in this part, so as to harm or injure human health or welfare, animal, plant, or aquatic life or property", and another violation failure to obtain a required permit or to comply with rules or orders.[7]

The Department of Environmental Protection (DEP) has "the power and the duty to control and prohibit pollution of air and water in accordance with the law and rules and regulations adopted and promulgated by it, and for this purpose, to:...(8) Issue such orders as are necessary...and enforce the same by all appropriate administrative and judicial proceedings....(28) Perform any other act necessary to control and prohibit air and water pollution, and to delegate any of its responsibilities, authority, and powers, other than rulemaking powers, to any state agency now or hereinafter established."[8] Counties and municipalities may also be delegated functions, with oversight and backup enforcement by DEP. Local programs have access to both their own enforcement processes and those provided to DEP.[9] DEP enforcement powers include civil actions for damages; actions for civil penalties up to $10,000 per day; administrative actions for damages; and administrative orders for abatement or other corrective action, subject to administrative hearings.[10] The law also provides for injunctions,[11] and for criminal prosecution for violations committed with intent.[12] The state's Environmental Protection Act also allows the attorney general, any political subdivision, or any citizen to enforce laws and regulations for the protection of the air, water, and other natural resources of the state in court.[13]

Water pollution laws are administered by the DEP and the WMDs;[14] areas within WMDs may be further divided into basins with basin boards.[15] Each WMD establishes a list, updated every 3 years, prioritizing water bodies of regional or statewide significance using criteria "based on their need for protection and restoration"; then WMDs develop plans, including identification of land uses, "point and nonpoint sources of pollution" and lists of sources operating without permit and sources presently violating effluent limits or water quality standards, recommendations and schedules for compliance, measures needed to restore and maintain water quality.[16] The proposed plans must be reviewed by DEP, Dept. of Ag and Consumer Services, Game and Freshwater Fish Commission, Dept. of Community Affairs, and local governments.[17] Plans adopted by the WMD are then reviewed by DEP for "consistency" with the state water plan and state comprehensive plan.[18] While the plans are not themselves enforceable mechanisms, they can serve to identify where such mechanisms may be used.

Other Discharge Limitations

• It is unlawful to "dump litter in any manner or amount...(b) In or on any freshwater lake, river, canal, or stream or tidal or coastal water of the state, including canals"[19] Litter is defined as any "garbage; rubbish; trash; refuse:...sludge from a waste treatment facility, water supply treatment plant, or air pollution control facility; or substance in any form resulting from domestic, industrial, commercial, mining, agricultural, or governmental operations."[20] The statute provides for civil penalties of $50 to $5,000 based on the amount and purpose of the dumping; and criminal prosecution.[21]

• State law protects water supplies, and provides that "in coordination with the Department of Health and Rehabilitative Services, the department [of Environmental Protection], upon receipt of information that a contaminant which is present in, or is likely to enter, public or private water supplies may present an imminent and substantial danger to the public health, may take such actions as it may deem necessary in order to protect the public health..." including corrective action orders and injunctions.[22] Criminal prosecution is available for willfully or maliciously corrupting a spring or reservoir.[23]

• "Any person...who shall deposit, or who shall permit or allow any person or persons in their employ or under their control, management, or direction to deposit in any of the waters of the lakes, rivers, streams, and ditches in this state, any rubbish, filth, or poisonous or deleterious substance or substances, liable to affect the health of persons, fish, or livestock, or place or deposit any such deleterious substance or substances in any place where the same may be washed or infiltrated into any of the waters herein named, shall be guilty of a misdemeanor of the second degree" punishable by a fine of up to $500 and/or 60 days imprisonment.[24]

• "A sanitary nuisance is the commission of any act...or the keeping, maintaining, propagation, existence, or permission of anything...by which the health or life of an individual, or...individuals, may be threatened or impaired, or by which or through which, directly or indirectly, disease may be caused."[25] "The following conditions..shall constitute prima facie evidence of maintaining a nuisance injurious to health: (a) Untreated or improperly treated human waste, garbage, offal, dead animals, or dangerous waste materials from manufacturing processes harmful to human or animal life....(f)Any other condition determined to be a sanitary nuisance...."[26] Nuisances may be enjoined, abated by the Dept. of Health and Rehabilitative Services, and/or prosecuted as misdemeanors of the second degree.[27] Farm operations in existence for one or more years are not nuisances if they conform to "generally accepted agricultural and management practices."[28]

Fish/Fisheries Laws

• State law provides that "No person, except as provided herein, shall take...freshwater fish...within this state without first having obtained a license, permit, or authorization..."[29] "Take" is defined as "taking, attempting to take, pursuing, hunting, molesting, capturing, or killing any...freshwater fish... whether or not such actions result in obtaining possession..."[30]

• The law also provides that "No person may throw or place, or cause to be thrown or places any dynamite....acids, filtration discharge, debris from mines, Indian berries, sawdust, green walnuts, walnut leaves, creosote, oil, or other explosives or deleterious substance or force into the freshwaters of this state whereby fish therein are or may be injured..."[31]

• "It shall be unlawful for any person..to cause any dyestuff, coal tar, oil, sawdust, poison or deleterious substances to be thrown, run or drained into any of the fresh running waters of this state in quantities sufficient to injure, stupefy, or kill fish..."[32]

Violations of these pollution provisions are misdemeanors of the second degree punishable by fine of up to $500 and/or 60 days imprisonment.

• State law also provides for recovery of money damages for injury to "air, waters, or property, including animal, plant, and aquatic life...and for reasonable costs and expenses of the state in tracing the source of the discharge, in controlling and abating the source and the pollutants, and in restoring the air, waters, and property, including animal, plant, and aquatic life, of the state to their former condition" as well as for a civil penalty of up to $10,000 per day. It also provides for a table of dollar amounts recoverable per fish killed.[33]

OPERATIONAL REQUIREMENTS

Forestry Requirements

The state relies on voluntary BMPs; enforcement, if necessary, is under the water pollution discharge laws identified above. Forest harvest operations also must file a "notice of general permit" with a Water Management District, where applicable.

Agriculture Requirements

Agricultural operations are not required to obtain permits under the water pollution law for nonpoint source activities. CAFOs are regulated as point sources.

• Florida has a program that operates collectively to reduce phosphorous loading in the Everglades watershed. The law provides for a scheduled phased-in increase in agricultural taxes over the course of a long period, but if the collective loadings are reduced by certain targets, agricultural operators do no not have to pay the scheduled increases. In addition part of the program provides individual credits against these taxes for operators that take actions themselves on identified parcels. Sanctions in the form of higher taxes are imposed automatically on identified entities where prescribed results are not achieved.[34]

• Florida imposes special requirements on dairy farms in the Lake Okechobee drainage basin. These include enforceable requirements to fence all dairy cattle out of watercourses, requirements for setbacks, and the regulation of the land application of manure.[35]

• The state provides for certifications and licensing with respect to pesticide dealers and applicators.[36] "Prohibited acts" include "apply[ing] any pesticide directly to, or in any manner cause any pesticide to drift onto, any person or area not intended to receive the pesticide", as well as handling, distributing, etc in a manner "as to endanger human beings or the environment"[37] Violations are addressed by orders, license revocation or suspension, administrative fines and misdemeanor prosecution.[38]

Development and Other Earth-Disturbing Activities

• There are regional and state comprehensive planning requirements.[39] Local governments are required to do local plans and land regulation consistent with these: "comprehensive plans or elements thereof shall be implemented...by the adoption and enforcement of appropriate local regulations on the development of lands and waters within an area."[40]

• State law also provides for designation of "areas of critical state concern" which, if designated, must be taken into account and protected by state and local agency regulations and decisions.[41] Such areas must include, or have a significant impact upon, "environmental or natural resources of regional or statewide importance."

Local land use regulations must be conformed to the designation. Developments of regional impact must be evaluated under these standards as well if located in an area of critical state concern.[42]

• Stormwater permitting requires permitting of facilities by DEP or as delegated to local governments or by the Water Management District; it includes general permits for certain types of facilities.[43] State law sets out provisions for stormwater and wetlands permitting (environmental resource permitting) under jurisdiction of water management districts.[44]. Stormwater plans are required from water management districts; local governments must cover in comprehensive plans.[45] Sedimentation and erosion controls are covered under Water Management District regulations. Enforceable mechanisms are those available to DEP under the water pollution law, to Water Management Districts, or to local governments under local authorities.

GEORGIA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Georgia's water pollution control law authorizes a permit program to control nonpoint sources that may impair water quality. It also includes a separate provision allowing the state to recover damages for intentional or negligent discharges (including nonpoint point source discharges) resulting in a polluted condition, or that consist of particularly harmful substances in harmful amounts.

• Georgia law requires a permit for anyone seeking to "erect or modify facilities or commence or alter an operation of any type which will result in the discharge of pollutants from a nonpoint source into the waters of the state, which will render or is likely to render such waters harmful to the public health, safe, or welfare, or harmful or substantially less useful for domestic, municipal, industrial, agricultural, recreational, or other lawful uses, or for animals, birds, or aquatic life."[1] The regulations limit this provision. They require only "written approval" and use of BMPs "under the circumstances described" in the statute, but not application for or issuance of a permit unless the Director of the Environmental Protection Division (EPD) "has issued one to the same person for a point source discharge."[2] Injunctive relief and civil penalties of up to $50,000 per day are provided for, as are criminal penalties of $2,500 to $25,000 and/or imprisonment.[3]

• A person who "intentionally or negligently causes or permits any sewage, industrial wastes, or other wastes, oil, scum, floating debris, or other substance or substances to be spilled, discharged, or deposited in the waters of the state, resulting in a condition of pollution . . . shall be liable in damages . . . for any and all costs, expenses, and injuries." The amount of damages includes costs of abatement and "expenses reasonably incurred in replacing aquatic life."[4] A person who "intentionally, negligently, or accidentally causes or permits any toxic, corrosive, acidic, caustic, or bacterial substance or substances to be spilled, discharged, or deposited" in harmful amounts is strictly liable.[5]

Other Discharge Limitations

• Nuisance law also applies to water pollution.[6] But agricultural facilities may not be deemed a nuisance based on changed conditions; however, the exemption is not available if the nuisance results from a negligent, improper, or illegal operation.[7]

Fish/Fisheries Laws

• It is unlawful to "throw, dump, drain, or allow to pass into any waters of this state which belong to the department or which are being utilized by the department for fish propagation any sawdust, dyestuff, oil, chemicals, or other deleterious substances that will or may tend to injure, destroy, or drive away from such waters any fish or aquatic organisms which may inhabit such waters." Damages are available for unlawful or negligent injury or destruction of fish; the measure of damages is the "amount which will compensate for all the detriment proximately caused by the destruction or injury of such fish or aquatic organism."[8] In addition, any person who takes wildlife in violation of the Game and Fish Code is guilty of the offense of theft by taking.[9] Civil penalties are available up to $1,000 per violation, administrative orders and enforcement of administrative orders in superior court are available, as is misdemeanor prosecution.[10]

OPERATIONAL REQUIREMENTS

Forestry Requirements

Georgia's forestry laws do not appear to contain enforceable provisions relating directly to nonpoint source pollution. But Georgia does require registration of professional foresters, with continuing education and relicensing. Forest practices for hire must be conducted by a professional forester.[11] Enforcement of licensing requirements include injunction, license revocation, and misdemeanor prosecution.[12]

Agriculture Requirements

• Supervisors of each soil and water conservation district have authority to adopt enforceable regulations "governing the use of lands within the district, in the interest of conserving soil and soil resources and preventing and controlling soil erosion."[13] District regulations may include: 1) provisions requiring engineering operations, including terrace construction, dams, dikes, etc; 2) provisions requiring particular cultivation methods, including "contour cultivating; contour furrowing; lister furrowing; sowing; planting; strip cropping; changes in cropping systems, seeding, and planting of lands to water-conserving and erosion-preventing plants, trees, and grasses; forestation; and reforestation" and 3) provisions requiring highly erosive areas to be retired from cultivation.[14] However, supervisors may adopt such enforceable regulations only with the approval by referendum of the owners of the lands within the district. The regulations are binding on all landowners within the district.[15] Enforcement is by injunctive relief. If an injunction is not obeyed, the district may go on the land to perform the work and recover its expenses with interest.[16]

• It is unlawful to transport, store, or dispose of any pesticide in manner to "cause injury to humans, vegetation, crops, livestock, wildlife, or beneficial insects or in such a manner as to pollute any waterway in a way harmful to any wildlife therein." In determining standards governing the storage and disposal of such pesticides, commissioner shall consider any regulations issued by U.S. EPA or state DNR.[17] Licensing of contractors and applicators is required.[18] Violations of the pesticide statute are enforced by injunction, civil penalty, criminal prosecution, and license revocations/suspensions.[19] However, no one engaged in "agricultural, silvicultural, farming, horticultural, or similar operation . . . who has applied or used or arranged for the application or use of any fertilizer, plant growth regulator, or pesticide" as defined in FIFRA, the Georgia labeling and registration statute, or the Georgia pesticide application statute "shall be responsible or liable under this title, without proof of negligence or lack of due care, for any damages, response costs, or injunctive relief relating to any direct or indirect discharge or releaser into, or actual or threatened pollution of, the land, waters, air, or other resources of the state that is or may be associated with or resulting from such application of use." The application must have been consistent with the labeling, in accord with acceptable agricultural practices; the item must have been properly licensed or registered. Causes of action against agricultural or farming operations for injury to person or property are not affected.[20]

• Irrigation systems used for application of fertilizers, pesticides, or chemicals "must be equipped with an anti-siphon device adequate to protect against contamination of the water supply." Enforcement is via administrative order and civil penalty of up to $1,000.[21]

Development and Other Earth-Disturbing Activities

• Georgia's Erosion and Sediment Control Act establishes a permit process for land-disturbing activities. County and municipalities are directed to adopt comprehensive ordinance to establish procedures governing land-disturbing activities; local authorities may delegate responsibilities to local planning and zoning commission.[22] If a county or municipality enacts ordinances that meet or exceed standards and which are enforceable, EPD may certify the local entity to be an "issuing authority."[23] BMPs are required for all land-disturbing activities. BMPs must include "sound conservation and engineering practices to prevent and minimize erosion and resultant sedimentation" consistent with a manual published by the soil and water conservation commission, and including specific requirements protecting waters from nonpoint source pollution.[24] Permits are not required for some activities, such as construction of individual single-family residences and land-disturbing activities conducted by public utilities so long as they conform to BMPs. Activities on sites of 1.1 acres or less are exempt from both permit and BMP requirements unless they are within 200 feet of lakes or perennial streams. Agriculture and forestry operations are wholly exempt.[25] Enforcement is by EPD or the issuing authorities, using administrative orders, injunctions, and civil penalties. Civil penalties for non-certified counties and municipalities are authorized up to $2,500 per day. Permit revocation, suspension, modification, and bond forfeiture are also enforcement sanctions.[26]

• Georgia has a river corridor protection law. The DNR is authorized to develop minimum standards for the "protection of the natural resources, environment, and vital areas of the state, including, but not limited to, the protection of mountains, the protection of river corridors, the protection of watersheds of streams and reservoirs which are to be used for public water supply, for the protection of the purity of ground water, and for the protection of wetlands, which minimum standards and procedures shall be used by local governments in developing" comprehensive plans.[27] The minimum standards for watershed protection shall include buffer areas along streams and reservoirs, land development densities, and land use activities. Minimum standards for protection of ground water shall include land use activities and development densities. Minimum standards for protection of wetlands shall include land use activities, land development densities, and activities involving alteration of wetlands.[28] Standards for protection of river corridors shall include natural vegetative buffer areas for a distance of 100 feet on both sides of stream as measured from stream banks.[29] Local governments are mandated to identify existing river corridors and adopt river corridor protection plans.[30] Local governments may exempt certain activities from requirements of river corridor protection plans: existing land uses; permitted mining activities; utilities, from buffer criteria; specific forestry and agricultural activities, from buffer criteria, if activity is consistent with BMPs established by forestry commission or soil and water conservation commission and the activity will not impair drinking quality of stream water.[31] Enforcement is under local ordinances.

• The Metropolitan River Protection Act requires governing authorities to adopt ordinances protecting the Chattahoochee and its tributaries, including buffer areas prohibiting land-disturbing activities, and soil erosion and sediment provisions consistent with the above Act. Failure to enforce these provisions can give rise to enforcement action by EPD upon request by the Atlanta Regional Commission or Georgia Mountains Regional Development Center.[32]

• The Shore Protection Act also provides some authority affecting activities along the shoreline that may result in nonpoint source water pollution. Permitting and other requirements are enforceable by local governments or the state.[33] The Coastal Marshlands Protection Law also provides enforceable mechanisms, including permitting and order authority relevant to some forms of nonpoint source pollution in the estuarine area of the state.[34]

HAWAII

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Hawaii's water pollution control law includes some provisions that may be used to take enforcement action against nonpoint source discharges that are not permitted or that result in water quality violations.

• Hawaii law prohibits discharges of "any water pollutant into state waters" except in compliance with the law or a permit or variance thereunder.[1] This prohibition is not limited to point source discharges. The director of the Department of Health ("DoH") shall issue a permit for a term of up to five years, if "issuance is in the public interest."[2] Under this statute, "water pollution" is broadly defined as "discharge of any liquid, gaseous, solid...or other substances into any state waters... likely to create a nuisance or render such waters....harmful....to public health...including harm...to public water supplies, fish and aquatic life and wildlife...or as will or is likely to violate any water quality standards, effluent standards..."[3] Where a violation occurs, DoH sends written notice to alleged violator and, if the violation continues, another notice containing an order for corrective action.[4] DoH may also modify, suspend or revoke a permit.[5] Administrative and civil (up to $10,000 for each offense) penalties are authorized.[6] Criminal sanctions are more stringent if the violation was "knowing" rather than "negligent."[7]

Other Discharge Limitations

• Under Hawaii's Nonpoint Source Pollution Management and Control statute, DoH has explicit authority to "reduce, control and mitigate nonpoint source pollution,"[8] which is defined as "water pollution not originating from a point source."[9] This law is in addition to the broad water pollution law described above and "should not be construed or interpreted to diminish the scope of that law."[10] DoH is to adopt "water quality standards for specific areas, types of nonpoint source pollution discharges, or management measures..."[11] The Director may enforce the rules, enter and inspect areas to investigate sources of nonpoint pollution and determine compliance.[12] Civil penalties of up to $10,000 are authorized for each separate offense and each day of violation.[13]

• State law authorizes the Department of Land and Natural Resources ("DLNR") to adopt rules that prevent "the discharge or throwing into ... ocean waters and navigable streams..." substances that are likely to affect the quality of the water or contribute to making these areas "unsightly, unhealthful, or unclean."[14] DLNR has authority to conduct searches and seize equipment used in violation of the title. Fines of up to $10,000 are authorized.[15] A violator is guilty of a misdemeanor with fines and/or imprisonment, if he fails to appear at the time and place specified under a DLNR summons or citation.[16]

• The statutory nuisance laws direct that DoH examine "all nuisances... ...and...any and all conditions created or existing which cause or tend to cause sickness or disease or to be dangerous or injurious to health, and shall cause the same to be abated, destroyed, removed, or prevented."[17] Although there are exceptions to the nuisance provision under the Hawaii Right to Farm Act, the exceptions do not apply to water pollution.[18] If a landowner does not comply with a DoH abatement order, then DoH may apply for a judicial order of abatement. DoH may recover expenses incurred for abatement, removal, destruction or prevention of a nuisance. Administrative civil penalties up to $20,000 for each offense are authorized.[19]

• Counties have the authority to maintain channels to carry off storm waters and "to remove from the channels, and from the shores and beaches, any debris that is likely to create an unsanitary condition or become a public nuisance."[20] Counties also have the authority to enact and enforce ordinances that "prevent or summarily remove nuisances...and to enforce liens upon the property for the cost to the county of completing the necessary work" where owners fail to comply.[21]

Fish/Fisheries Laws

General discharge limitations described above define "water pollution" as including discharges that cause harm to "fish and aquatic life and wildlife."[22] Other fisheries provisions appear limited to prohibiting the introduction of certain substances into state waters "for the purpose of taking aquatic life." [23]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• Hawaii laws relating to forestry do not appear to contain enforceable provisions with respect to nonpoint source discharges.

Agriculture Requirements

• County governments, in cooperation with soil and water conservation districts and other state and federal agencies, are to enact ordinances to control soil erosion and sediment, including standards for soil and land uses that identify "criteria, techniques, and methods for the control of erosion and sediment resulting from land disturbing activities."[24] See the Other Discharge Limitations section for authorized sanctions pursuant to DLNR authority.

• Hawaii law has general pesticide licensing and labeling requirements.[25] In addition, every person who sells or distributes restricted use pesticides is required to obtain an annual permit.[26] Refusal to license or cancellation or suspension of licenses are authorized,[27] in particular, when pesticide usage is determined to have unreasonable adverse effects on the environment, specifically when pesticide residues are detected in drinking water.[28] Administrative civil penalties and criminal penalties may result.[29]

Development and Other Earth-Disturbing Activities

• Hawaii law requires all county ordinances to control soil erosion and sediment from land disturbing activities, and the standards are deemed to be met if the land is managed in accordance with practices acceptable to the local soil and water conservation districts.[30] See the Other Discharge Limitations section for authorized sanctions pursuant to DLNR authority.

• No development is allowed in any county within a "special management area" without a permit, although use of land for activities such as cultivating, planting, or harvesting plants and crops for agricultural or forestry purposes is exempt.[31] Variances are authorized for certain activities "that are clearly in the public interest."[32] Civil fines may be imposed, and injunctive relief is available.[33]

IDAHO

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Idaho's water pollution control law includes a few provisions that may authorize enforcement against nonpoint source discharges that adversely affect water quality in outstanding resource waters and in certain impaired waters for which Total Maximum Daily Loads (TMDLs) have been developed.

• Idaho law provides that "no person shall conduct a new or substantially modify an existing nonpoint source activity that can reasonably be expected to lower the water quality of an *outstanding resource water*, except where the nonpoint source activities are temporary or short-term and do not alter the essential character of a stream segment."[1] Prior agency approval is required to conduct any new nonpoint source activities affecting such waters.[2]

• Where total maximum daily loads (TMDLs) are required -- for example, in high-priority impaired waters where there is significant risk to the designated water uses[3] -- the state must develop "pollution control strategies for both point sources and nonpoint sources for reducing those sources of pollution."[4] For "reasonably foreseeable nonpoint source activities," the agency is to develop and implement best management practices (BMPs).[5] For medium and low priority waters, where there are "risks" or "minimal risks" to the designated uses, nonpoint source BMPs must be adjusted to stop further impairment of water quality.[6]

However, BMPs may not be required for agricultural operations, except on a "voluntary basis," even in cases where TMDLs are required.[7] And, unless a TMDL is required to be developed and nonpoint strategies have been prescribed, there is no requirement for persons who conduct nonpoint activities to meet water quality standards other than those necessary to support the *existing* beneficial use of the water body.[8]

If a person fails to obtain new nonpoint source approval in those few instances where it is required (outstanding resource waters), or fails to implement BMPs and violations of water quality result, the agency may institute a civil action.[9] Nonpoint source activities that are conducted according to BMPs are, moreover, not subject to enforcement action, unless the discharge is causing an imminent or substantial danger to public health. Nonpoint source activities not conducted according to BMPs may be subject to compliance schedules, administrative and civil relief including injunctive relief.[10] The statute contains general penalty authority for environmental violations, including administrative and civil actions.[11] Also, where a TMDL has been developed, normal enforcement practices by other designated agencies are available under the state's water quality management plan.[12]

Other Discharge Limitations

• Public nuisance is defined as anything that is "injurious to health" or "unlawfully obstructs the free passage or use...of any navigable lake, or river, stream, canal or basin..."[13] Idaho's Right to Farm Act and its Right to Conduct Forest Practices Act limit the circumstances under which agricultural operations and forest practices, respectively, may be deemed a nuisance,[14] specifically exempting agricultural operations from nuisance claims if they have been in operation for more than one year and operation is not "improper" or "negligent."[15] Also, local government entities are prohibited from enacting any laws that declare generally recognized agricultural practices to be a public or private nuisance.[16]

Fish/Fisheries Laws

• Idaho law prohibits the placing in waters of any "...toxicants, chemicals, poisonous...or other material which may tend to destroy, kill, disable, or drive away fish..." Violation of this provision is punishable by fines and/or prison sentence.[17]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• Under Idaho law, the Forest Board is required to "develop methods for controlling watershed impacts resulting from cumulative effects" of forest practices.[18] Under the Idaho Forestry Act ("Act"), a BMP is defined as practices that the Forest Board determines to be the "most effective and practicable means of preventing or reducing the amount of nonpoint pollution generated by forest practices,"[19] and the rules under the Act establish site-specific BMPs for stream segments of concern.[20] If under the rules, implementation of BMPs is insufficient to protect beneficial uses, the forest activity may be deemed "an imminent or substantial threat."[21] The Act implements this language by requiring that operators post a notice of intent to engage in forestry practices.[22] An operator will be required to post an operating bond where an operator has failed to apply BMPs or willfully caused degradation of water resources.[23] The forestry rules and practices are enforced through issuance of notice of violation and cease and repair orders. Relevant sanctions include suits for reparations, attachment of liens, bond forfeiture and injunctive relief.[24] Variances from these rules and practices can be obtained for approved alternatives that provide equivalent or better results.[25] The Right to Conduct Forest Practices Act limits the circumstances under which forest practices may be deemed a nuisance.[26]

Agriculture Requirements

• Due to provisions under Idaho's Right to Farm Act (see supra nuisance section and the prohibition against enactment of a zoning ordinance that forces the closure of an agricultural operation operating in accordance with recognized practices[27]) and due to the general water pollution control law provision exempting agricultural operations from BMPs not adopted on a voluntary basis[28] (see supra general discharge prohibitions), there are relatively few general enforceable agriculture requirements under Idaho state law. Similarly, the Idaho Local Land Use Planning Act ("LLUPA") prevents county commissioners from enacting any law that "deprives any owner of full and complete use of agricultural land..." Idaho law does establish soil conservation districts with authority to develop comprehensive plans and provides for the adoption of "appropriate soil-conserving land-use practices."[29] Rules require these districts to adopt BMPs and incorporate them into a five-year plan that protects water quality.[30] But these are not enforceable except as conditions on receipt of assistance. Similarly, rules for the agricultural water quality program provide financial assistance that may be conditional on implementation of BMPs, to the districts for the control and abatement of water pollution from agricultural lands.[31]

• Idaho law requires the department of health and welfare to promulgate a state nutrient management plan for surface waters.[32] State and local governments enforce the plans using their "police powers."[33]

• The state's chemigation law establishes design standards for use of irrigation systems for application of fertilizers and pesticides.[34] The Department of Agriculture ("DOA") can enter and inspect to determine compliance with chemigation standards.[35] Conducting chemigation without a license is subject to civil penalties ranging from $1-25,000, and other chemigation-related violations are subject to fines and a misdemeanor charge.[36]

• Idaho law also has general pesticide registration, labelling and application requirements and prohibits "applying pesticides in a faulty, careless or negligent manner."[37] The Department of Agriculture ("DOA") can enter and inspect to determine compliance with general pesticide use requirements.[38] Any individual claiming damage from pesticide use must file a report with the DOA. Applying pesticides without a license is subject to fines and injunction, and other violations are subject to up to $3000 in civil penalties.[39]

Development and Other Earth-Disturbing Activities

No operating requirements are set forth apart from any that may be authorized by general land use regulation such as zoning.

• The LLUPA establishes planning goals that include ensuring that the important environmental features of the state and localities are protected and enhanced; protecting fish, wildlife and recreation resources; and avoiding undue air and water pollution.[40] Exemptions from uses that are otherwise prohibited under the LLUPA are provided through issuance of special use permits.[41] Also, the LLUPA states that county commissioners are not empowered to enact to enact any law that "deprives any owner of full and complete use of agricultural land..."[42]

• Idaho regulations defining the development of comprehensive state water plan include provisions for designation of protected rivers and designation of interim protected rivers while the plan is being developed.[43] No enforcement provisions or sanctions specific to these regulations exist.

ILLINOIS

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Illinois' water pollution control law includes some provisions that may be used to take enforcement action against nonpoint source discharges that pollute the waters of the state or that violate state regulations or standards.

• The general discharge prohibition in Illinois states that "No person shall cause or threaten or allow the discharge of any contaminants that would cause or tend to cause water pollution, or that would violate regulations or standards adopted" by the Illinois Pollution Control Board (hereafter "IPCB").[1]

• Another general provision restricts a person from depositing "any contaminants upon the land in such place and manner so as to create a water pollution hazard."[2]

While these statutory provisions are not specifically limited to point sources, another provision which restricts a person from causing, threatening or allowing the "discharge of any contaminant into the waters of the State without a permit" applies only to point source discharges, and specifically only to those sources for which a federal permit is required.[3]

There are several avenues of enforcement. Following an investigation, the Agency may issue a notice and complaint and hold a hearing, or the Board may enforce an order by injunction, mandamus, or other appropriate remedy and/or civil penalties.[4] Civil penalties of a maximum of $50,000 for the violation and $10,000 for each continuing day may be assessed,[5] and it is a class A misdemeanor to violate the Act or regulations.[6] In addition, the Attorney General has broad authority to seek an injunction "to prevent air, land or water pollution within this State," notwithstanding any proceeding before any administrative agency.[7]

Other Discharge Limitations

• The organization of a *conservancy district* is authorized under the Illinois River Conservancy Districts Act (as distinguished from the Soil and Water Conservation Districts Act under Agriculture Requirements *infra*) "whenever the unified control of a lake or...river system...shall be deemed conducive to the prevention of stream pollution development, conservation and protection of water supply...development of irrigation, conservation of soil...and the promotion of the public health..."[8] State law endows the conservancy board with the right "to prevent pollution of ..." and "cause any and all parties, person,...to cease any and all pollution of" any stream or any other body of water in the district, although it cannot supersede the authority of the IPCB.[9] Although not specified in this section of the state statute, the Illinois Municipal Code authorizes sanctions of up to $750 or imprisonment of up to six months.[10]

• The Illinois Metropolitan Water Reclamation District Act authorizes the establishment of local districts, such as a "sanitary district" which has the authority to prevent the pollution of a public water supply.[11] If the district Superintendent determines that "sewage or industrial wastes or other wastes" are causing "pollution," then it may bring an action in circuit court for mandamus or injunction, or issue a cease and desist order with accompanying fines.[12] "Other wastes" include "oil, tar and chemicals." "Pollution" means "such alteration of ...properties of any waters of the State, or such discharge of any contaminant into any waters as will or is likely to create a nuisance or render such waters harmful..." A violation of an order is considered a nuisance.[13] The state Water Authorities Act[14] also authorizes creation of a "water authority" which has the broad power to make regulations that "protect public health, welfare, and safety and to prevent pollution of its water supply" and may by ordinance "prevent pollution of waters which feed its reservoir for a distance of five miles upstream from the headwaters of its reservoir and may abate any cause of pollution...as a nuisance."[15]

• The state authorizes municipalities to adopt local land resource management plans to protect the land, air, water, natural resources and environment of the state to "ensure good quality and quantity of water resources," among other things and to adopt implementing ordinances.[16] Municipalities further have the power to pass laws that specifically protect from pollution any "reservoir or artificial lake constructed or maintained by the municipality for water supply purposes."[17] These local ordinances are enforced through local law enforcement and criminal prosecutions.[18] Civil and criminal penalties are authorized.[19]

Other state discharge prohibitions are narrowly defined by an express limitation on the specific substances that can be discharged.

• One Illinois statute prohibits the discharge of oil in quantities greater than standards set by the IPCB. However, this same provision also prohibits the discharge of "*other pollutants* directly or indirectly into the waters...,"[20] and "other pollutants" are defined as "any floating materials which may cause unsightly appearance on the surface of such waters or are detrimental to aquatic life or the water quality of such waters."[21] Read broadly, this provision could be interpreted as a general discharge prohibition.

• Another discharge prohibition applies to "litter." It prohibits a person from dumping, depositing, dropping, throwing, discarding, leaving, causing of litter or permitting any of the above on public or private property or into "a river, lake, pond, or other stream or body of water in this state" (except in an emergency situation or for designated litter disposal areas).[22] "Litter" includes but is not limited to "garbage, trash, refuse, debris, rubbish, grass clippings or other lawn or garden waste...any nauseous or offensive matter of any kind...or anything else of an unsightly or unsanitary nature, which has been discarded, abandoned or otherwise disposed of improperly."[23]

• It is a public nuisance "to throw or deposit offal, other offensive matter or the carcass of a dead animal in a water course, lake, pond, spring, well or common sewer..." and "to corrupt or render unwholesome or impure the water of a spring, river, stream, pond, or lake to the injury or prejudice of others."[24] It is enforced locally with a maximum fine of $100 for a first offense and a class B misdemeanor for subsequent offenses.[25]

Illinois law provides that no farm is a nuisance because of changed circumstances in the surrounding area where it has been in operation more than one year and was not a nuisance when it began operation, unless the nuisance results from "negligent or improper operation of the farm."[26] However, even this exception from nuisance liability does not prevent recovery of damages resulting from water pollution.[27]

Fish/Fisheries Laws

Illinois laws relating to fish and fisheries do not appear to contain enforceable provisions applicable to nonpoint source discharges.

OPERATIONAL REQUIREMENTS

Forestry Requirements

- Illinois laws relating to forestry do not appear to contain enforceable operating requirements with respect to nonpoint source discharges.

Agriculture Requirements

- Illinois statutes authorize the organization of soil and water conservation districts that have the power to formulate land-use regulations, including soil erosion measures, requirements for cultivation and other soil and erosion management methods, and provisions prohibiting the clearcutting of trees within thirty feet of any navigable waters, except for trees in a forestry management plan or other licensed activities.[28] Three-fourths of the landowners must approve the regulations in order for them to enforceable as a local ordinance within the district, and the regulations are binding upon all of the landowners in the district.[29] The state municipal code grants these districts authority to pass ordinances that impose $750 maximum civil penalties and/or up to six years imprisonment.[30]

- With respect to regulating pesticides, the IPCB may adopt "standards and conditions regarding the sale, offer, or use of any pesticide, detergent or any other article determined...to cause a water pollution hazard," provided that regulations related to pesticides are adopted in accordance with the Illinois Pesticide Act.[31] The state statute also states that "it is unlawful to store, display, use or distribute pesticides in such manner as to endanger man and his environment."[32] Under this provision, the Director may issue an order to stop use or regulate removal of a pesticide or related substance, or the Director may seek an injunction in circuit court.[33]

Development and Other Earth-Disturbing Activities

No operating requirements are set forth, apart from any that may be contained in urban stormwater programs under the Clean Water Act or that may be authorized by general land use regulation such as zoning.

INDIANA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Indiana's water pollution control law includes several provisions that may be used to take enforcement action against nonpoint source discharges that contribute to a polluted condition of the state's waters.

• "A person may not: (1) throw, run, drain, or otherwise dispose into any of the streams or waters of Indiana; or (2) cause, permit, or suffer to be thrown, run, drained, allowed to seep, or otherwise disposed into any waters; any organic or inorganic matter that causes or contributes to a polluted condition of any waters, as determined by a rule of the [water pollution control] board."[1] The water pollution control board is authorized to adopt rules to determine what constitutes a "polluted condition" of the water in any stream or water of the state.[2] Whenever the commissioner of the environment "determines that a person: (1) is in violation; or (2) is about to violate [this prohibition]" the department of environmental management must issue an order to abate the violation.[3]

• The board has power to "adopt rules restricting the polluting content of any waste material and polluting substances discharged or sought to be discharged into any of the streams or waters of Indiana."[4] This authority is not limited to point sources. The board also has authority to establish requirements for permits "to control or limit the discharge of contaminants into state waters;" while this is not limited to point sources, the current regulations cover permitting for point sources[5] and do not require permits for "any introduction of pollutants from nonpoint source agricultural and silvicultural activities."[6]

• In addition to the prohibition on causing or contributing to a polluted condition, and the permitting provisions, the commissioner of the environment has general authority to "take appropriate steps to prevent any pollution that is determined to be unreasonable and against public interests in view of the condition in any stream or other waters of Indiana."[7]

• Another provision prohibits the discharge of any contaminant or waste into the environment in "any form that causes or would cause pollution that violates or would violate rules, standards, or discharge or emission requirements" adopted by the board.. and prohibits deposit of a contaminant on the land that "creates or would create a pollution hazard that violates or would violate a rule" and prohibits deposit of "solid waste...in or immediately adjacent to a lake or stream"[8]

• A separate provision of the water pollution law requires reporting of spills, including those not reported under federal spill response requirements.[9] "Spill" for purposes of this law includes "any unexpected, unintended, abnormal, or unapproved dumping, leakage, drainage, seepage, discharge, or other loss of...oil, a hazardous substance; or *other objectionable substance* that enters or threatens to enter the waters of Indiana"[10]

These laws are enforced by the commissioner by administrative order, civil penalties of up to $25,000 per day, and injunctions.[11] Failure to comply with an order or discharge a duty imposed by the water pollution control laws is a Class B misdemeanor.[12] Minor violations that do not present an immediate or reasonably foreseeable danger to the public health or environment, and that do not include violation of a numerical limit or permit condition applicable to a business required to correct the violation before disclosure, and that are not failure to possess a required permit, may result in a reduced penalty limited to $500 if the business corrects the violation within 90 days.[13]

Other Discharge Limitations

• Indiana also has broad general authorities applicable to pollution events. The governor may issue an emergency order if contamination of air, water, or land presents a "clear and present danger" to the "health and safety of persons in any area," and the commissioner may file suit if a pollution source is presenting "an imminent and substantial endangerment" to health or livelihood.[14] An environmental enforcement law authorizes the attorney general, a political subdivision of the state, a citizen or a corporation or association to bring actions in the name of the state "for the protection of environment from significant pollution, impairment, or destruction" after notice to the state and failure of the appropriate state agency to act.[15]

• Nuisance law may apply to some nonpoint source pollution events. Indeed, the water pollution law defines "water pollution" as including discharges of contaminants that can "create a nuisance or make the waters harmful, detrimental, or injurious" to public health, safety or welfare, legitimate uses of water, or animals, fish or aquatic life.[16] Indiana law also provides that "Whatever is injurious to health, or indecent, or offensive to the senses, or an obstruction to the free use of property, so as essentially to interfere with the comfortable enjoyment of life or property is a nuisance, and the subject of an action."[17] However agricultural and industrial operations are insulated from public and private nuisance actions by virtue of changed conditions in the vicinity if they have operated for more than one year, were not a nuisance when they began, and there was no significant change in the operation; the exception does not apply if the nuisance results from "negligent" operation.[18]

• Indiana's Flood Control Act prohibits any person from putting contaminants or solid waste in, upon, or within 15 feet of a lake or within a floodway.[19] Violations may be abated by injunction and by civil penalty of up to $1,000 per day.[20] But this provision does not apply to persons using chemicals in a normal manner in the production of agricultural products, nor to persons acting in accordance with discharge permits issued by IDEM or DNR.[21]

• Indiana expressly prohibits "discharge of a nonpoint source of pollution to waters of the United States" from municipal solid waste land fills, if such discharge "violates any requirement of an area wide or state wide water quality management plan...under § 208" of the federal Clean Water Act.[22]

• Indiana's recreational rivers law provides that any person who "throws, dumps, or leaves refuse in the water or on the banks" of a designated stream, is guilty of a misdemeanor, punishable by fine of up to $1,000 and/or imprisonment for up to 180 days.[23]

Fish/Fisheries Laws

Indiana's fisheries laws do not appear to contain enforceable provisions relating to nonpoint source discharges.

OPERATIONAL REQUIREMENTS

Forestry Requirements

State law does not appear to include enforceable requirements aimed specifically at controlling nonpoint source pollution from forestry on private lands.

Agriculture Requirements

• Although soil and water conservation districts and conservancy districts can develop comprehensive plans and adopt rules and regulations, no enforcement powers are provided; they have the power to condition receipt of benefits on agreements with landowners.[24]

• The state does regulate water pollution from confined animal feeding operations similarly to federal requirements, but with somewhat different size limits and including operations in violation of water pollution laws or rules.[25] Prior approval from IDEM is required before commencing construction of a CAFO, but not a construction permit.[26] Enforcement is via administrative orders, injunctions, and penalties.[27]

• The pesticide law includes registration of pesticides, requirements for certifications and licensing of applicators and others. Enforcement mechanisms include registration and licensing actions, injunctions, orders, and civil penalties.[28]

• The Drainage Board Act establishes county drainage boards[29] does not provide for much environmental protection; however, IDEM approval is needed if connection of a drain to a regulated drain would result in a discharge of liquid wastes that "would cause or contribute to pollution of the receiving waters."[30] The Ditch Act requires a permit for ditching or drain activities within ½ mile of freshwater lake of more than 10 acres; DNR may issue the permit only if it finds that the proposed action "will not result in unreasonably detrimental effects upon fish, wildlife, or botanical resources."[31] The Ditch Act is enforceable by injunction, notice of violation, civil penalty, or petty criminal prosecution.[32]

Development and Other Earth-Disturbing Activities

Indiana has several provisions apart from regulation of urban stormwater under the federal Clean Water Act.

• Although construction activities affecting 5 or more acres must control erosion, including filing a notice of intent and preparing an erosion control plan, local regulation under zoning codes can reach smaller sites.[33]

• It is unlawful to build any structure, place any obstruction, or "...make any deposit or excavation" in any floodway without a permit from the Dept. of Natural Resources. A permit may be issued only if the action will not, among other things, result in "...unreasonable detrimental effects upon fish, wildlife, or botanical resources..."[34] However permits are not required for drain reconstruction or maintenance if the stream or drain is 10 miles or less in length, [35] nor for production of crops, or for pasture, forests, and park and recreational uses provided they do not involve any structure, obstruction, deposit, or excavations.[36] Enforcement is by injunction, criminal prosecution, and civil penalty of up to $1,000 per day.[37]

• A person may not substantially affect "natural or scenic qualities of a [designated natural, scenic, or recreational] river that is the subject of a river commission unless the person has secured a permit to do so from the river commission.[38] Enforcement is by injunction, and civil penalty of $10 to $300 per day.[39]

IOWA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Iowa's water pollution law contains a general prohibition against unpermitted discharges of pollutants (defined as "wastes") into waters, which may be used to reach some types of nonpoint source discharges.

• "A pollutant shall not be disposed of by dumping, depositing, or discharging such pollutant into any water of the state...."[1] This prohibition, which is generally applicable, does not apply to the discharge of adequately treated sewage, industrial waste, or other waste pursuant to a permit. Pollutant is defined as "sewage, industrial waste, or other waste." [2] "Other waste" is defined as "heat, garbage, municipal refuse, lime, sand, ashes, offal, oil, tar, chemicals and all other wastes which are not sewage or industrial waste."[3] In addition, "[a] pollutant, whether treated or untreated shall not be discharged into any state-owned natural or artificial lake."[4]

Enforcement is primarily through cease and desist orders, civil penalties up to $5,000 per day, injunctions, and criminal (serious or aggravated misdemeanor) prosecution.[5] Cities and counties are authorized to assess a civil penalty equal in amount to the penalty assessed by the state.[6]

Other Discharge Limitations

• "A person shall not discard solid waste onto or in any water...of the state...."[7] Enforcement of this provision is by civil penalty not to exceed $500 for each violation.[8]

• "No person shall discard any litter onto or in any water... of this state...." Discard means "to place, cause to be placed, throw, deposit or drop," while litter is defined as "any garbage, rubbish, trash, refuse, waste materials or debris."[9] Enforcement is by criminal (simple misdemeanor) prosecution. The court may also direct and supervise litter gathering in addition to or in lieu of any other sentence.[10]

• In 1987, Iowa adopted the Groundwater Protection Act, which authorizes the adoption of health-related groundwater standards. Although it expressly imposed no new legal liabilities, the Act created a linkage between the requirements of the state's water quality law and the Act's goal of preventing "contamination of groundwater from point and nonpoint sources of contamination to the maximum extent practical, and if necessary [restoring] the groundwater to a potable state, regardless of present condition, use, or characteristics."[11] The Act states generally that the "discovery of any groundwater contamination shall require appropriate actions to prevent further contamination. These actions may consist of investigation and evaluation or enforcement actions if necessary to stop further contamination as required under the water quality law.[12] More specifically, the Act states that "documentation of any contaminant which presents a significant risk to human health, the environment, or the quality of life shall result in either passive or active cleanup," as defined in the law.[13] The Groundwater Protection Act also provides an exemption from liability for certain agricultural activities - providing that liability shall not be imposed upon an agricultural producer for active cleanup costs or damages resulting from the detection of any quantity of nitrates if "application [of the fertilizer] has been in compliance with soil test results and...the applicator complied with label instructions for the application of the fertilizer."[14] Liability also may not be imposed for pesticides in the groundwater provided the applicator had a license and complied with the label.[15]

• Under Iowa law, some nonpoint source discharges may be abatable as a nuisance. "Whatever is injurious to health, indecent, or offensive to the senses, or an obstruction to the free use of property, so as essentially to interfere with the comfortable enjoyment of life or property, is a nuisance...."[16] The law also specifically lists a number of nuisances, including: "the obstructing or impeding without legal authority the passage of any navigable river, harbor, or collection of water," and "the corrupting or rendering unwholesome or impure the water of any river, stream or pond, or unlawfully diverting the same from its natural course or state, to the injury or prejudice of others."[17]

If no other punishment is specifically provided for, those convicted of causing a public nuisance are guilty of an aggravated misdemeanor, and the court may order the nuisance abated and issue a warrant.[18]

Iowa law specifically provides that an animal feeding operation is not a nuisance under common law. But this provision does not apply if the person bringing an action proves either that an injury to the person or damage to the person's property is caused by failure to comply with a federal or state statute or rule applicable to such operation, *or* that the operation unreasonably interferes with the person's comfortable use and enjoyment of life and property and such operation failed to use existing prudent generally accepted management practices reasonable for the operation.[19] Iowa law also provides that a farm operation located in a defined agricultural area is not a nuisance; however, this provision was recently struck down by the Iowa Supreme Court as an infringement on the property rights of neighboring property owners.[20] In any event, the exemption did not apply to actions involving negligence, nor did it affect or defeat the right to recover damages for "pollution or change in condition of the waters of a stream, the overflowing of the person's land, or excessive soil erosion onto another person's land."[21] The exemption also did not restrict nuisance actions based on a structure, dam obstruction, deposit or excavation in a floodway in an agricultural area.[22]

Fish/Fisheries Laws

State fisheries laws do not appear to contain enforceable provisions relating to nonpoint source discharges.[23]

OPERATIONAL REQUIREMENTS

Forestry Requirements

State forestry laws do not appear to contain enforceable provisions relating to nonpoint source discharges.

Agriculture Requirements

• Iowa's Soil Conservation Districts Law provides that in order to "conserve the fertility, general usefulness, and value of the soil and soil resources of this state, and to prevent the injurious effects of soil erosion," owners of real property in the state must establish and maintain soil and water conservation practices or erosion control practices, pursuant to regulations adopted by the commissioners of the respective soil and water conservation districts.[24] Unless the claim is based on gross negligence, a landowner may not be liable for a claim based on a negligent soil or water conservation practice if that practice was in accordance with generally recognized engineering standards, or in compliance with the district's rules.[25]

• The commissioners must adopt reasonable regulations to establish a soil loss limit for the district. The commissioners may require the owners of real property in the district to employ either soil and water conservation practices or erosion control practices. The law places certain limits on the type of controls that may be required.[26] An owner of agricultural land is not required to establish any new permanent or temporary soil and water conservation practice unless cost-share or other public moneys have been specifically approved for that land and made available to the owner.[27]

• The state Soil Conservation Districts Law also requires that prior to initiating a "land-disturbing activity" a person must file a signed affidavit that the project will not exceed the soil loss limits. Land-disturbing activity is defined as land changes such as the tilling, clearing, grading, excavating, transporting or filling of land which may result in soil erosion from water or wind and the movement of sediment and sediment related pollutants into the waters of the state. However, the definition excludes a number of activities, including the tilling, planting or harvesting of agricultural, horticultural or forest crops.[28]

If, upon inspection, the commissioners find that sediment damages are occurring to the land of the complainant, the commissioners are to issue an administrative order to the landowner. The order states the time framework for establishing or maintaining soil and water conservation practices or erosion control measures.[29]

• Iowa law, substantially expanded in 1998, addresses animal feeding operations, which are defined as "a lot, yard, corral, building or other area in which animals are confined and fed and maintained for forty-five days or more in any twelve-month period, and all structures used for the storage of manure from animals in the operation....An animal feeding operation does not include a livestock market."[30] State law authorizes the department of natural resources to adopt rules relating to the construction or operation of animal feeding operations. The law mandates that these rules include minimum manure control requirements, requirements for obtaining permits, and departmental evaluations of animal feeding operations.[31] Construction permits are required for such operations, and must include provision of an indemnity fee, a manure management plan, notice and comment managed by the county board of supervisors, and other requirements.[32] Iowa law expressly provides that no permit may be issued if an enforcement action is pending or if the applicant is a "habitual violator" and the violation occurred within the past five years. The department is instructed to conduct an annual review of each feeding operation of a habitual violator.[33]

Other statutory requirements relating to the construction and operation of animal feeding operations include:

(1) Manure controls. "A confinement feeding operation shall not discharge manure directly into water of the state or into a tile line that discharges directly into water of the state."[34] The law requires that manure be disposed of in a manner that will not cause surface or groundwater pollution. An owner who discontinues a confinement feeding operation must remove all manure within at least six months.[35] The applicant for a permit must submit a manure management plan, the requirements of which are outlined in the law.[36] The law also sets out detailed requirements for commercial manure applicator certification, and requirements governing application of manure to land.[37]

(2) Separation distance requirements. State law prescribes the minimum separation distance between an animal feeding operation constructed and a residence not owned by the owner of the operation, or a commercial enterprise, religious institution or educational institution.[38] In addition, an animal feeding operation structure must be located 500 or more feet away from a major water source (meaning any navigable lake, reservoir, river, or stream), and from a surface intake, wellhead, or cistern of an agricultural drainage well or known sink hole; and it most be located more than 200 feet away from any watercourse that is not a major water source.[39]

Enforcement of the animal feeding operation requirements is through cease and desist orders, civil penalties up to $5,000 per day, and injunctions. The law provides additional penalties ($500 per day) for violation of a court order mandating compliance with an order issued by the department. In addition, the law provides for civil penalties up to $25,000 per day for "habitual violators."[40]

• Under Iowa law, "(a) pesticide shall not be applied to any water of this state which has been classified by the department [of natural resources] as a class "A" or class "C", high quality, or high quality resource water, except that this section shall not...prohibit the application of such a pesticide by a certified applicator who is trained in aquatic applications and who has received a permit from the department."[41] This provision may be enforced through the same mechanisms used to enforce the general pollutant discharge provisions described above.

• The department of agriculture is required by law to adopt rules establishing the proper use of pesticides, including their formulations, times, and methods of application, and other conditions of use.[42] The law also provides that commercial applicators must comply with certification requirements. The department of agriculture is required to adopt rules for the assessment of civil penalties up to $500 for violations by commercial applicators.[43]

Development and Other Land-Disturbing Activities

Apart from any programs for the control of urban stormwater under the federal Clean Water Act or that may be authorized by general land use regulation such as zoning, state law provides the following authorities applicable to nonpoint source discharges.

- The state's soil conservation law, described above, applies to "land-disturbing activities," defined to include land changes such as "tilling, clearing, grading, excavating, transporting or filling of land which may result in soil erosion from water or wind and the movement of sediment and sediment related pollutants into the waters of the state...."[44] Among the excluded activities are preparation of single family homes (unless as part of a subdivision development) and disturbed land areas of less that 25,000 square feet (unless a local ordinance provides otherwise).

- State law prohibits the building of "any pier, wharf, sluice, piling, wall, fence, obstruction, building, or erection of any kind upon or over any state-owned land or water under the jurisdiction of the [Conservation] commission, without first obtaining from the commission a written permit."[45] Enforcement of this provision is by criminal (simple misdemeanor) prosecution. In addition, the commission may order removal of the structure, or the commission may remove the structure and recover costs from the owner.[46]

- "Where operations are entirely on private property adjacent to a public lake or stream the natural bank between the state and privately owned areas shall not be removed except by permission of the commission."[47] Violation is a simple misdemeanor.[48]

KANSAS

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Kansas' water pollution law contains enforceable permitting provisions that may be applied to some nonpoint source discharges. The law also directs the state's attorney general to pursue abatement of pollution of surface waters affecting animal or aquatic life.

• "No person shall place or permit to be placed or discharge or permit to flow into any of the waters of the state any sewage, except pursuant to a permit."[1] The Kansas Department of Health and Environment may require nonpoint sources to obtain a permit. The law states that the "secretary...may establish...procedures for issuance of general permits to...(1) a category of point and nonpoint sources of sewage such as storm water; (2) other categories of point and nonpoint sources of sewage...."[2] For purposes of the above provisions, sewage is defined as "any substance that contains any of the waste products or excrementitious or other discharges from the bodies of human beings or animals, or chemical or other wastes from domestic, manufacturing, or other forms of industry."[3]

• "The secretary of health and environment shall make such rules and regulations, including registration of potential sources of pollution, as may...be necessary to...(2) control the disposal, discharge or escape of sewage...and (3) establish water quality standards for the waters of the state to protect their beneficial uses."[4]

• "If the secretary finds that...refuse in any surface pond is causing or is likely to cause pollution of soil or waters of the state, the secretary shall issue an order prohibiting such surface pond."[5]

• In addition, if the secretary of health and environment finds evidence of "abatable pollution of the surface waters detrimental to the animal or aquatic life in the state," it is the duty of the attorney general to take such action as may be necessary to secure the abatement of such pollution.[6]

Enforcement of these provisions is by corrective action orders, civil penalties of up to $10,000 and criminal prosecutions.[7] Where a violation results in the "death of, or injury to, fish, animals, vegetation or other resources of the state, or otherwise causes a reduction in the quality of the waters of the state below the standards set by the secretary," the violator is liable to the state for damages in an amount equal to that necessary to "restock such waters, replenish or replace such resources and otherwise restore the water."[8]

Other Discharge Limitations

• State nuisance law potentially addresses some activities that may result in nonpoint source pollution. "The secretary of health and environment and the county or joint boards of health shall have the power and authority to examine into all nuisances, sources of filth and causes of sickness that in their opinion may be injurious to the health of...inhabitants. Whenever any such nuisance, source of such filth or cause of sickness is found to exist on any private property or upon any watercourse in this state...[the health authorities] shall have the power and authority to order, in writing, the owner or occupant thereof at his or her own expense to remove the nuisance or source of filth or cause of sickness within 24 hours, or within such reasonable time thereafter" as ordered.[9] Failure to obey an order results in a fine of not less than $10 nor more than $100 per day.[10]

Kansas' solid waste law provides an exemption from nuisance actions for agricultural activities. "Agricultural activities conducted on farmland, if consistent with good agricultural practices and established prior to surrounding nonagricultural activities, are presumed to be reasonable and do not constitute a nuisance, public or private, unless the activity has a substantial adverse effect on the public health and safety. If such agricultural activity is undertaken in conformity with federal, state, and local laws and regulations, it is presumed to be good agricultural practice and not adversely affecting the public health and safety."[11] The law also prohibits open dumping, but exempts normal farming operations provided the practice does not create a public nuisance or adversely affect public health. Violation is a Class A misdemeanor.[12]

Fish/Fisheries Laws

The state's fisheries laws do not appear to contain enforceable provisions relevant to nonpoint source discharges.

OPERATIONAL REQUIREMENTS

Forestry Requirements

State forestry laws do not appear to contain enforceable provisions relating to nonpoint source discharges.

Agriculture Requirements

• Kansas' agriculture law regulates CAFOs of different sizes than the federal regulations. "Prior to any new construction of a confined feeding facility with an animal unit capacity of 300 to 999, such facility shall register with the secretary of health and environment. Facilities with less than 300 units may register...."[13] Within 30 days, the department of health and environment must identify any significant water pollution potential or separation distance violations; if water pollution potential is identified, the facility is required to obtain a permit. If no water pollution potential is found, the secretary is to certify that no permit is required. Confined feeding facility means any

R0017113

lot, pen, pool or pond: which is used for the confined feeding of animals or fowl for food, fur or pleasure purposes; which is not normally used for raising crops; and in which no vegetation intended for animal food is growing.[14] Violators are subject to a civil penalty of up to $10,000 per day.[15]

•State agriculture law also requires licenses and sets standards of operation for livestock feedlots or feed yards having more than 1,000 head of livestock at one time. Other livestock feedlots may elect to come under the act. Operating standards contained in the law include requiring that the feedlot provide adequate drainage to control pollution of streams and lakes.[16] Enforcement is through revocation or suspension of licenses, or by criminal prosecution.[17]

•Kansas' pesticide law addresses disposal and storage practices that might result in nonpoint source pollution. "It shall be unlawful for any person to...discard or store any pesticide or pesticide container in such a manner as to cause injury to humans, vegetation, crops, livestock, wildlife, pollinating insects or waterways and wildlife therein...or to fail to comply with" regulations adopted under the law.[18] Enforcement of the pesticide law is through criminal (Class A misdemeanor) prosecution and, in the case of violations by certified applicators, through civil penalties of between $100 and $500 per day.[19]

•The pesticide law also authorizes the board of agriculture to develop pesticide management areas if a pesticide poses a serious threat to the public health, safety and welfare or the natural resources of the state.[20] "Pesticide management plans may include provisions for the handling or release of pesticides, including, but not limited to, the application, mixing, loading, storage, disposal or transportation and guidelines for best management practices.[21] Enforcement is by civil penalty of between $100 and $5,000, and by criminal (Class A misdemeanor) prosecution.[22]

•State agriculture law requires that any person who applies any chemical by the chemigation process in an irrigation system must register and use anti-pollution devices specified under state law. Chemigation is defined as "any process whereby pesticides, fertilizers or other chemicals or animal wastes are added to irrigation water applied to land or crops, or both, through an irrigation distribution system." Registration must include, among other things, a plan for handling tail water or accumulations of water.[23] It is unlawful for any person to use the chemigation process without registration or refuse or neglect to comply with restrictions, and enforcement is through permit suspension or revocation, civil penalties of between $100 and $5,000, and criminal prosecution.[24]

•Other provisions of Kansas law relating to irrigation practices include the requirement that "(a)ny person who is using a ditch, conduit, or reservoir for irrigation purposes shall be responsible that no injury be done to the embankment thereof, or the fence enclosing it, or other parts of it, and that the waters thereof be not fouled or polluted by any animal driven to or watered there."[25]

Development and Other Earth-Disturbing Activities

Apart from any programs for the control of urban stormwater under the federal Clean Water Act or that may be authorized by general land use regulation such as zoning, state law provides the following authority applicable to nonpoint sources.

- Kansas law authorizes the regulation of land development activities around some water bodies for the purpose of preventing water pollution. The secretary of health and environment may adopt regulations designating "sanitation zones" to regulate and control development of areas of the state surrounding certain impoundments of water to prevent pollution of such impoundments.[26] A sanitation zone is the land designated by the secretary that is not more than 3 miles from the waterline of any existing or proposed state or federal reservoir that is more than 100 acres in surface area.[27] Owners of land in the zone must obtain approval to construct a building, structure or facility.[28] Exempted from these requirements are (1) land used for agricultural purposes or land under the control of the department of wildlife and parks; (2) subdivisions approved prior to Aug. 1, 1965; and (3) land subject to sanitary codes controlling the subsurface disposal of sewage enforced by the local health department.[29] County attorneys are authorized to enforce these requirements through appropriate actions of injunction, mandamus or quo warranto.[30]

KENTUCKY

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Kentucky's water pollution control provisions may be enforced against nonpoint source discharges that pollute state waters in violation of applicable standards or regulations. However, violations that are traceable to specific agricultural sources must be addressed under a separate law.

• "No person shall, directly or indirectly, throw, drain, run or otherwise discharge into any of the waters of the Commonwealth, or cause, permit, or suffer to be thrown, drained, run or otherwise discharged into such waters any pollutant, or any substance that shall cause or contribute to the pollution of the waters of the Commonwealth in contravention of the standards adopted by the cabinet or in contravention of any rule, regulation, permit or order or in contravention of any provision of the statute."[1] The Natural Resources and Environmental Protection Cabinet's Office of Legal Services or the Attorney General may institute an action to recover penalties or bring an action seeking an injunction.[2] Violators are subject to a civil penalty not to exceed $25,000 per day for each violation.[3] Knowing violations are a Class D felony punishable by a fine not to exceed $25,000, imprisonment of one to five years, or both.[4] However, where there is documented evidence that a violation of water pollution laws or administrative regulations is traceable to a specific agriculture operation, then the provisions of the Agriculture Water Quality Act (discussed below) govern resolution of the violation.[5]

Other Discharge Limitations

• Kentucky law has restated and codified the common law of nuisance as it existed in the Commonwealth on May 24, 1991.[6] The codification defines what would constitute permanent and temporary nuisances; private and public nuisances; and how damages should be determined. The section does not specify what actions, such as polluting, constitute a nuisance. However, no agricultural or silvicultural operation is abatable as a nuisance or may be deemed in violation of any zoning ordinance that would restrict the right of the operator to utilize "normal and accepted practices" after it has been in operation for more than one year, provided that the operation was not a nuisance at the time it began.[7] This provision does not apply if the violation or nuisance results from negligence. Nor does it affect the right of any person to recover damages for any injuries or damages sustained by them on account of pollution of the waters of any stream or groundwater.[8]

• Kentucky law also makes it a violation if any person "places or causes to be placed in any stream, dam, pool or pond any substance that renders the water unfit for use or produces a stench."[9] This violation is punishable by a fine of $10 to $100 and imprisonment for a period of 30 days to six months.

• A person is guilty of "criminal littering," a Class A misdemeanor, if he or she knowingly and willfully places or throws litter in any public or private water.[10] For purposes of this provision, litter is defined as "rubbish...waste material...or any foreign substance."[11]

Fish/Fisheries Laws

• Under the wildlife code, "no person shall place or cause to be placed in any public waters any substance that might injure, interfere with, or cause the waters to be unfit for the support of wildlife."[12] Further, "no person shall willfully place or attempt to place in any public waters any substance which has a poisonous or intoxicating effect upon wildlife."[13] The section is enforced by the Department of Fish and Wildlife Resources.[14] Violators may be fined not less than $100 nor more than $500, imprisoned for not more than 6 months, or both. Violators are also liable to the Department for the replacement value of the fish and wildlife killed.[15]

• Similarly, the water quality code requires that "where the injury, death, or destruction of fish or other wildlife results from pollution or from any violation of the orders, rules, regulations, or other determinations of the Cabinet, the person responsible shall be liable to the Commonwealth in an amount reasonably necessary to restock or replenish."[16] The Commonwealth may seek civil penalties of up to $1000 plus actual damages in any court of competent jurisdiction.[17]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• In 1998 Kentucky enacted a Forest Conservation Act, which establishes some enforceable mechanisms applicable to commercial timber harvesting practices.[18] The law does not apply to cutting firewood or Christmas trees, to removal of trees incidental to mining and mineral extraction activities, to right-of-way construction or maintenance, or to the cutting of trees by "an individual, nonindustrial landowner on his own property" if the cutting is done by the owner.[19]

The new law requires that after July 15, 2000, no person shall conduct commercial timber harvesting operations within the Commonwealth unless there is a certified "master logger" on site who has completed the required educational and training requirements (including continuing education every three years).[20]

Such timber harvesting operations must use "appropriate best management practices" which are defined as "effective practical, economical structural, or nonstructural methods that prevent or reduce the movement of sediment, nutrients, pesticides, and other pollutants from the land to surface or groundwater, or that otherwise protect water quality from potential adverse effects of timber harvesting operations."[21] Best management practices are to be defined by the Division of Forestry and approved by the Agriculture Water Quality Authority (see below), and are to be reviewed by a newly created Forestry Best Management Practices Board, which is to be convened by July 15, 1999 and given one year to review such BMPs. The Board is to review the BMPs not more often than every five years thereafter.[22]

In addition, "no logger or operator shall conduct any timber operation in a manner that is causing or will likely cause water pollution."[23]

If the Commonwealth's Natural Resources and Environmental Protection cabinet determines that a logger or operator is failing to use the appropriate best management practices or is causing water pollution, it must give the operator a written warning and prescribe "a reasonable period for abatement and compliance." If the logger or operator fails to comply after the time specified for abatement, the logger or operator will then be provided "an opportunity for an informal conference with the district forester." If, after this opportunity, the logger or operator has failed to comply, then the cabinet must issue a notice of violation and order the implementation of corrective measures "within a specified period of time." If, after the notice, the logger or operator fails to comply, then the cabinet must issue a "special order" mandating the immediate implementation of the corrective measures, and may order cessation of all or a portion of the timber harvesting operation. This special order is reviewable in an administrative hearing, to be held within 5 working days of receipt of a request for hearing.[24] However, notwithstanding the previous provisions, if the cabinet finds that the logger or operator is conducting timber harvesting without a master logger or in a manner "that is causing or is likely to cause water pollution that is presenting or will likely present an imminent and substantial danger" to public health, safety or welfare, or to the health of animals, fish or aquatic life, or to a public water supply or other beneficial uses of water, the cabinet may issue an emergency order requiring immediate cessation of the activity and implementation of corrective measures within a reasonable time; this order, too, is subject to hearing within 5 working days.[25] If the logger or operator fails to comply with a special order or emergency order, he or she is deemed a "bad actor" and is subject to civil penalties of up to $1,000, assessable after an opportunity for administrative hearing, and recoverable in court.[26]

• The Agriculture Water Quality Act,[27] discussed below, establishes enforceable best management practices (BMPs) that apply to farm operations of ten or more acres, including silviculture conducted on such operations. This law can reach some non-industrial private timber harvesting activities not subject to the Forest Conservation Act.

Agriculture Requirements

• The Agriculture Water Quality Act[28] created Kentucky's Agriculture Water Quality Authority, which shall "evaluate the adoption and effectiveness of best management practices for agriculture operations," and develop "statewide agriculture water quality plans to address identifiable water pollution problems from agriculture operations."[29] The plans establish applicable requirements to be used by agriculture operations, defined as "any farm operation on a tract of land ... situated on ten (10) contiguous acres or more of land used for the production of livestock, livestock products, poultry, poultry products, milk, milk products, or silviculture products, or for the growing of crops such as, but not limited to, tobacco, corn, soybeans, small grains, fruit and vegetables; or devoted to and meeting the requirements and qualifications for payments to agriculture programs under an agreement with the state or federal government."[30]

Within five years of approval of the statewide plan, persons engaged in agriculture operations across the state are required to implement its applicable requirements.[31] It is a violation to conduct or allow the conduct of any agriculture operation in a manner which results in water pollution or to fail to implement the provisions of the plan.[32] The Division of Water, working with the Agriculture Water Quality Authority, must designate water priority protection regions where it is documented that agriculture is contributing to water quality pollution problems. In those regions, the Water Quality Authority shall reevaluate the effectiveness of the best management practices in the plan.[33] A person engaging in agriculture operations in a water priority protection region where water pollution has been documented shall be presumed to be in compliance with the Act if the person has implemented the practices required by the plan.[34]

If the Division of Water documents a violation, the Division shall notify the person in writing, setting forth a reasonable period for compliance.[35] If any person engaged in agriculture operations fails or refuses to comply or respond to a written notice on noncompliance with the plan, the person shall be deemed a "bad actor" and subject to enforcement action, as well as loss of eligibility for financial assistance.[36] The Cabinet's Office of Legal Services or the Attorney General shall institute an action for the recovery of any penalties and costs and shall bring an action for injunction.[37] Violation of the statute is punishable by civil penalty not to exceed $1000;[38] compliance with the statewide and any regional agriculture water quality plan is a mitigating factor in determining whether to impose civil penalties.[39]

• A soil conservation district may be created if the Conservation Commission determines that the operation of the district is administratively practicable and feasible, and if there has been a majority vote of landowners in favor of creation.[40] Soil conservation districts are authorized to propose land-use regulations for lands within the soil conservation district whenever the Board of Supervisors of a conservation district determines that uncontrolled soil erosion on some lands within the district is causing damage to other lands.[41] These regulations may be adopted by the Board after a referendum in which at least 90% of the landowners have approved.[42]

Land use regulations may include: 1) requirements for the construction of terraces, terrace outlets, check dams, dikes, ponds, ditches and other structures; 2) requirements for particular methods of cultivation, including contour cultivating, contour furrowing, lister furrowing, sowing, planting, strip cropping, seeding and plants of land to conserve water; 3) specifications of cropping programs and tillage practices; 4) requirements on the retirement of highly erosive areas; and 5) other measures and programs as may assist conservation of soil resources and prevent or control soil erosion.[43]

The Board may file a petition in circuit court to compel observance with the land-use regulations if it determines that nonobservance tends to increase erosion on those lands and is interfering with the prevention or control of erosion on other lands within the district.[44] The board may provide by ordinance that any landowner who sustains damages from a land-use violation may recover from the violator.[45] The court may require the violator to perform the work or, if the violator fails to do so within the time specified, the board may perform the work and recover costs and expenses with interest of 5% per annum.[46]

• The pesticide law establishes licensing requirements, and states that the Department of Agriculture may "restrict or prohibit the use of pesticides in designated areas during specified times and the storage of fertilizer ... to prevent damage or injury by drift or misapplication to ... fish and other aquatic life in waters in reasonable proximity to the area to be treated."[47] Further, "no person shall discard or store any pesticide or pest containers so as to pollute any waterway in a way harmful to any wildlife therein."[48] Individual farmers are not subject to any liability or response costs unless there is a finding of negligence.[49]

A notice of violation is issued to the licensee for violation of the statute or regulations.[50] If the violation is not abated, the Agriculture Commissioner must issue an order for immediate compliance and may assess civil penalties. If the order is not complied with, the applicator's license may be revoked, with an opportunity to appeal to circuit court.[51] Civil penalties may be recovered in an action brought by the Attorney General or the Department of Agriculture; the Attorney General also may bring an action for injunction for violation of the act, or a violation or threat of violation of an order.[52] Violations of the act or an order are punishable by a civil penalty not to exceed $1000 per day; failure to abate is punishable by a civil penalty of not less than $100; and willful violation of the act or an order is a misdemeanor punishable by a fine of not less than $100 and up to $1000, imprisonment for not more than one year, or both.[53]

Development and Other Earth-Disturbing Activities

Apart from any programs for the control of urban stormwater or that may be authorized by general land use regulation such as zoning, Kentucky law provides the following enforceable authorities potentially relevant to nonpoint source discharges.

• "No person shall commence the filling of any area with earth, debris ... or place a building, barrier or obstruction of any sort on any area located adjacent to a river or stream or in the floodway of the stream so that such filling, raising or obstruction will in any way affect the flow of water in the channel or in the floodway of the stream" unless a permit has been issued by the Natural Resources and Environmental Protection Cabinet.[54] However, the Cabinet has no jurisdiction or control over the construction, improvement, maintenance or operation of any drainage district, ditch or system established for agricultural purposes, nor can it require approval of the same, except where it determines the obstruction of the stream or floodway is a detriment or hindrance to the beneficial use of water resources in the area.[55]

If this provision or a regulation has been violated, the Cabinet may issue a written notice of violation and require the person to answer the charges at a hearing not less than 30 day from the notice. Appeals may be taken from all final orders of the Cabinet by filing a petition for review in Circuit Court.[56] The Cabinet's Department of Law or the Attorney General may bring an action for the recovery of penalties and bring an action for an injunction to prevent or correct a condition constituting or threatening to constitute a violation of the chapter.[57] Violators are subject to a civil penalty of not more than $1000 and may be enjoined from continuing.[58]

• Streams that meet certain criteria are eligible for inclusion in the Wild Rivers System.[59] Criteria for inclusion include streams that are free-flowing, with unchanged shorelines and scenic vistas; their waters "shall not be polluted beyond feasible correction and shall be kept unpolluted once corrected according to standards established by the natural resources and environmental protection cabinet."[60] Land use restrictions for wild rivers include prohibitions on dredging and strip mining. Select cutting or timber or other resource removal and agricultural use may be allowed by permit only pursuant to regulation.[61] The restrictions on land uses do not apply to uses already existing at the time the stream is included in the system,[62] and the law also states that existing agricultural areas in the boundaries may continue.[63] The Attorney General shall bring an action to recover civil penalties or for an injunction to prevent or correct a condition that is or threatens to violate the provisions of the law.[64]

LOUISIANA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Louisiana's water pollution control law includes some provisions that may be used to take enforcement action against nonpoint source discharges that are not permitted or that pollute the waters, but the provisions do not apply to unintentional nonpoint source discharges from agriculture. Agricultural or silvicultural nonpoint sources do not require permits, and are not subject to enforcement under the unpermitted discharge provisions.

• The Louisiana Environmental Quality Act prohibits any person from conducting an activity "which results in the discharge of any substance into the waters of the state without the appropriate permit, variance, or license..."[1]

• The statute also prohibits any person from discharging "any waste or any other substance of any kind that will tend to cause water pollution in violation of any rule, order or regulation" or "any substance" that violates the terms or conditions imposed by a permit.[2]

Neither of these provisions is applicable to "unintentional nonpoint source discharge resulting from or in connection with the production of raw agricultural, horticultural, or aquacultural products."[3] The Louisiana regulations also exclude from the permitting requirement "introduction of pollutants from nonpoint sources resulting from normal agricultural and silvicultural activities."[4]

A civil enforcement action may be brought by the Department of Environmental Quality ("DEQ"). Where a violation is determined to have occurred, the court may assess costs or where the violation is on-going, the Secretary may issue a cease and desist order. The violator may be subject to civil penalties of not more than $25,000 for each day of violation where the substance does not endanger human life or health and where the substance does endanger human life or health, then a person may be liable for not more than one million dollars.[5]

Other Discharge Limitations

• Louisiana has a general nuisance statute[6] which may apply to some forms of nonpoint source pollution. Louisiana's Right to Farm statute prohibits any agricultural operation from being deemed a public or private nuisance if it is conducted "in accordance with generally accepted agricultural practices" and the person bringing the action acquired the interest in the affected land after the date the operation was established or the operation was established prior to any change in character of the property in the vicinity of the operation.[7] Illegal acts or actions based on negligence or intentional injury are exempt from this prohibition.[8]

Fish/Fisheries Laws

• "A person who [unlawfully] kills ...takes ...or injures any fish, wild birds, wild quadrupeds, and other wildlife and aquatic life...is liable to the state for the value of each..."[9] Civil penalties, civil suits for recovery of value, fines, and criminal prosecution are permissible.[10]

• Louisiana law that provides for regional watershed districts (see Development and Other Earth-Disturbing Activities section) prohibits any person from knowingly or willingly draining from any pumps, reservoirs, wells, or oil fields into any stream or watershed "any oil...noxious or poisonous gases or substances which would render the water unfit for irrigation purposes or would destroy aquatic and fish life in the stream." Each day substances flow into the watershed waters constitutes a separate offense. Sanctions include fines of $100-200 or imprisonment of three months or less.[11]

OPERATIONAL REQUIREMENTS

Forestry Requirements

Louisiana law has few enforceable provisions relating to forestry operations that may be relevant to nonpoint source requirements.

• Louisiana law provides that any person who cuts standing cypress trees on water bottoms owned by the state of Louisiana, except in the exercise of rights under a state lease, right-of-way, or permit, is subject to a fine (up to $5000) and/or imprisonment (up to six months).[12]

• The Louisiana Natural and Scenic Rivers Act allows the agency to regulate pollution of waters and provides for civil penalties of up to $1000 per day for each violation.[13] The Act also prohibits commercial harvesting of timber within 100 feet of the low water mark, with exceptions including selective harvesting of trees, cutting to control disease or insects, and harvesting timber for personal use by the person who owns or leases the property.[14]

Agriculture Requirements

• Conservation district supervisors may formulate regulations governing the use of lands within the district in the interest of conserving soil and soil resources and preventing and controlling soil erosion.[15] The regulations to be adopted may include specifications of cropping programs and tillage practices; provisions requiring terminating cultivation in highly erosive areas; and provisions to assist in the conservation of soil resources and prevent or control soil erosion in the district.[16] The regulations require approval by at least 2/3 of the landowners in the district in order to be effective and enforceable.[17]

• Louisiana law requires certification of private applicators of restricted use pesticides, commercial pesticide applicators and pesticide salespersons, licenses for pesticide dealers, and both licenses and certifications for all commercial agricultural consultants.[18] For violations, the commissioner may assess civil penalties, suspend or revoke a license or certificate or institute civil proceedings to enforce his rulings or seek injunctive relief.[19] When the commissioner of agriculture ("commissioner") determines that the concentrations of pesticides exceed promulgated federal or state standards or pose a threat to human health or the environment, the commissioner may take appropriate action.[20] The commissioner is empowered to issue a stop order "prohibiting the distribution, sale, offer for sale, application, movement or disturbance of the pesticide, pesticide wastes or contaminated agricultural commodities or material."[21] Upon determining that the pesticide concentrations exceed government standards, the commissioner may also issue protective orders to limit restrict or prohibit application of a pesticide; issue a remedial order directing any responsible person to take prompt action to correct any situation causing any waters of the state to be affected; communicate his determination to any appropriate agency; and/or issue a public communication.[22] The commissioner may seek and obtain injunctive relief to prevent violation of the above orders, and he may impose civil penalties not to exceed $25,000 per offense pursuant to an adjudicatory hearing. Each day is considered a separate offense.[23]

• Discharges from concentrated animal feeding operations are subject to the LWDPS permit program, which is similar to federal NPDES regulation of these entities as point sources.[24] A concentrated animal feeding operation is designated as such on a case-by-case basis upon determining that it is a "significant contributor of pollution to the waters of the state," based on such factors as the size and location of the operation, the amount of wastes reaching the state waters, and the means of conveyance of animal wastes and process waste waters into the waters of the state.[25]

Development and Other Earth-Disturbing Activities

Louisiana has several potentially applicable enforceable provisions in addition to any that may be contained in urban stormwater programs under the Clean Water Act or that may be authorized by general land use regulation.

• Louisiana law allows parishes to create environmental protection districts "to insure the prudent development of the land areas adjacent to and bordering the Mississippi River..." The powers of the board of commissioners of such a district include establishing and maintaining a master plan for the subdivision and development of those lands and preserving the natural environment of the lands along the river through the restriction of land usage.[26] Penalties include a $5000 fine and imprisonment for not more than 30 days for each day of the violation.[27]

• Louisiana law provides for regional watershed districts in which the board of commissioners may make and enforce rules that prevent damage to the district by solid or liquid pollution or substance or misuse of the waters of the district or any water course therein.[28]

• "No industrial wastes...nor any noxious or harmful matter, solid, liquid or gaseous, shall be discharged into the side or cross ditches or placed upon the state highways without the prior written consent of the chief engineer...and the secretary of the department of health and hospitals.[29]

• Coastal use permits are required for a variety of enumerated uses and activities, but this law excludes activity occurring wholly on lands five feet above mean sea level or activities occurring within fast lands, except for an activity that is found to have "direct and significant impact on coastal waters." Also excluded are agricultural, forestry and aquaculture activities on lands consistently used in the past for such activities.[30] Enforcement actions include injunctive, declaratory or other relief brought by the state (secretary or attorney general), district attorney or local government. The Secretary and local government with approved program have the authority to suspend, revoke, or modify coastal use permits. Sanctions include civil liability, damages, fines and/or imprisonment, and the Secretary may assess costs and administrative penalties.[31]

• Also see the Louisiana Natural and Scenic Rivers Act allowing the agency to regulate pollution of waters[32] (described above under the forestry requirements section).

MAINE

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Maine's water pollution control law includes several provisions that may be used to take enforcement action against nonpoint source discharges.

• "No person may directly or indirectly discharge or cause to be discharged any pollutant without first obtaining a license therefor from the department."[1] "Discharge" means "any spilling, leaking, pumping, pouring, emptying, dumping, disposing or other addition of any pollutant to water of the State." "Pollutant" is broadly defined and includes "rock, sand, dirt and industrial, municipal, domestic, commercial or agricultural wastes of any kind." This prohibition includes nonpoint source discharges. It further provides, however, that "No person may be deemed in violation of this section for the discharge of rock, sand, dirt, or other pollutants resulting from erosion related to agricultural activities [if]... A. The appropriate soil and water conservation district has recommended an erosion and sedimentation control plan or conservation plan for the land where this erosion originates. B. The commissioner has certified that the plan meets the objectives of this chapter. [and] C. The commissioner determines that the agricultural activities are in compliance with the applicable portion of the plan, or the soil and water district has certified that funds from existing federal and state programs are not available to implement the applicable portion of the plan."[2]

• Maine law also prohibits violations of water quality "notwithstanding any exemptions or licenses," but requires establishment of a mixing zone "prior to the commencement of any enforcement action to abate a classification violation."[3]

• A narrower prohibition on discharges or placement of certain materials may apply to some forms of nonpoint source pollution: "No person, firm, corporation or other legal entity may place, deposit or discharge, directly or indirectly into the inland waters or tidal waters of this State, or on the ice thereof, or on the banks thereof in such a manner that it may fall or be washed into these waters, or in such manner that the drainage from any of the following may flow or leach into these waters, except as otherwise provided by law: 1. *Forest products refuse.* Any slabs, edgings, sawdust, shavings, chips, bark or other forest products refuse; 2. *Potatoes.* Any potatoes or any part or parts of potatoes; or 3. *Refuse.* Any scrap metal, junk, paper, garbage, septic tank sludge, rubbish, old automobiles or similar refuse..."[4]

• The law also provides a general injunctive remedy for water pollution without regard to violations: "If the department finds that the discharge, emission or deposit of any materials into any waters, air or land of this State constitutes a substantial and immediate danger to the health, safety or general welfare of any person, persons or property the department shall forthwith request the Attorney General to initiate immediate injunction proceedings to prevent such discharge. The injunction proceedings may be instituted without recourse to the issuance of an [administrative] order."[5]

Enforcement mechanisms under the water pollution law include administrative consent orders and civil injunctive remedies,[6] and civil penalties of up to $10,000 per day.[7] Criminal violations are Class E crimes with a fine of not less than $100 nor more than $25,000 per day of violation.[8]

Other Discharge Limitations

• The Attorney General has broad authority to bring actions in court to abate nuisances. This authority is not limited either by the existence of licenses or by provisions of the water pollution control law.[9]

• Statutory nuisances specifically include "causing or suffering any offal, filth or noisome substance to collect or to remain in any place to the prejudice of others;....corrupting or rendering unwholesome or impure the water of a river, stream, pond, or aquifer."[10]

• "A farm or farm operation may not be considered a public or private nuisance if the farm or farm operation alleged to be a nuisance conforms to best management practices, as determined by the Commissioner of Agriculture, Food and Rural Resources..."[11] However, "The commissioner shall investigate all complaints involving a farm or farm operation, including, but not limited to, complaints involving the use of waste products, ground and surface water pollution.....If the commissioner identifies the source or sources of the problem, has reason to believe that the source is a nuisance and finds that the nuisance is caused by the use of *other than best management practices,* the commissioner shall...determine the changes needed in the farm or farm operation to comply with best management practices and prescribe site specific best management practices for that farm operation,"[determine whether the changes are implemented, and make written findings]...If the person responsible for the farm or farm operation does not adopt best management practices, the commissioner shall send a written report to an appropriate agency if a federal or state law has been violated and to the Attorney General. The Attorney General may institute an action to abate a nuisance and the court may order the abatement with costs..."[12]

• A "nuisance caused by the use of other than best practices for manure handling" is also abatable upon suit by the Attorney General, upon referral from the Commissioner of Agriculture, Food, and Rural Resources.[13]

Fish/Fisheries Laws

State laws relating to fish and fisheries do not appear to contain enforceable provisions relating to nonpoint source discharges independent of those identified above.

OPERATIONAL REQUIREMENTS

Forestry Requirements

• The commissioner of forestry is authorized to promulgate rules establishing forest practices for clearcuts and forest harvests adequate to assure regeneration, and setting performance standards for clearcuts including standards to protect water quality and minimize erosion. Management plans are required for clearcuts in excess of 50 acres.[14] Landowners are required to notify the Bureau of Forestry prior to harvesting timber, and to file reports on timber sales.[15] The law prescribes civil forfeitures of $1,000 per violation of the performance standards in the law and regulations.[16] Violation of notice requirements results in a civil forfeiture of $50 for harvests of 50 cords or less and $1000 for larger harvests or for failure to submit other reports.[17] The commissioner of forestry has been directed by the state legislature to recommend a set of statewide forestry standards in 1999. If adopted, such standards may affect future nonpoint source-related enforcement for forest practices.

• The Land Use Regulation Commission (LURC) provides land use regulation for portions of Maine that are unorganized (see discussion below under "Development and Other Earth-Disturbing Activities). LURC regulations include timber harvesting standards; these include provisions for slash disposal, clearcut size/location, retention of buffer strips, and a general requirement to "reasonably avoid sedimentation of surface waters."[18]

• The mandatory shoreland zoning law protects areas within 250 feet of the normal highwater line of any great pond, river or saltwater body, within 250 feet of a coastal wetland or the upland edge of a freshwater wetland, and within 75 feet of the highwater line of a stream. The Board of Environmental Protection adopts minimum guidelines for municipal zoning and land use controls; municipalities must adopt ordinances and have them approved by the commissioner as consistent with and no less stringent than the guidelines. If a municipality does not adopt an approvable ordinance, the board may do so.[19] The statute limits timber harvesting in the protected areas to selective cutting of no more than 40 percent of the trees 4 inches or more in diameter in any ten-year period, prohibits timber harvests within 75 foot areas abutting great pond shoreland zoned for resource protection, and requires reforestation within 2 growing seasons of any harvest beyond the 75 foot buffer.[20]

Agriculture Requirements

Apart from the nuisance-related provisions and water pollution discharge provisions noted above -- where use of best management practices and conservation plans, respectively, constitute exemptions -- other provisions of state law relate to agricultural practices that may result in nonpoint source discharges.

• "When the ground is frozen, a person may not spread manure on agricultural fields within a great pond watershed unless this activity is in accordance with a conservation plan for that land on file with a state soil and water conservation district."[21]

• The Maine Land Use Review Commission rules require all spreading or disposal of manure, in the unorganized areas of the state subject to the commission, to be accomplished in accordance with published guidelines; these rules are enforceable.[22]

• In 1998 the legislature enacted a Nutrient Management Act, which requires farms with more than 50 animal units or that receive 100 or more tons of manure per year to hold and implement a certified nutrient management plan. New farms with more than 300 animal units, or existing farms that expand to more than 300 animal units must hold a livestock operations permit issued by the Maine Department of Agriculture. In addition, beginning December 1, 1999, manure spreading is prohibited between December 1 and March 15 (although the commissioner may issue hardship variances).[23] Failure to develop a nutrient management plan, to implement a nutrient management plan, or to obtain or comply with a permit are offenses punishable by civil forfeiture of up to $1,000 plus $250 per day; winter spreading of manure is punishable by civil forfeiture of up to $1,000 for every day that spreading occurs.[24]

The law also placed a moratorium on new swine feeding operations that confine and feed 500 or more swine, pending a 1998 legislative study on a proposed permit process for large CAFOs. The law also provided for a study by the Maine Department of Agriculture and DEP to evaluate the impact of agriculture on nonpoint source pollution. The study, due January 15, 2001, must evaluate progress in implementing BMPs to exclude livestock from access to streams and lakes for drinking water, evaluation of practices to reduce soil erosion from cropland, and evaluation of BMPs to reduce runoff of nutrients from farmland. The law contemplates, and authorizes the reporting out of legislation to address the findings of the report.[25]

• State law concerning pesticide applications provides for regulation of the places in which pesticides may be used.[26] It provides for certification of commercial applicators and spray contracting firms by the Board of Pesticides Control, and certification of private applicators who intend to use limited or restricted use pesticides; it also provides for establishment of critical areas where pesticide use would "jeopardize endangered species or critical wildlife habitat, present an unreasonable threat to quality of the water supply, be contrary to a master plan for the area where such area is held or managed by an agency of the State or Federal Government, or would otherwise result in unreasonable adverse effects on the public health, welfare or the environment of the area. The designation of a critical area may prohibit pesticide use or may include such limitations on such use as the board deems appropriate..."[27] Civil injunctions, orders, license actions, and criminal prosecutions are available for enforcement.[28] Violations are subject to a civil forfeiture of up to $1500 for a first violation and $4000 for subsequent violations; $500 and $1000 respectively for private applicators.[29]

Development and Other Earth-Disturbing Activities

A number of laws provide enforceable land use mechanisms that may address some nonpoint sources of water pollution. Some of these provide direct authority to regulate nonpoint activities while others cross-reference erosion and sediment control requirements.

• Maine's Site Location of Development Law addresses "development of state or regional significance that may substantially affect the environment."[30] It includes developments in excess of 20 acres, subdivisions for single family homes of 15 or more lots aggregating more than 30 acres, buildings and parking lots and other paved areas that occupy a ground area in excess of 3 acres, or development that generates 100 or more passenger car equivalents at peak hour. Prior approval for construction, operation, sale, or lease is required from department of environmental protection.[31] The proposed development must stormwater and erosion and sediment control standards in laws discussed below.[32] The law exempts certain subdivisions of low density with conservation easements, preservation of certain areas, avoidance of slopes, habitats, and adherence to locally approved erosion control plans.[33] It also exempts development within unorganized areas of the state subject to the jurisdiction of the Maine Land Use Regulation Commission;[34] and exempts from certain requirements developments within designated growth areas under a growth management program.[35]

• Another law provides for land use regulation in the unorganized portions of Maine.[36] The Land Use Regulation Commission (LURC) establishes regulations for protection districts, management districts, and development districts, and reviews structures and subdivisions. A LURC permit is needed to commence construction or operation of a development.[37] Rules require land clearing activities to maintain vegetative buffer zones of 75 feet around any standing body of water <10 acres and 100 feet for any >10 acres, and removal of no more than 40% of the volume of trees 4 inches or more in diameter in any 10 year period in the zone between 100 and 250 feet. Regulations also prescribe standards for drainage ditches and stream crossings, timber harvests, and filling and grading. Within 250 feet of water bodies and wetlands, the maximum size of a filled or graded area on a single parcel is 5,000 square feet, and beyond 250 feet it is 20,000 square feet; these limits also require compliance with the vegetative clearing limits described above. Minimum lot sizes and frontages are prescribed.[38] LURC land use standards for "management districts....may not limit the right, method or manner of cutting or removing timber or crops, the construction and maintenance of hauling roads, the operation of machinery or the erection of buildings and other structures used primarily for agricultural or commercial forest product purposes..."[39]

• Maine's Growth Management Law applies to municipalities not within the jurisdiction of the LURC.[40] Each municipality may adopt a local growth management program; the implementation strategy must be developed in accordance with guidelines including to "Protect, maintain and, when warranted, improve the water quality of each water body...and ensure that the water quality will be protected from long-term and cumulative increases in phosphorous from development in great pond watersheds."[41]

• Another law provides for river corridor commissions to do comprehensive planning and zoning and to adopt rules covering an area "up to 500 feet from the normal high-water mark", and to issue permits subject to reasonable conditions.[42] Under the River Commission law,[43] enforcement by the commission may be by injunction and penalties, as provided in Title 38.[44]

• Maine law authorizes the organization of local watershed districts.[45] Such districts may adopt rules as necessary to carry out the purposes of the district, but have no regulatory powers over land use except by agreement with municipalities.[46]

• Mandatory shoreland zoning provides another enforceable mechanism.[47] It protects areas within 250 feet of the normal highwater line of any great pond, river or saltwater body, within 250 feet of a coastal wetland or the upland edge of a freshwater wetland, and within 75 feet of the highwater line of a stream. The Board of Environmental Protection adopts minimum guidelines for municipal zoning and land use controls; municipalities must adopt ordinances and have them approved by the commissioner as consistent with and no less stringent than the guidelines. If a municipality does not adopt an approvable ordinance, the board may do so. The statute requires setback requirements, limits on timber harvesting, and vegetation buffers between buildings and shoreland.[48] Another section of the law provides further protections for "significant river segements" including minimum setbacks of 125 feet and limitations on roads and gravel pits.[49] Municipalities may zone even more restrictively to protect public health, safety and welfare and to avoid problems associated with floodplain development; zoning ordinances must designate as a resource protection zone all areas within the floodway of the 100 year floodplain along rivers.[50] Local enforcement is by municipal code enforcement officers, with enforcement by the state under the water pollution laws where local zoning is not adopted or enforced.[51] Water utilities may bring civil suits for injunctive relief as well against any violator affecting the water supply.[52]

• The Natural Resource Protection Act prohibits any "dredging, bulldozing, removing, or displacing soil, sand, vegetation or other materials", any "draining or otherwise dewatering", any "filling", or "any construction, repair or alteration of any permanent structure without a permit if the activity is located "in, on or over any protected natural resource or is located adjacent to and operated in such a manner that material or soil may be washed into..a coastal wétland, great pond, river, stream or brook or significant wildlife habitat contained within a freshwater wetland[,or]...freshwater wetlands consisting of or containing [at least 20,000 square feet... or peatlands dominated by shrubs, sedges and sphagnum moss]."[53] Permit standards require that "the activity will not cause unreasonable erosion of soil or sediment...[that it] not unreasonably harm any significant wildlife habitat, freshwater wetland plant habitat, threatened or endangered plant habitat, aquatic habitat, travel corridor, freshwater, estuarine or marine fisheries or other aquatic life....[that it] will not violate any state water quality law...[and] not unreasonably cause or increase the flooding of the alteration area or adjacent properties."[54] The permit program may be delegated by the board of environmental protection to municipalities.[55] The law exempts from permitting requirements various activities including normal farming activities, and forest management provided that other requirements are met.[56] A permit by rule for activities under the Natural Resource Protection Act covers soil disturbances adjacent to wetlands, great ponds, rivers, streams, brooks "if operated in such manner that material or soil may be washed into them." It requires a setback of 25 feet between the normal high water line or upland edge of the protected natural resource and the activity; and erosion into the buffer and the resource "must be prevented" and sediment control measures must be in place before the project begins and must function as intended until the project area is permanently stabilized.[57] Enforcement may be by the municipal government or the department of environmental protection, and both may collect penalties.[58]

Erosion and sediment control requirements are established in several laws identified below. They include some nonpoint source as well as stormwater requirements.

• "A person who conducts, or causes to be conducted, an activity that involves filling, displacing or exposing soil or other earthen materials shall take measures to prevent unreasonable erosion of soil or sediment beyond the project site or into a protected natural resource [viz. "coastal sand dune system, coastal wetlands, significant wildlife habitat, fragile mountain areas, freshwater wetlands, great ponds or rivers, streams or brooks"]"[59] This law applies only within organized areas of the state, and "does not apply to agricultural fields. Forest management activities, including associated road construction or maintenance, conducted in accordance with applicable standards of the Maine Land Use Regulatory Commission, are "deemed" to comply. The law "may not be construed to limit a municipality's authority under home rule to adopt ordinances containing stricter standards than those contained in this section." Erosion control measures must be in place before the activity begins. Measures must remain in place and functional until the site is permanently stabilitized. Adequate and timely temporary and permanent stabilization measures must be taken."

• Maine's stormwater law covers some nonpoint sources as well. "A person may not construct, or cause to be constructed, a project that includes 20,000 square feet or more of impervious area or 5 acres or more of disturbed area in the direct watershed of a body of water most at risk from new development or one acre or more of impervious area or 5 acres or more of disturbed area in any other area without prior approval from the department [of environmental protection]....The department shall adopt rules specifying quantity and quality standards for storm water. Storm water quality standards for projects with 3 acres or less of impervious surface may address phosphorous, nitrates and suspended solids but may not directly address other dissolved or hazardous materials unless infiltration is proposed. Storm water quality standards apply only in the direct watersheds of waterbodies most at risk from development and in sensitive or threatened geographic regions or watersheds defined by the department..." The department is to define both of these categories by rule...based on susceptibility to degradation, sensitivity, cumulative effects.[60] The law applies only within organized areas of the state; a permit required by this law is not required if a permit is required under another similar law, "but the project may be required to meet standards for management of storm water adopted pursuant to this section." Specific exemptions include "forest management activities, including associated road construction or maintenance", disturbing areas "for the purpose of normal farming activities", projects within municipalities where the commissioner has certified the ordinance as meeting or exceeding the state law provisions, industrial facilities that have a federal stormwater permit, construction or expansion of a single-family detached residence, and "projects involving roads, railroads, and associated facilities conducted by or under the supervision of the Department of Transportation or the Maine Turnpike Authority...so long as the projects are constructed pursuant to storm water quality and quantity standards set forth in a memorandum of agreement between the department and the conducting or supervision agency and the project does not require review under [the site location of development program]."

• Another law regulates excavations for borrow, clay, topsoil or silt for areas of 5 or more acres, requiring a notice of intent to comply, and imposing performance standards to protect groundwater, protected natural resources (including surface waters), and buffer strips.[61] Excavations of less than 5 acres have fewer requirements, but sediment may not leave the parcel or enter a protected area, erosion control measures must be in place, and vegetated cover must be established after final grading.[62] This law applies only within organized areas of the state and does not apply to excavations within the jurisdiction of the LURC or to excavations regulated under the Natural Resource Protection Act.

All of these laws are enforceable under the environmental enforcement provisions summarized above under the water pollution control law section of this summary. In addition, those delegated to local land use authorities are enforceable by those authorities.

MARYLAND

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Maryland's water pollution control law includes some provisions that may be used to take enforcement action against nonpoint source discharges of pollutants; and the state's Department of the Environment may require permits for certain nonpoint source discharges. In addition, soil or sediment pollution is prohibited, except for agricultural activities conducted in accordance with agricultural soil conservation and water quality plans.

• "Except as provided in this subtitle and Subtitle 4 of Title 4 [relating to soil or sediment emissions] of this article and the rules and regulations adopted under those subtitles, a person may not discharge any pollutant into the waters of this State."[1] "Discharge" means: (1) The addition, introduction, leaking, spilling, or emitting of a pollutant into the waters of this State; or (2) The placing of a pollutant in a location where the pollutant is likely to pollute."[2] "Pollutant" means...(2) Any other liquid, gaseous, solid or other substance that will pollute any waters of this State."[3]

• The Maryland Department of the Environment may require nonpoint source dischargers to obtain permits under some circumstances. "A person shall hold a discharge permit issued by the Department before the person may construct, install, modify, extend, alter, or operate any of the following if its operation could cause or increase the discharge of pollutants into the waters of this State:...Any other outlet or establishment."[4] "By rule or regulation, the Department may require a discharge permit for any other activity."[5]

Enforcement of these provisions is by administrative corrective action orders, injunctions, civil penalties not exceeding $10,000 per day (judicially) or $1,000 per day (administratively), or criminal prosecution.[6]

• Except as authorized under the discharge permit provisions described above, or on land managed under an agricultural soil conservation and water quality plan approved by the local soil conservation district, "it is unlawful for any person to add, introduce, leak, spill, or otherwise emit soil or sediment into waters of the State or to place soil or sediment in a condition or location where it is likely to be washed into waters of the State by runoff of precipitation or by any other flowing waters."[7]

Enforcement may be by injunctive relief,[8] or corrective action orders.[9] Civil penalties are available up to $25,000 per day; or criminal penalties of up to $50,000 and/or one year imprisonment.[10] A person engaged in agricultural land management practices without an approved soil conservation and water quality plan is not liable for penalties for a discharge if the person complies with a corrective action order.[11]

Other Discharge Limitations

• The Secretary of the Environment has authority to investigate and bring injunctive actions to abate nuisances, which may include drainage, waste disposal, and other activities affecting public health.[12]

Fish/Fisheries Laws

• "Whenever there occurs in the waters of the State any condition indicative of damage to aquatic resources, including, but not limited to, mortality of fish and other aquatic life, the Department shall investigate the incident, determine the nature and extent of the damage, and establish the cause and source of the occurrence. The Department shall act on these findings and require repair of any damage done and restoration of water resources to a degree necessary to protect the best interest of the people of the State."[13] Any person responsible for the discharge is "personally and/or severally responsible" for abatement and for restoration of the natural resources.[14]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• The Department of Natural Resources "shall administer forest conservation practices on privately owned forest land and manage publicly owned forest lands."[15] The Department *may* promulgate rules and regulations, including minimum forestry practices, and enforce them.[16] These rules may be enforced by district forestry boards.[17] State law also provides for licensing of professional foresters.[18]

• Under the state's Nontidal Wetlands program, "forestry activities required to have an erosion and sediment control plan that are not exempted under subsection (a) of this section shall incorporate nontidal wetlands best management practices..."[19] "The following agricultural and forestry activities are exempt from the approval and mitigation requirements of this section: (1) Agricultural activities undertaken in accordance with public drainage regulations; (2) Agricultural and forestry activities, including the repair and maintenance of farm ponds, drainage ditches, channels, subsurface drains, causeways, bridges, or water control structures, provided that they do not drain, dredge, fill, or convert nontidal wetlands on which agricultural and forestry activities are not presently conducted; (3) Agricultural and forestry activities on areas that have laid fallow as part of a conventional rotational cycle or due to a civil action involving ownership of the property; (4) Agricultural and forestry activities on areas that have been set aside or taken out of production under a formal State or federal program; (5) Forestry activities not requiring an erosion and sediment control plan; (6) Construction or maintenance of forest roads and skid trails in accordance with best management practices..." However,"This subtitle does not apply to agricultural, forestry, or regulated activities located within the Chesapeake Bay critical area" as these activities are separately regulated under that bay protection statute.[20] The regulations include provisions that "... a person conducting a forestry activity shall implement best management practices to protect nontidal wetlands through a sediment and erosion control plan ..."[21] "Best management practices for forestry activities in nontidal wetlands shall be designed to achieve the following goals: (1) Control soil loss and sediment deposition in nontidal wetlands; (2) Minimize water quality degradation caused by sediment..."[22]

• Under the Chesapeake Bay Critical Area Protection Program, "At a minimum, a program sufficient to meet the goals...includes: ...(10) Provisions requiring that all harvesting of timber in the Chesapeake Bay Critical Area be in accordance with plans approved by the district forestry board"[23] (Operation of the Critical Area Program itself is discussed at greater length below under "Development and Other Earth-Disturbing Activities.").

Agriculture Requirements

• Agricultural land managed under a soil conservation and water quality plan approved by the local soil conservation district is not liable for emission of soil or sediment into waters of the State or placement of soil or sediment in a condition or location where it is likely to be washed into waters of the State by runoff of precipitation or by any other flowing waters.[24] A person engaged in agricultural land management practices without an approved soil conservation and water quality plan is not liable for penalties for a discharge if the person complies with a corrective action order.[25]

• A law passed in 1998 requires farmers that use commercial fertilizers to prepare nitrogen and phosphorous management plans by December 31, 2001 and to implement them by December 31, 2002. It requires farmers that use manures and sludges on their fields to have a nitrogen management plan in place and to implement it on the same schedule. Farmers using manure and sludge must also prepare management plans addressing phosphorous by July 1, 2004, and implement them by July 1, 2005. The requirements apply to all agricultural operations with an annual income of at least $2,500, and livestock operations with 8 or more animal units. Farmers who fail to develop a plan may be fined up to $250; those who fail to implement a plan by the required date receive a warning for a first offense and an administrative penalty of up to $100 for each subsequent violation, but not to exceed $2,000. Farmers applying commercial fertilizer inconsistently with nutrient management plans are subject to a penalty of up to $1,000 for a first violation, and up to $2,000 for subsequent violations, but not to exceed a total of $10,000.[26]

• "The General Assembly...finds that agricultural drainage projects, if not properly designed, operated, and maintained, have the potential to contribute nonpoint source pollutants to the waters of the State." The Secretary of Agriculture and the Secretary of Natural Resources "shall jointly promulgate by regulation ... criteria for the design, construction, operation, and maintenance of agricultural drainage projects which will assure, to the maximum extent practicable, the prevention of pollution of the waters of the State." "[B]efore initiating an agricultural drainage project, a public drainage association shall obtain from the Secretary approval of construction, operation, and maintenance plans for the project." "An agricultural drainage project shall be constructed, operated, and maintained in accordance with the approved plans."[27] Either Secretary may issue corrective action orders, enforceable by injunction, and violators are liable for double damages for projects not done in accordance with approved plans.[28]

• Nontidal wetlands requirements are applicable to agriculture. If not exempt from regulation (see forestry above), then an agricultural operation must employ BMPs under a soil conservation district-approved soil conservation and water quality plan to protect nontidal wetlands.[29] "Best management practices for agricultural activities in nontidal wetlands shall be designed to achieve the following goals: (1) Control soil loss and minimize sediment deposition in nontidal wetlands; (2) Minimize water quality degradation..."[30] "This subtitle does not apply to agricultural, forestry, or regulated activities located within the Chesapeake Bay critical area."[31]

• The Secretary of Agriculture "shall [a]dopt rules and regulations governing the storage, sale, distribution, exchange, use, and disposal of any pesticide and its container"[32] Applicators "shall obtain an annual certificate indicating competence in one or more established categories from the Secretary."[33] "When using or recommending pesticides, a person shall: ... Observe all precautions in the handling, use, storage, and disposal of pesticides and their containers so that: (a) Pesticides do not move from the intended site of application, (b) Nontarget areas or organisms, including humans, do not suffer injury, and (c) Unreasonable adverse effects on the environment do not occur or are minimized..."[34] Violations are misdemeanors punishable by fines not exceeding $1,000, or imprisonment not exceeding 60 days, or both.[35] "The Department may issue a civil penalty or suspend, revoke, or deny any license, certificate, or permit" for violations of the law or regulations,[36] or impose a civil penalty of "not more than $2,500 for a first violation and not more than $5,000 for each subsequent violation. The total penalties imposed on a person for violations that result from the same set of facts and circumstances may not exceed $25,000."[37]

• Under the Chesapeake Bay Critical Area Protection Program "At a minimum, a program sufficient to meet the goals ... includes: ... Establishment of buffer areas along shorelines within which agriculture will be permitted only if best management practices are used, provided that structures or any other use of land which is necessary for adjacent agriculture shall also be permitted in any buffer area."[38]

Development and Other Earth-Disturbing Activities

Apart from any programs that may be authorized by general land use regulation such as zoning, state law provides the following authorities.

• Each local jurisdiction is responsible for developing and implementing a program, subject to review and approval by the Chesapeake Bay Critical Area Commission. A program "shall consist of those elements which are necessary or appropriate: (1) to minimize adverse impacts on water quality that result from pollutants that are discharged from structures or conveyances or that have run off from surrounding lands."[39] Under the Chesapeake Bay Critical Area Protection Program "At a minimum, a program sufficient to meet the goals ... includes: ... Provisions to limit the amount of land covered by buildings, roads, parking lots, or other impervious surfaces, and to require or encourage cluster development."[40] Project approval may not be granted unless the project is consistent with and complies with the program.[41] Injunctive relief is available for enforcement.[42]

R0017143

• The state nontidal wetlands program provides that the Department of Natural Resources shall "Adopt standards for planning, regulating, restoring, creating, and enhancing nontidal wetlands"[43] and that the Department may "delegate all or part of its authority under this subtitle to any county that enacts a nontidal wetland protection program ... that meets at least the minimum standards adopted by the Department."[44] "[A] person may not conduct a regulated activity without first obtaining a permit from the Department."[45] A permit may not be issued unless the Department finds that the applicant has demonstrated that the regulated activity "will minimize alteration or impairment of the nontidal wetland, including existing topography, vegetation, fish and wildlife resources, and hydrological conditions; [and w]ill not cause or contribute to a degradation of groundwaters or surface waters ..."[46] Enforcement is via permit revocation, stop work orders, civil penalties of up to $10,000 per day, injunction, and misdemeanor fines of up to $10,000 for a first offense, and $25,000 for subsequent offenses.[47]

• "To protect the natural resources of the State, the Secretary of the Environment, in consultation with the Secretary of Natural Resources shall adopt criteria and procedures for the counties and the local soil conservation districts to implement soil erosion control programs. These procedures may provide for departmental review and approval of major grading, sediment, and erosion control plans."[48] "Regardless of planning, zoning, or subdivision controls, a county or municipality may not issue a permit for grading or construction of any building, other than those matters exempted by the provisions of this section, unless the grading or construction conforms with plans approved as provided in this subtitle."[49] "A grading or building permit may not be issued until the developer (1) submits a grading and sediment control plan approved by the appropriate soil conservation district, and (2) certifies that all land clearing, construction, and development will be done under the plan."[50] "A person may not begin or perform any construction unless the person: (I) Obtains an approved sediment control plan; (ii) Implements the measures contained in the approved sediment control plan; (iii) Conducts the construction as specified in the sequence of construction contained in the approved sediment control plan; (iv) Maintains the provisions of the approved sediment control plan; and (v) Implements any sediment control measures reasonably necessary to control sediment runoff."[51] "The provisions of this subtitle do not apply to agricultural land management practices, construction of agricultural structures, or, except in Calvert County, to construction of single-family residences or their accessory buildings that disturb an area of less than one-half acre and occur on lots of two acres or more."[52] Enforcement includes stop work orders, corrective action orders, injunctions, civil penalties of up to $1,000 per violation, not exceeding $20,000 for any action, and misdemeanor fines of up to $5,000 and/or one year imprisonment.[53]

• The state also has an enforceable forest conservation program with respect to land development. "A unit of local government having planning and zoning authority shall develop a local forest conservation program, consistent with the intent, requirements and standards of this subtitle."[54] "Before the approval of the final subdivision plan, or the issuance of the grading or sediment control permit by the State or local authority, the applicant shall have an approved forest conservation plan..."[55] The forest conservation subtitle applies "to any public or private subdivision plan or application for a grading or sediment control permit on areas 40,000 square feet or greater;" it does not apply to construction of highways, forest cutting in areas governed by the Chesapeake Bay Critical Area Protection Law, and agricultural activity that does not result in a change in land use category.[56] Enforcement includes a penalty of 30 cents per square foot of the area found to be in noncompliance,[57] plan revocation,[58] a stop work order by the state or local authority, injunctive relief, and civil penalty of up to $1,000 per day.[59]

MASSACHUSETTS

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Massachusetts prohibits the discharge of a pollutant from any source, not just point sources, without a permit; but agricultural and silvicultural nonpoint source discharges are exempt from the permit requirement by regulation.

• "Any person who, directly or indirectly, throws, drains, runs, discharges or allows the discharge of any pollutant into waters of the commonwealth, except in conformity with a permit...shall be punished by a fine...or by imprisonment...or shall be subject to a civil penalty not to exceed twenty-five thousand dollars per day of such violation."[1] "Pollutant" is defined as "any element or property of sewage, agricultural, industrial or commercial waste, runoff, leachate, heated effluent, or other matter, in whatever form and whether originating at a point or major nonpoint source..."[2] The definition in the regulations lacks the word "major" preceding "nonpoint source."[3]

• Another section of the law prohibits the discharge of "pollutants" without a permit, and provides that "[n]o person shall engage in any other activity that may reasonably be expected to result, directly or indirectly, in discharge of pollutants into waters of the commonwealth" without a permit "unless exempted by regulation of the director."[4]

The regulations exempt from permit requirements "[a]ny introduction of pollutants from non-point source agricultural and silvicultural activities, including runoff from orchards, cultivated crops, pastures, range lands, and forest lands."[5] Massachusetts may be able to directly enforce its surface water quality standards with respect to these activities.[6]

Enforcement mechanisms, in addition to civil penalties, include orders and injunctive relief.[7]

Other Discharge Limitations

• "Whoever places, throws, deposits, discharges, or causes to be placed, thrown, deposited or discharged, any trash, bottles or cans, refuse, rubbish, garbage, debris, scrap, waste or any other material of any kind . . . in or upon coastal or inland waters . . . or within twenty yards of any such water . . . shall be punished by a fine" and may be required to remove the material.[8]

• "No sewage, drainage, refuse or polluting matter, of such kind and amount as either by itself or in connection with other matter will corrupt or impair the quality of the water of any pond or stream used as a source of ice or water supply by a town, public institution or water company for domestic use, or render it injurious to

R0017148

health...shall be discharged into any such stream or pond, or upon their banks if any filter basin so used is there situated, or into any feeders of such pond or stream within twenty miles above the point where such supply is taken."[9]

• A similar provision provides for the abatement of situations where "manure, excrement, garbage, sewage or any other matter pollutes or tends to pollute the waters of any stream, pond, spring, underground waters, or watercourse used by [a] city, town, institution or company as a source of water supply."[10] Failure to obey an order to abate the pollution is punishable by a fine, imprisonment, or civil penalty of up to $25,000 per day.[11] Willful defilement of water supplies is defined as a criminal offense.[12]

• Several prohibitions apply to nonpoint source discharges in particular managed public water supply watersheds. One provides that "no person shall take or divert any water of the watershed system of the division [of watershed management], and no person shall corrupt, render impure, waste or improperly use any such water."[13] Within these designated watersheds, the alteration of land or the "generation, storage, disposal, or discharge of pollutants" is prohibited within 200 feet of the bank of a tributary or surface water, or within 400 feet of the bank of a reservoir. The law specifically prohibits in these areas outdoor storage of fertilizers, herbicides, pesticides, road salt, uncovered storage of manure, rendering more than ten percent (or 2500 sq. ft.) of any lot impervious, altering vegetated wetlands, or "any other activity which could degrade the quality of the water in the watersheds."[14] This section does not apply to "activities relating to the normal maintenance or improvement of land in agricultural use...provided, however, that such activities do not impair the quality of the water."[15] Enforcement includes fines.[16]

• The attorney general also has general authority to prevent or remedy damage to the environment, including water pollution, and may enforce any statute, ordinance, bylaw or regulation or secure any common law right or remedy, including the abatement of public nuisances.[17] Local boards of health have power, like the department of environmental protection, to enforce certain state environmental laws dealing with on-lot sewage disposal systems.[18] Boards of health also may abate nuisances that may be injurious to public health. While this may include agricultural nuisances, it may not include odors and noise from normal farming and livestock practices.[19]

• The state's environmental agency may "for the purpose of promoting the public safety, health and welfare, and protecting public and private property, wildlife, fresh water fisheries, and irreplaceable wild, scenic and recreational river resources, adopt...orders regulating, restricting or prohibiting...polluting the scenic and recreational rivers and streams of the commonwealth."[20] The commissioner's jurisdiction under this section extends to the rivers and streams themselves and to such contiguous land not to exceed one hundred yards on either side of the natural bank of such river; and the orders are to be recorded in the property records for the county wherein the lands are located. Enforcement is by injunction, and by fines.[21]

R0017149

Fish/Fisheries Laws

• Placing or allowing the runoff into coastal waters of "any oil, poisonous or other injurious substance, including but not limited to, sawdust, shavings, garbage, ashes, acids, sewage, and dyestuffs...or heated effluent, which directly or indirectly materially injure fish, fishspawn or seed therein" is an offense punishable by fine and/or imprisonment.[22]

• A similar provision applies to the discharge of "sewage or any other substance which might be injurious to the public health or might tend to contaminate any shellfish areas or shellfish therein....or injuriously affect the fisheries therein..."[23]

• "A person shall not put, throw, discharge or permit to be discharged or to escape into any inland waters of the commonwealth any waste or other material, in violation of [Massachusetts' wetlands act or clean water act]... which may directly or indirectly injure or kill the fish or fish spawn therein." Any actions that "directly or indirectly" injure or kill or damage fish or fish spawn in the inland waters of the state, except as specifically authorized, result in liability to the state for twice the amount of the damage thereby done.[24] Fines or imprisonment are also provided for.[25]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• Under the Forest Cutting Practices Act the state forestry committee, subject to approval of the commissioner for environmental management, must prepare minimum forest cutting practices and guidelines.[26] Under the Act, landowners must give prior notice of intent to harvest to both the director of the division of forests and parks and to neighboring property owners. The notice must include the proposed cutting plan. The harvest may not begin until the director has provided a final work order, unless the director fails to act within ten days (this exception does not apply in wetland areas).[27] Enforcement is by stop work order and fine of up to $100 per acre.[28] The law does not apply to cutting for the owner's own use, to cutting or sale not exceeding 25,000 board feet or 50 cords, or land clearing activities.[29] The law requires a license to harvest timber or other forest products for hire or profit, and requires licensees to demonstrate familiarity with the state's laws on forestry and timber harvesting; enforcement is by fine and injunction.[30]

• State law prohibits the placement of slash within 25 feet of any continuously flowing stream, any pond, river, or water supply.[31]

• Forestry operations in wetlands are subject to additional regulations and to Best Management Practice requirements.

Agriculture Requirements

• Massachusetts law does not appear to prescribe enforceable practices with respect to agriculture, except with respect to certain agricultural activities occurring in or near wetlands. Use of Best Management Practices in these areas is required by regulations.[32]

• Massachusetts does regulate pesticides, including licensing of dealers, and its law provides that "no person shall distribute, handle, dispose of, discard, or store any pesticide or pesticide container in such a manner as to cause injury to humans, vegetation, crops, livestock, wildlife, beneficial insects, to cause damage to the environment, or to pollute or contaminate any water supply, waterway, groundwater or waterbody."[33] The law also provides general order authority whenever it appear that there is an imminent hazard or a potential threat of unreasonable adverse effect on the environment.[34] Enforcement provisions include fines, injunctions, criminal sanctions, and injunctions.[35]

Development and Other Earth-Disturbing Activities

Apart from any programs for the control of urban stormwater under the federal Clean Water Act or that may be authorized by general land use regulation such as zoning, state law does not prescribe detailed operating requirements.

• However, certain construction activities in wetlands, floodplains, and riverbanks are regulated under state law and bear on nonpoint source pollution in these areas.[36] Massachusetts has detailed wetlands protection regulations.

MICHIGAN

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Michigan's water pollution control laws include provisions that may be used to take enforcement action against nonpoint source discharges that cause environmental harm. They also provide general authority for the state to adopt rules and issue orders with respect to polluting substances. Virtually all of Michigan's laws relating to the environment are codified as the "Natural Resources and Environmental Protection Act," administered by the state's departments of natural resources and environmental quality.[1] Chapter and article headings in the Act *are not part of the act and are not to be used to construe the scope of the act.*[2] This has particular relevance to the interpretation of nonpoint source enforceable mechanisms, as the following enforceable provisions are found in a part of the Act captioned "Article II, Chapter 1-Point Source Pollution Control."[3]

• The broadest prohibition apparently applies to nonpoint sources as well as point sources. "A person shall not directly or indirectly discharge into the waters of the state a substance that is or may become injurious to any of the following: (a) To the public health, safety or welfare. (b) To domestic, commercial, industrial, agricultural, recreational, or other uses that are being made or may be made of such waters. (c) To the value or utility of riparian lands. (d) To livestock, wild animals, birds, fish, aquatic life, or plants or to the growth, propagation, or the growth and propagation thereof be prevented or injuriously affected; or whereby the value of fish and game is or may be destroyed or impaired."[4]

• In addition, the Department of Environmental Quality "may promulgate rules and issue orders restricting the polluting content of any waste material or polluting substance discharged or sought to be discharged into any...waters of the state. The department shall take all appropriate steps to prevent any pollution the department considers to be unreasonable and against public interest in view of the existing conditions in any...waters of the state."[5] This broad provision also apparently covers nonpoint as well as point source categories.

A related requirement provides for issuance of waste discharge permits. However, the regulations apply the permit requirement most clearly to point source dischargers.[6] Definitions in the state regulations nevertheless create the possibility that nonpoint source dischargers could also fall within the permit requirement.[7]

The state agency may enforce the laws and regulations noted above, and may bring or cause to be brought civil actions or criminal prosecutions in court.[8] It may revoke a permit, issue an order of abatement, or refer a case to the attorney general.[9]

Sanctions include civil fines of not less than $2,500 nor more than $25,000/day, and criminal penalties and terms of imprisonment for knowing violations.[10]

Other Discharge Limitations

• The Michigan Environmental Protection Act (MEPA) allows the Attorney General or "any person" to bring an action in court "for declaratory and equitable relief against any person for the protection of the air, water, and other natural resources and the public trust in these resources from pollution, impairment, or destruction."[11] Natural resource damage actions may also be brought by the state.

• Nuisance law provides additional remedies that may be used to address some instances of nonpoint source pollution. Michigan law provides that causing pollution ("directly or indirectly discharg[ing] into the waters of the state" any substance that is or may become injurious to public health, safety, or welfare, or to human uses of waters or to aquatic life or wildlife or to riparian land) is "prima facie evidence of a public nuisance and in addition to the remedies provided for in this part may be abated according to law in an action brought by the attorney general in a court of competent jurisdiction."[12]

However, a farm may not be found to be a nuisance if it "conforms to generally accepted agricultural and management practices according to policy determined by the Michigan commission of agriculture." The law provides that these "[g]enerally accepted agricultural and management practices shall be reviewed annually by the Michigan commission of agriculture and revised as considered necessary."[13]

• An anti-litter law has some potential applicability to nonpoint source water pollution as well. It provides that "[a] person shall not knowingly, without the consent of the public authority having supervision of public property or the owner of private property, dump, deposit, place, throw, or leave, or cause or permit the dumping, placing, throwing, or leaving of, litter on public or private property or water other than property designated and set aside for such purposes."[14] Litter is defined as "all rubbish, refuse, waste material, garbage, offal, paper, glass, cans, bottles, trash, debris, or other foreign substances." "Public or private property or water includes....a body of water or watercourse, or the shore or beach of the body of water or watercourse, including the ice above the water..."[15] Offenses are punishable by civil fines of up to $800 or $2,500 depending upon the volume of the discarded litter, and costs of removing the material and "the costs of damages to any land, water, wildlife, vegetation, or other natural resource or to any facility damaged by the violation."[16]

Fish/Fisheries Laws

• "A person shall not put into any stream, pond, or lake any sand, coal, cinders, ashes, log slabs, decayed wood, bark, sawdust, or filth."[17] Violation of this provision is a misdemeanor punishable by a fine of not more than $100, and/or imprisonment for up to 90 days, and damages.[18]

• The Michigan DNR also uses its general enforcement authorities to "protect and conserve the natural resources" and "guard against the pollution of lakes and streams and enforce all laws provided for that purpose."[19] To that end, it can use its authority to impose sanctions for fish kills, based on the unlawful taking of fish by "means" other than rods and lines.[20]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• Michigan has a law that applies to forest improvement districts. These are governmental subdivisions containing at least 4 working forests, and are established by 10 or more forest owners with 50,000 acres in the aggregate filing a petition with the DNR.[21] Districts have power to develop comprehensive forest management plans; and the DNR participates in the plan if state land encompassed by the district's gross boundary is greater than 5% of the total forest area.[22] But the state does not provide financial or other support for the district. "For the public benefit, the [district's] board shall mandate the continuous growing, improvement, and harvesting of forest tree species so as to protect and maintain the forest soil, air, water resources, wildlife, and aquatic habitat within a district. The board of a district shall establish minimum standards for the conduct of forest practices on forest land within a district. These standards shall do all of the following: (a) Provide for the improvement and harvesting of forest tree species in a manner that will increase the productivity of the forest land, reduce soil and debris entering streams, and protect wildlife and fish habitat....."[23] "A member shall notify the district of compliance with the forest practice rules by submitting a forest management plan on forms prescribed and provided by the board."[24] The district board must issue a notice of violation if a forest practice rule was violated. The notice must order that further violations cease and may order the member to make "reasonable efforts to repair the damage or correct the unsatisfactory condition."[25] If the member fails to comply, the board may take action and then file a lien to recover the costs of the action.[26] This is essentially a cooperative, member-enforced approach, under which timber sales are inspected by foresters employed by the district. But state enforcement actions for forestry nonpoint source water pollution are basically limited to those identified in the "Discharge Prohibitions" portion of this summary.

• Michigan also has a tax incentive program for commercial forests.[27] It requires forest management plans to be prepared by a registered forester or natural resources professional, and requires compliance with such plan to receive the favorable tax benefits. This program is considered an enforceable mechanism because violation of the plan does not simply lead to loss of tax benefits, as in many other states, but is also a misdemeanor (or felony, depending upon the value of removed forest products).[28]

• Michigan's law relating to sand dune protection and management has some relevance to forest cover.[29] The Department of Environmental Quality notifies local governments that have critical dune areas, and local governments adopt zoning ordinances with approval by the department, or the department regulates directly under a model zoning plan.[30] Permitting is carried on by the local government or the department.[31] The local zoning ordinance must cover at least lands within 250 feet of critical dune area if essential to the dune area; direct departmental regulation is limited to the 250 feet (unless the local government authorizes an extension).[32] The ordinance must assure that removal of trees corresponds to instructions or plans of the local soil conservation district.[33] In addition, zoning ordinances may not allow silvicultural practices "that are likely to increase erosion, decrease stability, or are more extensive than required to implement a use for which a permit is requested."[34]

• Michigan's Inland Lakes and Streams law (discussed below under "Development and Other Earth-Disturbing Activities") has some bearing on such forestry activities as construction of stream crossings.

Agriculture

• The Department of Agriculture is required to investigate "all complaints involving a farm or farm operation, including, but not limited to, complaints involving the use of manure and other nutrients, agricultural waste products,...surface- or groundwater pollution..." If the department finds that the operation is using generally accepted agricultural and management practices, then it notifies the farm and the complainant of its finding. If the department finds that "the source or potential sources of the problem [is] caused by the use of other than generally accepted agricultural and management practices," the department must "advise" the farm operation to resolve or abate the problem and to conform to such practices.[35] As noted above, conformance to such practices is necessary if a farming operation is to enjoy the protection from actions to abate a nuisance. There is also a memorandum of understanding between the Department of Agriculture and the Department of Environmental Quality that provides that if there is a discharge to surface water, the DEQ will address the complaint and can take enforcement action if needed under the Natural Resources and Environmental Protection Act (as described above under "Discharge Limitations").

• The soil conservation district law[36] empowers districts to act as governmental subdivisions, but does not give them broad powers (apart from making rules consistent with their other responsibilities). [37] However, conservation districts may act as the enforcing agencies for a county under agreement under the soil erosion and sedimentation control program.[38] Some agricultural practices -- but not "plowing, tilling, or harvesting" of crops[39] -- fall within the scope of Michigan's Soil Erosion and Sedimentation Control program, discussed below under Built Environment. If a person engaged in agricultural practices enters into an agreement with the appropriate soil conservation district to pursue agricultural practices consistent with the rules, then such person is not subject to site plans, approvals, or permit requirements under the law, but only to the enforcement provisions.[40]

• Michigan law provides for pesticide registration, groundwater protection fees and state management plans to protect groundwater. The law also provides for dealer licensing and applicator certifications including training requirements.[41] The law provides for action by the government where there is confirmed contamination of groundwater, including requiring the person whose "action or negligence" was "potentially responsible" to develop and submit an activity plan for approval and to implement it.[42] Also the state may issue an order if an applicator is using a pesticide in an unsafe or inadequate manner or a manner inconsistent with its labeling.[43] Enforcement is via registration and certificate actions, orders, administrative fines of up to $1,000, civil fines of up to $5,000, injunctions, and misdemeanor prosecutions for knowing violations.[44]

Development and Other Earth-Disturbing Activities

Apart from any programs for the control of urban stormwater under the federal Clean Water Act or that may be authorized by general land use regulation such as zoning, state law provides the following authorities relevant to nonpoint source discharges.

• The Soil Erosion and Sediment Control Act[45] provides for some enforceable mechanisms directed at erosion from a variety of activities. The Department of Agriculture must, with assistance of soil conservation districts, prepare and submit to DEQ for its approval a "unified statewide soil erosion and sedimentation control program" identifying land uses and controls, including agricultural practices (other than plowing, tilling, and harvesting).[46] DEQ provides information on effects of sediment on water quality, location of degraded or at risk waters, and water quality standards to be included in the program to protect designated uses. DEQ then adopts rules for the program.[47] Counties administer the rules, but cities, villages or charter townships may, by ordinance, provide for their own corresponding controls.[48] State, local, or county *agencies* may also apply to DEQ for designation as an authorized public agency by submitting the erosion and sedimentation control procedures used for all land uses normally undertaken by the agency; if approved, authority is delegated. This means that such agencies may self-regulate and may not need permits (e.g. DOT, county road commissions, etc.).[49] "A person shall not maintain or undertake a land use or earth change governed by this part or the rules or governed by an applicable local ordinance, except in accordance with this part and the rules or with the applicable local ordinance and pursuant to a permit approved by the appropriate county or local enforcing agency."[50] An owner of land on which an earth change has been made that may result in or contribute to soil erosion or sedimentation of waters must implement and maintain control measures that will "effectively reduce" such erosion or sedimentation. [51] Subdividers must, with filing of the subdivision plat, attach a statement of compliance, and certificate of permitting in accordance with this law or the applicable local ordinance.[52] And no building permit may be issued for construction involving disturbance of an acre or more, or within 500 feet of a lake or stream, until there is proof of compliance.[53] The Soil Erosion and Sediment Control Act does not apply to logging, mining, nor to plowing, tilling, or harvesting of crops.[54] Enforcement includes administrative notices and orders, injunctions, misdemeanor prosecutions, civil fines of up to $500, and cost-recovery if the agency needs to enter on the land and construct and maintain the necessary measures.[55]

• Other laws dealing with riparian and littoral lands also have some potential bearing on nonpoint source water pollution and controls. DEQ has jurisdiction over "alterations of natural or present watercourses of all rivers and streams in the state to assure that the channels and the portions of the floocplains that are the floodways are not inhabitated and are kept free and clear of interference or obstruction that will cause any undue restriction of the capacity of the floodway."[56] "A person shall not occupy or permit the occupation of land for residential, commercial, or industrial purposes or fill or grade or permit the filling or grading for a purpose other than agricultural, of land in a floodplain, stream bed, or channel of a stream...or undertake or engage in an activity on or with respect to land that is determined by the department to interfere harmfully with the discharge or stage characteristics of a stream" without a permit.[57] DEQ makes rules and issues orders for the prevention of harmful interference with the discharge and stage characteristics of streams.[58] Enforcement may include prosecution for misdemeanor with a civil fine of up to $500, or up to $2,500 for more serious violations.[59]

• Michigan law also provides protection for inland lakes and streams.[60] The law requires a permit for dredge or fill, for structures therein, or for connecting a ditch or other channel with a lake or stream.[61] The permit is issued if the department finds that the structure or project "will not adversely affect the public trust or riparian rights....the department shall consider the possible effects of the proposed action upon the inland lake or stream and upon waters from which or into which its waters flow and the uses of all such waters, including uses for recreation, fish and wildlife, aesthetics, local government, agriculture, commerce, and industry. The department shall not grant a permit if the proposed project or structure will unlawfully impair or destroy any of the waters or other natural resources of the state...A permit shall specify that a project completed in accordance with this part shall not cause unlawful pollution as defined by part 31."[62] Enforcement is by civil action for compliance and civil fine of up to $5,000 per day, or a misdemeanor prosecution with a fine of up to $10,000 per day for more significant violations.[63]

• Other laws protect shorelands and sand dune areas,[64] as well as littoral and riparian wetlands and certain isolated wetlands.[65] These laws provide some basis for local nonpoint source controls, but a number exempt agricultural uses. Designated state natural rivers also are entitled to protection, including local zoning and subdivision controls over activities on adjacent lands, or DEQ controls absent such local action.[66]

MINNESOTA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Minnesota's water pollution control law includes some provisions that may be used to take enforcement action against nonpoint source discharges.

• Minnesota has a general statutory provision obligating every person to "notify" the state of the discharge of "any substance or material" that "may cause pollution of the waters" and the discharger to take all reasonable actions to "minimize or abate" the pollution caused.[1] However, the most explicit discharge limitation on nonpoint sources is found in the state rules, stating, "No sewage, industrial waste or other wastes shall be discharged from either a point or *nonpoint source* into the waters of the state in such quantity or in such a manner alone or in combination with other substances as to cause pollution..."[2] Enforcement includes criminal prosecution, civil penalties, injunction, action to compel performance, and any "other appropriate action."[3]

Other Discharge Limitations

• A separate authority addresses the pollution of public water supplies. "No sewage or other matter that will impair the healthfulness of water shall be deposited where it will fall or drain into any pond or stream used as a source of water supply for domestic use." The state Commissioner of Health has broad authority to issue to any person orders and direction that it deems "proper and expedient" to desist from causing pollution.[4]

• The state law generally authorizes county boards of commissioners to adopt ordinances that "provide for the cleaning and removal of obstructions from waters in the county and to prevent obstruction or pollution."[5]

• General nuisance law in Minnesota identifies nuisance as, "Anything which is injurious to health, or indecent or offensive to the senses, or an obstruction to the free use of property, so as to interfere with the comfortable enjoyment of life or property..."[6] The state regulations apply nuisance directly to nonpoint sources by specifying that "No sewage, industrial waste or other wastes shall be discharged from either point or nonpoint sources into any waters of the state so as to cause any nuisance conditions, such as the presence of significant amounts of floating solids, scum,...excessive suspended solids, material discoloration...undesirable slimes or fungus growths, aquatic habitat degradation, excessive growth of aquatic plants or other harmful effects."[7] Agriculture operations are not considered a nuisance, except where the operations are negligent or contrary to acceptable agricultural practices, cause direct injury or threat of injury to health/safety of any person, cause water pollution, are large animal feedlots; or result in criminal prosecution.[8] The maximum fine for causing nuisance is $700, and prosecution or civil action may result.[9]

• Minnesota's groundwater protection law requires the pollution control agency to develop best management practices; and the commissioner of agriculture must develop best management practices for agricultural chemicals and practices.[10] The respective regulatory agency may adopt water source protection requirements "if the implementation of best management practices has proven to be ineffective."[11] Violators of a water source protection requirement are subject to the penalties prescribed under the pollution control act, except for agricultural chemical violations, which are subject to the penalties prescribed for agrichemical spills and violations.[12]

Fish/Fisheries Laws

• The state has a general prohibition against disposing of "substances" in state waters that "injure or are detrimental to the propagation of wild animals or taint the flesh of wild animals,"[13] which are specifically defined to include fish.[14] Each day of propagation is a separate offense.[15] Another provision prohibits "taking" fish with a range of specific substances, including "explosives, drugs, poisons, lime,... or other similar substances" or substances that "kill, stun or affect the nervous system of fish."[16] Pesticides are excluded from this list of substances.[17] Punishment for violation of these provisions are fines ranging from $100 to $3000 and incarceration for between 90 days and one year. [18] The Commission of Natural Resources is charged with deciding whether to take action against a violator.[19]

OPERATIONAL REQUIREMENTS

Forestry Requirements

Minnesota has few provisions regulating private forestry operations with respect to nonpoint source water pollution and none that appear to be enforceable. Its Sustainable Forest Resources Act of 1995 provides for voluntary guidelines.[20]

• The Department of Natural Resources commissioner retains some discretion to protect state lands and related water bodies. A statutory provision prevents the commissioner from selling for private forest management state forests that "border on or are adjacent to meandered lakes or public waters and water courses," and if the commissioner harvests these state lands, the commissioner must "reserve the timber and impose other conditions deem(ed) necessary to protect watersheds, wildlife habitat, shorelines and scenic features." [21] Clear cutting is prohibited where "soil, slope or other watershed conditions are fragile" and where it occurs within certain distances within a "wild, scenic and recreation river."[22]

Agriculture Requirements

• Local governments are "encouraged" to adopt a soil loss ordinance, which states that "a person may not cause, conduct, contract for or authorize an activity that causes excessive soil loss," as "evidenced by sedimentation on adjoining land or in a body of water." *However, agricultural uses are exempted* from the soil loss ordinance as long as the farmer is using "best practicable conservation practices." The soil loss also applies to pastures used for grazing or cattle paths. *Where a locality has chosen to adopt it,* the soil loss ordinance is enforced by a complaint submitted to the local government from, an adversely affected landowner, an official of local government, or a soil and water district board member.[23] Following filing of the complaint, the landowner must participate in mediation and failure to comply with the mediated settlement may result in a civil penalty of up to $500.[24] Other statutory provisions provide that local ordinance violations can result in criminal prosecution and a maximum fine of up to $700.[25]

• State permits or agency certificates of compliance are required for construction, location and operation of animal feedlots, or manure storage facilities that create a "potential pollution hazard" and where animal manure used for domestic fertilizer is stored for longer than one year.[26] Feedlots with more than 1000 animal units must obtain a discharge permit from the pollution control agency. Proposed regulations slated for consideration in 1999 would require permits for all facilities with greater than 50 animal units by the year 2004. A 1998 law also requires commercial manure applicators to be licensed by March 2000.[27]

• The state has a relatively broad prohibition addressing harm from pesticide use, handling and application. "A person may not use, store, handle, distribute or dispose of a pesticide...that endangers humans, damages agricultural products, food, livestock, fish or wildlife or that will cause *unreasonable effects on the environment.*"[28] Pesticide applicators require licensing.[29] Application of chemigation requires a permit from the commissioner.[30] Where there are violations, the commissioner is authorized, but not required, to "take action necessary to prevent" groundwater contamination resulting from leaching, backsiphoning or backflowing of pesticides through the soil or water wells or from the direct flow of pesticides to the groundwater. Agrichemical practices that adversely affect groundwater are described above under "Other Limitations." In addition, Minnesota law provides for corrective action and enforcement actions with respect to agrichemical spills.[31]

• Minnesota also regulates fertilizer activities, prohibiting the storage, handling, distribution, or disposal of fertilizer, rinsate, or application equipment in such a manner that will endanger humans, fish, or wildlife, that will cause unreasonable adverse effects on the environment or that will cause contamination of public or other waters of the state.[32] It also licenses applicators.[33]

• Minnesota has a broad prohibition against draining materials into a ditch, providing that it is a misdemeanor to "drain any noisome materials into any ditch,"[34] The drainage authority is also required to consider various environmental impacts resulting from a proposed drainage project including the "effect on water quality.[35]

Development and Other Earth-Disturbing Activities

Designation of a "critical area" and a statutory provision requiring a sediment control plan and a permit for "development activity" disturbing over one acre of land are enforceable restrictions on development activities that may cause nonpoint source pollution.

• Prior to engaging in a "development activity" that will disturb over one acre of land, a person must seek and obtain a permit from the local government contingent upon implementation and completion of a sedimentation control plan and time schedule that prevents excess soil loss.[36] A "development activity" means "a physical disturbance of the land that may result in sedimentation of adjacent lands or waters, associated with activities that include clearing, grading, excavating, transporting and filling lands," but excludes "road construction."[37] Failure to obtain a permit or to make satisfactory progress to complete the plan is subject to a civil penalty.[38]

• A critical area is "an area significantly affected by, or having effect upon, an existing or proposed major government development which is intended to serve substantial numbers of persons beyond the vicinity in which the development is located and which tends to generate substantial development or urbanization," or "an area containing or having significant impact upon historical, natural, scientific, or cultural resources or statewide importance"[39] Once such an area is established, then the statute prohibits issuance of development permits by local or state agency.[40] However, certain exceptions exist that result in issuance of a development permit: If no critical site plans and regulations have been adopted by the local government (as required under the Rules), if a local ordinance was in effect immediately prior to the designation of the critical area that would have granted a development permit, and there is an emergency or need to protect public health and safety, then the local government may grant a development permit.[41] If the Minnesota Environmental Quality Board determines that the administration of the local plans and regulations "is inadequate to protect the state or regional interests," then the Board may compel enforcement of the plans and regulations.[42]

• To protect the state shoreline, the DNR Commissioner shall adopt model standards and criteria for the "subdivision, use and development of shoreland" and adapt the model ordinance for use in a county that has an inadequate shoreland conservation ordinance or none at all.[43] Violations of the shoreland conservation ordinance or model standards are considered misdemeanors and are enforced through the actions by the county commissioners or by mandamus proceedings instituted by any taxpayer to compel specific performance by an official.[44] Fines of $700 can be assessed.[45] As part of a locally-enforced, ordinance-based shoreland management system, "on-site sewage treatment systems must be set back from ordinary high water level by distances ranging from 50 to 150 feet." (Certain designated areas within the wild, scenic and recreation rivers program have required set backs of 50 feet.")[46] There is criminal prosecution for violation of these ordinances and a maximum fine of $700.[47]

• A floodplain management ordinance, which is required to be adopted, administered and enforced by local governments, prohibits placement of a structure, fill, deposit or other floodplain use that is "unreasonably hazardous to the public."[48] Placement of any of the aforementioned is considered a public nuisance and can be enjoined or abated through civil action or prosecuted criminally as a violation of a local ordinance. Each violation is subject to prosecution as a misdemeanor, and the maximum fine is $700.[49]

MISSISSIPPI

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Mississippi's water pollution control law prohibits causing pollution or discharging wastes into waters so as to violate water quality standards. The law appears to provide a basis for enforcement against nonpoint source discharges.

- "It shall be unlawful for any person (I) to cause pollution of any waters of the state or to place or cause to be placed any wastes in a location where they are likely to cause pollution in any waters of the state; (II) to discharge any wastes into any waters of the state which reduce the quality of such waters below the water quality standards established therefor by the commission.....Any such action is hereby declared to be a public nuisance."[1]

The law defines "wastes" as "sewage, industrial wastes, oil field wastes, and all other liquid, gaseous, solid, radioactive, or other substances which may pollute or tend to pollute any waters of the state."[2] Pollution is defined as contamination or alteration of waters "unless in compliance with a valid permit."[3] But Mississippi's regulations provide that no permit may be required for nonpoint agriculture and silviculture pollution.[4] Violations are enforceable by administrative orders, civil penalties of up to $25,000 per day, injunction, or misdemeanor prosecution.[5]

Other Discharge Limitations

Mississippi's laws do not appear to contain other discharge limitations addressing nonpoint sources, apart from the use of nuisance remedies which would be supported by the referenced provision above defining water pollution as a nuisance.

Fish/Fisheries Laws

Mississippi's laws do not appear to contain fisheries provisions that appear to address nonpoint source water pollution, but do provide that any person who violates water pollution laws or regulations and thereby causes the death of fish or wildlife must pay the state the amount necessary to restock.[6]

OPERATIONAL REQUIREMENTS

Forestry Requirements

- The Forest Harvesting Law declares a state policy for sound forestry, to encourage better management of forest lands...and "to prevent soil erosion and consequent silting of stream channels and reservoirs; to protect watersheds and reservoirs and to insure at all times an adequate supply of water of the forest quality..."[7]

But the enforceable regulatory standards require simply that certain numbers of trees be left on each acre for growing stock and/or seed trees.[8] The law does not apply to land clearing for crop production or pasture, building sites or roads, nor to noncommercial cutting by owners for their own use.[9] The law is enforceable by injunction or by misdemeanor prosecution with a fine of $25-$50 per working unit of 40 acres or less.[10]

Agriculture Requirements

• State wastewater permit regulations cover some sizes and types animal feeding operations not required to receive NPDES permits, and may contribute to control of nonpoint source water pollution from such establishments. In addition, such operations must be at least 1000 feet from the nearest dwelling or commercial establishment not owned by the applicant, and at least 300 feet from the property line.[11] Land application of animal waste must be at least 50 feet from the property line and 300 feet from the nearest dwelling not owned by the applicant.[12] Enforcement is under the water pollution control law.

• The water pollution control law also prohibits the following activities unless they have a permit "as may be required for the disposal of all wastes which are or may be discharged thereby into the waters of the state...[:] the construction, installation or operation of any industrial, commercial or other establishment, *including irrigation projects* or any extension or modification thereof or addition thereto, the operation of which would cause an increase in the discharge of wastes into the waters of the state or would otherwise alter the physical, chemical or biological properties of any waters of the state in any manner not already lawfully authorized..."[13] Unlike the agricultural and silvicultural nonpoint exemption from permitting identified above, the inclusion of irrigation projects gives authority for permitting.

• State law requires registration of pesticides and certification and licensing of applicators.[14] If the Commission on Environmental Quality finds groundwater contamination by a chemical not within its jurisdiction, it must notify the Department of Agriculture and Commerce which must proceed under the pesticide law.[15] Enforcement includes license and certification actions, injunctions, and criminal prosecutions.[16] Non-registration and registration violations with respect to pesticides, or to "handle, transport, store, display, distribute, or dispose of any pesticide or container in such manner as to endanger man and his environment," is a criminal offense punishable as a misdemeanor with a fine of $500.[17]

• Drainage districts, swampland districts, and conservation districts do not have express powers for enforceable regulation except that districts may adopt "necessary regulations, programs, and procedures" for prevention of erosion, floodwater, and sediment damage, "subject to approval of the chancery court or chancellor and on proper notice to the interested parties."[18] However this portion of the law further provides that none of these powers shall be exercised except for the purpose of participating in federally authorized programs for "soil and water conservation and utilization."[19]

Development and Other Earth-Disturbing Activities

No operating requirements are set forth, apart from any that may be contained in urban stormwater programs under the Clean Water Act or that may be authorized by general land use regulation such as zoning.

State law provides typical authorities to municipalities and counties to regulate building location and development, but "no permits shall be required with reference to land used for agricultural purposes including forestry activities...outside the corporate limits of municipalities."[20] Penalties for violation of a zoning ordinance are fines not to exceed $100 per day.[21]

MISSOURI

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Missouri's water pollution law contains discharge prohibitions that may be enforced against nonpoint source discharges that cause pollution or result in violations of water quality standards.

• "It is unlawful for any person (1) To cause pollution of any waters of the state or to place or cause or permit to be placed any water contaminant in a location where it is reasonably certain to cause pollution of any waters of the state; or (2) To discharge any water contaminants into any waters of the state which reduce the quality of such waters below the water quality standards established by the commission if not subject to effluent regulations...."[1] Pollution is defined as "such contamination or other alteration of the physical, chemical or biological properties of any waters of the state...or such discharge of any liquid, gaseous, solid, radioactive, or other substance into any waters of the state as will or is reasonably certain to create a nuisance or render such waters harmful, detrimental or injurious to public health, safety or welfare, or to domestic, industrial, agricultural, recreational, or other legitimate beneficial uses, or to wild animals, birds, fish or other aquatic life."[2] Discharge is defined as "the causing or permitting of one or more water contaminants to enter the waters of the state."[3]

Enforcement is through administrative penalties up to $10,000 per day, civil penalties up to $10,000 per day, and criminal prosecution.[4]

Other Discharge Limitations

•Under Missouri's Solid Waste Management Act, it is unlawful to "(d)ump or deposit...any solid wastes...into streams, springs, and all bodies of surface or ground water, whether natural or artificial, within the boundaries of the state...."[5] The law lists a number of exceptions to the prohibition, including: solid waste processing facilities or solid waste disposal areas that have the required permit; farming operations or manufacturing operations that use solid wastes in a manner that will not create a public nuisance; and disposal by an individual of solid wastes resulting from his own residential activities on property he owns or occupies, in a manner that does not create a public nuisance.[6] Enforcement of this provision is through administrative fines of up to $1,000 per day, civil penalties not to exceed $1,000 per day, and injunctions.[7] Civil monetary penalties are not available if an administrative penalty has been assessed in the case.

•Missouri statutes also establish public safety offenses and miscellaneous criminal offenses that potentially address some activities resulting in nonpoint source pollution. For example: "Whoever willfully or maliciously poisons, defiles or in any way corrupts the water of a well, spring, brook or reservoir used for domestic or municipal purposes, or whoever willfully or maliciously diverts, dams up and holds back from its natural course and flow any spring, brook or other water supply for domestic or municipal purposes...shall be adjudged guilty of a misdemeanor...." [8] The statute further provides that in a civil suit, the offender is liable to injured party for three times the actual damages sustained.[9]

•In addition, it is a criminal offense to "purposely introduce into any cave, cave system, sinkhole or subsurface waters of the state any substance or structure that will or could violate any provision of the Missouri clean water law...or any water quality standard or effluent limitation promulgated pursuant thereto."[10] This provision does not apply to underground mining operations or to situations where "natural subsurface drainage systems including, without limitation, caves, cave systems, sinkholes, fissures and related openings are used for purposes of stormwater drainage, artificial recharge of aquifers, and irrigation return flow, and where modifications of natural drainage systems are made for purposes of improving natural drainage relationships."[11] Enforcement is through criminal (class A misdemeanor) prosecution.[12]

•Nuisance law may also apply. Missouri's water pollution law states generally that "pollution of the waters of this states...creates a public nuisance...."[13]

Fish/Fisheries Laws

•Under Missouri's fish and game law, it is unlawful "for any person to cause any deleterious substance to be placed, run or drained into any of the waters of this state in quantities sufficient to injure, stupefy or kill fish which may inhabit the same at or below the point where any substance was thrown, run or drained into such waters...."[14] This prohibition does not apply to those engaged in industry who discharge water "under such precautionary measures as have been specifically approved" by the state conservation commission.[15] Enforcement is through criminal (Class A misdemeanor) prosecution.[16]

OPERATIONAL REQUIREMENTS

Forestry Requirements

•Missouri's forestry laws do not appear to provide enforceable operating requirements related to nonpoint source pollution. However, the law includes a tax incentive program which defines "forest croplands" as lands devoted exclusively to growing wood and timber and provides that all persons "interested in any way in the forest croplands or the cutting of crops therefrom...shall comply with and follow such forest management rules and regulations as required" by the state conservation commission.[17] State regulations establishing requirements for forest croplands provide that private landowners must ensure that forest land is managed so as to protect the watershed and prevent damage to tree growth, must not build any structures on the land, and must not use the land for animal grazing.[18] The sanction for failing to comply with the state rules is cancellation of "forest cropland" status and consequent loss of tax benefits that accrue with such status.[19]

Agriculture Requirements

• Under the Missouri Pesticide Use Act, "(n)o person shall discard, transport, or store any pesticide or pesticide containers in such a manner as to...pollute any waterway."[20] Enforcement of the law is through administrative "stop sale, use or removal" orders to enjoin future use and through criminal (misdemeanor) prosecution.[21]

• Missouri regulates the disposal of dead animals; these requirements became generally applicable in 1992, but were extended to poultry and turkeys in 1995. The law allows disposal of dead animals at state licensed rendering facilities, in properly designed animal composters, in approved sanitary landfills, by incineration in a designed incinerator facility, or by on-site burial (but subject to specific loading rates for areas with and without major groundwater pollution potential, and subject to setback distances from wells, surface waters, and neighboring properties). Permits are required for transport of dead animals, and for operation of substations for the collection of dead animals. Enforcement includes civil penalties, and misdemeanor sanctions.[22]

• Missouri has CAFO provisions that are similar to federal requirements, but which establish various subclassifications for regulatory purposes.

Development and Other Land-Disturbing Activities

Other than urban and industrial stormwater programs, and general planning and zoning authority (which exists only in urban and urbanizing areas) , there appear to be no specific enforceable nonpoint source requirements relating to land-disturbing activities.

MONTANA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Montana's water pollution control law includes some provisions that may be used to take enforcement action against nonpoint source discharges. A general provision prohibits discharges or placement of wastes that cause pollution, including pollution from nonpoint sources. The law also establishes a nondegradation policy that applies to certain nonpoint sources, though it does not apply to agricultural discharges covered under a ground water management plan.

• The water quality code makes it unlawful to "cause pollution ... of any state waters or to place or cause to be placed any wastes where they will cause pollution of any state waters."[1] "Pollution" is defined broadly, and clearly includes pollution from nonpoint sources.[2] However, exempt from the prohibition is "any placement of materials that is authorized by a permit issued by any state or federal agency ... if the agency's permitting authority includes provisions for review of the placement of materials to ensure that it will not cause pollution of state waters."[3]

• The code also makes it unlawful to "cause degradation of state waters without authorization," and establishes a detailed nondegradation policy for state waters.[4] Under the non-degradation policy, degradation of high-quality waters may not be authorized without an extensive cost-benefit analysis and consideration of non-degrading options.[5] However, several potentially polluting activities are exempted from the nondegradation policy and classified as "nonsignificant." These include: nonpoint sources existing on or before April 29, 1993; new nonpoint sources that follow "reasonable land, soil, and water conservation practices"; use of agricultural chemicals under an approved agricultural ground water management plan; land application of manure and sewage sludge; nonpoint source activities that cause short-term changes in water quality and result from streambed preservation activities or permitted water uses; and dam maintenance and repair that causes short-term changes in water quality.[6]

The Department of Environmental Quality has general inspection and penalty authority for violations of the water quality code, including the discharge prohibition.[7] For alleged violations, the DEQ may serve a notice letter or an administrative notice and order, and may require public hearing of the charges.[8] After finding a violation, a hearing board may issue an order for prevention, abatement, or control of pollution, and administrative penalties of up to $10,000 per violation per day.[9] The DEQ also may issue specific compliance orders, cleanup orders for any material that is "accidentally or purposely dumped, spilled, or otherwise deposited in or near state waters and that may pollute state waters," or emergency orders; it also may bring civil actions for appropriate relief, including temporary and permanent injunctions.[10] Judicial remedies include civil penalties of up to $25,000 per day and, for willful or negligent violations of the discharge prohibition, criminal fines of up to $25,000 per day, imprisonment of up to one year, or both.[11] Criminal penalties may be doubled for repeat violations.[12]

Other Discharge Limitations

• The civil code defines nuisance as "anything which is injurious to health, indecent or offensive to the senses...or which unlawfully obstructs the free passage or use, in the customary manner, of any navigable lake, river, bay, stream, canal or basin...."[13]

• Similarly, the criminal code defines public nuisance as a "condition which defines safety or health, is offensive to the senses, or obstructs the free use of property so as to interfere with the comfortable enjoyment of life or property by an entire community or neighborhood or by any considerable number of persons," or which "renders dangerous for passage ... waters used by the public."[14]

Both the civil and criminal nuisance provisions contain "coming to the nuisance" exemptions for agricultural or farming operations that are operating normally and have been in operation "longer than the complaining resident has been in possession or commercial establishment has been in operation."[15] Moreover, there is a "right to farm" law that intends "to protect agricultural activities from governmental zoning and nuisance ordinances," by pre-empting local governments from passing any "ordinance or resolution that prohibits any existing agricultural activities or forces the termination of any existing agricultural activities outside the boundaries of an incorporated city or town."[16]

Within these limitations, "any person whose property is injuriously affected or whose personal enjoyment is lessened by the nuisance" may bring a civil action for damages, as well as for an injunction or abatement.[17] Public nuisances may be enforced against by indictment or information as well as civil actions or abatement.[18] Public nuisances under the criminal code are subject to fines not to exceed $500, imprisonment of up to six months, or both.[19] Abatement may be sought in an equity action for public nuisance filed in the name of the state by the county attorney or any resident of the state, and may include forfeiture of fixtures, closing and/or temporary seizure of the premises.[20]

Fish/Fisheries Laws

• The fish and wildlife code does not provide an enforceable authority for nonpoint source pollution. It does make the use of explosives or "any corrosive or narcotic poison or other deleterious substance...for the purpose of catching, stunning, or killing fish" a misdemeanor,[21] and requires restitution for illegal killing of wildlife, including fish, where killing is done "knowingly or purposely."[22] The general penalties for violation of the code include fines of $50-$1,000 and/or imprisonment of up to 6 months.[23] The restitution requirement is $10 per game fish illegally taken.[24]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• The forestry code requires creation of "streamside management zones" for forest streams.[25] A streamside management zone must "encompass[] a strip at least 50 feet wide on each side of a stream, lake, or other body of water, measured from the ordinary high-water mark, and extends beyond the high-water mark to include wetlands and areas that provide additional protection in zones with steep slopes or erosive soils."[26] Within these zones, there are specific prohibitions on certain forest activities, including: broadcast burning; off-road vehicle operation; clearcutting; road construction unless necessary for stream crossing; handling, storage, application or disposal of hazardous or toxic substances in a manner that pollutes water bodies or that may damage humans, land, animals, or plants; side-casting of road material into water bodies; or deposit of slash in water bodies.[27]

There are detailed regulations delineating the stream management zones and defining prohibited practices and site-specific alternative practices.[28] The department of natural resources and conservation has inspection authority on federal, state and private land to ensure compliance with the rules for streamside management zones.[29] The department may issue civil penalties of up to $1,000 per day, as well as rehabilitation orders.[30]

• The forestry code also contains a section titled "protection of forest resources,"[31] which "encourages" the use of best management practices and includes a requirement that notice be given prior to commencement of any forestry practices.[32] Upon receiving such notice, the department of natural resources and conservation must decide whether to require an onsite consultation with the operator, based on whether "the proposed timber sale is in a high-priority location for watershed resources" or whether "a consultation could contribute to improved watershed management."[33] However, this procedure is not in itself enforceable; the code expressly states that consultation "is intended only for the purpose of providing information to owners and operators and does not confer upon the department or any other agency of state or local government authority to compel an owner or operator to undertake or refrain from undertaking specific management practices that are not otherwise regulated by law or rule."[34]

Agriculture Requirements

• The soil conservation code allows for creation of soil conservation districts to conduct research, implement projects and provide technical assistance and education on soil conservation.[35] These districts are authorized to formulate and propose soil and water conservation regulations, which are subject to approval by referendum.[36] Once approved, the regulations may prescribe specific agricultural practices for soil and water conservation within the district.[37] Affected parties may petition for a variance where "there are great practical difficulties or unnecessary hardship in the way of ... carrying out ... the strict letter of the land use regulations."[38] The district's decision whether to issue a variance is reviewable in court.[39]

Soil conservation districts have authority to enter and inspect premises to determine compliance with their regulations.[40] They may petition the state district court for an order enforcing the regulations where nonobservance "tends to increase erosion on [defendant's] lands ...and is interfering with the prevention or control of erosion on other lands."[41] The court may order specific performance of required practices, or permit the district to perform the work and recover its costs from the landowner.[42]

• The Natural Streambed and Land Preservation Act requires that any "project," defined as the physical alteration of a stream resulting in change in the state of the stream, be approved by the local soil conservation district or board of county commissioners before commencing work.[43] Approval decisions are made by the district board based on recommendations made by an onsite inspection team, and are subject to judicial review.[44] The decision is based on multiple factors, including: the effects on soil erosion and sedimentation; upstream or downstream flooding and erosion effects; streamflow, turbidity, and water quality effects; and effect on fish and aquatic habitat.[45] Projects engaged in without approval or outside the scope of the approval are declared a public nuisance and subject to abatement proceedings; they are also subject to civil penalties of up to $500 per day and/or a misdemeanor fine of up to $500.[46] However, "customary and historic maintenance and repair of existing irrigation facilities that do not significantly alter or modify the stream" are excluded from the definition of "project," and thus from the approval requirement.[47]

• The Agricultural Chemical Ground Water Protection Act covers both pesticides and fertilizers, and requires the department of agriculture and the department of environmental quality to cooperate to administer ground water standards for agricultural chemicals.[48] It requires them to develop numerical standards and interim standards for agricultural chemicals, primarily based on EPA's promulgated and nonpromulgated standards under the Clean Drinking Water Act.[49] Both departments are authorized to "implement appropriate actions ... to mitigate any existing impacts of an agricultural chemical found in ground water."[50] These include development of a general ground water management plan[51] and site-specific management plans, which must be complied with by all persons in the covered geographic area.[52] The plans are adopted by rulemaking or with emergency authority.[53] Site-specific management plans may include restrictions on chemical use in certain areas; best management practices; certification, training and licensing requirements; setback areas near water wells; and alternative practices.[54]

It is unlawful to violate any provision of a site-specific ground water management plan, any order issued pursuant to the Act, or any provision of the Act.[55] Both the department of agriculture and the DEQ have monitoring authority.[56] The department of agriculture is the lead department for determining compliance with groundwater management plans, and is granted inspection authority under the Act.[57] The DEQ is the lead department for determining health risks, and may enforce the Act using its enforcement authority under the water quality code.[58] The department of agriculture may issue compliance orders, assess administrative civil penalties of up to $1,000 per violation, and file civil actions seeking a temporary or permanent injunction.[59] Violators are also subject to judicial penalties of up to $10,000 per violation and, for intentional violations, criminal penalties of up to $25,000 and/or imprisonment of up to one year, which can be doubled for repeat offenses.[60]

• Montana's general pesticide law makes it illegal "to discard any pesticide or pesticide container in a manner that causes injury to humans, domestic animals, or wildlife or that pollutes any waterway in a way harmful to any wildlife in the waterway or to the environment."[61] The department of agriculture has general entry, investigation and enforcement authority for pesticide violations, including violations of the handling, use and application standards.[62]

Violation of the pesticide law or rules is a misdemeanor, punishable by a fine of $100-$1,500; the department also may issue compliance orders, including cleanup requirements, and/or seek injunctive relief in court.[63] "Major violations," which include misuse that is inconsistent with labelling and results in "proven exposure" or "proven harm" to humans, agricultural commodities, livestock, or the environment, are subject to civil penalties of up to $25,000 per violation; and, if committed willfully, subject to a $50,000 fine and imprisonment of up to 10 years.[64]

Development and Other Earth-Disturbing Activities

Apart from any programs for the control of urban stormwater under the federal Clean Water Act or that may be authorized by general land use regulation such as zoning, state law provides the following authorities.

• The water quality code allows, but does not require, the creation of local water quality districts "to protect, preserve, and improve the quality of surface water and ground water."[65] County commissions and/or city councils may establish such districts, whose directors may then develop a local water quality program that is implemented through local ordinances, including administrative and civil enforcement and penalties.[66] Specific focuses of the programs include onsite waste water disposal, storm water runoff, and engine lubricants.[67] The districts also have authority to assess fees for water use, although irrigation and livestock uses are exempt from these fees.[68] Upon approval of the programs, state enforcement authority may be delegated to the district level.[69]

• The legislature also has enacted a law protecting lakeshores, and declared that "local governments should play the primary public roles in establishing policies to conserve and protect lakes."[70] Under that law, "a person who proposes to do any work that will alter or diminish the course, current, or cross-sectional area of a lake or its lakeshore must first secure a permit for the work from the local governing body."[71] Local jurisdictions are required to adopt regulations, including criteria for issuing and denying permits for work in lake areas; factors for consideration include water quality, fish and wildlife habitat, navigation and recreation, public nuisance, and visual and aesthetic values.[72] Regulations and decisions of these governing bodies are judicially enforced and judicially reviewable.[73] Violation of orders or regulations is a misdemeanor, subject to up to 30 days in jail and/or a $500 fine; violators may also be required to restore the lake to its original state before the unauthorized work was commenced.[74]

• As discussed above, the Natural Streambed and Land Preservation Act requires that any "project," defined as the physical alteration of a stream resulting in change in the state of the stream, be approved by the local soil conservation district or board of county commissioners before commencing work.[75]

NEBRASKA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Nebraska's water pollution law includes provisions that may be used to take action against nonpoint source discharges that pollute state waters or result in water quality violations.

• Under Nebraska's Environmental Protection Act, it is unlawful to "cause pollution of any...waters...of the state or to place or cause to be placed any wastes in a location where they are likely to cause pollution" of any waters of the state.[1] Waste is defined as "sewage, industrial waste, and all other liquid, gaseous, solid, radioactive, or other substances which may pollute or tend to pollute any air, land or waters of the state."[2]

• It is unlawful to violate any water quality standards, any permit or license condition, any order, or any rule or regulation adopted under the state Environmental Protection Act.[3]

• The law also declares it unlawful and a public nuisance to "discharge or emit any wastes into any...waters...of the state which reduce the quality of such...waters" below water quality standards.[4] (This section further provides that a livestock operation is not a nuisance if it is in compliance with applicable regulations and zoning regulations, and if the nuisance action is brought by a private person whose ownership or possession of land allegedly affected by the nuisance was subsequent to (a) the issuance of an appropriate permit for the livestock operation or (b) when operation of the feedlot began and an inspection by the department revealed that no permit was required.[5])

Enforcement of these water pollution control provisions is through corrective action orders, injunctions, civil penalties up to $10,000 per day, and criminal (felony and misdemeanor) prosecution. The state may recover damages for restocking the waters with fish or replenishing wildlife.[6]

Other Discharge Limitations

• In addition to the above nuisance provision, Nebraska law provides that the "corrupting or rendering unwholesome or impure of any watercourse, stream, or water, or unlawfully diverting any such watercourse from its natural course or state to the injury or prejudice of others," shall be deemed nuisances.[7] Maintenance of a nuisance is a class III misdemeanor, and courts "shall order every such nuisance to be abated or removed."[8]

• Under Nebraska's Groundwater Management and Protection Act, each natural resources district is required to prepare a groundwater management plan, which must include information on groundwater supplies, crop water needs, groundwater quality concerns, etc. The groundwater management plan must be approved by the director of water resources.[9] If a district determines from the groundwater management plan that a "management area" should be established to protect groundwater supplies, it shall by order designate the management area and adopt one or more of the controls authorized by the law, which include best management practices.[10]

Each state agency and political subdivision is directed to report promptly to the department of environmental quality any information which indicates that groundwater contamination is occurring.[11] After being informed that contamination is occurring, the department must study the problem. Upon determining that contamination is coming from a point source, the director "shall expeditiously use the procedures authorized ... to stabilize or reduce the level and prevent the increase or spread of such contamination."[12]

If the director of environmental quality determines from a study that one or more sources of contamination are not point sources, and if a management area has been designated covering that affected area, the director shall consider whether to require the natural resources district to adopt an "action plan." If there is no management area covering the contaminated area, the director shall hold hearings and determine whether to designate a management area and prepare an action plan.[13] If the director determines an action plan is necessary, the district shall prepare an action plan designed to stabilize or reduce the level and prevent the increase or spread of groundwater contamination, and shall include any of the controls authorized by law, including best management practices.[14] If the district fails to adopt an action plan in a specific time, the power to specify the controls authorized by law is vested in the director of environmental quality, along with enforcement authority.[15]

Enforcement of the Groundwater Management and Protection Act by natural resources districts is primarily through cease and desist orders, which may be enforced judicially. Any violation of a cease and desist order issued by a district is a Class IV misdemeanor.[16]

Fish/Fisheries Laws

• Nebraska's game and parks code contains fisheries provisions that may relate to nonpoint source pollution. The code provides that it is unlawful to "dump or drain any refuse from any factory, slaughterhouse, gas plant, garage, repair shop, or other place whatsoever or any refuse, junk, dross, litter, trash, lumber, or leavings into or near any of the waters of this state or into any bayou, drain, ditch, or sewer which discharges such refuse or an part thereof into any of the waters of this state. It shall be unlawful to place, leave, or permit to escape any such refuse in such manner that it or any part of it is through the action of the elements or otherwise carried into any of the waters of this state."[17] Refuse is defined to include "oils, tars, creosote, blood, offal, decayed matter, and all other substances which are injurious to aquatic life."[18]

• It is also unlawful to "place the carcass of any dead animal, fish, or fowl in or near" waters of the state or to "leave such carcass where the whole or any part thereof may be washed or carried into" waters of the state.[19]

• Finally, it is unlawful to "place, run, or drain any matter harmful to fish into any of the waters of this state that have been stocked by the [Game and Parks] commission."[20]

Enforcement of these provisions is through criminal (Class II or IV misdemeanor) prosecution.

OPERATIONAL REQUIREMENTS

Forestry Requirements

The state's Erosion and Sediment Control Act, described in the following section, may be applicable to forestry activities to control soil loss.[21]

Agriculture Requirements

• Each natural resources district in the state is required under the Erosion and Sediment Control Act to adopt a program for implementing the state erosion and sediment control program. The district program must include (1) soil-loss limits for the various types of soils, which are to be adopted and promulgated as rules and regulations and which must be at least as stringent as those adopted by the state director of natural resources; (2) recommended erosion or sediment control practices; and (3) programs, procedures, and methods to implement the program.[22]

The Act also delegates authority to municipalities and counties to adopt rules governing erosion and sediment control that are in substantial conformance with the state erosion and sediment control program.[23] In such cases, the municipality or county may assume jurisdiction to enforce applicable soil-loss limits.

Any person who has a farm unit conservation plan approved by the district and is implementing it in strict compliance, or any person whose normal agricultural, horticultural, and silvicultural practices are in conformance with the applicable soil-loss limit is deemed to be in compliance with the Erosion and Sediment Control Act. Except for cases where erosion occurs on the site of any nonagricultural land-disturbing activity, a landowner will not be required to conform his practices to the applicable soil-loss limit or will not be required to implement the soil and water conservation practices in the plan unless and until there is made available to the landowner at least 90 percent cost-sharing assistance.[24]

Where there are violations of a district's soil-loss limits, the district may reach an agreement with the owner for eliminating excessive erosion, which agreement is enforceable in district court. The district may also, following a hearing, issue administrative orders. In the case of agriculture, silviculture or horticulture activities, the administrative order is to direct the owner to conform to the applicable soil-loss limit. For "non-agriculture" activities, the administrative order may authorize the owner to either conform to the soil-loss limits or prevent the sediment caused by excessive erosion from leaving the land.[25] The order may specify alternative soil and water conservation practices or erosion or sediment control practices that may be used.[26] The district court issues an order directing the owner to comply with the district's administrative order, and any person who fails to comply with the court order is deemed in contempt of court and punished accordingly.[27]

• While the Department of Environmental Quality is responsible for adopting standards for pesticides in surface and groundwater, the Department of Agriculture is charged with developing and implementing a state management plan for the prevention, evaluation, and mitigation of occurrences of pesticides or pesticide breakdown products in ground water and surface water. The Department of Agriculture is authorized to promulgate regulations specifying methods to be used in the application of pesticides, including time, place, manner, methods, materials, amounts, and concentrations, and may restrict or prohibit the use of pesticides in designated areas. The regulations "shall encompass all reasonable factors which the department deems necessary to prevent damage or injury by drift or misapplication" to plants, wildlife, fish and other aquatic life, surface and groundwater and humans.[28]

Nebraska law further provides that it is unlawful to use a pesticide contrary to the labeling or to a rule of the department limiting its use. It is also unlawful to "dispose of, discard or store a pesticide...in a manner that the person knows or should know is...likely to cause injury to humans, the environment, vegetation, crops, livestock, wildlife or pollinating insects...(or) likely to pollute a water supply or waterway....[29]

Enforcement of the Pesticide Act is through administrative cease and desist orders, license revocation, administrative fines of up to $5,000, injunctions, civil fines of not more than $15,000, and criminal (misdemeanor) prosecution.[30]

• A permit is required for anyone who applies chemicals to land or crops through the use of chemigation. An application for a permit is approved if the irrigation distribution system complies with the statutory requirements and the applicator has been certified.[31] Enforcement is through criminal (misdemeanor) prosecution, civil penalties of up to $1,000, and injunctions.[32]

• "In order to conserve groundwater supplies and to prevent the inefficient or improper runoff of such ground water, each person who uses ground water irrigation in the state shall take action to control or prevent the runoff of water used in such irrigation."[33] Each district is directed to adopt regulations prescribing: standards for what constitutes the improper runoff of groundwater used in irrigation; procedures to prevent, control, and abate such runoff; remedial measures to prevent, control or abate runoff; and enforcement procedures.[34] Enforcement is through cease and desist orders issued by the district.[35]

Development and Other Earth-Disturbing Activities

• The Erosion and Sediment Control Act discussed above applies to non-agricultural, land-disturbing activities, though the Act excludes residential, commercial and industrial construction involving less than two acres.[36]

NEVADA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Nevada's water pollution control law includes some provisions that may be used to take enforcement action against some nonpoint source discharges that pollute the waters of the state.

• Nevada's water pollution control act ("Act") allows the state environmental commission ("commission") to prescribe controls for those "diffuse sources" (equivalent to nonpoint sources)[1] existing on January 1, 1979 that are "significantly causing or adding to water pollution in violation of a water quality standard."[2]

• The commission also may prescribe controls for new diffuse sources to prevent degradation of high quality waters,[3] except with respect to "normal agricultural rotation, improvement or farming practices."[4] The Act further provides that new or increased diffuse sources must provide measures that are designed to prevent, eliminate or reduce water pollution from the source and are reasonably consistent with the economic capability of the project or development.[5]

The Act directs the commission to delegate administration of the diffuse sources program to counties and cities that request it and have sufficient resources.[6] For violations involving diffuse sources, an administrative order prescribing corrective actions can be issued or a civil action can be brought with the court ordering injunctive relief or posting of a bond or other security, but no civil or criminal penalty is authorized.[7]

• Special regulations exist to protect the Lake Tahoe watershed. The Act makes it illegal to discharge waste within 100 feet of the lake or a stream or other water supply in the Lake Tahoe watershed.[8]

Other Discharge Limitations

• The county and city boards of health are authorized to define and abate nuisances.[9]

• Nevada law creates a cause of action for damages against any person who maintains, dumps, turns or flows "anything of a liquid nature poisonous or injurious to...livestock, into an open ditch...pond, reservoir or any other place," unless the livestock are fenced out of the affected water body.[10]

Fish/Fisheries Laws

• Any person who places in or allows to fall into waters of the state "any substance deleterious to fish or wildlife" is guilty of a misdemeanor for the first offense and gross misdemeanor for a subsequent offense.[11] Misdemeanor convictions that are punishable by fines ($50 to $500) and/or imprisonment (six months or less).[12] Conviction of the unlawful killing of a mammal, bird or fish results in additional civil penalties.[13] A court may also revoke or suspend wildlife-related licenses,[14] and licenses may be suspended administratively after conviction, based on a point system reflecting the severity of the offense.[15]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• The Nevada forestry statute requires a permit from the state forester firewarden for logging or cutting operations, which may be denied if the operation will cause significant soil erosion and siltation.[16] The forestry statute also requires a certificate before the conversion of timberland "to any use other than the growing of timber,"[17] which the firewarden may deny for, among other reasons, failure to give satisfactory proof that adequate provision will be made "to stabilize, revegetate or rehabilitate disturbed soils in order to minimize erosion, flooding or other damage to the watershed."[18] According to rules promulgated under the Act, all logging permits and timberland conversion certificates must require the use of best management practices to prevent, eliminate or reduce water pollution from diffuse sources.[19] A violation of permit conditions or forest practice rules can result in administrative suspension or revocation of any logging permit;[20] and lack of compliance with timberland conversion certificate may also result in administrative suspension or revocation.[21] Violation of these provisions is a misdemeanor punishable with a fine (up to $1000) and/or imprisonment (six months or less).[22]

• The Nevada forestry statute provides for variances for certain otherwise prohibited forestry activities. Nevada law prohibits "felling of trees, skidding, rigging or construction of roads...within 200 feet of a waterbody"[23] without a variance, which may be granted if, among other standards, the goal of maintaining water quality standards will not be compromised.[24] It is illegal to engage in tractor logging on slopes of 30 percent or more without a variance, and, in deciding whether to grant and/or what conditions to the variance, the firewarden must consider displacement and erosion of soils and siltation of streams.[25] The enforcement provisions and sanctions are noted above.

• The forestry statute also requires tractor skid trails, landings, logging truck roads and firebreaks to be located, constructed, used and left so as to not "appreciably diminish the quality of the water"[26] and includes standards that require that the waterbreak and culvert system on all tractor skid trails, landings, logging truck roads and firebreaks be designed so as to prevent degradation of water quality.[27]

Agriculture Requirements

• A "diffuse source" as described above includes "agricultural activity" and "return flows from irrigation."[28] The enforceable mechanisms are also described above.

R0017191

• A conservation district may petition the state conservation commission to formulate land use regulations that may include provisions that prevent soil erosion and sedimentation.[29] Variances from these provisions may be available from a board of adjustment set up by the commission.[30] The commission may request a court to enforce the land use regulations[31] or authorize a land occupier to recover damages from another occupier for a violation.[32] A court may order a defendant to bring the land into compliance or allow the commission to perform the work and recover the costs.[33]

• Nevada law prohibits grazing in areas into which water is diverted for municipal, drinking or domestic purposes in the state, with some exceptions including prospectors or other persons with ten head of livestock passing over or being temporarily upon such lands, livestock running at large upon the range and persons herding on their own lands.[34] Violation of this provision is a misdemeanor, and each day constitutes a separate violation.[35]

• Nevada regulates pesticides and certifies pesticide applicators.[36]

Development and Other Earth-Disturbing Activities

• State law empowers local governments to regulate land improvements and location of structures and to take into account the potential impairment of natural resources.[37] Also zoning regulations must be designed to preserve the quality of water resources.[38] Nevada law broadly provides for the state land use planning agency to assist local governments in planning for "areas of critical environmental concern"[39] and requires preparation of regional land use plans that include goals relating to conservation and protection of water and other natural resources.[40]

• Also see "diffuse sources." Nevada regulations provide for permits to construct or grade, which "must require that practices be used to prevent, eliminate or reduce water pollution from any diffuse source during the activity.[41]

NEW HAMPSHIRE

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

New Hampshire's water pollution control law has several provisions that may be used to take enforcement action against nonpoint source water pollution. Two of these provisions prohibit disposal of "wastes" or discharges of "pollution" that result in violation of water quality classifications. A third prohibits the discharge of "wastes" to any waters of the state without a written permit. And a fourth, more narrowly defined prohibition, identifies some specific substances that may not be placed into the state's waters or onto the banks of such waters. None of these provisions is expressly limited to point sources.

- "After adoption of a given classification for a stream, lake, pond, tidal water, or section of such water, the department [of environmental services] shall enforce such classification by appropriate action in the courts of the state, and it shall be unlawful for any person or persons to dispose of any sewage, industrial, or other wastes, either alone or in conjunction with any other person or persons, in such a manner as will lower the quality of the waters of the stream, lake, pond, tidal water, or section of such water below the minimum requirements of the adopted classification...."[1] "

- "If, after adoption of a classification of any stream, lake, pond, or tidal water, or section of such water...it is found that there is a source or sources of pollution which lower the quality of the waters in question below the minimum requirements of the classification so established, the person or persons responsible for the discharging of such pollution shall be required to abate such pollution within a time to be fixed by the department...."[2]

- "It shall be unlawful for any person or persons to discharge or dispose of any sewage or waste to the surface water or groundwater of the state without first obtaining a written permit from the department of environmental services. Applications for permits shall be made upon forms prescribed by the department..."[3]

For purposes of these prohibitions, "Waste" means "industrial waste and other wastes;" while "other wastes" means "garbage, municipal refuse, decayed wood, sawdust, shavings, bark, lime, ashes, offal, oil, tar, chemicals and other substances other than sewage or industrial wastes, and any other substance harmful to human, animal, fish or aquatic life."[4]

Enforcement of these prohibitions is by the department of environmental services, which may establish the period for abatement, issue a cease and desist order, or seek injunctive relief in court.[5] "On application of the department of environmental services, the superior court or any justice of such court...may enjoin any act in violation of any lawful order of the department of environmental services."[6] "The department shall issue a written cease and desist order against any discharge or act in violation of this subdivision...or lawful regulation of the department...or any condition of any

R0017194

permit lawfully issued by the department, and any such discharge or act may be enjoined by the superior court upon application of the attorney general..."[7] "The written cease and desist order...shall be recorded by the department in the registry of deeds for the county in which the property is situated and, upon recordation, said order shall run with the land..."[8] Enforcement against timber operations in violation of this chapter is conducted by the director of the division of forests and lands, department of resources and economic development.[9] Violators are subject to civil penalties of up to $10,000 per day; or administrative penalties of not more than $2,000 per offense. Willful or negligent violations, or knowing failure to obey a lawful order subjects the violator to a fine of up to $25,000 per day and/or imprisonment for up to 6 months.[10]

• A separate, and more narrow water pollution provision may be applicable to a limited set of nonpoint problems. "It shall be unlawful for any person to put or place, or cause to be put or placed into a surface water of the state or on the ice over such waters, or on the banks of such waters, any bottles, glass, crockery, cans, scrap metal, junk, paper, garbage, tires, old automobiles or parts thereof, tree, or similar litter."[11] Enforcement is by abatement order, abatement and cost recovery, injunction, and fine.[12]

In interpreting and applying its laws to nonpoint source water pollution, New Hampshire may rely in part upon its law declaring a public trust in the waters of the state, creating obligations for all of its land management and regulatory agencies: "[T]he water of New Hampshire whether located above or below ground constitutes a limited and, therefore, precious and invaluable public resource which should be protected, conserved and managed in the interest of future generations. The state as trustee of this resource for the public benefit declares that it has the authority and responsibility to provide careful stewardship over all the waters lying within its boundaries. The maximum public benefit shall be sought, including the assurance of health and safety, the enhancement of ecological and aesthetic values, and the overall economic, recreational and social well-being of the people of the state. *All levels of government within the state, all departments, agencies, boards and commissions, and all other entities, public or private, having authority over the use, disposition or diversion of water resources, or over the use of the land overlying or adjacent to, the water resources of the state, shall comply with this policy and with the state's comprehensive plan and program for water resources management and protection.*"[13] Under the water pollution law, state law provides that the department of environmental services shall be governed solely by criteria related to a more narrowly defined purpose: "to protect water supplies, to prevent pollution in the surface and groundwaters of the state and to prevent nuisances and potential health hazards."[14]

Other Discharge Limitations

Public health and nuisance-type provisions also provide enforceable mechanisms applicable to some forms of nonpoint source pollution.

• "The health officers of towns may make regulations for the prevention and removal of nuisances, and such other regulations relating to the public health as in their judgement the health and safety of the people require, which shall take effect [upon approval by the selectmen, and publication]."[15] The department of health and human services has the same power, with enforcement by the department or by local boards of health.[16] These may extend to some forms of nonpoint source water pollution.

Agricultural operations are not abatable as a public or private nuisance "if such agricultural operation has been in operation for one year of more and if it was not a nuisance at the time it began operation." However, this provision does not apply "when any aspect of the agricultural operation is determined to be injurious to public health or safety under [the health officer provisions noted above]."[17] Also, the exemption does not apply "if a nuisance results from the negligent or improper operation of an agricultural operation. Agricultural operations shall not be found to be negligent or improper when they conform to federal, state and local laws, rules and regulations."[18] This appears to say that unless agricultural operations are in violation of a law, they cannot be abated as a nuisance apart from the public health risk provisions cited above.

• "No privy, toilet, sink, drain, cesspool, septic tank, or the discharges from such facilities, and no pen or sty for swine, shall be erected or continued in such place or condition as, in the judgment of the health officers, to be a nuisance or injurious to the public health. The health officer may make, in the manner provided in RSA 147:1, such regulations as necessary to ensure the safety and adequacy of subsurface sanitary disposal systems within the municipality..."[19]

• Whoever places "any animal or other substance liable to become putrid or offensive, or injurious to the public health, or deposits garbage or refuse on premises not designated as public dumping facilities...shall be guilty of a violation."[20]

• "If a person shall place, leave, or cause to be placed or left, in or near a lake, pond, reservoir or stream tributary thereto, from which the domestic water supply of a city, town or village is taken, in whole or in part, any substance or fluid that may cause such water to become impure or unfit for such purposes he shall be guilty of a misdemeanor if a natural person, or guilty of a felony if any other person."[21] "The health officer of the town or the water commissioners having charge of the water supply, or the proprietors of the water supply, may remove such substance or fluid; and they may recover the expense of removal from the person who placed the same, or caused it to be placed."[22] It is also a criminal offense to knowingly and willfully poison, defile, or pollute a water supply "in such a manner as to affect the purity of the water or ice so supplied at the point where the water or ice is taken for such domestic use" or to put "the carcass of any dead animal or other offensive material into said waters or upon the ice."[23]

Fish/Fisheries Laws

• "Whoever unlawfully discharges contaminants into the inland or coastal waters of the state shall be liable to the state for any damage to the fish, other aquatic life and wildlife or their habitat in said waters caused by such contamination."[24]

OPERATIONAL REQUIREMENTS

Forestry Requirements

The Director of the Division of Forests and Lands, within the Department of Resources and Economic Development, enforces provisions on timber harvesting on private and public lands; the Director also makes rules on "the cutting of timber near

R0017196

certain waters and public highways."[25] These provisions create some enforceable obligations related to nonpoint source water pollution.

• The timber harvesting law requires filing of a notice of intent to cut.[26] The law requires cross-compliance with the state's wetlands permitting program including implementation of best management practices; and it requires compliance with the state's alteration of terrain program. Licensing of professional foresters also provides some basis for enforcement.[27]

• The law prohibits the felling in any 12 month period of more than 50 percent of the basal area of trees within 150 feet of any great pond, standing body of water 10 acres or more, or any fourth- or high-order stream, or within 50 feet of any perennial stream.[28] However, the director may grant a variance from these geographical harvest prohibitions; and the prohibitions do not apply to timber cutting for land conversion purposes, rather than for timber, if all relevant local permits have been secured.[29]

• The law also prohibits disposal of slash and mill residue in any perennial stream or standing body of water, within 25 feet of any fourth order stream, or within 50 feet of any great pond or standing body of water 10 acres or more in area.[30]

A cease and desist order is to be issued by the department against any timber operation in violation of the law; violations may also be enjoined by superior court.[31] In addition, the department must "[i]ssue cease and desist orders to temporarily suspend logging or other operations in forest areas when the director determines that such actions have resulted in, or are likely to result in, pollution of surface water or groundwater." The cease and desist order remains in effect while the director notifies the department of environmental services, which will conduct its own investigation and determine what, if any, orders to issue.[32] Administrative fines may be also assessed for any offense, not to exceed $2,000 per offense.[33] The limits on harvesting adjacent to bodies of water are enforceable as misdemeanors by the local municipality, with notice to the director of forests and lands, who may act to assure uniform statewide enforcement.[34] Violations of these harvest limits or of the prohibitions on disposal of slash and mill residue are misdemeanors (each 200 linear feet or fraction thereof on the affected water body is a separate offense).[35]

• Apart from the forest practices law, the Alteration of Terrain program (described in detail under "Development and Other Earth-Disturbing Activities") also provides some basis for enforcement. Timber harvesting operations are entitled to a permit under this program provided they have filed the notice of intent to cut. The regulations require loggers to obtain the site specific permit by signing a statement on the notice of intent to cut that expresses familiarity with legal obligations and "hereby agree to abide by appropriate Best Management Practices to include all state laws pertaining to logging operations."[36] "Appropriate Best Management Practices" means "those contained in the manual 'Best Management Practices for Erosion Control on Timber Harvesting Operations in New Hampshire' prepared by the New Hampshire department of resources and economic development."[37]

• Persons who have filed the necessary notice of intent to cut wood and have given written notice to the department of environmental services and the department of resources and economic development also satisfy the requirements for "minimum impact activities" under the state's wetland fill and dredge permit program.[38] Under this program, however, logging operations must locate all skid trails, truck roads, and log landings far enough from streams and ponds so that waterborne particles will settle out before reaching the streams or ponds. Skid trails and roads, culverts, bridges, crossings, etc must be installed in accordance with Best Management Practices, and crossings must be removed when logging is complete; permanent crossings must handle the 25-year flood.[39] Erosion and siltation measures must be installed and maintained.[40] Wetland enforcement measures are described below under "Development and Other Earth-Disturbing Activities."

• Comprehensive shoreland protection is partly applicable to forestry activities;[41] it requires maintenance of a natural woodland buffer within 150 feet (limiting harvest to not more than 50 percent of basal area and 50 percent of saplings within a 20 year period).[42] However, forest management not associated with shoreland development or land conversion is exempt from these provisions if conducted in compliance with the forest practices provisions described above limiting the cut adjacent to waters to 50 percent of basal area in any year.[43]

Agriculture Requirements

• The commissioner of agriculture, markets, and food is to consult with other agencies and publish best management practices "so as to permit the maximum use of nutrient and soil conditioning values, while achieving the least possible adverse impact upon the environment or human, animal and plant health."[44] These are voluntary/advisory in the first instance, and must rely on other authorities for enforceability. The commissioner is to investigate complaints of improper handling and application of manure, compost, or chemical fertilizer, and if the commissioner "has reason to believe such handling is a nuisance caused by failure to use best management practices," must notify the responsible person of the changes needed to conform to BMPs and require a plan for compliance if the changes are not made within 10 days of the notification. If the person fails to implement the recommended changes, the commissioner must notify local health officers and the department of environmental services *"who shall take such action as their authority permits."*[45]

• The commissioner also has rulemaking power over storage, use, and application of fertilizers.[46] Mislabeling and registration violations are misdemeanors (if committed by a natural person) or felonies (if by other, such as corporation); civil forfeitures are not to exceed $5,000 per violation per day, and administrative fines are not to exceed $1,000 per violation. These provisions offer limited utility for nonpoint source pollution unless the commissioner has adopted rules proscribing certain uses and applications aimed at water bodies.

• The pesticide control board may make rules for the times, places, and conditions of use of pesticides in different areas of the state if "such pesticides may be injurious to persons, animals, or crops" other than the target pests, and may require that pesticides be used only under permit of the board.[47] Regulations prohibit application of pesticide by commercial applicator or homeowner within 25 feet of surface waters; special permits are required under special conditions such as aerial applications, public water supply watersheds, etc.[48] Enforcement sanctions and penalties are like those for fertilizer registration violations.[49]

The Alteration of Terrain erosion control program (described below under "Development and Other Earth-Disturbing Activities") does *not* apply to "normal agricultural practices." Likewise, the Comprehensive Shoreland law exempts all agricultural activities and operations "provided such activities and operations are in conformance with the most recent best management practices determined by...[USDA's Natural Resources Conservation Service, USDA's Cooperative Extension Service] and the [state's] department of agriculture, markets, and food."[50]

Development and Other Earth-Disturbing Activities

Apart from any programs for the control of urban stormwater under the federal Clean Water Act or that may be authorized by general land use regulation such as zoning, state law provides the following authorities.

- The Alteration of Terrain program provides some enforceable mechanisms. "Any person proposing to dredge, excavate, place fill, mine, transport forest products or undertake construction in or on the border of the surface waters of the state, and any person proposing to significantly alter the characteristics of the terrain, in such a manner as to impede the natural runoff or create an unnatural runoff, shall be directly responsible to submit to the department [of environmental services] detailed plans concerning such proposal and any additional relevant information requested by the department, at least 30 days prior to undertaking an such activity. The operations shall not be undertaken unless and until the applicant receives a permit from the department. The department shall have full authority to establish the terms and conditions under which any permit may be exercised, giving due consideration to the circumstances involved and the purposes of this chapter, and to adopt such rules as are reasonably related to the efficient administration of this section, and the purposes of this chapter..."[51]

The regulations require a permit if "dredging, excavation, filling, mining, transporting of forest products, earth moving or other significant alteration of the characteristics of the terrain" will occur "in or on the border of the surface waters of the state"; and if "construction, earth moving or other significant alteration of the characteristics of the terrain" when the contiguous disturbed area is 50,000 or more square feet if within the protected shoreline as defined by RSA 483-B, or 100,000 or more square feet in any other area.[52] "Significantly alter..." is defined as activity that "changes or disturbs the terrain so as to impede the natural runoff or create an unnatural runoff that has the potential to adversely affect water quality in the state's surface waters."[53] Regulations provide that permit applications (except for general permit applications) must be reviewed for "(a) Water quality protection measures proposed to be used during the construction phase of the proposed activity for the prevention of soil erosion; (b) Permanent water quality protection measures to be constructed as part of the project...; and (c) Impacts due to changes in runoff hydrology...[calculated for 2-year and 10-year storms]."[54] Regulations establish detailed design and performance criteria for various kinds of stormwater and erosion control features.[55] Enforcement provisions and sanctions are the same as those provided for violation of the state's water pollution control laws.

• The Comprehensive Shoreland Protection Act, administered by Dept. of Env. Services, provides a variety of enforceable mechanisms.[56] It provides for "establishment of standards for the subdivision, use, and development of the shorelands of the state's public waters. The development standards provided in this chapter shall be the minimum standards necessary to protect the public waters of the state of New Hampshire. These standards will serve to.....prevent and control water pollution..."[57] Protected shoreland includes all land within 250 feet of public waters. The law requires persons engaged in excavation, land disturbance, subdivision, and onlot septic system installation, within the protected shoreland to obtain required permits under other programs...but allows department to grant, deny, or attach reasonable conditions "to protect the public waters or the public health, safety or welfare."[58] The law prohibits the establishment or expansion of "salt storage yards, automobile junk yards, and solid or hazardous waste facilities"; requires a setback of 50 feet for primary structures; prohibits use of fertilizer within 25 feet; requires a natural woodland buffer within 150 feet (limiting removal for land conversion purposes to not more than 50 percent of basal area and 50 percent of saplings within a 20 year period); specifies minimum setbacks for septic systems; and requires all new structures within protected shorelands to meet terrain alteration rules (and requires permits for disturbances exceeding 50,000 square feet); and sets minimum lot size and frontage standards.[59] The law does not apply within any municipality that has adopted an ordinance that is at least as stringent as the state law and that has been certified as such.[60] The comprehensive shoreland law is enforced by the commissioner of environmental services.[61] Enforcement tools include cease and desist orders, injunctive relief, civil penalties of up to $20,000, and administrative fines of up to $5,000.[62] Municipalities may also enforce.[63] A knowing violation is misdemeanor (if natural person), or felony (if other person).[64]

• The River Management and Protection Program is managed by the department of environmental services. "The state shall....regulate the quantity and quality of instream flow along certain protected rivers or segments of rivers to conserve and protect outstanding characteristics including recreational, fisheries, wildlife, environmental...[etc.]"[65] Designations are "natural rivers", "rural rivers", "rural-community rivers," and "community rivers."[66] Protections of all 4 types of designated rivers include 250-foot setbacks of land application of solid waste (but not including "manure, lime and wood ash used for fertilizer, and sludge and septage")[67] Channel alterations are not allowed on natural rivers, but the commissioner may approve temporary alterations in connection with repair or maintenance of bridges, roads, or riprap. Also, channel alterations are not allowed on the latter 3 types of rivers that alter the flow characteristics of the river or adversely affect the resources for which the river is designated, but the commissioner may approve alterations necessary for construction, repair or maintenance of a project including public water supply intake facilities.

• The Lakes Management and Protection program administered by the department of environmental services develops "management criteria" for the state's lakes to "provide the basis for state agency decisions regarding lakes management and protection."[68] Criteria are to "ensure that (a) Water quality shall not be degraded from existing water quality standards...(b) Potential sources of pollution, whether point or non-point sources on the land or deriving from activity on the lake, shall be managed in such a way as to minimize their adverse impact on water quality. No significant adverse impact or cumulative adverse impact on water quality shall be permitted." The program results in the development of plans, while the implementation is by cooperation of state agencies. Thus, any enforcement is based on use of other statutory and regulatory authorities.

• The wetlands program requires permitting, and use of erosion and siltation control measures.[69] The department of environmental services has emergency order authority to direct the cessation of activities posing "immediate risk" to wetlands; and compliance order authority.[70] A wetland violation is a misdemeanor (if natural person) or felony (if other person).[71]

NEW JERSEY

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

New Jersey's water pollution control law includes several provisions that may be used to take enforcement action against certain nonpoint source discharges.

• New Jersey law prohibits the discharge of any pollutant except as authorized by statute or under permit. "Pollutant" means "any dredged spoil, solid waste, incinerator residue, sewage, garbage, refuse, oil, grease, sewage sludge, munitions, chemical wastes, biological materials, radioactive substance, thermal waste, wrecked or discarded equipment, rock, sand, cellar dirt, and industrial, municipal or agricultural waste or other residue discharged into the waters of the state."[1] Enforcement provisions include compliance orders, injunctive relief, and civil penalties of not more than $50,000 for each violation;[2] and criminal sanctions if there is a knowing or reckless violation which causes a significant adverse environmental effect.[3]

• The law further provides that no person shall put or place into, drain into, or place where it can run, flow, wash or be emptied into, or where it can find its way into, any of the fresh or tidal waters of the state, any petroleum products, debris, hazardous, deleterious, destructive, or poisonous substances of any kind. The penalty for violation is $6,000 for each offense. Exemptions from this provision, however, include chemicals used on agricultural, horticultural or forestry crops, or in connection with livestock...in a manner approved by the department of environmental protection.[4]

It is worth noting that the state's Water Quality Planning Act also authorizes the state to designate areawide waste treatment management planning areas.[5] The areawide plan is to include establishment of a regulatory program which would, among other things, provide control or treatment of all point and nonpoint sources of pollution, including in-place or accumulated pollution sources, to the extent practicable.[6] The plan should also include a process 1) to identify agriculturally and silviculturally related nonpoint sources of pollution, including runoff from manure disposal areas and from land used for livestock and crop production; and 2) to set forth procedures and methods including land use requirements, to control to the extent feasible such sources. The plan should also include a process 1) to identify construction activity related sources of pollution; and 2) to set forth procedures and methods, including land use requirements, to control to the extent feasible such sources. The areawide plan is not itself enforceable, but is intended to identify appropriate enforceable mechanisms where needed.

Other Discharge Limitations

• Special provisions prohibit the discharge of "sewage or other polluting matter" directly or indirectly into certain waters of the Passaic river and tributaries; enforcement is by injunction and fine of up to $100 per day.[7]

• Local boards of health have power to pass ordinances and make rules and regulations with regard to the public health in order "to protect the public water supply and prevent the pollution of any stream of water or well...."[8]

• Common law nuisance remedies may also be available. However, there is an irrebuttable presumption created by statute that no agricultural operation, activity or structure which is conducted or located within a municipally approved farmland preservation program *and* which conforms to agricultural management practices approved by the state agricultural development committee *and* does not pose a direct threat to public health and safety shall constitute a public or private nuisance.[9]

Fish/Fisheries Laws

• See the prohibition on draining of "deleterious substances" above. It is not necessary, to sustain a violation, for the state to show that the substances have caused the death of fish, birds, or mammals.[10]

OPERATIONAL REQUIREMENTS

Forestry Requirements

State laws relating to forestry do not appear to contain independently enforceable requirements relating to nonpoint source discharges.

Agriculture Requirements

State laws relating to agriculture do not appear to contain independently enforceable requirements relating to nonpoint source discharges.

• State law does include authority to regulate or condition uses of pesticides.[11]

Development and Other Earth Disturbing Activities

Apart from any programs for the control of urban stormwater under the federal Clean Water Act or that may be authorized by general land use regulation such as zoning, state law provides the following authorities.

• Under the Soil Erosion and Sediment Control Act, the state Soil Conservation Committee in the Department of Agriculture must develop standards for the control of soil erosion and sedimentation.[12] Any person proposing to engage in any project must receive certification by the local soil conservation district of a plan for soil erosion and sediment control. A "project" means any disturbance of more than 5000 sq. feet for the surface area of land for 1) construction that would require a construction permit; 2) the demolition of one or more structures; 3) construction of a parking lot; 4) construction of a public facility; 5) for the operation of any mining; 6) for the clearing or grading of any land for other than agricultural or horticultural purposes. [13] No one shall be issued a certificate unless there is compliance with a certified plan for permanent measures to control soil erosion and sedimentation.[14] Municipalities may enforce a conforming ordinance; otherwise enforcement is by the soil /conservation district; enforcement is by stop-construction order, civil action, and civil penalty of $25 to $3000.[15]

• The state's Freshwater Wetlands Act requires a freshwater wetlands permit for anyone engaging in a "regulated activity".[16] A "regulated activity" is "1) the removal, excavation, disturbance or dredging of soil, sand, gravel, or aggregate material of any kind; 2) the drainage or disturbance of the water level or water table; 3) the dumping, discharging, or filling with any materials; 4) the driving of pilings; 5) the placing of obstructions; 6) the destruction of plant life which would alter the character of a freshwater wetland, including the cutting of trees."[17] The law exempts from the permit requirements, unless required by federal EPA rules, "normal farming, silviculture and ranching activities" and "normal harvesting of forest products in accordance with a forest management plan approved by the state forester."[18] [The forest management plan statute authorizes the dept to develop a forest management plan for the state parks and forests and to provide technical assistance to promote BMPs for forest operators on the harvesting of forest products. It has no enforceable requirements, however].[19] Enforcement of the Freshwater Wetlands Act is by order, civil action, civil penalty, or criminal action. The civil penalty is authorized up to $10,000.[20]

• The Coastal Area Facility Review Act requires a permit from the department of environmental protection for all new development proposed on a beach or dune, as defined in the statute. "Development" means "the construction, relocation, or enlargement of any building or structure and all site preparation therefor, the grading, excavation or filling on beaches or dunes, and shall include residential development, commercial development, industrial development, and public development."[21] It is enforceable by orders, civil actions, and penalties up to $25,000 per violation.[22]

• The Waterfront Development Law regulates those developments not covered and not superseded by the Coastal Area Facility Review Act.[23] The department of environmental protection may, by appropriate action in any court, prevent the encroachment or trespass upon the water front of any navigable waters and compel the removal of any such encroachment or trespass, and restrain, prevent and remove any construction, erection or accretion injurious to the flow of any such waters, which may be detrimental to the proper navigation thereof and the maintenance and improvement of commerce thereon. Approval is required for such construction. It is enforceable by orders, civil actions, and penalties up to $1000 per violation.

NEW MEXICO

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

New Mexico's Water Quality Act does not contain an enforceable prohibition directly applicable to nonpoint source discharges, but the Act does authorize the Water Quality Control Commission broadly to "promulgate and publish regulations to prevent or abate water pollution in the state" and to require permits.[1] Thus, the availability of any enforceable authority depends entirely on the promulgation of specific regulatory requirements. The general permitting and enforcement scheme operates as follows.

• "Water pollution" is defined as "introducing or permitting the introduction into water, either directly or indirectly, of one or more water contaminants in such quantity and of such duration as may with reasonable probability injure human health, animal or plant life or property, or to unreasonably interfere with the public welfare or the use of property."[2] The Act directs the commission to "adopt water quality standards for surface and ground waters of the state,"[3] and gives it discretion to adopt regulations requiring "a permit for the discharge of any water contaminant."[4] However, the Act allows "reasonable degradation of water quality resulting from beneficial use [provided] such degradation shall not result in impairment of water quality to the extent that water quality standards are exceeded."[5] The same section also exempts activities regulated under the state oil and gas act, and limits the Act's application to activities regulated under the state's groundwater, hazardous waste, or solid waste acts, "except to abate water pollution or control the disposal or use of septage or sludge."[6] Moreover, the Commission is barred from placing a permit requirement on "the use of water in irrigated agriculture, except in the case of employment of a specific practice in connection with such irrigation that documentation or actual case history has shown to be hazardous to public health or the environment."[7]

The Commission is required to assign responsibility for administering its regulations to "constituent agencies," such as the department of environment, state engineer, department of game and fish, and department of agriculture, among others.[8] The constituent agencies are empowered to issue administrative compliance orders (including penalties) or commence civil actions.[9] The Act provides for administrative orders with penalties up to $15,000 per day for violations of permit and certification requirements, and $10,000 per day for other violations of the Act and its regulations or water quality standards.[10] For failure to take corrective actions required in a compliance order, the penalty may be up to $25,000 per day. Further, a permit may be terminated or modified upon violation of its conditions.[11]

There are also judicial civil penalties paralleling the $15,000 and $10,000 administrative penalties (though not the $25,000 penalty for noncompliance with an order).[12] The Act also sets out criminal penalties for knowing violations. Knowingly violating a permit or discharging when a permit is required is a fourth degree penalty, with stricter penalties for subsequent violations (third degree felony), causing substantial adverse environmental impact (third degree felony), or a substantial danger of death or serious bodily injury (second degree felony).[13]

Other Discharge Limitations

The Water Quality Act includes a savings provision, which preserves "rights of action or remedies in equity under the common law or statutory law, criminal or civil."[14] Accordingly, "no provision of the Water Quality Act or any act done by virtue thereof estops the state or any political subdivision or person as owner of water rights or otherwise, in the exercise of their rights in equity or under the common law or statutory law, to suppress nuisances or to abate pollution."[15] Several statutory provisions on nuisance law could also be applied to nonpoint source water pollution.

- A public nuisance is defined as an unlawful act that either is "injurious to public health, safety, morals or welfare" or "interferes with the exercise and enjoyment of public rights, including the right to use public property."[16] Committing a public nuisance is a misdemeanor.

- The state code also makes "polluting water for which the act is not otherwise prescribed by law" a misdemeanor.[17] It defines "polluting water" as "knowingly and unlawfully introducing any object or substance into any body of public water causing it to be offensive or dangerous for human or animal consumption or use" and declares the act to be a public nuisance.[18]

- Municipalities are authorized to "appoint a board of health" or "perform any act or adopt any regulation necessary or expedient for the promotion of health and the suppression of disease."[19] They also may regulate plumbing and sewage disposal,[20] "direct the location, regulate and prohibit any offensive and unwholesome business or establishment" within one mile of their boundaries,[21] and "define a nuisance, abate a nuisance and impose penalties upon a person who creates or allows a nuisance to exist."[22]

"Any public officer or private citizen" may bring a civil action to abate a public nuisance.[23] Plaintiffs may seek an injunction against a public nuisance, with court costs and attorneys fees, but a recent case held that the court is not empowered to award damages.[24] Criminal prosecution is the prerogative of the state, through the usual channels. The punishment for a petty misdemeanor is a fine of up to $500 or a jail term of up to 6 months or both; the punishment for a misdemeanor is $1000 or a year or both.[25]

The Right to Farm Act[26] exempts from public or private nuisance claims any "agricultural operation or agricultural facility if the operation was not a nuisance at the time the operation began and [if it] has been in existence for more than one year," provided that the operation or facility is not "operated negligently, improperly or illegally such that the operation or facility is a nuisance." Cities with agricultural operations or facilities within their limits at the time the Right to Farm Act was passed cannot apply nuisance ordinances against these farms.

Fish/Fisheries Laws

• No provisions relate explicitly to fish kills or habitat destruction due to nonpoint pollution. The state game commission is empowered to "prohibit the killing or taking of any ... game fish of any kind or sex."[27] It is a misdemeanor to "hunt, take, capture, kill or attempt to take, capture or kill, at any time or in any manner, any ...game fish in the state" except as permitted by the state game commission or otherwise by law."[28] Further, every "poisonous or stupefying substance ... used ... in taking or killing game or fish in violation of this chapter" is declared to be a public nuisance.[29] The game and fish code is enforced by "the director of the department of game and fish, each conservation officer, each sheriff in his respective county and each member of the New Mexico State Police."[30] "Any person violating any of the provisions of [the code] or any regulations adopted by the state game commission which relate to the time, extent, means, or manner that game animals, birds or fish may be hunted, taken, captured, killed, possessed, sold, purchased or shipped is guilty of a misdemeanor."[31] The penalty for most violations is a fine of at least $50 but not more than $500, or up to six months in jail, or both.[32] The department of fish and game also can collect civil damages for unlawful destruction of "any game quadruped, bird, or fish."[33]

OPERATIONAL REQUIREMENTS

Forestry Requirements

New Mexico forestry laws do not appear to contain enforceable provisions relating to nonpoint source discharges. However, New Mexico counties may enact enforceable ordinances addressing harvest practices.[34]

Agriculture Requirements

• New Mexico law has provisions for creation of local soil and water conservation districts,[35] and conservancy districts.[36] Neither seems to have regulatory authority.

• In contrast, once created, local wind erosion districts can respond to landowner complaints of property damage due to "effects of wind erosion on lands of an adjoining freeholder."[37] The districts can serve notice on a land owner that preventive measures need to be taken to minimize or avoid damage to neighbors from wind erosion, and can specify a reasonable time for the land owner to implement those measures.[38] If the owner does not implement the measures, the district must have the work performed at county expense.[39] The district must then levy a special assessment against the land to recoup the costs of performing the work.[40]

Development and Other Earth-Disturbing Activities

No relevant operating requirements are set forth, apart from those that may be contained in urban stormwater programs under the Clean Water Act or those authorized under the general zoning and construction authorities of municipalities and counties.

NEW YORK

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

New York's Environmental Conservation Law provides some enforceable authority applicable to nonpoint source discharges. Support for applying the law broadly to include nonpoint source enforcement may be provided by a declared statutory policy to maintain reasonable standards of purity of the waters of the state "and to that end require the use of all known available and reasonable methods to prevent and control the pollution of the waters of the state."[1]

• "It shall be unlawful for any person, directly or indirectly, to throw, drain, run or otherwise discharge into such waters organic or inorganic matter that shall cause or contribute to a condition in contravention of the standards adopted by the department pursuant to section 17-0301 [which establishes classification of waters and water quality standards.]"[2] Enforcement is by administrative order, injunction, civil penalty of up to $25,000 per day, or for willful violations by criminal prosecution.[3]

• "Sewage, industrial waste or other wastes, or any substance injurious to edible fish and shellfish, or the culture or propagation thereof, or which shall in any manner affect the flavor, color, odor or sanitary condition of such fish or shellfish so as to injuriously affect the sale thereof, or which shall cause any injury to the public and private shell fisheries of this state shall not be placed or allowed to run into the waters of the state in the marine district nor into any waters of Long Island, tributary to the marine district."... "Garbage, cinders, ashes, oils, sludge or refuse of any kind shall not be thrown, dumped or permitted to run into the waters of the marine district."[4] Enforcement is under the same provisions.

Other Discharge Limitations

• The Department of Health "may make rules and regulations for the protection from contamination of any or all public supplies of potable waters and water supplies...and the commissioner of environmental protection of the city of New York and the board of water supply of the city of New York may make such rules and regulations subject to the approval of the department..."[5] Enforcement is via notice of violation, enforcement by local board of health; injunction; summary abatement; and civil penalties of up to $200 for noncompliance.[6] Violations are punishable as misdemeanors punishable by fines of up to $200 and up to 1 year imprisonment.[7]

• "The commissioner [of health] shall have all necessary powers to make investigations and examinations into nuisances, or questions affecting the security of life and health in any locality."[8] The governor may request investigation by commissioner of health, and upon approval of report, the governor may declare the matters public nuisances and may order them to be changed, abated or removed; such orders are judicially enforceable.[9] In addition, "Every local board of health shall order the suppression and removal of all nuisances and conditions detrimental to life and

R0017212

health found to exist within the health district;"[10] and local health officers have power to "investigate and abate public nuisances which may affect health."[11] Such orders are judicially enforceable. Also, the Environmental Conservation Law expressly preserves state, local and private rights and remedies to "suppress nuisances or to abate any pollution now or hereafter existing".[12]

• "A person, who throws or deposits gas tar..or offal, refuse, or any other noxious offensive, or poisonous substance into any public waters, or into any sewer or stream running or entering into such public waters, is guilty of a misdemeanor."[13]

• "A person, who deposits, leaves or keeps, on or near a route of public travel...on the water, any noisome or unwholesome substance...is guilty of a misdemeanor," which is punishable by a fine of not less than $100 and/or imprisonment for 3-6 months.[14]

There is only a limited exception from nuisance liability for certain agricultural activities. "Notwithstanding any other provision of law, the agricultural activities conducted on a farm...shall not be considered a *private* nuisance, provided such agricultural activities were commenced prior to the surrounding activities, have not increased substantially in magnitude or intensity and have not been determined to be the cause of conditions dangerous to life or health as determined by the [state health] commissioner, the local health officer or local board of health...."[15]

Fish/Fisheries Laws

In addition to the provision of the water pollution title of the Environmental Conservation Law summarized above, relating to discharges of substances "injurious to edible fish and shellfish, or the culture or propagation thereof," New York law provides several other enforceable authorities potentially applicable to nonpoint discharges affecting or potentially affecting fish.

• "No person shall, at any time of the year, pursue, take, wound or *kill in any manner*, number or quantity, any fish protected by law,...shellfish,...crustacea protected by law, or protected insects, except as permitted by the Fish and Wildlife Law."[16] Moreover, "No fish, other than migratory food fish of the sea in the marine and coastal district, shall be taken except by angling."[17]

• "No dyestuffs, coal tar, refuse from a gas house, cheese factory, creamery, condensary or canning factory, sawdust, shavings, tan bark, lime, acid, oil *or other deleterious or poisonous substance* shall be thrown or allowed to run into any waters, either private or public, in quantities injurious to fish life, protected wildlife or waterfowl inhabiting those waters or injurious to the propagation of fish, protected wildlife or waterfowl therein."[18]

• New York law prohibits the placement of "sewage or other matter injurious to fish" and the erection or maintenance of any "privy, pigsty, inclosure for poultry, barn or barnyard" from which drainage or refuse can "find its way into water used by any state fish hatchery."[19]

• "No earth, soil, refuse, or solid substances...shall be disposed of in any stream or tributary thereto which is inhabited by trout" or placed on the banks "in such a manner that such solid substance can enter the stream at any stage of water level."[20]

These provisions are punishable as petty criminal violations, including imprisonment for up to 15 days and/or fine of not more than $250, plus penalties per fish, shellfish, or other aquatic creature taken.[21] Fines are slightly higher for violations of the second and third provisions noted above.[22]

OPERATIONAL REQUIREMENTS

Forestry Requirements

State forest-related laws do not appear to contain enforceable provisions related to nonpoint source discharges from forestry activities.

Agriculture Requirements

• "Every owner or occupier of agricultural land as defined [a landholding exceeding 25 acres and used for raising agricultural or forestry products; and smaller holdings with "concentrated agricultural operations" such as feedlots and poultry operations]...shall apply to the appropriate soil and water conservation district for a soil and water conservation plan for the land under his ownership or control."[23] While the obligation of the district to prepare a plan is enforceable, there is no penalty for failing to apply for or implement the required plan.

• New York also provides for registration of pesticides, certification of applicators, and other general requirements relating to pesticide use, although none that specifically address nonpoint source discharges.[24]

Development and Other Earth Disturbing Activities

Apart from requirements that may be contained in urban stormwater programs under the Clean Water Act or that may be authorized by general land use regulations, New York's nonpoint source regulatory mechanisms of this type are largely local or pursuant to state programs designed to protect particular kinds of water resources.

• The State Environmental Quality Review Act requires state and local agencies to prepare environmental impact statements, consider alternatives, and mitigate harm. SEQRA can affect control of nonpoint sources with respect to state and local government projects, major development decisions, etc.[25]

• Under the state's Wild, Scenic and Recreational Rivers law,[26] "[t]he commissioner or agency shall make and enforce regulations necessary for the management, protection, and enhancement of and control of land use and development in the wild, scenic and recreational river areas..." This authority can address nonpoint source-related activities in these areas. In wild river areas, structures and development are prohibited. In scenic river areas, mining, excavation, and public roads are prohibited, as is large-scale development (but the rules allow development on lots of 4 acres or greater). In scenic river areas, moreover, "the continuation of present agricultural practices, the propagation of crops, forest management pursuant to forest management standards duly promulgated by regulations, limited dispersed or cluster residential developments and stream improvement structures for fishery management purposes shall be permitted." In recreational river areas, the lands may be developed for the full range of agricultural uses, forest management pursuant to forest management standards duly promulgated by regulations, stream improvement structures for fishery management purposes, and may include small communities as well as dispersed or cluster residential developments and public recreational areas, as well as roads and railroads.[27] Enforcement remedies include civil penalties of $100 to $1000 per day and injunctive relief. [28]

• The Shoreowners' Protection Act[29] regulates "activities or development" which means "any land use, construction or placement by any person of a structure, or any action which materially alters the condition of land, including grading and excavating or other disturbance of soil. The term shall include the division of land into lots, parcels or sites."[30] This law too may provide usable authority in dealing with nonpoint source discharges and potential discharges. Enforcement is under the general enforcement provisions of the Environmental Conservation Law.[31]

• The Freshwater Wetlands Act[32] also provides some regulatory authority that may affect some forms of nonpoint source water pollution. Local governments may administer the law if they adopt their own ordinance; local governments may transfer these functions to the county, or the Department of Environmental Conservation may assume enforcement and implementation. DEC may designate by rule special wetlands of unique value to be subject to DEC administration. Unmapped wetlands of less than 12.4 acres in size are reserved to jurisdiction of local governments.[33] Permits are required for any form of drainage, dredging, excavation, dumping, filling of any soil, stones, sand, gravel, mud, rubbish, or fill of any kind, either directly or indirectly; erecting any structures or obstructions; "any form of pollution, including but not limited to, installing a septic tank, running a sewer outfall, discharging sewage treatment effluent or other liquid wastes into or so as to drain into a freshwater wetland; and any other activity which substantially impairs any of the several functions served by freshwater wetlands or the benefits derived therefrom..."[34] These activities are regulated within 100 feet from the boundary of any wetland; a local government or the DEC may regulate a greater distance "where necessary to protect and preserve the wetland."[35] The law provides for DEC determining what uses of mapped and classified wetlands are "compatible" and directs the commissioner to "prepare minimum land use regulations to permit only such compatible uses." Local governments must adopt consistent regulations unless "overriding economic and social considerations vital to" the local jurisdiction require a variance.[36] Freshwater wetlands permits are not required for grazing and watering livestock, or for making reasonable use of water resources, harvesting natural products of wetlands, selectively cutting timber, draining land or wetlands for growing agricultural products; public health activities and orders.[37] The law is enforceable by civil penalty of up to $3,000, order, or injunction.[38] (Also potentially relevant in some instances is a law regulating placement of fill in navigable waters).[39]

• The Tidal Wetlands Act[40] requires the commissioner to adopt "land-use regulations governing the use of" inventoried tidal wetlands. "No permits may be

R0017215

granted by any local body, nor shall any construction or activity take place at variance with these regulations."[41] The law requires state permits for draining, dredging, dumping, filling etc. as with freshwater wetlands, but lacks the "any form of pollution..." clause found in the freshwater wetlands act. It also requires a permit for "any other activity within or immediately adjacent to inventoried wetlands which may substantially impair or alter the natural condition of the tidal wetland area."[42] The law is enforceable by civil penalties of up to $10,000 per day, orders, or misdemeanor prosecutions.[43]

• The Long Island Pine Barrens maritime reserve act[44] requires a management plan to guide land use to protect the pine barrens and underlying aquifer. It is administered by participating towns, per approval by the governor. Towns and local jurisdictions must review all development applications, and must implement the law consistently with the management plan. The commission responsible for implementing the act reviews development activities in critical resource areas and reviews developments of regional significance as identified in the plan.

NORTH CAROLINA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

The North Carolina water pollution law establishes several discharge prohibitions that are potentially enforceable against nonpoint sources. A general provision prohibits the discharge of waste in violation of water quality standards; the state may issue special orders to abate water pollution; and there are specific prohibitions against unpermitted discharges to the Atlantic Ocean and other defined areas.

• Absent a permit or special order, no person shall "cause or permit any waste, directly or indirectly, to be discharged to or in any manner intermixed with the waters of the State in violation of the water quality standards applicable to the assigned classifications."[1] "Discharge of waste" is defined broadly to include "discharge, spillage, leakage, pumping, placement, emptying, or dumping into waters of the State"[2]; "waste" is defined to include sewage, industrial waste, toxic waste, and "other waste."[3] "Other waste" is defined as "sawdust, shavings, lime, refuse, offal, oil, tar chemicals, dissolved and suspended solids, sediment, and all other substances ... which may be discharged into or placed in such proximity to the water that drainage therefrom may reach the water."[4]

• Even more broadly, the Environmental Management Commission may issue special orders "to any person whom it finds responsible for causing or contributing to any pollution of the waters of the State within the area for which standards have been established."[5] The law defines "water pollution" as "the man-made or man-induced alteration of the chemical, physical, biological, or radiological integrity of the waters of the State, including, but not specifically limited to, alterations resulting from the concentration or increase of natural pollutants caused by man-related activities."[6]

• There are also specific prohibitions against the discharge of wastes or thermal discharges to waters of the Atlantic Ocean within state jurisdiction;[7] discharge of pollutants to "defined managed areas," such as fisheries, without a permit;[8] and stormwater discharges that result in water pollution.[9]

Violations of the water pollution law may be assessed civil penalties of up to $10,000 per violation per day, misdemeanor criminal fines of up to $15,000 per violation per day, or felony criminal fines of up to $250,000 per violation per day; they also are subject to injunctive relief.[10]

Other Discharge Limitations

North Carolina nuisance law may be applicable to some forms of nonpoint source pollution. There does not appear to be a statutory definition of "nuisance" that expressly includes water pollution, but common-law definitions should cover some forms of nonpoint discharge.

• State and local health officials are authorized to bring civil actions for abatement of public health nuisances,[11] as are county officials.[12] Private suits for "injuries remediable by the old writ of nuisance" are allowed under the common law and civil procedure code, and may seek damages, removal of the nuisance, or both.[13]

A recent statutory enactment makes it more difficult to bring either private or public nuisance suits against agricultural or forestry operations where the operation has been in existence for more than one year.[14] However, that provision in turn contains an exception, stating that it "shall not affect or defeat the right of any person, firm, or corporation to recover damages for any injuries or damages sustained by him on account of any pollution of, or change in condition of, the waters of any stream."[15]

Fish/Fisheries Laws

• The Environmental Management Commission is authorized "to direct the investigation of any killing of fish and wildlife which, in the opinion of the Commission, is of sufficient magnitude to justify investigation and is known or believed to have resulted from the pollution of the waters or air."[16] The Commission is required to develop and to follow fish kill response protocols for coordinating investigation of and response to "significant fish kill events."[17] Where investigation determines that a person has, with or without a permit, "negligently, or carelessly or unlawfully, or willfully and unlawfully, caused pollution of the water or air...in such quantity, concentration or manner, that fish or wildlife are killed as the result thereof, the Commission may recover, in the name of the State, damages from such person" according to an established schedule of damages.[18]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• The Sedimentation Pollution Control Act requires the Department of Environment, Health and Natural Resources to adopt "Forest Practice Guidelines Related to Water Quality," which are best management practices for forest activity.[19] The Forest Practice Guidelines are found in the North Carolina Administrative Code[20] as well as in a Forestry Practices Manual issued by the Division of Forest Resources. Forest activities conducted in accordance with these Guidelines are exempt from the other provisions of the Act,[21] which regulates certain kinds of "land-disturbing activity" that causes erosion and sedimentation.[22]

Agriculture Requirements

North Carolina has extensive provisions regulating agricultural activity that could cause nonpoint source pollution. These fall into three main categories: soil conservation measures aimed at preventing soil erosion and sedimentation; regulations on siting and operation of animal feeding operations; and pesticide-related laws. Agricultural activities also may be affected by the Watershed Supply Water Protection Act, which is discussed below in the "Development" section.

• Soil and Water Conservation Districts are authorized to prepare comprehensive plans for soil conservation, including best management practices, and "to bring such plans and information to the attention of occupiers of lands within the district."[23] Districts also may condition any grants or other assistance on landowners covenanting to adopt such practices on their lands.[24] Further, "the supervisors of any district shall have authority to formulate regulations governing the use of lands within the district in the interest of conserving the soil and soil resources and preventing and controlling soil erosion"; in such cases, regulations must be proposed by the district and approved by a two-thirds vote of district residents in a referendum.[25] When land-use regulations are in place, district supervisors are authorized to enter and inspect lands to determine whether the regulations are being observed,[26] and to file civil actions for injunctive relief, to take remedial measures, and to seek compensation for any costs incurred.[27]

• For animal feeding operations, the Animal Waste Management Systems Act "intends to establish a permitting program for animal waste management systems that will protect water quality and promote innovative systems and practices while minimizing the regulatory burden."[28] It applies to feeding operations of more than 250 swine, 100 confined cattle, 75 horses, 1000 sheep, or 30,000 confined poultry with a liquid waste management system.[29] These operations must maintain an "animal waste management system" which is defined as a "combination of structures and nonstructural practices serving a feedlot that provide for the collection, treatment, storage, or land application of animal waste,"[30] and which must be designed "so that the animal operation served by the animal waste management system does not cause pollution in the waters of the State except as may result because of rainfall from a storm event more severe than the 25-year, 24-hour storm."[31]

Operators are required to obtain a permit before constructing or operating an animal waste management system, and permit applications must include animal waste management plans with "best management practices for riparian buffers or equivalent controls, particularly along perennial streams."[32] The operations are required to undergo an annual inspection and review, and to give immediate notification of direct discharges of animal waste or other immediate threats to the environment.[33] However, "except as required by federal law or regulations, the [Environmental Management] Commission may not adopt effluent standards or limitations applicable to animal or poultry feeding operations," though it may assess fines of up to $10,000 against conveyances "constructed for the purpose of willfully discharging pollutants to the waters of the State."[34]

• Similarly, the Swine Farm Siting Act applies to operations raising more than 250 swine on a single site.[35] It requires that swine houses or lagoons holding animal waste "shall be located at least 1,500 feet from any occupied residence; at least 2,500 feet from any school, hospital, or church; and at least 500 feet from any property boundary"; it also requires that "the outer perimeter of the land area onto which waste is applied from a lagoon that is a component of a swine farm shall be at least 50 feet from any boundary of property on which an occupied residence is located and from any perennial stream or river, other than an irrigation ditch or canal."[36] However, swine houses or lagoons can be sited closer to residences, schools, hospitals, churches or property boundaries (though apparently *not* to rivers and streams) than the stated limits "if written permission is given by the owner of the property and recorded with the Register of Deeds."[37] "Any person owning property directly affected by the siting requirements" may bring a civil action against the swine farmer; "persons directly affected" are defined to include those owning "property that abuts a perennial stream or river, or on which a perennial stream or river is located."[38] Plaintiffs may seek injunctive relief, damages and, in appropriate cases, court costs, attorney and expert witness fees.[39]

• The North Carolina Pesticide Law[40] provides that "no person shall handle, transport, store, display or distribute pesticides in such a manner as to endanger man and his environment or to endanger food, feed, or any other products that may be transported, stored, displayed, or distributed with pesticides" and that "no person shall dispose of, discard, or store any pesticides or pesticide containers in such a manner as may cause injury to humans, vegetation, crops, livestock, wildlife, or to pollute any water supply or waterway."[41] It also establishes pesticide registration requirements and prohibits distribution or sale of unregistered or mislabelled pesticides.[42]

The Pesticide Board is authorized to adopt regulations for carrying out the Pesticide Law, including regulations governing handling, transport, storage, display, distribution, and disposal of pesticides.[43] The Board issues licenses for pesticide dealers and applicators,[44] and may require reports and conduct inspections, investigations and administrative hearings.[45] Violations of the Act or regulations are subject to misdemeanor criminal penalties and/or civil penalties of up to $2,000 per violation.[46] The Board may seek civil injunctive relief in court, and has emergency authority for license suspensions and seizures in cases of imminent hazard caused by any pesticide, whether registered or unregistered.[47]

• The Watershed Supply Water Protection Act, discussed in detail below, requires local governments to develop water supply watershed protection programs that govern development in key areas and that could affect agricultural activities. However, the Act expressly states that "the reduction of agricultural nonpoint source discharges shall be accomplished *primarily* through the Agriculture Cost Share Program for Nonpoint Source Pollution Control,"[48] a separate program that encourages voluntary implementation of best management practices.[49] In addition, the Act provides that any local watershed protection ordinances governing agricultural and silvicultural activities "shall be no more restrictive than those adopted by the [Environmental Management] Commission."[50]

Development and Other Earth-Disturbing Activities

• The Sedimentation Pollution Control Act[51] applies to certain kinds of "land-disturbing activity" that causes erosion and sedimentation. "Land-disturbing activity" is defined as "any use of the land by any person in residential, industrial, educational, institutional or commercial development, highway and road construction and maintenance that results in a change in the natural cover or topography and that may cause or contribute to sedimentation."[52] It excludes agricultural activities, forestry activities conducted in accordance with best management practices, mining, or emergency activities.[53] For land-disturbing activity, the Act establishes mandatory standards including: (1) no activity is permitted in proximity to a lake or natural watercourse unless there is a buffer zone "along the margin of the watercourse of sufficient width to confine visible siltation within the twenty-five percent of the buffer zone nearest the land-disturbing activity"; (2) graded slopes and fills shall not be steeper "than the angle which can be retained by vegetative cover or other adequate erosion-control devices or structures"; and (3) tracts where more than an acre of land is uncovered must include, "such sedimentation and erosion control devices and practices as are sufficient to retain the sediment generated by the land-disturbing activity within the boundaries of the tract" during construction, and permanent ground cover following completion of construction."[54]

Under the Act, the Sedimentation Control Commission is authorized to "develop, promulgate, publicize and administer a comprehensive State erosion and sedimentation control program," including rules and regulations. The rules are to "contain conservation standards for various types of soils and land uses, which standards shall include criteria and alternative techniques and methods for the control of erosion and sediment resulting from land-disturbing activities."[55] The Commission is also required to develop a model local erosion control ordinance and to review and approve proposed programs submitted by local governments and State agencies and erosion control plans submitted by project proponents.[56] The Act sets out a procedure for approval of proposed erosion control plans; in addition to decisions on the merits, plans may be disapproved based on a finding of previous violations of the Act or failure to pay a previous penalty.[57] The Commission may delegate its authority to review and approve erosion control plans to local governments with State-approved erosion control programs.[58]

The Commission and local governments with delegated authority are authorized to inspect sites, issue notices of violation, and specify dates for compliance.[59] Further, the Secretary of Environment, Health and Natural Resources is authorized to issue stop-work orders for violations of the Act or Rules if the violation is knowing and willful and: "(1) Off-site sedimentation has eliminated or severely degraded a use in a lake or natural watercourse or ... such degradation is imminent; (2) Off-site sedimentation has caused severe damage to adjacent land or ... such damage is imminent; [or] (3) the land-disturbing activity is being conducted without an approved plan."[60] The Act provides for up to $500 per violation per day for violation of the Act, an ordinance, rule or order; civil penalties of up to $5,000 per violation per day for violation of a stop-work order; and criminal misdemeanor fines of up to $5,000 for knowing and willful violations.[61] The Secretary, or a local government with delegated authority, may also impose restoration requirements or seek an injunction, and "any person injured by a violation" of the Act or the rules may seek injunctive relief and/or damages.[62]

• The Watershed Supply Water Protection Act requires the Environmental Management Commission to "adopt rules for the classification of water supply watersheds and that establish minimum statewide water supply watershed protection requirements applicable to each classification to protect surface water supplies by (I) controlling development density, (ii) providing for performance-based alternatives to development density controls that are based on sound engineering principles, or (iii) a combination of both (I) and (ii)."[63] Further, the Commission "may designate water supply watersheds or portions thereof as critical water supply watersheds and impose management requirements that are more stringent than the minimum statewide water supply watershed management requirements," and adopt rules that require that any permit issued by a local government for a development or construction activity conducted by that local government within a designated water supply watershed be approved by the Department [of Environment, Health, and Natural Resources] prior to issuance."[64]

Under the Act, local governments are required to develop a water supply watershed protection program and ordinances for enforcing the minimum management requirements, and they "may adopt such ordinances pursuant to their general police power, power to regulate the subdivision of land, zoning power, or any combination of such powers."[65] The Commission must assume enforcement authority where a local government "fails to adopt a program that meets the requirements of this section or whenever a local government fails to adequately administer and enforce the provisions of its program."[66] However, if a local government wishes to adopt an ordinance more stringent than Commission requirements, it must give notice to the Commission;[67] and local ordinances governing agricultural and silvicultural activities "shall be no more restrictive than those adopted by the Commission."[68] Local governments that fail to adopt or enforce water supply watershed management programs are subject to civil penalties of up to $10,000 per month; persons who violate the management requirements are subject to civil penalties of up to $10,000 per violation per day.[69]

• Under the Natural and Scenic Rivers Act, "the State Utilities Commission may not permit the construction of any dam, water conduit, reservoir, powerhouse transmission line, or any other project works on or directly affecting any river that is designated as a component or potential component of the State Natural and Scenic Rivers System. No department or agency of the State may assist by loan, grant, license, permit, or otherwise in the construction of any water resource project that would have a direct and adverse affect on any river that is designated as a component or potential component of the State Natural and Scenic Rivers System."[70] The Act's provisions "shall not, however, preclude licensing of or assistance to a development below or above a designated or potential component."[71] The Act authorizes the Department of Environment, Health and Natural Resources to adopt rules to implement the Natural and Scenic Rivers System,[72] and violations of the Act or rules is subject to injunctive relief and to a misdemeanor fine of no more than $50 per violation per day.[73]

• The Coastal Area Management Act applies only to counties within the coastal zone, and requires the "development and adoption of State guidelines for the coastal area and the development and adoption of a land-use plan for each county within the coastal area, which plans shall serve as criteria for the issuance or denial of development permits."[74] The guidelines "shall consist of statements of objectives, policies, and standards to be followed in public and private use of land and water areas within the coastal area," and "shall give particular attention to the nature of development which shall be appropriate within the various types of areas of environmental concern that may be designated by the [Coastal Resources] Commission.[75] "Areas of environmental concern" are defined to include coastal wetlands, estuarine waters, renewable resource areas (public water supplies and forest land), fragile or historic areas, areas with rights of public access or public trust, natural-hazard areas, outstanding resource waters, and fisheries;[76] there is a public procedure for designating areas of environmental concern.[77] Once areas of environmental concern are designated, all local land-use plans, local ordinances, and permits issued within the areas must be consistent with the state guidelines.[78]

Within the coastal zone, city and county governments must submit implementation and enforcement plans to the state, which either approves the plan and delegates enforcement authority or assumes enforcement until an adequate plan is approved.[79] The Act authorizes the Secretary to seek injunctive relief, misdemeanor criminal penalties for knowing and willful violations, and administrative civil penalties of up to $250 for "minor developments" or $2500 for "major developments."[80] Local officials also may seek injunctions for minor developments.[81]

NORTH DAKOTA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

North Dakota's water pollution control law includes a provision that may be used to take enforcement action against nonpoint sources that pollute the waters of the state. Another provision may allow enforcement action against certain unpermitted nonpoint source activities that cause pollution.

- North Dakota's Water Pollution Act empowers the state Department of Health ("Department") generally to prevent "new or existing pollution of waters of the state" and, in cooperation with the state water commission, to formulate water quality standards.[82] More specifically, North Dakota law makes it unlawful "to cause pollution of any waters of the state or to place or cause to be placed any wastes in a location where they are likely to cause pollution of the waters of the state."[83] This provision is not restricted to point sources nor to "discharges."

- State law also requires a permit for a range of activities and facilities that would cause a "discharge" or "*would otherwise alter the physical, chemical, or biological properties of any waters of the state in any manner not already lawfully authorized.*"[84] Although the term "discharge" is defined as limited to discharge from a point source,[85] the remaining language may allow the state to apply this provision to some nonpoint sources that cause pollution.

Enforcement provisions authorize the Department to initiate court action, administrative enforcement proceedings, issue emergency orders or seek emergency injunctions.[86] Fines of up to $25,000 for the first and $50,000 for subsequent convictions for willful violations and/or jail terms of one or two years are available. Civil penalties of up to $10,000 per day are also available for violations without willful intent.[87]

Other Discharge Limitations

- State law establishes water resource districts that are empowered, among other acts, "to make rules and regulations concerning the management, control, regulations, and conservation of waters and *prevent the pollution, contamination, or other misuse of water resources*, streams, or bodies of water included within the district"[88] and, also, to protect native woodland bordering within two hundred feet of a riverbank subject to overflow flooding by ordering or taking "appropriate legal action" (civil suits and administrative orders) to halt its destruction or ordering "appropriate planting of a shelterbelt."[89] Violation of these provisions constitutes a Class B misdemeanor, which means up to 30 days in jail and a $500 fine.[90]

- Municipalities have the authority "to prevent the pollution" of a municipal or public water supply within one mile of the municipal limits and "to compel cleaning, abatement or removal of...any other unwholesome nauseous thing..."[91] Municipalities may order abatement of violations and seek fines and penalties as set by ordinance.[92]

• Under North Dakota law, "nuisance" is defined as an act that interferes with or obstructs "a lake, navigable river, bay, stream, canal, basin..." However, this statute protects an agricultural operation from a nuisance action if it has been in operation for more than one year and was not a nuisance at the time the operation began, except where there is negligence or improper operation.[93] Any action taken under "the express authority of a statute" cannot be deemed a nuisance.[94] A range of actions on behalf of the state are possible to abate a nuisance, including actions brought by the attorney general, the state health officer, local boards of health, state's attorney or any citizen of the county where a nuisance exists.[95] A private nuisance may be abated by a public body or officer and is actionable by a private person to whom the nuisance is "specially injurious."[96] Sanctions include an action for abatement and/or past damages[97] and, for public nuisances, criminal sanctions of up to one year in prison and a $1000 fine.[98]

• Municipalities have their own power to determine what constitutes a nuisance and "to prevent, abate and remove the same."[99]

Fish/Fisheries Laws

• State law prohibits the "deposit [of] any refuse or other matter which may prove harmful to fish or fish eggs," in waters in which the state or federal government "has deposited or may deposit, fish, fish eggs, or fry, or in which fish naturally abound..."[100] These are considered criminal actions that are Class B misdemeanors punishable by a maximum of 30 days in jail and a $500 fine.[101]

OPERATIONAL REQUIREMENTS

Forestry Requirements

North Dakota does not appear to have laws relating to forestry that contain enforceable provisions with respect to nonpoint source discharges, apart from the water resource district law described above.

Agriculture Requirements

• North Dakota law provides for the creation of soil conservation districts to prevent and control soil erosion through the formulation of land use regulations.[102] These districts may set up boards that grant variances from the regulations and that are also authorized to bring enforcement actions for violations that increase erosion. In the absence of compliance, the court may empower the district to enter upon the land, force compliance and assess costs and interest.[103]

• The water quality regulations require the Department's approval of concentrated livestock feeding operations.[104] The Department enforces these provisions as part of the water pollution program. See enforcement mechanisms outlined <u>supra</u> under the general discharge limitations section.

• The Commissioner of Agriculture ("Commissioner") is charged with enforcement of the state pesticide laws. The Commissioner is authorized to develop pollution prevention criteria for areas utilized for mixing and storing agricultural chemicals at the retail and end use levels.[105] In addition, the state pesticide law makes it illegal to discard, store, display or dispose of pesticide "in such a manner as to endanger the environment."[106] The Commissioner may seek civil action, issue an administrative order or file a criminal complaint if the administrative order is ignored.[107]

• State law directs the Commissioner to adopt rules "to minimize the possibility of chemical, pesticide, fertilizer, or other contamination of irrigation water supply"[108] and may issue an administrative order for compliance or seek relief in court.[109] The statute provides for civil penalties of up to $5000 or, for criminal proceedings, a fine of up to $1000 of a year in jail.[110] A violation also constitutes a Class A misdemeanor.[111]

Development and Other Earth-Disturbing Activities

• North Dakota statutes contain general language delegating various zoning authorities to cities and counties. Counties are authorized to regulate property development through zoning regulations that are designed to promote certain purposes, including "to conserve and develop natural resources"[112] a violation of which is a Class B misdemeanor. Local authorities determine the "means and methods" for enforcement of zoning ordinances,[113] and affected property owners may seek civil enforcement of township regulations.[114]

No specific enforcement requirements relating to earthmoving or construction activities were identified, apart from any that may implement urban stormwater programs under the Clean Water Act.

OHIO

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Ohio has a broad prohibition that prohibits nonpoint source water pollution as well as point source water pollution. However, it has exemptions that are intended to assure that certain nonpoint source discharges regulated under other state laws are not subject to this section. It also exempts nonpoint source animal waste discharges.

• "No person shall cause pollution or place or cause to be placed any sewage, industrial waste, or other wastes in a location *where they cause pollution* of any waters of the state, and any such action is hereby declared to be a public nuisance, except in such cases where the director of environmental protection has issued a valid and unexpired permit, or renewal thereof...or an application for renewal is pending."[1] The prohibition is enforced by administrative orders, injunctions, and civil penalties of up to $10,000 per day.[2] However, this prohibition exempts "[a]pplication of materials to land for agricultural purposes or runoff of such materials from such application[,] or pollution by animal waste or soil sediment including attached substances, resulting from farming, silvicultural, or earthmoving activities regulated by Chapter 307 or 1515 of the Revised Code."[3] The referenced sections are laws under which Ohio counties regulate earthmoving associated with development, and under which soil and water conservation districts regulate nonpoint source discharges of sediment as described below. The broad prohibition also does not apply to excrement of domestic and farm animals and runoff therefrom.[4]

Other Discharge Limitations

• Ohio has multiple provisions in its general nuisance laws applicable to nonpoint source pollution.[5] The water pollution law expressly preserves common law nuisance remedies for water pollution.[6] Local governments also have inherent power to abate nuisances.[7] However, Ohio law provides that complaints regarding agricultural nuisances may only be made to the chief of the Department of Natural Resources' Soil and Water Conservation Division, so that they may be investigated by the division.[8] In a private civil action for a nuisance involving agricultural pollution it is an affirmative defense that the defendant is operating under a management plan approved by the division.[9]

State law also defines the following offenses:

• "No person, regardless of intent, shall deposit litter or cause litter to be deposited on any public property, or private property not owned by him or in or on waters of the state..."[10] "Litter" means "garbage, trash, waste, rubbish, ashes, cans, bottles, wire, paper, cartons, boses, automobile parts, furniture, glass, or anything else of an unsightly or unsanitary nature."[11] This provision is enforceable by any sheriff, police officer, constable, wildlife officer, conservancy district officer or any other law enforcement officer.[12] Forest officers are specifically directed to enforce this provision "in or along any water course within, abutting, or upstream of any area administered by" the Department of Natural Resources.[13] This is a misdemeanor of the third degree (no more than 60 days and/or $500). The court may also impose restitution for all or part of any property damage. And the court may, in lieu of or in addition to any penalty, require such person to "remove litter from any public or private property, or in or on waters of the state.[14]

• "No person shall cause or allow offal, filth, or noisome substances to be collected or remain in any place to the damage or prejudice of others or of the public."[15] The law exempts persons engaged in agriculture provided they are operating outside the city limits of a municipal corporation and "in such manner so as not to have a substantial effect on the public health, safety or welfare." This exemption also applies to "any similar ordinances, resolutions, rules, or other enactments of a state agency or political subdivision"[16] This offense is a misdemeanor of the third degree (no more than 60 days and/or $500); The court may also impose restitution for all or part of any property damage.[17]

• "No person shall....corrupt or render unwholesome or impure, a watercourse, stream, or water."[18] This is a misdemeanor of the third degree (no more than 60 days and/or $500); the court may also impose restitution for all or part of any property damage.[19]

• "No person shall intentionally throw, deposit, or permit to be thrown or deposited [various wastes associated with coal and coal products, cheesemaking, and petroleum handling]" either into water "or a place from which it may wash therein."[20] This is a misdemeanor of the first degree (no more than 6 months and/or $1,000); the court may also impose restitution for all or part of any property damage.[21]

• "No person shall put the carcass of a dead animal, or the offal from a slaughterhouse, butcher's establishment, packing house, or fish house, or spoiled meat, spoiled fish, or other putrid substance or the contents of a privy vault" into the waters or lands where it may enter the water.[22] "No person shall maliciously put a dead animal, carcass, or part thereof, or other putrid, nauseous, or offensive substance into, or befoul, a well, spring, brook, or branch of running water, or a reservoir of a water works, of which use is or may be made for domestic purposes."[23] These offenses are minor misdemeanors punishable by up to $100 fine; the court may also impose restitution for all or part of any property damage.[24]

Fish/Fisheries Laws

• Ohio's wildlife law contains a provision stating that "No person shall place or dispose of in any manner, any garbage, waste, peelings of vegetables or fruits, rubbish, ashes, cans, bottles, wire, paper, cartons, boxes, parts of automobiles, wagons, furniture, glass, oil, or anything else of an unsightly or unsanitary nature...in any ditch stream, river, lake, pond, or other water course...or upon the bank thereof where the same is liable to be washed into the water either by ordinary flow or floods."[25] However, this provision does not apply to substances placed in accordance with a permit under the water pollution control provision referenced above "or exempted by such section" -- hence exempting runoff of waste or sediment from agriculture, silviculture, and earthmoving where otherwise regulated, and exempting animal manure generally. The wildlife law prohibition is enforced in local courts as a misdemeanor by wildlife officers or local law enforcement officials.[26] The first offense is punishable by no more than 60 days and/or $500 fine; subsequent offenses by no more than 6 months and/or $1,000 fine.[27] The court may also impose restitution for all or part of any property damage.

OPERATIONAL REQUIREMENTS

Forestry and Agriculture Requirements

• Ohio law specifically provides a program for control of sediment and related runoff from agricultural and silvicultural activities. The law directs Ohio DNR's Division of Soil and Water Conservation, with the approval of the Soil and Water Conservation Commission, to adopt rules establishing "technically feasible and economically reasonable standards to achieve a level of management and conservation practices in farming or silvicultural operations that will abate wind or water erosion of the soil or abate the degradation of the waters of the state by animal waste or by soil sediment including substances attached thereto."[28] The law further empowers the Division to "establish procedures for...enforcement of rules for agricultural pollution abatement."[29] The law is implemented at the farm and forest level by soil and water conservation districts.[30]

The regulations under this program provide for control of sheet and rill erosion, wind erosion, and concentrated channel erosion.[31] Farmers are required to apply and maintain "Field Office Technical Guide" measures.[32] The regulations specifically provide that there shall be no earth disturbing practices (including tillage) immediately adjacent to waters of the state "except for those practices constructed or implemented in accordance with generally accepted agricultural, silvicultural and engineering practices."[33] The regulations make Best Management Practices enforceable, and provide that operation and maintenance plans "may" be filed with county soil and water conservation districts.[34] The districts must approve operations and management plans.[35]

The statute expressly does not regulate the excrement of domestic or farm animals or runoff therefrom into the waters of the state, however, except from concentrated animal feeding operations (CAFOs).[36] With respect to CAFOs the regulations provide that to abate pollution by animal waste from collection, storage, or treatment facilities, the operator shall "design, construct, operate, and maintain" such facilities to prevent discharge, and follow the standards in the "Field Office Technical Guide."[37] The operator must prevent seepage from animal waste management facilities and "if pollution of waters of the state occurs from an existing facility, corrective measures shall be taken."[38] CAFO pollution from land application, flooding, waste waters, and other related activities must also be prevented.[39]

If the sediment and erosion control program is being administered by the local soil and water conservation district, complaints may be investigated by the district and -- after the district invites the violator to comply, provides any assistance, and gives a voluntary period to correct the problem[40] -- orders may be issued by the Division based on the district's findings of violation, subject to an administrative hearing.[41] The Division of Soil and Water Conservation may order compliance with an operation and maintenance plan, after conducting an adjudicatory hearing.[42] However, the Division may not issue an order requiring the recipient to implement a pollution abatement practice eligible for cost sharing unless public funds are actually available at not less than 75 percent of the cost (not to exceed $15,000/person/yr).[43] Division enforcement orders are appealable to the court of common pleas.[44] The orders are also judicially enforceable.[45] Violation of an order is a misdemeanor punishable by imprisonment up to 6 months, up to $1,000 per day, and restitution.[46] Also the state may recover any expenditures from the "agricultural pollution abatement fund" for expenditures to protect public health.[47] In addition, the Division may seek a court order against a discharger at any time if the violation "causes pollution of the waters of the state and constitutes a danger to public health."[48]

• Ohio law provides for pesticide regulation, including custom applicator licensing, public operator licensing, and private applicator certification.[49] It sets out prohibitions including uses inconsistent with labeling "or other restrictions imposed by the director of agriculture."[50] It also provides that "no person shall transport, store, dispose of, display, or distribute any pesticide or pesticide container in such manner as to have unreasonable adverse effects on the environment."[51] Enforcement includes misdemeanor prosecution, and injunction, as well as civil penalties not to exceed $5,000 for a first offense and $10,000 for any subsequent offense.[52]

Although Ohio has numerous laws relating to agricultural ditching and drainage, none speaks directly to the issue of preventing or controlling nonpoint source water pollution.[53]

Development and Other Earth-Disturbing Activities

Apart from any programs for the control of urban stormwater under the federal Clean Water Act, or that may be authorized by general land use regulation, such as zoning, state law also provides the following authorities applicable to nonpoint source discharges.

• State law empowers the Division of Soil and Water Conservation, subject to approval of the Ohio Soil and Water Conservation Commission, to adopt rules for "technically feasible and economically reasonable standards to achieve a level of management and conservation practices that will abate wind or water erosion of the soil or abate the degradation of the waters of the state by soil sediment in conjunction with land grading, excavating, filling, or other soil disturbing activities on land used or being developed for nonfarm commercial, industrial, residential, or other nonfarm purposes."[54] Municipalities and counties may develop their own programs. The division "may recommend" criteria and procedures for "approval of urban sediment pollution abatement plans and issuance of permits" prior to the disturbance of five or more acres; while areas less than five acres do not need plans or permits, they are not exempt from the "other provisions of this chapter and rules adopted under them."[55] Developments of five or more acres must develop an "erosion and sediment control plan" which must be approved by the state or local approving agency, and must institute stormwater controls.[56] Areas of any size require use of conservation practices including sediment trapping, stabilization of denuded areas, stream crossing work; no dumping into water resources or into such proximity that it may slough, slip, or erode into the waters unless authorized.[57]

• Coastal erosion areas are designated for Lake Erie jurisdictions by DNR. Rules govern "erection, construction, and redevelopment" of structures in these erosion areas; a permit is required and may be granted only if "the proposed site is protected by an effective erosion control measure approved by the director."[58] Enforcement mechanisms include stop work orders, injunctions, fines, and civil penalties of up to $5,000.[59] A state permit is not required if the county or municipality has its own equivalent program.

OKLAHOMA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Oklahoma's water pollution control law contains a general prohibition against water pollution or placement of wastes that are likely to cause pollution. This prohibition has been construed by regulation to apply to nonpoint sources and to be enforceable by the state's Department of Environmental Quality (DEQ). However, Oklahoma law also removes agricultural and silvicultural nonpoint sources from the DEQ's jurisdiction, and places them under voluntary or cost-share programs.

• The water quality code makes it "unlawful for any person to cause pollution of any waters of the state or to place or cause to be placed any wastes in a location where they are likely to cause pollution of any air, land or waters of the state," and declares any such action to be a public nuisance.[1] This provision is expressly construed by regulations to include nonpoint sources.[2] The regulations also expressly state that nonpoint sources of pollution are to be investigated and enforced as in other cases of pollution.[3] Generally, in water pollution cases, the Executive Director of the Department of Environmental Quality "shall make an order requiring such pollution to cease within a reasonable time, or requiring such manner of treatment or of disposition of the sewage or other polluting material as may in his judgment be necessary to prevent further pollution. It shall be the duty of the person to whom such order is directed to fully comply with the order of the Executive Director."[4] In cases of noncompliance, the Department may institute an action in the proper court, and seek an injunction, a civil penalty of up to $10,000 per violation, and/or misdemeanor criminal penalties of $200 to $10,000, imprisonment for up to 6 months, or both.[5]

However, Oklahoma law divests the DEQ of jurisdiction over agricultural and silvicultural nonpoint sources, instead assigning jurisdiction to the Department of Agriculture for agricultural discharges and to the Conservation Commission for erosion control.[6] Neither of these entities appears to have enforcement authorities applicable to nonpoint source discharges.[7]

Other Discharge Limitations

• The Oklahoma code provides that "a nuisance consists in unlawfully doing an act ... which either: (1) [a]nnoys, injures or endangers the comfort, repose, health, or safety of others; or (2) [o]ffends decency; or (3) [u]nlawfully interferes with, obstructs or tends to obstruct, or renders dangerous for passage, any lake or navigable river, stream, canal or basin, or any public park, square, street or highway; or (4) [i]n any way renders other persons insecure in life, or in the use of property, provided, this section shall not apply to preexisting agricultural activities."[8] It also states that "a public nuisance is one which affects at the same time an entire community or neighborhood, or any considerable number of persons, although the extent of the annoyance or damage inflicted upon the individuals may be unequal."[9] The statutory definition of "nuisance" has been held to encompass both private and public nuisances in the context of a water pollution case.[10] However, prior existing agricultural activities are presumed reasonable and not a nuisance unless they have "substantial adverse effects."[11]

Remedies against public nuisance include indictment or information, civil actions, or abatement.[12] A "private person may maintain civil action for a public nuisance if it is specially injurious to himself."[13] Public nuisances also are subject to abatement by "any public body or officer,"[14] or by the person injured.[15] Public nuisance also is a misdemeanor offense where penalties are not otherwise prescribed.[16] While most Oklahoma nuisance cases dealing with water pollution stem from petroleum industry operations, there are cases finding liability for discharge of improperly treated municipal sewage,[17] ejection of excess storm water,[18] and crop damage from drifting herbicides.[19] One case enjoined development of a landfill based on anticipatory nuisance theory.[20]

• The Oklahoma code also provides that "no person, firm, [etc.] shall pollute or permit the pollution of the water supply of a municipality, or any stream, pond, spring, lake, or other water reservoir or groundwater aquifer, which is used or which is being held for use as a water supply by a municipality."[21] For purposes of this section, "pollution" is defined as "contamination or other alteration of the physical, chemical, or biological properties of any natural waters of the state, or such discharge of any liquid, gaseous, or solid substance into any waters of the state as will or is likely to create a nuisance or render such waters harmful or detrimental or injurious to the health, safety, or welfare of the general public, or to domestic, commercial, industrial, agricultural, recreational, or other legitimate beneficial uses, or to livestock, wild animals, birds, or fish or other aquatic life."[22] To enforce this section, "a municipality may bring an action in the district court to enjoin any activity that will cause pollution of the water supply of a municipality whether or not such activity is regulated, licensed, or inspected."[23] Municipalities also may bring a civil action in which "the measure of damages shall be the amount which will compensate for the detriment caused" by the pollution.[24]

• Finally, "every person who throws or deposits any gas tar, or refuse of any gas house or factory, into any public waters, river or stream, or into any sewer or stream emptying into any such public waters, river or stream, is guilty of a misdemeanor."[25]

Fish/Fisheries Laws

• The Wildlife Conservation Code provides that "no person may deposit, place, throw, or permit to be deposited, placed or thrown, any lime, dynamite or other explosive, poison, drug, sawdust, salt water, crude oil or any other deleterious, noxious or toxic substance in any waters of this state, or in any place where such substances may run or be washed into such waters."[26] Violators are subject to a criminal fine of from $100 to $500 per day.[27] In addition, restitution damages "may be recovered by a state environmental regulatory agency on behalf of the state in a civil action brought in the district court."[28] Offending parties are "liable to pay the state an amount equal to the sum of money reasonably necessary to restock such waters, [including] the replacement cost of fish killed, costs of shipment and handling, and costs incurred in investigating, locating or establishing the responsible person."[29]

R0017237

OPERATIONAL REQUIREMENTS

Forestry Requirements

• The State Board of Agriculture "shall administer silviculture best management practices in cooperation with forestry land users under the provisions of state and federal water pollution laws, which include the process to identify silviculturally-related nonpoint sources of pollution as defined by the Oklahoma Environmental Quality Code and setting forth procedures and methods to control to the extent feasible such sources."[30] The statute does not expressly set out enforcement authority for best management practices.

Agriculture Requirements

• The boards of county commissioners are "authorized to devise methods and means to stop and/or prevent soil erosion or soil drifting in their respective counties."[31] The board may issue orders directing "that the land subject to soil erosion and drifting be cultivated, plowed, listed or planted, or may in any other manner take such steps as are necessary to prevent such soil erosion and drifting."[32] If the land owner fails to comply with the order, the board is authorized to enter the land to take action to prevent soil erosion and drifting. In this case, the board also may assess reasonable restitution charges for the services taken against the affected lands. There also is a Conservation District Act,[33] which establishes a Conservation Commission that administers cost-share programs to encourage the adoption of management practices to prevent soil erosion and nonpoint source pollution. However, "[t]he Commission is not authorized to implement mandatory compliance with management practices to abate agricultural nonpoint source pollution," and does not appear to have enforcement authority.[34]

• The Oklahoma Feed Yards Act establishes a license requirement for animal feed yards, and states that "owners and operators who are granted a feed yards license shall ... provide adequate drainage from feed yards premises of surface waters falling upon the area occupied by such feed yards; [and] take such action as may be necessary to avoid pollution of any stream, lake, river or creek."[35] Regulations implementing the act require that Best Management Practices (BMPs) shall be utilized by concentrated animal feeding operations. The Act also requires that "a Pollution Prevention Plan shall be developed for each licensed facility. Pollution Prevention Plans shall ... include measures necessary to limit pollutants in runoff or groundwater."[36]

It is unlawful to operate a feed yard without a permit from the State Board of Agriculture.[37] The Board is authorized to enter premises to determine whether there are any violations,[38] and may revoke a permit after a hearing and an administrative determination that the operator has violated the act or regulations.[39] The Board also may institute a civil action or criminal prosecution; a feed yard owner or operator "who fails to take such action as may be reasonable and necessary to avoid pollution of any stream, lake, river or creek ... or who violates any rule or regulation of the Board adopted to prevent water pollution from feed yards pursuant to this act shall, upon conviction, be deemed guilty of a misdemeanor, and upon conviction thereof may be punished by a fine of $200 to $10,000 for each violation, by imprisonment for not more than 6 months for each violation, or by the assessment of a civil penalty up to $10,000 for each violation, or by any of such fine, imprisonment, and civil penalty."[40]

In 1998, amendments provided additional coverage, including requiring annual training for employees responsible for treatment, storage or application of animal waste, increased setback requirements, and additional specific requirements for the Pollution Prevention Plan and design standards for waste retention structures.[41]

• In 1998, Oklahoma also enacted legislation to regulate poultry waste in order to protect water quality. The law requires submittal of an animal waste management plan by every poultry feeding operation. It prohibits application of waste to land when the ground is frozen, during rainstorms, or where the land is already saturated by phosphorous or subject to severe erosion. Soil testing is require every three years, except in watersheds threatened by nutrients, where it is required annually. Commercial and private applicators of poultry waste must be certified by the state. All poultry feeding operations must register with the state annually and must utilize Best Management Practices, including no discharge of poultry wastes to the waters of the state, and isolation of stored poultry wastes from outside surface drainage by dikes and other structures. Penalties for violations will be under a point system established by the Board of Agriculture; applying poultry waste without a certificate is punishable by a $5,000 fine.[42]

• Under the agriculture code, "no person owning or operating a fertilizer storage facility or a commercial fertilizer facility shall discharge, ... place or cause to be placed any fertilizer material in a location where it is likely to cause contamination of any surface water or groundwater of this state."[43] However, "the provisions of this subsection shall not prohibit or otherwise restrict the land application of fertilizer for agriculture purposes or plant growth."[44] After a public hearing, the Board of Agriculture has authority to assess an administrative penalty of $100 to $1,000 for each violation.[45] The Board or its agent also may apply to court for an injunction, notwithstanding the existence of other remedies at law. Violations also are reported to the district attorney, who may institute appropriate proceedings to prosecute. Criminal violations are misdemeanors, punishable by a fine of $200 - $10,000, and/or imprisonment of up to 6 months.[46]

• The water quality code contains prohibitions on the agricultural use of sewage sludge near water. Under these provisions, "sludge shall not be applied within two (2) feet of the highest seasonal water table nor applied to the land within one hundred (100) feet of a stream or body of water; and ... sludge shall not be applied within two hundred fifty (250) feet of a public or private water supply.[47] As in other kinds of pollution cases, the Executive Director of the Department of Environmental Quality "shall make an order requiring such pollution to cease within a reasonable time, or requiring such manner of treatment or of disposition of the sewage or other polluting material as may in his judgment be necessary to prevent further pollution."[48] For noncompliance, the Department may institute an action in the proper court, and seek an injunction, a civil penalty of up to $10,000 per violation, and/or misdemeanor criminal penalties of $200 to $10,000, imprisonment for up to 6 months, or both.[49]

• The pesticide law [50] includes registration of pesticides and licensing of pesticide applicators, but no provisions directly applicable to nonpoint pollution. The Board of Agriculture is authorized to adopt regulations on pesticide use as appropriate.[51]

Development and Other Earth-Disturbing Activities

• The water quality code directs the Environmental Quality Board to promulgate rules bringing stormwater discharges into the state point source permitting program.[52] These regulations require "construction sites associated with industrial activity, that will result in the disturbance of 5 or more acres total land area" to obtain a permit for discharge of stormwater.[53] The permit requires a storm water pollution prevention plan to be developed for each construction site covered by the permit. Enforcement of the prohibitions is through the state pollution discharge elimination system. Thus, strictly speaking, such sites are treated as point sources.

• The municipality code requires that "lands [acquired by the municipality for waterworks] within 660 feet of the margin of a reservoir at maximum high water and necessary for natural drainage into the reservoir, shall not be used ... for any purpose other than the protection of the reservoir and the waters thereof from contamination and pollution. No structures shall be placed on such lands by the municipality, individual or corporation, except as are necessary in the furtherance of the protection of the reservoir from contamination or pollution, and in the use of the water.[54] A municipality has a right of action for damages resulting from pollution of its water supply, and damages "shall be the amount which will compensate for the detriment caused thereby."[55]

OREGON

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Oregon's water pollution control law includes some provisions that may be used to take enforcement action against nonpoint source discharges that pollute the waters, that consist of wastes or that result in water quality violations except for forestry conducted in compliance with BMPs.

• Oregon's general discharge limitation provision prohibits persons from polluting "any waters of the state," from placing waste where it is "likely to escape or be carried into the waters of the state by any means," and from discharging wastes into water if the discharge reduces water quality "below the standards established by rule for such waters..."[1] There are exemptions for discharges in accordance with a valid discharge permit.[2] The general prohibition is not expressly limited to point sources and thus can address nonpoint source discharges as well. Violations of the general prohibition provision are deemed a "public nuisance."[3]

Other Discharge Prohibitions

• As noted above, public nuisance law applies to pollution discharges. However, Oregon law preempts any local government laws that make a forest or farm practice a nuisance, and the statute grants immunity from private nuisance actions for farming or forest practices "occurring on lands zoned for those uses" or "allowed as preexisting nonconforming use," unless the claim is for damage to crops, death, or serious physical injury.[4]

Fish/Fisheries Laws

• Oregon state law establishes liability "where the injury, death, contamination or destruction of fish or other wildlife...or other wildlife habitat results from pollution" or from a permit violation. The Oregon Department of Environmental Quality ("DEQ"), Department of Fish and Wildlife or Attorney General may bring a civil suit if 60 days have passed following state agencies issuing a notice of violation and demand for reparations without compliance.[5] The person is liable to the state for the value of the injured or destroyed fish or wildlife and for all costs of restoring fish and wildlife production and habitat.[6]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• Under the Forestry Practices Act (or "Act"), forest operations in Oregon must be conducted in accordance with the rules and standards "relating to air and water pollution control..." Further, state law requires the state Forestry Board to establish best management practices ("BMPs") "to insure that to the maximum extent practicable nonpoint source discharges of pollutants resulting from forest operations on forestlands do not impair the achievement and maintenance of water quality standards."[7] Operators are required to comply with BMPs, unless they can demonstrate that alternative practices yield better results.[8] BMPs are subject to review pursuant to a petition on the basis that forestry operations being conducted in accordance with them is contributing to violations of water quality standards. The Forestry Board must revise the BMPs within two years or dismiss the petition.[9] The State Forester enforces these requirements through inspection, enforcement, notice of violation, and issuance/service of administrative orders, such as cease and desist or reparation orders.[10] The Act provides for general criminal and civil penalties,[11] including potential civil sanctions of up to $5000 per violation.[12] However, where forest operators are in compliance with the BMPs, then the operations are not considered in violation of any water quality standards.[13] Also, forestry operations are immune from private nuisance actions if they are in compliance with the Act and with BMPs.[14]

• The Act contains other requirements governing forestry operations, including authorizing the Forestry Board to require a written plan for forestry operations if operations are within one hundred feet of a stream used by fish or for domestic use.[15] Also, operators must give written notice of chemical applications to the State Forester who in turn must notify persons who request it, are within 10 miles of the application and hold downstream surface water rights.[16] Enforcement authorities are the same as those identified above under the Act.

• State law only permits the state Environmental Quality Commission and DEQ to impose "effluent limitations" on nonpoint source discharges resulting from forest operations if such limitations are federally mandated.[17] See supra enforcement of general discharge limitations.

Agriculture Requirements

• The Oregon Department of Agriculture ("DOA") is required to develop rules "that directly regulate farming practices...that are for the purpose of protecting water quality" and that are applicable to "exclusive farm zones" under the state planning law or other agricultural lands.[18]

• The DOA may also designate areas to be governed by a water quality management plan and adopt rules that require landowners in the affected area to perform those actions necessary to carry out the plan.[19] In general, all activities, which include pesticide use, irrigation, grazing, within the affected area of the plan must be conducted "in full compliance with the plan and rules implementing the plan and with all rules and standards of the EQC relating to water pollution control..."[20] The DOA is authorized to determine compliance with the management plan through entry and inspection and must give notice of violation and opportunity for compliance prior to assessing a civil penalty which can be up to $2500 for the first violation and up to $10,000 for a second violation.[21] In addition, violations of the plan and/or rules are subject to all remedies and sanctions available to the DEQ or the EQC.[22]

• In general, pesticide use is regulated under the water quality management plan discussed above, but Oregon law also contains a specific pesticide registration and labeling requirement with concomitant civil penalties.[23] However, "reasonable and prudent" pesticide use is an accepted farm practice and thus immune from private nuisance suits.[24]

• State law establishes a permit requirement for confined animal feeding operations containing conditions that "assure that wastes are disposed of in a manner that does not cause pollution of the surface and ground waters of the state."[25] The program is administered by the DOA which has the authority "to enter and inspect" and to conduct investigations at any time that a complaint alleges a violation presenting "an immediate threat to public health and safety."[26] The statute also authorizes civil penalties for operating without a permit and for violations "relating to the control and prevention of water pollution from a confined animal feeding operation."[27]

• Also Oregon regulations encourage all government agencies to coordinate planning and implementation of nonpoint source controls including "possible modification of irrigation practices to reduce or minimize adverse impacts from irrigation return flows" and "streambank erosion reduction projects."[28]

Development and Other Earth-Disturbing Activities

• Oregon has an integrated state land use planning process. When the state planning commission ("commission") prepares comprehensive land use plans, setting the parameters for local land use planning, it must "give consideration to" a variety of environmentally sensitive areas, including flood plains, estuarine areas, tide, marsh and wetland areas, lakes and lakeshores, coastal areas, and wilderness and scenic areas.[29] The commission also has authority to designate "areas of critical state concern" as part of the planning process.[30] In terms of enforcement, the commission is authorized to order local governments to bring land use requirements into compliance with the comprehensive plan.[31] The commission, as well as the county governing bodies, has investigative and hearing authority for alleged violations in the "areas of critical state concern," and injunctive relief is available.[32] Remedies for noncompliance include withholding state grant money to local governments and legal and equitable remedies.[33] Construction erosion control measures are authorized under the statewide land use planning law.

PENNSYLVANIA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Pennsylvania's Clean Streams Law contains several provisions that may be used to take enforcement action against nonpoint source discharges.

- "It shall be unlawful for any person or municipality to put or place into any of the waters of the Commonwealth, or allow or permit to be discharged from property owned or occupied by such person or municipality into any of the waters of the Commonwealth, any substance of any kind or character resulting in pollution as herein defined."[1] "Pollution" under the Clean Streams Law "shall be construed to mean contamination of any waters of the Commonwealth such as will create or is likely to create a nuisance or to render such waters harmful, detrimental or injurious to public health, safety or welfare, or to domestic, municipal, commercial, industrial, agricultural, recreational, or other legitimate beneficial uses, or to livestock, wild animals, birds, fish, or other aquatic life, including but not limited to such contamination by alteration of the physical, chemical or biological properties of such waters, or change in temperature, taste, color or odor thereof, or the discharge of any liquid, gaseous, radioactive, solid, or other substances into such waters."

- Regulations further specify that "The waters of the Commonwealth may not contain toxic substances attributable to point or nonpoint source waste discharges in concentrations or amounts that are inimical to the water uses to be protected."[2] And further that "Persons and municipalities engaged in an activity which includes the impoundment, production, processing, transportation, storage, use, application or disposal of polluting substances shall take necessary measures to prevent the substances from directly or indirectly reaching waters of this Commonwealth, through accident, carelessness, maliciousness, hazards of weather or from another cause."[3]

- "No person or municipality shall place or permit to be placed, or discharged or permit to flow, or continue to discharge or permit to flow, into any of the waters of the Commonwealth any industrial wastes, except as hereinafter provided in this Act."[4] The term industrial waste includes any substance other than sewage resulting from any "establishment."

- The Department of Environmental Protection also has the authority to regulate and "enforce reasonable orders and regulations for the protection of any source of water for present or future supply to the public, and prohibiting the pollution of any such source of water rendering the same inimical or injurious to the public health or objectionable for public water supply purposes."[5]

Violation of the Clean Streams Law is a summary offense punishable by a fine of not less than $100 nor more than $10,000 for each offense, and, in default of payment of such fine, imprisonment for ninety days.[6] Willful or negligent violations are

R0017246

misdemeanors of the third degree punishable by a fine of not less than $2,500 nor more than $25,000 for each separate offense and/or imprisonment in the county jail for a period of not more than one year.[7] Civil penalties may be assessed not to exceed $10,000 per day per violation,[8] and the department may issue orders or seek injunctive relief.[9]

Other Discharge Limitations

• Nuisance law is available as an enforcement mechanism, and the Clean Streams Law declares certain water pollution discharges abatable as nuisances. "The discharge of...any substance into the waters of this Commonwealth, which causes or contributes to pollution as herein defined or creates a danger of such pollution is hereby declared not to be a reasonable or natural use of such waters, to be against public policy and to be a public nuisance."[10] "Any activity or condition declared by this act to be a nuisance or which is otherwise in violation of this act, shall be abatable in the manner provided by law or equity for the abatement of public nuisances."[11]

While Pennsylvania law does limit nuisance claims against agricultural operations that have been in existence for a year or more, these limitations expressly do not restrict or impede the authority of the Commonwealth to protect the public health, safety and welfare, nor do they affect or defeat private actions for damages resulting from violations of law or "on account of any pollution of, or change in condition of, the waters of any stream."[12]

Fish/Fisheries Laws

• No person shall: "Allow any substance, deleterious, destructive, or poisonous to fish, to be turned into or allowed to run, flow, wash or be emptied into any waters ..."[13] "In criminal prosecutions under this section for water pollution known to be injurious to fish, it is not necessary to prove that the violation has actually caused the death of, or damage to, any particular fish."[14]

• "No person shall alter or disturb any stream, stream bed, fish habitat, water or watershed in any manner that might cause damage to, or loss of, fish without the necessary permits."[15]

• "It is unlawful for any person to throw, discard, leave, emit, deposit or allow the depositing of any garbage, bottles, cans, rubbish, wire, glass, paper, cardboard or wooden boxes, or cartons or any other type of debris, trash or other thing or substance in or along any waters or on any lands adjacent or contiguous to waters or in such manner that the thing or substance deposited flows into or is carried by wind into such waters or lands."[16] The Commonwealth may recover damages in a civil action against "any person who kills any fish or who injures any streams or stream beds by pollution or littering."[17]

The Fish & Boat Commission may pursue criminal prosecution for violations of the law and regulations. Sanctions are up to $5,000 and/or imprisonment for up to five years, and a fine of $10 per fish killed.[18]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• With respect to erosion and sediment control, forest harvesting activities involving earthmoving must comply with the regulatory program described under "Development and Other Earth-Disturbing Activities" below, including obtaining the necessary permit. Enforcement is under the Clean Streams Law.

Agriculture Requirements

• With respect to erosion and sediment control, although they do not need to obtain a permit, landowners engaged in plowing and tilling must nevertheless develop and implement an erosion and sediment control plan.[19] Enforcement is under the Clean Streams Law.

• The Nutrient Management Act requires livestock operations to engage in nutrient management planning for all operations where the animal density exceeds two Animal Equivalent Units per acre. All such plans must be developed for operators by nutrient management specialists, and must be fully implemented within three years of their approval by local conservation districts. Also, any agricultural operation found in violation of the Clean Streams Law may be required to submit a plan within three months thereof.[20] Final regulations under the Act were published in June 1997. Violations of plans are punishable by a civil penalty of not more than $500 for the first day of each offense and $100 for each additional day of continuing violation. The State Conservation Commission may issue a warning in lieu of penalty where the owner or operator takes mediation action to resolve the violation. Enforcement orders and injunctive relief are available.[21]

• Special water pollution control regulations provide that manure storage facilities and land application of animal manures are exempt from water pollution control permitting if the design and operation are in accordance with practices described in Pennsylvania publications of best practices for these activities.[22] Otherwise, permitting is needed under the Clean Stream Law.

• Pennsylvania requires certification of pesticide applicators,[23] and provides that "An application of a pesticide may not be made where weather conditions are such that it can be expected that the pesticide will move off of the proposed application site."[24]

Development and Other Earth-Disturbing Activities

• Earthmoving activities within the Commonwealth must "be conducted in such a way as to prevent accelerated erosion and the resulting sedimentation." The person engaged in such activities "shall develop, implement and maintain erosion and sedimentation control measures which effectively minimize accelerated erosion and sedimentation. The erosion and sedimentation control measures shall be set forth in a plan ... and be available at all times at the site of the activity."[25] A permit is required prior to commencement of the activity. A permit is not required if the activity involves "plowing or tilling for agricultural purposes" or if the earthmoving activity disturbs less than 25 acres. DEP can reduce the acreage limitation on a statewide basis, for special areas, or for counties or municipalities.[26] Administration and enforcement of the program may be delegated to counties and other units of local government that have an acceptable plan approved by the DEP.[27] Enforcement is under the Clean Streams Law, source of the discharge provisions discussed above, but also includes the withholding of building permits.[28]

PUERTO RICO

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Puerto Rico's water pollution control law includes one provision that may be used to take enforcement action against nonpoint source discharges capable of leading to violation of water quality standards, and another that allows the Commonwealth's regulatory authority to adopt enforceable prohibitions on unpermitted discharges that could be used to regulate nonpoint sources.

- "It shall be unlawful for any person, directly or indirectly, to throw, discharge, pour or dump, or permit to be thrown, discharged, poured or dumped into the waters, any organic or inorganic matter capable of polluting or of leading to the pollution of such waters in such manner as to place them out of the minimum standards of purity that the Secretary of Health [now Board of Environmental Quality] may establish..."[1] This provision is enforceable by a notice, and after one year, final order requiring cessation of water pollution.[2] Injunctive relief and penalties for violations are available.

- The Board of Environmental Quality is authorized "to forbid any discharge of pollutants by any natural or juridical person...which do not have the corresponding permit issued by the Board."[3] This provision allows the Commonwealth to regulate nonpoint source pollution by permit if it chooses to do so. Enforcement is via administrative orders, injunctions, and penalties.

Other Discharge Limitations

- Statutory authority over public health nuisances includes authority to promulgate regulations "guarding from contamination all streams from which water for drinking or domestic purposes is taken."[4] Violations of any such regulations are subject to fines of $25 to $100 and/or jail sentence of 1-2 months.[5]

- Placing "any dead animal, or the offal or filth from any slaughterhouse, pen or butcher shop" into a water body used for drinking water is prohibited, and is punishable by a fine up to $1000 and/or jail sentence up to one year.[6]

- There is also general authority to abate nuisances. Nuisance is defined as "anything which is injurious to health, or indecent, or offensive to the senses, or an obstruction to free use of property, so as to interfere with the comfortable enjoyment of life or property."[7] Public nuisance defined as "anything which is injurious to health, or indecent, or offensive to the senses, or an obstruction to free use of property, so as to interfere with the comfortable enjoyment of life or property by an entire community or neighborhood."[8]

Fish/Fisheries Laws

• "It is prohibited to throw or cause to be thrown or deposited into any lake, lagoon, spring, river, brook, channel, or any body of water of Puerto Rico, oils, acids, poisons, or any other substance which kills or destroys fish, crustacea, or mollusca."[9] But there is an exception from the prohibition for "the residue or waste of any factory or industrial or agricultural enterprise" if a permit is obtained from the Secretary of Agriculture and Commerce [later Secretary of Natural Resources]. Violations by legal persons are subject to a minimum fine of $500; by natural persons, a maximum fine of $200 and/or jail sentence of up to 90 days.

OPERATIONAL REQUIREMENTS

Forestry Requirements

Puerto Rico laws do not appear to contain specific enforceable requirements regarding forest practices.

Agriculture Requirements

• Soil conservation districts are authorized "to formulate regulations governing the use of lands within the district to formulate soil resources and prevent and control erosion....Land regulations adopted pursuant to this section shall have the force and effect of law in the said district, and shall be binding upon all occupiers of lands within such district."[10] Regulations may include: prohibition of operations or practices; requiring particular methods of cultivation or land use; cropping programs or tillage practices; "and provisions requiring any other means, measures, operations, and programs as may assist conservation of soil resources and prevent or control soil erosion in the district." Supervisors may file for judicial enforcement of regulations.[11] Violation of land-use regulations is a misdemeanor, punishable by fine of $25-$100.[12]

• "Cattle or horses shall be bathed or watered only at the places set aside for this purpose."[13]

• Laws regulating pesticide applicators may provide some basis for addressing nonpoint source pollution resulting from improper practices.[14]

Development and Other Earth-Disturbing Activities

No operating requirements are set forth, apart from any that may be contained in urban stormwater programs under the Clean Water Act or that may be authorized by general land use regulations. However, land use regulations, particularly in the coastal zone, address some activities that may result in nonpoint source discharges.

RHODE ISLAND

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Rhode Island's water pollution law includes a provision that may be used to take enforcement action against nonpoint source discharges of pollutants that are placed on land, or nonpoint source discharges of solid waste or debris.

- "It shall be unlawful for any person to place any pollutant in a location where it is likely to enter the waters or to place or cause to be placed any solid waste materials, junk, or debris of any kind whatsoever, organic or non organic, in any waters."[1] These prohibitions on the placement of "any pollutant" on land where it may enter water, and on the placement of solid wastes, junk, and debris in any water, can be applied to nonpoint source water pollution. (In contrast, another subsection prohibits "discharge [of] any pollutant" from a "point source.)"[2] Enforcement includes notices of violation, compliance orders, injunctive relief, criminal liability, and civil penalties of up to $25,000 per day.[3]

Other Discharge Limitations

- Common law nuisance liability may be available with respect to some instances of nonpoint source discharges. However, nuisance liability under Rhode Island law does not apply to odors or dust from farming practices, nor to the use of pesticides, rodenticides, insecticides, herbicides or fungicides.

- A state wetlands law contains a provision that may also provide some enforceable authority with respect to certain nonpoint discharges. "No person, firm, industry, company, corporation, city, town, municipal or state agency, fire district, club, nonprofit agency, or other individual or group, may...place trash, garbage, sewage, highway runoff, drainage ditch effluents [sic], earth, rock, borrow, gravel, sand, clay, peat or other materials or effluents upon... or otherwise change the character of any fresh water wetland as herein defined without first obtaining the approval of the director of the department of environmental management."[4] However, normal farming and ranching activities are exempt from the permitting process.[5]

Fish/Fisheries Laws

- "No person shall place, deposit, or explode any substance injurious to the health or life of a fish in any stream or fresh water pond within this state..."[6] This provision is enforceable by the attorney general in court; and the sanction is a misdemeanor punishable "by a fine of not more than $500 or imprisonment for up to 90 days or both."[7]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• Cutting of trees for commercial forest products requires registration with the department of environmental management as a "woods operator" and cutting without such registration is a misdemeanor punishable by a fine of $100 to $500.[8] This provision may serve as a basis for imposing some requirements.

Agriculture Requirements

The state's agriculture laws do not appear to contain independently enforceable provisions relating to regulation of agricultural nonpoint source discharges.

• Pesticides being used in violation of any requirements may be subject to an order, and violations may give rise to civil penalties of up to $10,000 and criminal penalties for knowing violations of up to $25,000 and/or 60 days imprisonment.[9]

Development and Other Earth-Disturbing Activities

Apart from any requirements that may be contained in urban stormwater programs under the Clean Water Act or that may be authorized by general land use regulation such as zoning, Rhode Island law provides some additional authority.

• Cities and towns may adopt a model soil erosion and sediment control ordinance that is an enforceable mechanism.[10]

• The state's Coastal Resources Management Program can adopt regulations affecting activities within 200 feet of shoreline features, which includes some limits relevant to nonpoint source pollution. Enforcement is via cease and desist orders, and administrative penalties of up to $1000 plus $100 per day (with aggregate limit of $5000); or misdemeanor convictions for knowing violations, with a $500 fine and/or 3 months imprisonment.[11]

SOUTH CAROLINA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

The state has a broad general pollution prohibition, applicable to nonpoint sources as well as point sources.

• "It shall be unlawful for any person, directly or indirectly, to throw, drain, run, allow to seep or otherwise discharge into the environment of the State organic or inorganic matter, including sewage, industrial wastes and other wastes, except as in compliance with a permit issued by the Department [of Health and Environmental Control]."[1] Enforcement includes administrative "orders requiring the discontinuance of the discharge of sewage, industrial waste, or other wastes into any waters of the state," injunctive relief, civil penalties of up to $10,000 per day, and criminal penalties for willful or negligent violation of $500 to $25,000 per day and/or imprisonment for up to two years.[2]

Other Discharge Limitations

• Common law and statutory nuisance remedies for water pollution are preserved by the state's Pollution Control Act.[3]

• Some nuisance-related provisions related to navigable waterways may have limited utility with respect to some forms of nonpoint source water pollution. Cutting trees, tree tops, brush or logs or "throwing any refuse material whatever into any navigable river or harbor" is a misdemeanor punishable by fine of up to $250 or imprisonment for up to two years.[4] "Any person who shall fell, cut, or throw or cause to be felled, cut, or thrown across or into any of such streams any tree, log or other timber or any trash, brush, debris or obstruction of any kind whatsoever will be guilty of a misdemeanor" and is punishable by fine of up to $50 or imprisonment for up to 30 days.[5] Obstruction of a navigable stream without a permit or authorization is a nuisance.[6]

Fish/Fisheries Laws

• "Any person who discharges organic or inorganic matter into the waters of this State ... to the extent that the fish, shellfish, aquatic animals, wildlife or plant life indigenous to or dependent upon the receiving waters or any property are damaged or destroyed shall be liable to the State for such damages as may be proved [in court]... The civil remedy herein provided shall not be exclusive and any agency, commission, department or political subdivision of the State with appropriate authority may undertake in its own name an action to recover such damages as it may deem advisable independent of this subsection." [7]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• State law requires registration of foresters and licensing, but does not directly regulate forest practices on private lands. Violation of registration requirements is punishable as a misdemeanor.[8]

• The "Erosion and Sediment Reduction Act,"[9] discussed at greater length under "built environment" below, applies to forestry and other land-disturbing activities on State-owned lands. "The Department [of Health and Environmental Control] must promulgate regulations for erosion and sediment reduction and stormwater management only on land either owned by the State, a State agency, or a quasi-state agency or land under the management or control of such an entity..."[10] A state agency found by DHEC in noncompliance must take steps to correct the problem. In addition, the State Engineer must ensure that the regulations are followed on all land and land disturbing activities within the State Engineer's jurisdiction. However, the DHEC regulations do not apply to lands controlled by the State Forestry Commission,[11] which applies its own "Erosion, Sediment and Stormwater Management Plan" on state forest lands.[12] The State Forestry Commission must develop this "plan" in consultation with DHEC to reduce erosion, sediment on forest land owned or managed by the Forestry Commission, and must implement these regulations.[13]

Agriculture Requirements

• "The commissioners of any [soil and water conservation] district may formulate regulations governing the use of lands within the district in the interest of conserving soil and soil resources and preventing and controlling soil erosion."[14] The process may include a public hearing, but must be approved by a referendum by landowners and garner at least 2/3 support; however, commissioners are not obliged to adopt regulations even if the 2/3 vote approves them.[15] A court may order the landowner to perform the work necessary to comply, or may authorize the commissioners to enter upon the land and do so and recover their costs from the landowner.[16]

• The state's chemigation law provides that any irrigation system which is designed or used for the application of fertilizer, pesticide, or chemicals must be equipped with an anti-syphon device adequate to protect against contamination of the water supply. Violations are punishable by a civil penalty of up to $500 per day.[17]

• South Carolina law provides for registration of pesticides, licensing of dealers, and certifying applicators, but has no specific water pollution provisions. Enforcement is via license actions, civil penalties, and misdemeanor prosecutions.[18]

Development and Other Earth-Disturbing Activities

• The Stormwater Management and Sediment Reduction Act applies throughout the state on lands not owned by the state.[19] It is administered by DHEC in coastal counties, elsewhere by local government - as a delegated program subject to DHEC oversight.[20] Unless exempted, no person may engage in a land disturbing activity without first submitting a stormwater management and sediment control plan to the appropriate implementing agency and obtaining a permit to proceed."[21] The law further provides for development of watershed master plans in designated watersheds, and all projects must be consistent with these plans.[22] Under the regulations, projects less than 2 acres must submit a simplified plan (no permit, but inspection and enforcement); projects 2-5 acres require a permit, meeting design and performance standards; projects 5 acres or greater require a permit (integrated with NPDES stormwater program); and projects 10 acres or greater must have sediment basin or other practice meeting an 80 % removal efficiency standard. The regulations also specify maintenance requirements and correction of offsite damage.[23] The law exempts: agricultural activities (except buildings larger than 1 acre); forestry activities; mining activities; single family residences not part of a common development; activities otherwise licensed or permitted where conditioned on compliance, public service corporation activities otherwise regulated, railroad activities, and state-owned or managed lands where the activities are regulated by the Erosion and Sediment Reduction Act, discussed below.[24] Enforcement includes issuance of stop work orders, required submission of plans, and correction of violations,[25] and civil actions for civil penalties of up to $1,000 per day, and injunctive relief.[26] This law also provides for designation of special protection areas. "In addition to the other regulatory requirements in this chapter, designated watersheds shall have the regulatory requirements for land disturbing activities within the watershed clearly specified through a watershed management plan which includes nonpoint source pollution control, stormwater management, and flood control components..."[27]

• The Erosion and Sediment Reduction Act applies only to state lands, and is administered by DHEC with the cooperation of various affected state agencies and land managers.[28] "The Department must promulgate regulations for erosion and sediment reduction and stormwater management only on land either owned by the State, a State agency, or a quasi-state agency or land under the management or control of such an entity..."[29] The DHEC and Dept. of Transportation are to promulgate regulations together for transportation related matters.[30] Regulations provide that there can be no land disturbing activity without an "erosion and sediment control and stormwater management plan approved by the State Engineer or the former Land Resource Conservation Commission.[31] Furthermore, all erosion, sediment, and stormwater problems not addressed by the plans must be corrected.[32] A state agency found by DHEC in noncompliance must take steps to correct the problem. In addition, the State Engineer must ensure that the regulations are followed on all land and land disturbing activities within the State Engineer's jurisdiction. No sanctions are specified in the law.[33]

• State law establishes a comprehensive regulatory scheme for South Carolina' 8 coastal counties.[34] The law provides for a management plan by DHEC's Coastal Division,[35] and that zoning ordinances in critical areas are adopted as part of the plan if they meet its provisions.[36] The law provides for a permit required for uses in the critical area,[37] gives DHEC exclusive regulatory authority,[38] and provides the criteria for permit approval or denial - including effects on marine life, erosion, etc.[39] Enforcement is via injunction, administrative order, permit revocation, civil penalties of up to $1,000 per day, or misdemeanor prosecutions.[40]

• Scenic river regulations and prohibitions apply only to lands and easements that have been acquired by the state.[41]

• A permit is required to obstruct navigable waters, and enforcement is via permit actions, abatement, and misdemeanor sanctions.[42]

SOUTH DAKOTA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

The South Dakota water pollution control law prohibits discharges of waste that result in water quality violations, and the placement of wastes in locations where they are likely to cause pollution.

• No person may discharge any wastes into any waters of the state which reduce the quality of such waters below the water quality level existing on March 27, 1973,[1] or place or cause to be placed any wastes in a location where they are likely to cause pollution of any waters of the state.[2] "Wastes" are defined as "sewage, industrial wastes, pollutants and all other liquid, gaseous, solid, radioactive, or other substances which may pollute or tend to pollute any waters of the state."[3]

The statute does not limit "discharge" to point sources, but the regulations provide permits only for point source discharges,[4] and expressly exclude from permitting requirements nonpoint discharges from agriculture.[5] This exclusion from permitting does not address the "place or cause to be placed" language of the statute.

The water management board is required to promulgate rules to establish water quality standards and classify water according to its beneficial uses.[6] The standards must protect public health, use of waters for public water supplies, propagation of fish and aquatic life and wildlife, recreational purposes and agricultural, industrial, and other legitimate uses.[7] Discharge of wastes is allowed when it is demonstrated to the water management board, after a hearing, that there may be a discharge that will not result in the violation of applicable water standards and that is justifiable as a result of "necessary economic or social development."[8] The water management board may not allow a discharge if the discharge results in a violation of the existing water standards. The state's antidegradation policy provides that regulatory requirements are to be achieved for point sources and that nonpoint sources are to be "controlled through cost-effective and reasonable best management practices."[9]

The water management board may issue an order for a violation of the water quality law or any rule or permit issued under it.[10] Violations may be abated as a public nuisance, and the department of water and natural resources also may bring an action for an injunction against the continuation of any threatened or actual violation or any final order of the secretary or the water management board.[11] In addition to or instead of issuing an order, the board or secretary may initiate an appropriate action for recovery of penalties.[12] Any person who violates an order is liable for a civil penalty not to exceed $10,000 or for damages to the environment, or both.[13] Criminal violations are Class 1 misdemeanors subject to a fine not to exceed $10,000 and/or a sentence of up to one year imprisonment.[14]

Other Discharge Limitations

• In addition to the prohibition in the water quality law, no person may dispose of or place solid waste in state waters without authorization.[15] "Solid waste" is defined as "any garbage, refuse, sludge from a waste treatment plant and other discarded materials, including solid, liquid, semisolid or contained gaseous material resulting from industrial, commercial and agricultural operations."[16] However, the solid waste statute may not be construed to prohibit a farmer or rancher from disposing of solid waste from normal farming operations or ordinary domestic activities upon his own land, provided such disposal does not create a nuisance or a hazard to public health, does not violate a local ordinance, will not unlawfully pollute ground or surface waters or does not violate the chapter.[17]

Suspected violations of this chapter may be addressed by notice, proposed corrective action, an administrative hearing, or suit for an injunction.[18] A violation is a Class 2 misdemeanor, and the violator is also subject to a civil action for recovery of penalties of not more than $10,000 per day per violation, for damages to compensate the state for impairment of the environment, or both.[19] Actions for civil penalties or damages shall, upon demand, be tried by a jury.

• The South Dakota Code defines a nuisance as, among other things, unlawfully doing an act which annoys, injures, or endangers the comfort, repose, health, or safety of others, or in any way renders other persons insecure in life or in the use of property.[20] Water pollution has been held to be a nuisance in specific cases.[21] Remedies for a nuisance include injunction, damages, abatement and, in cases of public nuisance, indictment or information as prescribed by statute.[22] By statute, no agricultural operation may be deemed a nuisance if it has been in operation for more than one year and was not a nuisance at the time that operation began, unless the nuisance results from negligent or improper operation.[23] However, this exemption does not apply to actions to recover damages for any injuries sustained as a result of pollution or other change in the quantity or quality of water, or as a result of any overflow of land.[24]

• In addition, boards of county commissioners have power to enact ordinances to regulate and prevent the placing of ashes, dirt, garbage or any offensive matter in any body or stream of water within the county (as long as it is outside of an incorporated municipality).[25] They also have the power to enact ordinances to regulate and compel the cleansing, abatement or removal of any sewer, cesspool, or any "unwholesome or nauseous thing or place."[26] Municipalities have similar powers within their jurisdictions.[27] If there is a violation or threatened violation of an ordinance, a board of county commissioners may institute an appropriate action to seek an injunction, to be brought by the state's attorney.[28] Counties and municipalities also may use their authority to enforce ordinances with fines not to exceed $200, imprisonment not to exceed 30 days, or both.[29]

Fish/Fisheries Laws

• The fish and wildlife code makes it a Class 1 misdemeanor to empty or place any sawdust, manure, refuse matter, sedimentary materials, pollutants or chemicals of any kind in the waters of the state containing fish and wildlife, or to deposit the same within such distance that it may be carried into such waters by natural causes, except as expressly permitted.[30] A knowing or willful violator is liable to compensate the department of game, fish and parks for restoration of losses.[31] However, liability may not be imposed upon an agricultural producer if the fish or wildlife kill occurred as a result of normal farming practices.[32] Enforcement is the responsibility of the department of game, fish and parks, as well as the state's attorney, sheriff, constables and other peace officers.[33]

OPERATIONAL REQUIREMENTS

Forestry Requirements

State forestry laws do not appear to contain enforceable provisions relating to nonpoint source discharges.

Agriculture Requirements

• Soil conservation districts may be organized upon petition of ten percent of the voters in a territory.[34] Districts may adopt conservation standards for the control of erosion and sediment resulting from land-disturbing activities.[35] "Land-disturbing activity" is defined as "any clearing, tilling, grazing, grading, excavating, transporting and filling of land, and the implementation of silviculture activities resulting in soil erosion from water or wind and the movement of sediments into any and all waters of the state."[36] Districts may also designate "fragile land" areas where the land is so erosive as to cause a public hazard when converted to cropland use.[37]

If conservation standards are adopted, each permit-issuing agency must include those provisions in its permit procedure for activities within the district to ensure compliance with the standards.[38] However, no person engaging in land-disturbing activities is required to prepare a plan, file an application or otherwise report these activities directly to the conservation district, unless the conservation district determines that an activity is violating adopted standards, in which case the land disturber shall be required to prepare an erosion and sediment control plan and have it approved by the district.[39]

Any person adversely affected by land-disturbing activities may file a petition alleging a violation of the chapter with the conservation district or the permit-issuing agency. The "petitioned agency" shall investigate and "take appropriate action and advise the petitioner of its disposition of his petition."[40] Any person who intentionally refuses or fails to comply with the action directed by the petitioned agency may lose eligibility for financial assistance from any state agency or political subdivision involved in natural resources.[41] Either a permit-issuing authority or a soil conservation district may, upon petition or upon its own volition, in the enforcement of its orders, commence an action in circuit court for an injunction or other relief to enforce the provisions of the chapter.[42]

• The pesticide law provides that "no person may transport, store, use, dispose of or handle any pesticide, pesticide container, rinsate or application equipment in such a manner as to endanger or cause injury to humans, vegetation, crops, livestock, wildlife or beneficial insects or to pollute the groundwater or surface water."[43] The secretary of agriculture may promulgate rules governing these activities, and commercial pesticide applicators are required to obtain a license.[44] Violation of the rules or the license requirement is subject to a civil penalty not to exceed $5000 per violation, and applying pesticides without a license is a Class 2 criminal misdemeanor.[45] The secretary of agriculture also may bring an action to enjoin violation of the chapter.[46]

• The water management board is required to promulgate rules for chemigation equipment standards, performance standards and installation requirements and for requirements regarding the use and location of antipollution devices.[47] Failure to comply with the board's rules is a Class 2 misdemeanor; in addition, a civil fine of not more than $500 may be imposed.[48]

• Counties and municipalities may adopt ordinances for the purpose of protecting public groundwater supplies from pollution.[49] The ordinances must be consistent with the voluntary wellhead protection strategies and guidelines established under the federal Safe Drinking Water Act,[50] and may include ordinances to: 1) establish wellhead protection areas; 2) zone for the purpose of protecting such areas from pollution; 3) monitor and regulate activities and sources of potential or actual pollution within the areas; and 4) provide for the containment and cleanup of pollution or other remedial action.[51] If there is a violation or threatened violation of an ordinance, a board of county commissioners may institute an appropriate action to seek an injunction, to be brought by the state's attorney.[52] County and municipal governments also may use their general authority to enforce ordinances with fines not to exceed $200, imprisonment not to exceed 30 days, or both.[53]

• A new provision prohibits confined animal feeding operations built after July 1, 1997 from being located over a shallow aquifer unless a groundwater discharge permit has been approved.[54]

Development and Other Earth-Disturbing Activities

Apart from any programs for the control of urban stormwater under the federal Clean Water Act or that may be authorized by general land use regulation such as zoning, state law provides the following authorities.

• As noted above, counties and municipalities may adopt ordinances for the purpose of protecting public groundwater supplies from pollution.[55] The ordinances must be consistent with the voluntary wellhead protection strategies and guidelines established under the federal Safe Drinking Water Act,[56] and may include ordinances to: 1) establish wellhead protection areas; 2) zone for the purpose of protecting such areas from pollution; 3) monitor and regulate activities and sources of potential or actual pollution within the areas; and 4) provide for the containment and cleanup of pollution or other remedial action.[57] If there is a violation or threatened violation of an ordinance, a board of county commissioners may institute an appropriate action to seek an injunction, to be brought by the state's attorney.[58] County and municipal governments also may use their general authority to enforce ordinances with fines not to exceed $200, imprisonment not to exceed 30 days, or both.[59]

TENNESSEE

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Tennessee's water pollution law contains general discharge provisions that may be enforceable against some nonpoint source discharges that consist of sewage or wastes. However, agricultural and silvicultural activities are exempted.

• The state's Water Quality Control Act of 1977 prohibits "the discharge of sewage, industrial wastes or other wastes into waters, or a location from which it is likely that the discharged substance will move into waters...."[1] The Act further provides that it is unlawful and a public nuisance to "discharge any substance into the waters of the state or to place...any substance...in any location where such substances, either by themselves or in combination with others" will cause damage as specified in the law.[2] The damages enumerated include: harm to the public health, safety or welfare; harm to the health of animals, birds, fish or aquatic life; hindering the uses of the waters of the state; or leaving waters of the state in a condition that violates state water quality standards.[3] The prohibition does not apply to discharge that are due to an unavoidable accident or that have been properly authorized.

However, the Act states that it does not apply to "any agricultural or forestry activity or the activities necessary to the conduct and operations thereof or to any lands devoted to the production of any agricultural or forestry products, unless there is a point source discharge from a discernible, confined, and discrete water conveyance."[4] And it "grants no new authority over non-point sources" that was not established under the previous Water Quality Control Act.[5]

Enforcement of the Act is through corrective action orders, civil penalties up to $10,000 per day, criminal (Class C misdemeanor) prosecution, and injunctions.[6] Violators are also subject to a cause of action for damages.[7]

Other Discharge Limitations

• Under the Sanitary Engineering Law, "(t)he defiling by any person of any water supply of a public water system or the damaging of any pipe or other part of a public water system, unless due to an act of God" is prohibited.[8] In addition, "(t)he discharge by any person of sewage or other waste at such location as will or will likely come into contact with the public water system intake, except in accordance with a permit issued by the department" is prohibited.[9] Enforcement of these provisions is through corrective action orders, civil penalties of not less than $50 nor more than $5,000, injunctions and criminal (Class E felony) prosecutions.[10] The law also provides that the state may recover damages for "any reasonable expenses incurred in investigating and enforcing violations...or any other actual damages caused by the violation."[11] The Water Quality Control Act explicitly states that the Act takes precedence in all cases of conflict with the state's Sanitary Engineering Law.

• Tennessee's Public Utilities and Carriers law provides that it is unlawful to "willfully corrupt or permit anything to run or fall into any stream or reservoir from which the (water company) takes water...which will corrupt the same or render it unpalatable, unwholesome, or unfit for use for any purpose for which it may be supplied....[12]

• Under the Tennessee Solid Waste Disposal Act it is unlawful to "place or deposit any solid waste into the waters of the state except in manner approved by the department or the Tennessee water quality control board...."[13] Solid waste is defined as "any garbage, refuse, including...solid, liquid, semisolid, or contained gaseous material resulting from industrial, commercial, and agricultural operations, and from community activities, but does not include solid or dissolved material in domestic sewage, or...irrigation return flows or industrial discharges which are point sources subject to permits...."[14]

Enforcement is through corrective action orders, civil penalties of not less than $100 nor more than $5,000 per day, injunctions and criminal (Class B misdemeanor) prosecution.[15] Enforcement may be delegated to local health officers.[16]

• In addition to the above provisions, Tennessee statutes provide for a variety of misdemeanor criminal offenses that involve activities related to water pollution.

For example, it is a Class A misdemeanor for any person to "knowingly [cause] damage to or the destruction of any real or personal property of another or of the state...knowing that he does not have the owner's effective consent."[17] Under the law, damage means destroying, polluting or contaminating property. Polluting is defined as "the contamination by manmade or man-induced alteration of the chemical, physical, biological or radiological integrity of the atmosphere, water, or soil to the material injury of the right of another."[18] Pollutant is defined broadly to include dredged soil, solid waste, incinerator residue, sewage, garbage, sewage sludge, munitions, chemical wastes, biological materials, radioactive materials, heat, wrecked or discarded equipment, rock, sand, cellar dirt and industrial, municipal, and agricultural waste.[19] This vandalism statute has been applied to water pollution by state courts.

Under Tennessee law, it is a Class B misdemeanor to knowingly place, drop or throw litter on any public or private property without permission and not immediately remove it.[20] Litter is defined to include garbage, refuse, rubbish, and "all other waste material."[21]

It is also a Class B misdemeanor to negligently discharge sewage, minerals, oil products or litter into any public waters or lakes within the state.[22]

It is a Class C misdemeanor to "unlawfully dispose of water carrying human waste, household or business waste, or to pipe or transmit raw sewage or the effluent from any septic tank or other system of any type, into or on public or private property."[23]

Fish/Fisheries Laws

• The state Wildlife Resources Code provides that "(n)o pollution, including, but not limited to, dye waste, petroleum products, brine waste, refuse from a mine, sawmill or construction activity, industrial or domestic sewage, or any deleterious or poisonous substance or activity shall be thrown or be caused, or allowed to run into, wash into or take place in any waters, either private or public, in a manner injurious to fish life or other aquatic organisms, or which could be injurious to the propagation of fish, or which results in the destruction of habitat for fish and aquatic life."[24] This provision is enforceable through criminal (Class A misdemeanor) prosecution. Each five days' continuous violation also constitutes a public nuisance, subject to abatement by permanent injunction.[25]

OPERATIONAL REQUIREMENTS

Forestry

State forestry laws do not appear to contain enforceable provisions relating to nonpoint source discharges.

Agriculture

• The supervisors of a soil conservation district organized under the Tennessee agriculture code may formulate regulations governing the use of the lands within the soil conservation district that are "in the interest of conserving soil and soil resources and preventing and controlling soil erosion."[26] The regulations may include necessary engineering operations, methods of cultivation, specifications of cropping programs and tillage practices, etc.[27] The regulations are contained in a proposed ordinance which must be passed by a two-thirds vote of the landowners. The land use regulations prescribed in the ordinances have the force and effect of law in the district and are binding on all landowners.[28]

When the supervisors identify a violation of the land use regulations and determine that the violation "tends to increase erosion on such lands and is interfering with the prevention or control of erosion on other lands within the district," the supervisors can request the court to require compliance or to allow them to perform the practice if compliance is not forthcoming.[29] The court may require compliance with the ordinance, and may require a landowner to reimburse the supervisors for performing the work.[30] In addition, a landowner may recover damages against a violator.[31]

• Tennessee's agriculture code provides that it is unlawful for any person to "handle, transport, store, display or distribute pesticides in such a manner as to endanger health and the environment" or to "dispose of, discard or store any pesticide or pesticide containers in such a manner as to cause injury to man, vegetation, crops, livestock, wildlife, beneficial insects or to pollute any water supply or waterways."[32] Enforcement is through injunction. The commissioner of agriculture may apply to chancery court for injunction restraining the violation.[33]

Development and Other Earth-Disturbing Activities

Apart from any programs for the control of urban stormwater under the federal Clean Water Act and general planning and zoning authority, there appear to be no specific enforceable requirements relating to land-disturbing activities.

TEXAS

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Texas' water pollution law contains general prohibitions that may be enforced against nonpoint source discharges that cause pollution of waters of the states. Certain polluting activities under the jurisdiction of other agencies, including some agricultural and silvicultural activities, are exempted.

• The state water code provides that, except as authorized, no person may "discharge sewage, municipal waste, recreational waste, agricultural waste, or industrial waste into or adjacent to any water in the state," discharge other waste which in itself or in conjunction with any other discharge or activity causes pollution of any water of the state, or commit any other act which causes pollution of any water in the state.[1] Exempted from this prohibition are: discharges authorized by permit, discharges in compliance with a certified water quality management plan as provided under the state agriculture code (see below), and activities under the jurisdiction of the Parks and Wildlife Department, the General Land Office (coastal management) or the Railroad Commission of Texas.

Enforcement of the water code, or any rule, permit or order issued pursuant to it, is through administrative penalties up to $10,000 per day, civil penalties of between $50 and $10,000, and injunctions.[2] The Parks and Wildlife Department may enforce the law where it appears that the violation affects aquatic life or wildlife, and local governments may bring suit for injunctive relief and/or civil penalties.[3] The water code also provides for certain criminal offenses. For example, it is a criminal offense to discharge or permit to discharge any waste or pollutant into any state water that causes or threatens to cause water pollution unless in strict compliance with all required permits.[4] It is also a crime (subject to greater fine and term of imprisonment) to "intentionally or knowingly discharge" a pollutant into or adjacent to water that causes or threatens to cause water pollution unless in strict compliance with permit.[5]

Other Discharge Limitations

• "No person may deposit in any canal, lateral, reservoir or lake...the carcass of any dead animal...garbage, ashes...earth, offal, or refuse of any character or any other article which might pollute the water or obstruct the flow of a canal or similar structure."[6] Enforcement is through local (misdemeanor) prosecution.

• Nuisance law may also apply. The water code requires the Department of Health to continue to apply its authority in the abatement of nuisances resulting from pollution not otherwise covered by the code.[7] The state agriculture code provides that no nuisance action may be brought against an "agricultural operation" that was in operation one year or more prior to the action, if the actions that were the basis of the nuisance action existed unchanged since the establishment of the operation. An agricultural operation includes the raising of stock or livestock, producing crops, viticulture, horticulture, as well as other activities.[8] However, the provision does *not* restrict the authority of the state or a municipality to enforce the law.

• A city may establish a water pollution control and abatement program. If watershed quality assessments or other assessment identify water pollution attributable to non-permitted sources in a city with a population of 10,000 or more, the Texas Natural Resources Conservation Commission (TNRCC), after providing the city an opportunity to correct the problem and after a public hearing, may require the city to establish such a program.[9] The law lists a number of program components, including "the development and execution of reasonable and realistic plans for controlling and abating pollution or potential pollution resulting from generalized discharges of waste which are not traceable to a specific source, such as storm sewer discharges and urban runoff from rainwater."[10]

• The water code authorizes the creation of various utility and water districts which may adopt rules and regulations to preserve water quality. These districts may also set reasonable civil penalties for the breach of a district rule. They are enforced by complaints in appropriate courts of jurisdiction in the county in which the district is located.[11]

• The state water codes's provisions on groundwater management authorize the creation of groundwater conservation districts with the approval of a majority of the voters in the area.[12] The district may make and enforce rules to provide for "conserving, preserving, protecting, and recharging of the groundwater...in order to control subsidence or prevent waste of groundwater...."[13] Waste includes "the pollution or harmful alteration of groundwater."[14] Enforcement of a district's rules is by injunction in court, as well as by "reasonable civil penalties....that shall not exceed the jurisdiction of a justice court...."[15]

Fish/Fisheries Laws

• Under the state parks and wildlife code, no person may place in the water an explosive, poison or other substance or thing deleterious to fish.[16] This does not apply to the use of explosives for construction purposes, if authorized. Enforcement is through local criminal (Class B misdemeanor) prosecution.[17]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• The state agriculture code provisions discussed below, governing the Soil and Water Conservation Board and the soil and water conservation districts, are applicable to silviculture activities.

Agriculture

• The state Soil and Water Conservation Board is the lead agency for the abatement of agricultural and silvicultural nonpoint source pollution.[18] The Board is required to plan, implement and manage programs and practices for abating such pollution, and other state agencies with responsibilities in this area must coordinate their actions with the Board. If the Board identifies an area as having agricultural or silvicultural nonpoint source water quality problems, or as being in a "coastal zone" designated by the Coastal Coordination Council, the state board establishes a "water quality management plan certification program" that provides, through the local soil and water conservation districts, for the supervision of individual water quality management plans for these areas. The state board adopts rules for these plans in compliance with state water quality standards.[19]

For those areas with "agricultural or silvicultural nonpoint source water quality problems" or for coastal zone areas, all complaints about violations of the water quality management plan or other rules relating to nonpoint source pollution are referred to the State Board. The State Board, in cooperation with the conservation district, investigates and if necessary, develops a corrective action plan. If the violator refuses to take corrective action, the state board refers the complaint to the TNRCC for enforcement.[20]

• The directors of a soil and water conservation district may propose an ordinance "in the interest of conserving soil and soil resources and preventing and controlling soil erosion."[21] An ordinance may require certain engineering operations, such as terraces, check dams, dikes, ponds, ditches; require the observance of certain methods of cultivations such as contour cultivating, furrowing, planting with erosion-preventing plants, forestation and reforestation; specify cropping programs and tillage practices; or adopt other land-use regulations that may assist conservation of soil resources and erosion.[22] Once an ordinance prescribing land use regulations is approved by 90 percent of the voters, it is adopted and has the "force and effect of law" and is "binding" on all owners of land in the district.[23] If the regulation is not being observed and that nonobservance "tends to increase erosion on that land and is interfering with the prevention and control of erosion on other land in the conservation district," the directors may bring suit in civil court.[24] After a hearing, the court may require the defendant to perform the work; order that if the defendant fails to perform the directors may enter the land and perform; and order that the directors recover their costs. The court retains jurisdiction until the work is done.[25]

• The water code authorizes the TNRCC to adopt rules to prohibit "the discharge of agricultural waste from a concentrated animal feeding operation into a playa; or...the use of a playa as a wastewater retention facility for agricultural waste."[26] Playa is defined as "a flat-floored, clayey bottom of an undrained basin that is located in an arid or semi-arid part of the state, is naturally dry most of the year, and collects runoff from rain but is subject to rapid evaporation."[27] An exception is provided for operations that were authorized to undertake these activities prior to the adoption of the rules. However, CAFOs that use a playa as a waste water retention facility are required to collect annual water samples; if the results show significant increases in chlorides or nitrates, and the TNRCC determines that the CAFO is the source of the pollution, the commission shall require "action to correct the problem."[28]

• The Department of Agriculture is authorized to adopt rules governing the storage and disposal of pesticides and pesticide containers for the purpose of preventing injury and "preventing any waterway pollution that is harmful to man or wildlife provided, however, that such rules be consistent with the Texas Natural Resources Conservation Commission rules" adopted under the state water code.[29] Enforcement is through administrative penalties not to exceed $4,000, injunctions, and civil penalties of not less than $50 nor more then $10,000.[30]

Development and Other Earth-Disturbing Activities

Apart from any programs that may be authorized by general land use regulation such as zoning, Texas law does have several other enforceable authorities applicable to nonpoint sources.

• The state water code requirement that certain cities adopt a water pollution control and abatement program, discussed above, is potentially applicable to the control of nonpoint source pollution from land-disturbing activities.

• While the agriculture code establishes the Soil and Water Conservation Board as the lead agency for abatement of agricultural and silvicultural nonpoint source pollution, the natural resources code provides that the General Land Office is the lead agency for the coordination of *coastal* erosion avoidance, remediation and planning. "The commissioner shall...promulgate rules, recommendations, standards, and guidelines for erosion avoidance and remediation...."[31] Thus, the law may potentially reach some land-disturbing activities in the coastal zone that result in nonpoint source pollution.

UTAH
Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

The Utah water pollution control law includes a general provision that may be enforced against nonpoint water pollution or placement of wastes that is likely to cause water pollution.

• It is unlawful for any person to discharge a pollutant into waters of the state or to cause pollution which constitutes a menace to public health and welfare, is harmful to wildlife, fish or aquatic life, or impairs domestic, agricultural, industrial, recreational or other beneficial uses of water.[1]

• The same provision of the Code also makes it unlawful to place any waste in a location where there is probable cause to believe that it will cause water pollution.[2]

Violations of these prohibitions are treated as a public nuisance. Moreover, when the Water Quality Board determines there are reasonable grounds to believe that a violation has been committed, it may give written notice with an order to appear before the board.[3] The board also may seek injunctive relief in a civil action.[4] Violators are subject to a civil penalty not to exceed $10,000; and a violation committed willfully or with gross negligence is subject to a fine not to exceed $25,000.[5]

Other Discharge Limitations

• Nuisance is defined as "any item, thing, manner, condition whatsoever that is dangerous to human life or health or renders soil, air, water, or food impure or unwholesome."[6] The county attorney, the city attorney, or the attorney general is empowered to institute an action to abate a public nuisance, and a person who creates a nuisance is guilty of a class B misdemeanor.[7]

There is an exemption for agricultural operations that are consistent with sound agricultural practices, which are presumed to be reasonable and do not constitute a nuisance unless the agricultural operation has a substantial adverse effect on public health and safety. Agricultural operations undertaken in conformity with federal, state, and local laws, regulations and zoning ordinances are presumed to be operating within sound agricultural practices.[8] "Agricultural operations" are defined as "any facility for the production for commercial purposes of crops, livestock, poultry, livestock products, or poultry products."[9]

• In addition to regulating nuisance, municipalities are authorized to enact ordinances "preventing pollution or contamination of the streams or watercourses from which the inhabitants of cities derive their water supply, in whole or in part, for domestic and culinary purposes."[10] Presumably these ordinances are enforced under the municipality's inherent police powers.

Fish/Fisheries Laws

• The Utah fish and wildlife code makes it "unlawful for any person to pollute any waters deemed necessary by the Wildlife Board for wildlife purposes or any waters containing protected aquatic wildlife and stoneflies, mayflies, dragonflies and damsel flies, water bugs, caddis flies, spongilla flies, and crustaceans."[11] Each day of pollution is a separate violation, and violations are treated as class B misdemeanors.[12] However, a person who violates the statute with intentional, knowing or reckless conduct and thereby injures or destroys protected wildlife is guilty of "wanton destruction of protected wildlife."[13] This violation is a third degree felony if the aggregate value of the protected wildlife is more than $500, a class A misdemeanor if the value is more than $250 but less than $500, and a class B misdemeanor if the value is less than $250.[14]

OPERATIONAL REQUIREMENTS

Forestry Requirements

State forestry laws do not appear to contain enforceable provisions relating to nonpoint source discharges.

Agriculture Requirements

• Soil conservation districts may be organized by petition of 25 or more land occupiers.[15] Each district is a political subdivision and has the authority to "devise and implement measures for the prevention of soil erosion, floodwater and sediment damages, nonpoint water pollution...."[16] Each district also is authorized to make recommendations governing land use within the district, including provisions requiring the observance of particular methods of cultivation, requiring specific crop programs and tillage practices, prohibiting the tillage and cultivation of highly erosive areas where erosion may not be adequately controlled if cultivated, and requiring the construction of terraces, terrace outlets, check dams, dikes, ponds, and other structures.[17] It appears that these "recommendations" may be made enforceable as ordinances, since the same statute also grants the district court jurisdiction to decide all cases and controversies involving construction, application, or enforcement of land use ordinances within the district.[18]

• A person is guilty of a Class B misdemeanor if he: "1) constructs or maintains a corral, sheep pen, goat pen, stable, pigpen, chicken coop, or other offensive yard or outhouse where the waste or drainage therefrom shall flow directly into the waters of any stream, well or spring of water used for domestic purposes; 2) deposits, piles, unloads, or leaves any manure heap, offensive rubbish, or the carcass of any dead animal where the waste or drainage will flow directly into the waters; 3) dips or washes sheep in any stream or in such close proximity to a stream used by inhabitants for domestic purposes as to make the waters impure or unwholesome; 4) constructs a yard for shearing or dipping sheep within 12 miles of a city where the refuse would naturally find its way into any stream used by the inhabitants; 5) establishes and maintains any corral, camp, or bedding place for the purpose of herding, holding or keeping any cattle, horses, sheep, goats, or hogs within seven miles of any city or town, where the refuse or filth from it will naturally find its way into any stream of water used by the inhabitants for domestic purposes."[19]

• The county legislative body may promulgate regulations to prevent the destruction or obstruction of channels, storm sewers, and drains that serve as natural channels for the carrying away and the safe disposal of natural storm and flood waters.[20] It may also provide by ordinance for the protection and use of flood channels and present flood plains on rivers, streams, and canals located within the county.[21] All laws and sanitary regulations against pollution of water in natural streams, canals and lakes shall be enforced by the county executives in their respective counties, or by the state, through the attorney general and in cooperation with the state board of health, state fish and game commission and the several county legislative bodies.[22]

• The Utah Department of Agriculture is authorized to adopt any rule consistent with federal regulations under FIFRA, including rules relating to the sale, distribution, use, and disposition of pesticides as deemed necessary to prevent damage and to protect public health.[23] The department shall serve notice of violation on alleged violators of the rules, and may order corrective action.[24] Any violator of an order issued under the title is subject to a penalty not to exceed $5000 in a civil proceeding, and in a criminal proceeding may be found guilty of a class B misdemeanor.[25]

Development and Other Earth-Disturbing Activities

• The Division of Parks and Recreation has the authority to regulate and control types of development along rivers and streams, designated by the Division, within their present flood plains.[26] "The division may not permit construction of any structures, subdivisions, or other developments on or along rivers or streams, or within their present flood plains, which are in violation of any ordinances of any political subdivision having jurisdiction in that area but may in respect to this development impose requirements in excess of and in addition to those provided in those ordinances."[27] The more restrictive of the requirements are applicable.[28] Any person who violates regulations adopted pursuant to this provision is guilty of a class B misdemeanor.[29]

No other specific operating requirements are set forth, other than those that may be found in urban stormwater programs under the federal Clean Water Act or that may be authorized by general land use regulation such as zoning.

VERMONT

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Vermont's Water Pollution Control Act draws no distinction between point and non-point sources, and its general prohibition is fairly broad.

• It prohibits "discharge [of] any waste, substance or material into the waters of the state" without a permit.[1] "Discharge" is defined as "the placing, depositing or emission of any wastes, directly or indirectly, into an injection well or into the waters of the state".[2] The law exempts from this prohibition "proper application of fertilizer to fields and crops".[3] While the broad prohibition of discharges applies to agriculture and silviculture, specific prohibitions on discharges to Class A and Class B waters "shall not regulate accepted agricultural or silvicultural practices, as are defined by the commissioners of agriculture, food and markets and forests, parks and recreation, respectively...nor shall those provisions prohibit stormwater runoff or the discharge of nonpolluting wastes..."[4] Essentially, this is interpreted to mean that those agricultural operations compliant with "accepted agricultural practices (AAPs)" and silvicultural operations compliant with "accepted management practices (AMPs)" are not required to obtain permits. They must not, however, cause water quality violations. With respect to violations of water quality standards, Vermont law further provides that persons engaged in farming and following accepted agricultural practices as described by the commissioner of agriculture, food and markets by rule "shall be presumed to be in compliance with water quality standards."[5] However, the rules implementing this provision clarify that this presumption is rebuttable "by water quality data or results from a water quality study deemed conclusive by the Secretary."[6]

The water pollution law is enforceable by a variety of mechanisms. [7]. These include administrative orders,[8] emergency orders,[9] administrative penalties of up to $25,000 for a single violation, and $10,000 per day (but not more than $100,000 total for a continuing violation),[10] civil enforcement,[11] and criminal enforcement.[12]

Other Discharge Limitations

• Towns, cities, and incorporated villages have the power to define what constitutes a public nuisance.[13] Boards of health may bring actions to abate nuisances.[14] But "Agricultural activities conducted on farmland, if consistent with good agricultural practices and established prior to surrounding non-agricultural activities, shall be entitled to a rebuttable presumption that the activity is reasonable and does not constitute a nuisance." This presumption is not available in suits brought by the local board of health, however.[15]

• While statutory nuisance law does not specifically address pollution of surface water, any person may seek equitable relief or damages "for unreasonable harm caused by another person withdrawing, diverting or altering the character of groundwater."[16] However, the law provides that in such an action, "a person who alters groundwater quality or character as a result of agricultural or silvicultural activities, or other activities regulated by the commissioner of the department of agriculture, food and markets, shall be liable only if the alteration was either negligent, reckless or intentional."[17] Similarly, "An owner or lessee of agricultural lands shall not be liable for personal injury or property damage resulting from contamination of a permitted [public drinking] water source so long as the owner or lessee was utilizing accepted agricultural practices...and the lands were agricultural at the time the [water supply] permit was issued."[18]

Fish/Fisheries Laws

• "A person shall not place in any waters lime, creosote, coculus inducus or other drug or poison destructive to fish."[19] The statute is silent on whether a violation requires intent to take fish, or even an intent to place the poison in the water. The list of substances suggests a narrow scope for any possible prosecution of nonpoint source pollution. The general penalty for violation is a fine of up to $1000.[20]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• State timber harvest rules are advisory for most operations.[21] But, In 1997, the legislature enacted a law regulating "heavy cutting," defined as a harvest of more than forty acres which leaves a residual stocking level of acceptable growing stock (at least 4.5 in. dba) which is below the C-line as defined by the U.S. Dept. of Agriculture guidelines for the applicable timber type. Heavy cutting operations on 40 acres or more must be preceded by a notice of intent to cut. The notice is filed by the landowner with the state forestry agency; if the state field forester determines that the cut is exempt, no further review is necessary. Exemptions include cuts for agricultural conversion, conversion regulated by Act 250 (see below under "Development"), or cuts consistent with a forest management plan in effect under the state's program for current use assessment taxation or several other forest planning programs. If an exemption does not apply, the forester must review the proposed heavy cut to determine its compliance with timber harvest rules. These rules include silvicultural guidelines and forestry standards, and requirements with respect to water quality, wetlands, and riparian zones.[22] After review, the state field forester will issue an authorization to proceed or denial of authorization to proceed, appealable to the commissioner of forests, parks, and recreation. Violation of the law or rules may result in a penalty of up to $50,000 and up to $25,000 per day for a continuing violation.

• As noted above, compliance with forestry AMPs can provide some shelter from permitting under the state's water pollution control law. Thus, these can be construed as indirectly enforceable mechanisms.

Agriculture Requirements

• Vermont's Agricultural Nonpoint Source Pollution Reduction Program,[23] includes two kinds of enforceable standards: 1) Farmers generally must follow "accepted agricultural practices"(AAPs) as designated by rule by the commissioner of agriculture, food and markets. 2) The commissioner may also require farmers to implement "best management practices" (BMPs) on a case-by-case basis. Both types of standards must be "practical and cost effective to implement."[24]

The rules for accepted agricultural practices prohibit the direct discharge of waste into surface waters; the "concentrated overland flow of waste into adjoining waters"; discharge of manure runoff from storage areas; overland flow of manure runoff following stacking of manure on fields; construction of manure, fertilizer, or pesticide storage structures in floodways; construction of the same in floodplains except in conformance with National Flood Insurance Program Standards; and field stacking of manure or fertilizers within 100 feet of neighbors' wells or springs or on lands subject to annual flooding (unless there is no practical alternative). They further limit unnecessary applications of plant nutrients or applications of nutrients or pesticides in specific ways likely to lead to runoff. They set an acceptable limit for soil loss and require management of agricultural wastes to "eliminate adverse water quality impacts." They require perennial vegetative buffer zones between row croplands and water, and require structures to be set back from surface waters.[25]

For enforcement purposes, the commissioner must, after responding to a complaint, first send the offender a written warning with proposed corrective action. After thirty days, the commissioner must offer opportunity for a public hearing, then issue an order or seek enforcement in civil court. Farmers may appeal administrative orders to the courts. Violation of an order may be punished by assessment of civil penalties, as well as enforced by injunction in court.[26]

BMPs may be required in order to meet water quality standards in particular places. The BMP rules provide that the commissioner, "upon receipt of a petition from a person with an interest in the agricultural nonpoint source component of the basin planning process," or acting on the commissioner's own initiative, is to determine "whether to require BMPs beyond AAPs on farms or in a specific basins in order to achieve compliance" with water quality goals.[27] A petition for imposition of BMPs must include identification of each farmer whose actions violate water quality standards, documentation as to the water quality violation, including a study conducted pursuant to USEPA quality assurance/quality control program standards for the Clean Water Act, a description of the specific actions sought by the petitioner, a detailed narrative as to which AAPs are insufficient, and other information. The petition, if complete, is set for public hearing, leading to a written decision. The decision may be appealed by the farmer or petitioner, resulting in a hearing *de novo* before the water resources board.[28] Imposing BMPs requires a finding that sufficient financial assistance is available to the farmer to implement the BMPs.[29] The BMP rules provide that a grant to the farmer of 85 percent of the cost is to be considered sufficient to make this finding.[30]

• Vermont also regulates large farm operations, based on animal units. (Regulatory thresholds are defined differently from federal CAFO requirements, but basically cover animal operations that are 95% the size of the federal threshold). The law requires the operator to obtain from the commissioner permits for construction of barns, and for operation of the large livestock operation. The operating permit must include demonstration of an adequately sized manure management system, and a nutrient management plan "to dispose of wastes in accordance with accepted agricultural practices" described above.[31] State regulations for this program are to be no stricter than the corresponding federal CAFO regulations, as adjusted for the differing size threshold.[32] Enforcement is under the general provisions applicable to the commissioner of agriculture, food, and markets, and may include civil penalties and injunctive relief.

• The commissioner of agriculture, food and markets has broad authority to regulate pesticide use, storage, and disposal.[33] Also, permit regulations for use of herbicides to maintain rights-of-way require applicants to prepare a long-term plan including establishments of standards for wetlands, wildlife, erosion control, and aesthetic considerations. Prior to spraying, permit holders must flag water supplies and other sensitive areas designed by the commissioner and must not spray near flagged areas. Permits must specify buffer strip distances to protect the waters of the state.[34] Golf courses must obtain permits to apply pesticides, and this includes "buffer strips to protect surface waters and environmentally sensitive areas."[35] The commissioner may enforce the standards administratively by revoking or suspending licenses, entering into consent agreements with violators, requiring "correction of sources of pesticide contamination that threaten human health or the environment", seeking injunctive relief,[36] or assessing administrative penalties of up to $1,000 by notice and hearing process.[37] Criminal penalties are also available.[38]

Development and Other Earth Disturbing Activities

• State law regulates the alteration of streams.[39] Permits are required to alter or modify the course, current, or cross-section of any watercourse with a drainage area greater than ten square miles at the location of the proposed modification, or any outstanding resource waters. This law does not apply to accepted agricultural practices or accepted management practices for silvicultural as defined by the respective commissioners. A permit may be issued only if the change will not increase flood hazards, significantly damage fish or wildlife, significantly damage the rights of riparian owners, or adversely affect outstanding resource waters. Violations are punishable by civil fine of not more than $10,000 per day, and restoration.

• State law also provides for regulations for the protection of "significant" wetlands.[40] Some of the activities affecting wetlands are also nonpoint sources of water pollution. The rules list activities that are allowed within protected wetlands and their buffer zones; other activities are considered "conditional uses" and require a conditional use determination from the state's wetlands office in the Department of Environmental Conservation. Enforcement is under the authorities described above for the water quality control program.

• Vermont has comprehensive land use regulation under its "Act 250," the Land Use and Development Law.[41] This law requires a land uses permit for numerous activities, some of which affect nonpoint sources. It does not, however, regulate the construction of improvements for farming, logging, or forestry unless they are 2500 feet or more above sea level. District environmental commissions must evaluate the grant of an Act 250 permit under a variety of criteria, several of which address water quality, water supply, and erosion.

• The municipal and regional planning and development laws allow municipalities to adopt restrictions and requirements as bylaws. The state program calls for regional plans, which must include a land use element, including areas "which require special consideration for aquifer protection, wetland protection, or for other conservation purposes". [42] Municipal plans must be consistent with regional plans, and must include elements parallel to the ones just outlined.[43] Once a municipality has a plan in place, it may adopt bylaws to enforce it.[44]

• Municipalities are also empowered to adopt bylaws governing shorelands, either as part of or in addition to zoning bylaws.[45] These bylaws may regulate design and maintenance of sanitary facilities, regulate alterations to wetlands and wildlife areas, control building locations, and require maintenance of vegetation. "Shorelands are "lands being between the normal mean water mark of a lake, pond or impoundment exceeding twenty acres and a line not less than five hundred feet nor more than one thousand feet from such mean water mark."[46]

• Municipalities are authorized to adopt flood hazard area regulations.[47] Specifically municipalities may regulate permitted uses and type of construction "[w]ithin any area designed by the department of environmental conservation as subject to periodic flooding".[48]

Notwithstanding these provisions, municipal bylaws may not restrict "accepted agricultural or farming practices, or accepted silvicultural practices, including the construction of farm structures".[49] Enforcement is by notice of violation, injunction, and penalty of $50 per violation per day.[50]

VIRGINIA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Virginia's water pollution control law includes some basis for enforcement actions against nonpoint source discharges that are not authorized by state permits and that either consist of wastes or that result in impairment of the state's waters.

• "Except in compliance with a certificate issued by the Board, it shall be unlawful for any person to (I) discharge into state waters sewage, industrial wastes, other wastes, or any noxious or deleterious substances, or (ii) otherwise alter the physical, chemical or biological properties of such state waters and make them detrimental to the public health or to animal or aquatic life, or to the uses of such waters for domestic or industrial consumption, or for recreation, or for other uses."[1] Enforcement is by special order, which may be issued "only after a hearing with at least thirty days' notice to the affected owners, of the time, place and purpose thereof, and they shall become effective not less than fifteen days after service..."[2] Injunctive relief and civil penalties of up to $25,000 per day are available.[3]

• "Except as otherwise permitted by law, it shall be unlawful for any person to dump, place, or put, or cause to be dumped, placed or put into, upon the bank of or into the channels of any state waters, any object or substance, noxious or otherwise, which may reasonably be expected to endanger, obstruct, impede, contaminate or substantially impair the lawful use or enjoyment of such waters and their environs by others." Violations are misdemeanors and upon conviction are punishable by "a fine of not less than $100 nor more than $500 or by confinement in jail not more than twelve months or both such fine and imprisonment." In addition, whether there is a criminal conviction or not, "upon a bill in equity, filed by the attorney for the Commonwealth of such county or by any person whose property is damaged or whose property is threatened with damage" the court may "award an injunction enjoining any violation of this law..."[4]

Other Discharge Limitations

• Nuisance law also may provide enforceable remedies. A special grand jury will be summoned when five or more citizens complain to a circuit court about the existence of a public or common nuisance.[5] Nuisance remedies are available and may result in abatement as against the property giving rise to the nuisance. "Every judgement in rem under this chapter shall be enforced in the same manner as an attachment levied on real estate."[6] If found guilty, a person may be fined not more than $10,000 and the nuisance may be ordered removed and abated.[7]

Fish/Fisheries Laws

• One provision directed at protection of fisheries provides some enforceable authority potential relevant to some forms of nonpoint source water pollution. "It shall be unlawful to knowingly cast any noxious substance or matter into any watercourse of the Commonwealth where fish or fish spawn may be destroyed, or to place or allow to pass into the waters of the Commonwealth any sawdust, ashes, lime, gas, tar, or refuse of gas works, injurious to fish." Violation of this provision is a misdemeanor.[8]

OPERATIONAL REQUIREMENTS

Forestry Requirements

• Virginia has an enforceable mechanism for silvicultural activities causing or threatening to cause pollution. "If the State Forester determines that an owner or operator is conducting or allowing the conduct of any silvicultural activity in a manner which is causing or is likely to cause pollution, he may advise the owner or operator of corrective measures needed to prevent or cease the pollution." The State Forester has "authority to issue special orders to any owner or operator who is conducting, or allowing to be conducted, any silvicultural activity in a manner which is causing or is likely to cause pollution, to cease immediately all or part of the silvicultural activities on the site, and to implement specified corrective measures within a stated period of time. Such special orders are to be issued only after a hearing with reasonable notice to the owner or operator, or both, of the time, place and purpose thereof, and they shall become effective not less than five days after service..."[9] The State Forester may also issue an emergency order, without advance notice or hearing, if he "finds that any owner or operator is conducting any silvicultural activity in a manner which is causing or is likely to cause an alteration of the physical, chemical or biological properties of any state waters resulting from sediment deposition presenting an imminent and substantial danger to (I) the public health, safety or welfare, or the health of animals, fish or aquatic life; (ii) a public water supply; or (iii) recreational, commercial, industrial, agricultural, or other reasonable uses..."[10] Despite these provisions, "The State Forester shall not issue a special order to any owner or operator who has incorporated generally acceptable water quality protection techniques in the operation of silvicultural activities, which techniques have failed to prevent pollution, if the State Forester determines that the pollution is the direct result of unusual weather events which could not have been reasonably anticipated."[11] A civil penalty of up to $5,000 per violation per day may be assessed by the State Forester after the owner or operator has been given an opportunity for a hearing.[12] Orders may be enforced by injunction.[13]

Agriculture Requirements

• Virginia's Agricultural Stewardship Act established a complaint-driven enforceable mechanism applicable to agricultural nonpoint source water pollution. After April 1, 1997, upon receiving a complaint (except for an anonymous complaint), the Commissioner of Agriculture and Consumer Services shall investigate and if it is determined "that substantial evidence exists to prove that an agricultural activity is creating or will create pollution, the Commissioner shall notify the owner or operator."[14] "The notice shall state that within sixty days of receipt of the notice, the owner or operator shall submit to the Commissioner and [local soil and water conservation] district an agricultural stewardship plan which includes stewardship measures needed to prevent or cease the pollution." If the Commissioner finds that the pollution is "not a threat to human health, animal health, or aquatic life, water quality or recreational or other beneficial uses," or that it is a "direct result of unusual weather events or other exceptional circumstances that could no have been reasonably anticipated," the Commissioner "may forego" any action.[15] If the notice is sent requiring submittal of a agricultural stewardship plan, the soil and water conservation district must review the submitted plan and the Commissioner must approve it within 30 days if sufficient.[16] "Pollution means any alteration of the physical, chemical, or biological properties of any state waters, resulting from sedimentation, nutrients, or toxins." "Stewardship measures means measures for controlling the addition of pollutants from existing and new categories and classes of nonpoint sources of pollution which reflect the pollutant reduction achievable through the application of the best available nonpoint pollution control methods, technologies, processes, siting criteria, operating methods or other alternatives" including use of BMPs.[17]

Failure to implement an approved agricultural stewardship plan subjects the owner or operator to a corrective action order, issued after hearing, which directs the recipient to complete implementation of the plan within a stated period of time, not to exceed 18 months from the date of the original notice.[18] A corrective action order may be enforced by injunction, by entry and abatement by the Commissioner with cost recovery if the court order is not complied with, and by assessment of a civil penalty of up to $5,000 per day.[19] An emergency corrective action order (with subsequent hearing) may be issued if runoff from an agricultural activity "is causing or is likely to cause an imminent or substantial danger to (I) the public health, safety or welfare or to the health of animals, fish or aquatic life, (ii) a public water supply, or (iii) recreational, commercial, industrial, agricultural, or other beneficial uses." An emergency order may direct cessation of all or part of the agricultural activity and require specific stewardship measures.[20] A corrective action order shall not be issued if the operator or land owner is actively implementing the approved agricultural stewardship plan, or actively implementing stewardship measures "that have failed to prevent pollution, if...the pollution is a direct result of unusual weather events or other exceptional circumstances which could not have been reasonably anticipated."[21] Decisions of the Commissioner are appealable first to the Virginia Soil and Water Conservation Board and then to the local circuit courts.[22] Local governments are authorized to adopt ordinances implementing the complaint-driven program set forth in the state law; but the local governments are not granted the power to impose sanctions for failure to implement a plan. They may only submit a complaint to the Commission to start the state process if there is no compliance with the local process.[23]

• In addition, "The Department [of Conservation and Recreation] shall operate a voluntary nutrient management training and certification program to certify the competence of persons preparing nutrient management plans for the purpose of assisting land owners and operators in the management of land application of fertilizers, municipal sewage sludge, animal manures, and other nutrient sources for agronomic benefits and for the protection of the Commonwealth's ground and surface waters."[24] While this is not an enforcement mechanism, the certification regulations provide for denial, suspension, or revocation of certifications.[25]

• For Chesapeake Bay areas, "Land upon which agricultural activities are being conducted, including but not limited to crop production, pasture, and dairy and feedlot operations, shall have a soil and water quality conservation plan."[26]

• Virginia certifies pesticide applicators; it also requires reporting of "significant pesticide accidents or incidents which constitute a threat to humans or the environment to appropriate environmental agencies."[27]

• Virginia law also addresses confined animal feeding operations, in a manner similar to the federal regulations.[28]

Development and Other Earth-Disturbing Activities

• Virginia's Erosion and Sediment Control Law regulates "land-disturbing activities" which include "clearing, grading, excavating, transporting, and filling of land."[29] Each conservation district, county, city, or town "shall adopt and administer an erosion and sediment control program..." to be approved by the Virginia Soil and Water Conservation Board.[30] "No person may engage in any land-disturbing activity until he has submitted to the district or locality an erosion and sediment control plan ... and the plan has been reviewed and approved by the authority."[31] State agency land-disturbing activities require annual submission of specifications and conservation plans.[32] "Agencies authorized under any other law to issue grading, building, or other permits for activities involving land-disturbing activities may not issue any such permit unless the applicant submits with his application an approved erosion and sediment control plan and certification that the plan will be followed."[33] The requirements do not apply to home gardening, underground public utility work, septic tank lines, mining, oil and gas exploration and drilling, agricultural operations, railway maintenance and operations, agricultural land drainage and irrigation, and shore erosion control projects. They also do not apply to activities under 10,000 square feet unless the local jurisdiction chooses to regulate them. [34] Under the regulations, the local plan approving authority "may waive or modify any of the chapters that are deemed inappropriate or too restrictive for site conditions, by granting a variance."[35] "If there is a failure to comply with the plan, notice shall be served upon the permittee or responsible person by certified mail....The notice shall specify the measures needed to comply with the plan and shall specify the time within which such measures shall be completed."[36] Localities may establish civil penalty schedules for violations of the erosion and sediment control program.[37] Upon receipt of a sworn complaint of violation, authority may order activity to cease until corrective measures have been taken. Upon failure to comply with a compliance order, "the permit may be revoked and the responsible person subject to penalties..[38] The authority or damaged party may make application to circuit court to enjoin a violation with prior notification in writing to the alleged violator and authority and as long as no corrective action has been undertaken within 15 days of notice.[39] Violators may be guilty of a Class I misdemeanor; civil penalties or civil charges in place of penalties may be assessed not to exceed $2,000.[40]

• Virginia also allows, but does not require, counties, cities, and towns to adopt further enforceable mechanisms. "Each locality may, by ordinance, to be effective on or after July 1, 1990, establish a local stormwater management program which shall include, but is not limited to" consistency with stormwater regulations of the Board of

Conservation and Recreation, provisions for longterm responsibility for devices and techniques to manage the quality and quantity of runoff, and provision for integration of programs with local erosion and sediment control programs.[41] The Board's regulations specify minimum technical criteria and administrative procedures, including "minimum design criteria for measures to control nonpoint source pollution."[42] "[A]fter the adoption of a local ordinance, a person shall not develop any land for residential, commercial, industrial, or institutional use in that locality until he has submitted a stormwater management plan to the locality...and has obtained approval of the plan from that locality."[43] This program does not apply to agricultural and forestry activities, single family construction, land development projects that disturb less than one acre (unless the locality chooses to apply the program to smaller areas), mining, and certain linear projects.[44] Violations are misdemeanors with a fine not to exceed $1,000 and/or 30 days imprisonment; injunctive relief is available, and civil penalties of up to $2,000.[45]

• "The protection of the public interest in the Chesapeake Bay, its tributaries, and other state waters ... require that: (I) the counties, cities, and towns of Tidewater Virginia incorporate general water quality protection measures into their comprehensive plans, zoning ordinances, and subdivision ordinances..." Localities in the region are required to establish Chesapeake Bay Preservation Areas -- identifying lands, which if improperly developed, "may result in substantial damage to the water quality of the Chesapeake Bay and its tributaries."[46] Local governments outside of Tidewater Virginia are allowed to adopt such provisions.[47] The regulations on land use standards are intended to prevent a net increase in nonpoint source pollution from new development, achieve a 10% reduction in nonpoint source pollution from redevelopment, and achieve a 40% reduction in nonpoint source pollution from agricultural and silvicultural uses.[48] Counties, cities, and towns in the region must incorporate water quality measures into their zoning and subdivision regulations.[49] The state regulations set out general performance criteria to establish performance standards to minimize erosion and sedimentary potential, reduce land application of nutrients and toxics and maximize rainwater infiltration for Chesapeake Bay areas.[50] The criteria become mandatory upon the local program adoption date.[51] Enforcement is under local police and zoning powers.[52]

• Virginia has enforceable programs regulating activities affecting tidal wetlands, water quality certification for activities affecting nontidal wetlands, and activities affecting submerged lands.[53]

WASHINGTON

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Washington's water pollution control law includes provisions that may be used to take enforcement action against nonpoint source discharges that pollute the waters or that consist of unpermitted disposal of waste, except for forest practices conducted in compliance with the state forest practices law.

• Washington's water pollution control statute prohibits the discharge of "any organic or inorganic matter that shall cause or tend to cause" water pollution[1] and requires a permit for the disposal of solid or liquid waste material into waters of the state.[2] The statute does not authorize the adoption of a permit system for nonpoint source pollution from forest practices, nor the imposition of penalties for nonpoint source pollution arising for forest practices conducted in compliance with the state's forest practices law.[3] The Department of Ecology ("DOE") enforces the law by bringing an action, issuing orders or directives, or imposing penalties. The attorney general, upon the request of DOE, may also bring an action.[4] With respect to bringing an enforcement action for discharges arising from agricultural activity on agricultural land, prior to issuing a notice of violation, the statute directs DOE to consider whether such an action would contribute to conversion of agricultural land to nonagricultural uses and to attempt to minimize the possibility of such conversion.[5] Willful violations are crimes punishable by a fine of up to $10,000 and/or imprisonment for not more than one year. Civil violations incur penalties of up to $10,000 per day per violation.[6]

Other Discharge Limitations

• The state's Public Health and Safety Code ("Code") regulates discharges into public water supplies. Under the Code, it is a gross misdemeanor to deposit "any matter or thing which may or could pollute" into waters that are used for drinking purposes.[7] It is also a misdemeanor for any person to place or cause to be placed "within any watershed from which a city or municipal corporation of any adjoining state obtains it water supply, any substance which either by itself or in connection with other matter will corrupt, pollute or impair the quality of said water supply..." Violation of this provision is punishable by a fine of up to $500.[8]

• State law also protects public water supplies. It provides that a person who does "any of the things which have the effect of polluting any such sources of water supply, or water," and any person who conducts a business or occupation, or allows any condition upon or sufficiently near the water supply or sources for the water supply, or "the property through which the same may be conveyed or conducted so that such water would be polluted..." is guilty of nuisance and may be fined up to $500.[9] Non-tidewater cities with a population of 100,000 or more are prohibited from "discharging, draining or depositing...any...substance, offensive, injurious or dangerous to health" into waters used for "human or animal consumption or for domestic

R0017292

purposes." Violation of this provision is a public nuisance, and abatement may be sought by secretary of social and health services or by any person whose water supply is affected.[10] If a violator fails to abate pollution of a water supply, then the sheriff abates the nuisance and assesses the cost against the violator.[11] Cities and towns are authorized to prescribe what acts constitute offenses against the purity of the water supply and the resulting punishment and penalties and enforce them.[12]

• Nuisance law may apply to some instances of nonpoint source pollution. Nuisance is generally defined as unlawfully committing or omitting an act that "endangers the comfort, repose, health of safety of others...or [that] unlawfully interferes with, obstructs or tends to obstruct...any lake or navigable..." water.[13] Any person whose property is affected may bring an action in court and get an order to abate the nuisance.[14]

• It is a public nuisance to "throw...offensive matter" into any waterway" or in any way to corrupt or render unwholesome or impure the water...to the injury or prejudice of others."[15] Any public body or authorized officer may abate a public nuisance,[16] or a private person may bring a civil action or remove and/or destroy the nuisance, if it is "specially injurious."[17] Abatement does not preclude action for private damages.[18] Fines for public nuisances of up to $1000 may be imposed.[19]

• A public nuisance is a crime where an act or omission "unlawfully interfere[s] with, befoul[s]...a lake, navigable river, bay, stream, canal or basin..."[20] The court or magistrate shall order the nuisance abated, in addition to any other fine or punishment.[21] Under this statute, a person who commits or maintains a public nuisance is guilty of a misdemeanor,[22] and a person who deposits an "unwholesome substance" on or near a highway on land or water is guilty of a gross misdemeanor, including maintenance of a business that is "noisome or detrimental to the public health."[23]

• Also see *supra* regarding nuisance actions for pollution of public water supplies.

Agricultural activities and forest practices are not a nuisance if conducted in a manner consistent with good practices and established prior to surrounding nonagricultural and nonforestry activities, unless they have a "substantial adverse effect on the public health and safety."[24] Also, nothing done or maintained under the express authority of a statute is a nuisance.[25]

Fish/Fisheries Laws

• State law declares that any person who acts illegally or otherwise reduces water quality below state standards or causes significant degradation of water quality, "thereby damaging the same; and...causes the death of, or injury to fish, animals, vegetation, or other resources of the state" shall be liable for damages to the state and affected counties and cities.[26] Operations undertaken in compliance with a waste discharge permit are not actionable under this provision.[27] See supra for general enforcement provisions under the Water Pollution Control statute.

OPERATIONAL REQUIREMENTS

Forestry Requirements

• Washington law requires the forest practices board (the "board) to promulgate regulations that establish minimum forest practices standards.[28] Regulations determine which forest practices fall within which of four classes, ranging from Class I, requiring no notification, through Classes II-IV requiring notification on submission of an application for approval. In particular, Class IV forest practices that have "a potential for substantial impact on the environment and therefore require an evaluation," require an application.[29] If an approved application authorizes "a forest practice which, because of...proximity to a water course...has a potential for causing material damage to a public resource," then the Department of Natural Resources ("DNR") may require notification two days before actual operations begin.[30] Additionally, the board and DOE are required to promulgate forest practices regulations relating to water quality from the minimum forest practices standards regulations.[31] The DNR enforces this statute by issuing a stop work order for any violation and taking immediate action if the operator fails to obey such an order; or the DNR may issue a notice setting forth the nature of the violation or damage, the operator's right to a hearing and the specific course of action.[32] Specifically, with respect to a violation relating to water quality, where DNA fails to act, DOE notifies DNR and, failing DNR action, petitions the appeals board chair who must deny the petition or direct DNR to act.[33] The attorney general also may enforce the statute, and a country may bring actions in superior court against the DNR, landowner, timber owner, or operator.[34] Sanctions include civil penalties, collect costs, or disapproval, for up to one year, of a forest practices application.[35]

Agriculture Requirements

• New state legislation requires dairy farms to establish waste management plans and directs the DOE to inspect all dairy operations at least every two years. All dairy farms are required to develop dairy nutrient management plans by July 1, 2002 and obtain approval from the local conservation districts and be implemented by the farmers by December 31, 2003. The sanctions for noncompliance by dairy farmers are fines of $100 per month up to maximum of $5000 for failing to develop the management plan.[36]

• A license is required from the Department of Agriculture (DOA) to operate a certified feed lot.[37] Denial, suspension, or revocation of feed lot licenses may result where violations occur.[38] Violators are guilty of a misdemeanor, and subsequent offenses are a gross misdemeanor.[39]

• The state's Pesticide Application Act requires licenses for commercial pesticide application[40] (with some exceptions including forest owners applying pesticides on their own lands and farmers occasionally applying pesticide themselves),[41] private commercial pesticide application,[42] and private pesticide application.[43] A person damaged by pesticide application may sue agencies, municipal corporation and public utilities, or the DOA director may seek to enjoin a violation.[44] Sanctions include revocation or suspension of licenses, permits or certifications.[45] A maximum of $7500 in civil penalties are available for each violation.[46] First offense is a misdemeanor; subsequent offenses are gross misdemeanors (except an offense committed more than five years after a previous conviction is a first offense).[47]

• The state's Pesticide Control Act regulates labeling and registration requirements, including required registration of all pesticides that are distributed within the state or are transported in or through the state, with some minor exceptions,[48] and licensing of pesticide dealers and consultants.[49] The DOA director and/or the county prosecuting attorney may bring an action,[50] and relevant sanctions include refusal to register pesticide or suspension of registration[51] and denial, suspension, revocation of licenses.[52] Civil penalties ($7500 per violation) are authorized.[53]

Development and Other Earth-Disturbing Activities

Apart from any programs for the control of urban stormwater under the federal Clean Water Act, state law provides the following authorities.

• Comprehensive plans required of counties and cities under the state's Growth Management Act ("GMA") must provide for "drainage, flooding, and storm water run-off...and provide guidance for corrective actions to mitigate or cleanse those discharges that pollute waters of the state."[54] Entities covered under the GMA are to adopt development regulations that assure protection of designated "critical areas,"[55] which include wetlands, "areas with a critical recharging effort on aquifers used for portable water," and fish and wildlife habitat conservation areas.[56] Shore Management Act, see infra, rather than plans under the GMA.) A noncomplying entity shall have up to 180 days to comply.[57] The Governor may modify state appropriation allotments, withhold revenue-sharing or temporarily rescind tax collection authority for counties or cities that fail to comply with GMA provisions.[58]

• The Shoreline Management Act prohibits shoreline development unless consistent with statutory policy and the applicable guidelines, rules or master program and requires a permit for "substantial development."[59] Substantial development, with some exceptions, is development whose total cost exceeds $2500 or "materially interferes with the normal public use of the water or shorelines."[60] If DOE believes permittee is not in compliance with permit, it notifies local government and permittee and, then, may petition shoreline hearings board ("board') for rescission of permit.[61] Appeals regarding permitting decisions or DOE rules may be made to the board.[62] Attorney general or local government attorney may bring injunctive, declaratory or other relief, and civil penalties (up to $1000 per violation) are authorized.[63] A willful violation is a gross misdemeanor punishable by fines and/or imprisonment.[64]

WEST VIRGINIA

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

West Virginia's water pollution control law appears not to provide for the regulation or prohibition of nonpoint source discharges.[1]

Other Discharge Limitations

• A separate law establishes criminal penalties for wastes (excluding commercial or industrial wastes regulated under the pollution control law) thrown or released "into any river, creek or stream, or upon the surface of any land adjacent to any river, creek or other stream in such a location that high water or normal drainage conditions will cause such offensive materials to be washed, drained, or cast into the river, creek or other stream". Violation is a misdemeanor subject to a fine of $100 to $1000.[2]

• Another provision establishes criminal penalties for "Any person who knowingly and willfully throws, causes to be thrown or releases any dead animal, carcass, or part thereof, garbage, sink or shower waste, organic substance, human or animal excrement, contents of a privy vault, septic tank, cesspool or the effluent from any cesspool or nauseous or offensive or poisonous substances into any well cistern, spring, brook, pond, stream, or other body of water which is used for domestic purposes".[3] The offense is a misdemeanor subject to a fine of $25 to $200. In addition, conviction creates a duty to remove and properly dispose of the materials as directed by the bureau of public health. Each day of failing to comply is a separate violation of the section.

• It is a misdemeanor "to place, deposit, dump, or throw, or cause to be placed, deposited, dumped or thrown, any litter ... garbage, refuse, trash, can, bottle, paper, ashes, carcass of any dead animal or part thereof, offal, or any other offensive or unsightly matter into any river, stream, creek, branch, brook, lake or pond, or upon the surface of any land within one hundred yards thereof, or in such location that high water or normal drainage conditions will cause any such materials to be washed into any river, stream, creek, branch, brook, lake or pond."[4] For a first offense, the sanction is a fine of $50 to $500 or alternatively, 8 to 16 hours community service cleaning up unlawfully deposited matter along stream or river banks. For a second offense, the sanction is a fine of $250 to $1000 plus a jail term of 24 hours to 6 months, with the court able to substitute 16 to 32 hours of clean-up for the fine or for the incarceration, but not for both. For third and subsequent offenses, the sanction is a fine of $500 to $2000 plus a jail term of 48 hours to one year, with the court able to substitute 32 to 64 hours of clean-up for the fine or for the incarceration, but not both.

• Nuisance remedies are expressly preserved for water pollution. West Virginia's statutory water pollution provisions do not "abridge or alter rights of action or remedies now or hereafter existing, nor shall any provisions of this article, or any act done by virtue of this article, be construed as estopping the state, municipalities, public health officers, or persons as riparian owners or otherwise, in the exercise of their rights to suppress nuisances or to abate any pollution now or hereafter existing, or to collect damages."[5]

Fish/Fisheries Laws

West Virginia does not appear to have enforceable provisions relevant to nonpoint source water pollution in its fisheries laws.

OPERATIONAL REQUIREMENTS

Forestry Requirements

• West Virginia provides enforceable authorities for nonpoint source water pollution resulting from commercial forestry practices. State law also requires a license for commercial timber harvest and purchase of timber or logs for resale, and certification of supervisors of logging sources.[6] "Upon notification of the chief [of the office of water resources of the division of environmental protection] or upon a finding by the director [of the division of forestry of the department of commerce, labor and environmental resources] that failure to use a particular best management practice is causing or contributing, or has the potential to cause or contribute, to soil erosion or water pollution, the director shall issue a written compliance order".[7] The director may issue written compliance orders; issue immediate suspension of work orders (if circumstances endanger life or threaten or result in uncorrectable soil erosion or water pollution); suspend licenses or certificates for 30 to 90 days for the second violation within two years of this article or the water pollution act; or revoke licenses or certificates for third violations within two years.[8] The director may seek civil penalties of up to $2,500 for the first offense and $5,000 for subsequent offenses.

Agriculture Requirements

• Local soil conservation districts, through referenda, may adopt land use regulations "in the interest of conserving soil and soil resources and controlling soil erosion." The regulations may include provisions for construction of soil-protective structures, provisions requiring particular methods of cultivation, specifications of cropping and tillage practices, provisions limiting cultivation of sensitive areas, and other measures.[9] The supervisors of the soil conservation district have authority to seek enforcement of the regulations in court if "nonobservance tends to increase erosion ... and is interfering with the prevention or control of erosion on other lands within the district".[10] Watershed improvement districts, organized within soil conservation districts, can also exercise these powers of a soil conservation district.[11]

• The commissioner of agriculture can develop mandatory BMPs for application and use of fertilizers and manures upon having evidence of groundwater pollution that could be effectively prevented with BMPs.[12]

• The state has authority for general groundwater protection rules for pesticides, including rules intended to prevent non-point pollution.[13] The only two stated rules are (1) to follow the label or special orders by the commissioner of agriculture to protect groundwater, and (2) to comply with the rules for certified applicators and pesticide businesses when applying restricted use pesticides. "Other non-point source management practices, voluntary and/or mandatory are reserved."[14] The commissioner may issue remediation orders, or may seek civil penalties.[15]

Development and Other Earth-Disturbing Activities

West Virginia does not appear to have specific provisions apart from any that may be contained in urban stormwater programs under the Clean Water Act, or that may be authorized by general land use provisions that provide for municipalities and counties to plan, zone, and regulate.[16] State law governing land use regulation notes that local land use plans may include measures for "sewers, sanitation and drainage", "stream pollution", and "conservation of water, soil, agricultural and mineral resources."[17] The law gives municipal and county governments authority to regulate land use and structures to carry out zoning objectives.[18] Enforcement is by civil injunction, or misdemeanor prosecutions with penalties of $10 to $300.[19]

WISCONSIN

Enforceable Provisions Applicable to Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Wisconsin's water pollution law does not contain a general discharge prohibition. However, the state may issue enforceable orders for the abatement of "significant" nonpoint source pollution, and for critical sites within priority watersheds.

Wisconsin law authorizes the department of natural resources (DNR) to issue general orders and adopt rules applicable throughout the state for "preventing and abating pollution of the waters of the state."[1] Pollution is defined as "contaminating or rendering unclean or impure the waters of the state, or making the same injurious to public health, harmful for commercial or recreational use, or deleterious to fish, bird, animal or plant life."[2]

• The law specifically authorizes the department to issue orders for the abatement of nonpoint source pollution which the department has determined to be "significant" on a case-by-case basis.[3] However, the department may not order abatement or best management practices with respect to pollution caused primarily by animal waste.[4] Investigations involving animal waste are handled under regulations described below under "Agricultural Requirements." Nor may the DNR order abatement of nonpoint source pollution from agricultural sources located in a priority watershed or priority lake area, unless the source has been designated as a "critical site" in the priority watershed plan.[5] The priority watershed program provides state funding for watershed staff and cost-sharing for necessary best management practices to control nonpoint sources of pollution within the watershed.[6]

One year's notice must be provided in orders for abatement or implementation of best management practices, unless the department determines that the pollution will cause severe water quality degradation that could be mitigated by action taken sooner.[7] The department may issue temporary emergency orders to abate nonpoint source pollution if certain statutory conditions are met.[8] Violators of agency orders are subject to administrative penalties of up to $5,000 per day. The state may recover the costs of investigation, as well as attorney's fees.[9] In addition, the department may take the action directed by its order and collect the costs incurred from the owner to whom the order was directed.[10]

• Where agricultural sources are involved, the department must first notify the county land conservation committee (LCC).[11] The department must also notify the state department of agriculture, trade and consumer protection (DATCP), which in turn issues a list of BMPs and financial and technical assistance sources to the person polluting and then submits a report to the department of natural resources within a year describing the actions taken and recommending whether to issue an order to abate pollution or implement best management practices. The DNR may not issue an order until it receives this report, unless it makes a determination of severe water quality degradation, concurred in by the DATCP.[12]

In addition, if the notice of intent is for a critical site in a priority watershed, the LCC may disapprove issuance of an order by acting within 60 days after the notice of intent was issued.[13] The DNR may appeal the disapproval to the state's Land and Conservation Board; the landowner may likewise appeal a proposed order that was not disapproved by the LCC.[14]

• In 1997, the legislature enacted a law requiring the DNR to prescribe performance standards for sources of nonpoint source pollution. For non-agricultural sources, the DNR must develop technical standards to implement the performance standards in order to "achieve water quality standards by limiting nonpoint source water pollution.[15] Provisions relating to agricultural sources are discussed below under "Agricultural Requirements."

Other Discharge Limitations

• The state's environmental health code gives local health officers the authority to order the abatement or removal of "human health hazards."[16] The state's water law, in addition to providing the order authorities described above, gives the department of natural resources authority to "order or cause the abatement of any nuisance affecting the waters of the state."[17] This includes nonpoint sources. However, Wisconsin's nuisance statute provides a general exception to nuisance cases involving agricultural sources. To qualify for the exemption, the agricultural use must be on land that was already used for agricultural purposes, use generally acceptable operating practices, and must not present a substantial threat to public health and safety. Relief granted must not substantially restrict or regulate agricultural uses or practices, unless the agricultural use or practice is a substantial threat to public health and safety.[18]

• Wisconsin's groundwater protection law establishes a framework for addressing activities that cause pollution of groundwater. The department of natural resources assigns groundwater enforcement standards, as well as "preventive action limits" -- more stringent restrictions on the permissible concentration levels of substances in groundwater.[19] A preventive action limit is not an absolute standard, but "shall serve as a means to inform regulatory agencies of potential groundwater contamination problems, to establish the level of groundwater contamination at which regulatory agencies are required to commence efforts to control the contamination and to provide a basis for design and management practice criteria in administrative rules."[20]

Each state agency is required to promulgate design and management criteria for facilities, activities and practices that are regulated by the agency and that affect groundwater.[21] This enforcement is linked to other statutory schemes. The department of natural resources "may not approve a proposed facility, practice or activity at a location where a preventive action limit or enforcement standard...has been attained or exceeded unless an exemption has been granted...."[22] For existing facilities, practices or activities, a response is required if a preventive action limit or an enforcement standard has been attained or exceeded.[23]

State regulations outline a variety of responses to be taken by agencies where a preventive action limit or enforcement standard is attained or exceeded. In cases involving enforcement standards, these response include requiring the following: monitoring; investigation; revision of operational procedures; change in design or construction; alternate methods of waste treatment or disposal; prohibition or closure and abandonment; remedial action to renovate or restore groundwater quality or to minimize further releases of the substance to groundwater; and revision of rules or criteria on facility design, location or management practices.[24] With limited exceptions, the regulations require the department to prohibit the activity or practice and require remedial actions unless the department can demonstrate that other responses will achieve compliance with enforcement standards.[25]

The law provides that regulatory agencies "shall enforce the provisions of this chapter in accordance with enforcement procedures and subject to the penalties established by statute for activities and practices regulated by the regulatory agency."[26]

Fish/Fisheries Laws

- Fisheries laws include the provision that no person shall "throw or deposit, or permit to be thrown or deposited, into any waters within the jurisdiction of the state any lime, oil, tar, garbage, refuse, debris, tanbark, ship ballast, stone, sand...slabs, decayed wood, sawdust, sawmill refuse, planing mill shavings or waste material of any kind, or any acids or chemicals or waste or refuse arising from the manufacture of any article of commerce, or any other substance deleterious to game or fish life."[27] (Exceptions are provided for approved operations involving sewage drainage and industrial waste, as well as certain highway work carried out under the direction of the department of transportation.)[28] This provision is enforced through forfeiture of not more than $200 per day, imprisonment of up to 90 days (for intentional violations), and natural resources damages.[29]

- Wisconsin's fish and game law also provides generally that no person "may take, capture or kill fish...in any waters of this state by means of...poisonous or stupefying substances or devices."[30] The wording may allow prosecution for fish kills even without a showing of intent to take fish. Enforcement is through fines of up to $500 and/or imprisonment up to 90 days.[31]

OPERATIONAL REQUIREMENTS

Forestry Requirements

- Wisconsin has a tax incentive program, which involves submitting a management plan.[32] While participation in the program is voluntary, there are penalties for violating the provisions of the program. For example, failure to file a notice of intent to cut, as required in the law, can result in a forfeiture not to exceed $1,000. In addition, any owner who intentionally cuts merchantable timber in violation of the law is subject to forfeiture equal to 20 percent of the current value of the merchantable timber cut.[33]

• "All slash, which during the process of cutting timber or taking out other forest products, falls into or is deposited in any lake or stream or on the land of an adjoining owner, shall be immediately removed therefrom by the timber owner or cutting operator...when in the opinion of the department such removal is in the public interest."[34] Violators are subject to a forfeiture of not more than $50, however repeat offenders are subject to higher fines and imprisonment.[35]

Agriculture Requirements

• As noted above, Wisconsin's water pollution law specifically authorizes the DNR to order abatement or best management practices with respect to nonpoint source agricultural pollution.[36] Certain limitations apply in priority watersheds.[37]

• The state soil and water conservation law authorizes the enactment of local ordinances for the control of nonpoint source pollution. County land conservation committees are authorized to "develop and adopt standards and specifications for management practices to control erosion, sedimentation and nonpoint source water pollution."[38] LCC's "may carry out preventive and control measures and works of improvement for flood prevention and for conservation, development, utilization and control of water within the county."[39]

In addition, county and municipal governments are authorized to enact ordinances to address nonpoint source pollution. Such ordinances are effective only if approved by referendum. "To promote soil and water conservation or nonpoint source water pollution abatement, a county, city, village or town may enact ordinances for the regulation of land use, land management and pollutant management practices....An ordinance enacted under this section may prohibit land uses and land management practices which cause excessive soil erosion, sedimentation, nonpoint source water pollution or storm water runoff."[40] The county board must adopt an ordinance setting forth administrative enforcement procedures and provide personnel for enforcement of ordinances enacted under the law.[41]

Enforcement is through civil forfeiture or injunction in an action initiated by the county or LCC. The court may award reasonable attorney fees to any plaintiff in a successful action for enforcement through injunction.[42] Notice to landowners or users is required, along with a list of BMPs and available financial assistance "at least one year before" the county or LCC may initiate an action for enforcement.[43]

The DATCP is also responsible for setting and implementing statewide soil and water conservation policies and administering the state's soil and water conservation programs. The department "shall coordinate" its soil and water conservation program with the state's nonpoint source water pollution abatement financial assistance program.[44]

• Wisconsin regulations contain permitting requirements for large animal feeding operations involving at least 1,000 animal units, requiring a WPDES permit. The regulations establish other requirements for smaller operations, where the state has determined through on-site investigation that the operation is responsible for a discharge of *significant* amounts of pollutants to waters of the state.[45] The DNR issues a notice of discharge allowing a specific time for a remedy. The regulations provide that the owner or operator must control the discharge by implementing necessary corrective measures in compliance with the regulations. [46] "Accepted animal waste management practices shall be used...in implementing the necessary corrective measures relative to runoff control, storage or disposal of animal wastes."[47] If an operation *fails to implement* necessary corrective measures, it must obtain a WPDES permit.[48] In addition, owners or operators of animal feeding operations subject to the regulations must design and install permanent runoff control structures, according to specified performances standards.[49] This standard can be modified by the department when the owner or operator demonstrates that such standards are more stringent than necessary to avoid detrimental effect on water quality.[50] Permitted facilities must provide manure storage and a landspreading plan.

• In 1997, the legislature enacted a law directing the DNR, in consultation with the DATCP, to promulgate rules setting performance standards and prohibitions for *agricultural* nonpoint sources, including performance standards and prohibitions for livestock operations.[51] The legislature also authorized local governmental units to regulate livestock operations consistent with state performance standards.[52] Such regulations may not apply to existing operations unless cost-sharing is available.[53]

• Wisconsin's pesticides law authorizes rule making to govern the use of pesticides, including their formulations, and to determine the times and methods of application and other conditions of use.[54] State regulations prohibit any person from using or directing the use of pesticides in a "negligent manner" or "in an manner that results in pesticide overspray or significant pesticide drift."[55] With limited exceptions, the regulations prohibit any person from causing a pesticide to enter waters of the state directly or through sewer systems, and from using a pesticide in a manner which the user knows or should know will result in contamination of state waters.[56] The regulations further require that chemigation systems be designed and operated to prevent pesticides used in the system from contaminating waters of the state.[57]

Enforcement of the state pesticide law is through forfeiture of between $100 and $500, with higher penalties for repeat violators. Commercial applicators, dealers or distributors who knowingly violates the misbranding and licensing provisions of the law are subject to a fine of $5, 000 and/or imprisonment for one year. The state may also apply to a circuit court for a temporary or permanent injunction to prevent, restrain or enjoin violations.[58] "In addition to other enforcement procedures, the department may issue a special order...prohibiting the use, application, storage, distribution or sale of pesticides...to prevent or control pesticide contamination of groundwater...."[59]

Development and Other Earth-Disturbing Activities

• Wisconsin's navigable waters protection law gives the department of natural resources a central role in the adoption of local shoreland zoning ordinances that relate to lands under, abutting or lying close to navigable waters. The purposes of such ordinances are to "further the maintenance of safe and healthful conditions; prevent and control water pollution; protect spawning grounds, fish and aquatic life; control building sites, placement of structure and land uses...."[60] The department is responsible for providing general recommended standards and criteria for navigable water protection regulations and their administration, and for authorizing such regulations.

Counties are required to adopt zoning and subdivision regulations for the protection of all shorelands in unincorporated areas.[61] State regulations require that these county shoreland ordinances include, at a minimum, zoning regulations for shoreland-wetland zoning districts.[62] The ordinances must "provide sufficient control of the use of shorelands to afford the protection of water quality...."[63] The regulations further specify certain minimum components, including building setbacks that "conform to health, safety and welfare requirements, preserve natural beauty, reduce flood hazards and avoid water pollution."[64] The regulations also require limits on alterations to existing nonconforming structures.[65] Exemptions from local shoreland zoning ordinances are provided for state highway and bridge work and for farm drainage ditches in certain circumstances.[66] Where a county has not adopted an ordinance that meets the "reasonable minimum standards," the department is to adopt an ordinance to be administered by the county.[67]

State law also explicitly requires municipalities (cities and villages) to adopt ordinances to regulate zoning of wetlands in shorelands.[68] State regulations establish minimum standards for the municipal ordinances. The regulations establish permitted and prohibited uses and address non-conforming structures and uses. If a municipality fails to establish an ordinance that meets "reasonable minimum standards," the department of natural resources is to adopt an ordinance for the municipality.[69]

Enforcement mechanisms are specified in the local ordinance. However, state law provides generally that county ordinances "shall be enforced by appropriate fines and penalties" and may be enforced as well by injunction in a suit by the local government or local affected property owners.[70] State law also provides that violations of city zoning ordinances are punishable by fine and by imprisonment for failure to pay such fine, and that violations are subject to suit by local government or affected property owners to prevent or correct the unlawful practice.[71] In addition, the department of natural resources may initiate enforcement through fines (not more than $50 per day) and injunctions if it determines that the city or village fails to keep its ordinance "current, effective and enforceable. [72]

- Wisconsin law also authorizes municipal construction site erosion control ordinances "for the efficient use, conservation, development and protection of this state's groundwater [and] surface water..." as well as for the prevention and control of water pollution, and the control of building sites and placement of structures and land uses.[73] State regulations require counties, cities, villages, and towns receiving financial assistance under the state's nonpoint source water pollution plan to adopt a construction site control ordinance if it is required in the watershed plan under the state program. Such ordinances also must require consistency with the Wisconsin Construction Site Best Management Practice Handbook.[74] The local ordinances are enforceable as explained above. A county board may authorize the local land conservation committee to administer and enforce the provisions of certain county zoning or construction site erosion control ordinances.[75]

WYOMING

Enforceable Mechanisms for the Control of Nonpoint Source Water Pollution

DISCHARGE PROHIBITIONS

Water Pollution Control Law

Wyoming's water pollution control law contains a general provision that may be used to enforce against nonpoint source discharges of pollution or waste. In addition, the permitting authority apparently can extend to nonpoint sources, and where permits are required, the state's antidegradation policy requires that permits be conditioned on implementation of best management practices to control nonpoint sources.

• The Wyoming Environmental Quality Act contains a general prohibition against "caus[ing], threaten[ing] or allow[ing] the discharge of any pollution or waste into the waters of the state" or "alter[ing] the physical, chemical, radiological, biological or bacteriological properties of any waters of the state" unless authorized by permit.[1] "Waste" is defined as "sewage, industrial waste and all other liquid, gaseous, solid, radioactive, or other substances which may pollute any waters of the state."[2] The prohibition has been held to apply to all polluting activities, not only those for which a permit could have been obtained.[3]

• The Act authorizes the Wyoming Department of Environmental Quality to issue environmental permits "when the department has, by rule or regulation, required a permit," and allows the department to "impose such conditions as may be necessary to accomplish the purpose of this act."[4] Since the permitting authority is not expressly limited to point sources, it arguably could be applied to nonpoint sources. Further, the water quality section of the Wyoming Administrative Code contains an antidegradation provision, which requires that "reasonable best management practices for nonpoint sources" be implemented before a permit can be issued.[5] In this context, "best management practices" are defined as practices "determined to be the most technologically and economically feasible means of preventing or reducing nonpoint source pollution."[6] The statute allows for variances from environmental permits after a notice-and-comment procedure;[7] however, the DEQ apparently has prohibited issuance of water pollution variances under this section, and this decision has been judicially upheld.[8]

The DEQ may investigate, hold administrative hearings, and issue cease-and-desist orders for violation*s of the environmental code.[9] It may assess administrative civil penalties of up to $10,000 per violation per day; criminal penalties of up to $25,000 per violation per day and/or imprisonment of up to one year; seek temporary and permanent injunctive relief; and receive reparations for violations that "cause the death of fish, aquatic life or game or bird life."[10]

Other Discharge Limitations

The Public Health and Safety Code provides two definitions of criminal nuisance that are relevant to nonpoint source pollution.

R0017310

• The first nuisance provision is a prohibition on placing dead animal matter or other waste, including "any refuse or garbage, or any offensive matter or substance whatever" into water bodies or in any place "so located that the said substance shall directly or indirectly cause or threaten to cause the pollution or impairment of the purity and usefulness" of water bodies.[11] This provision expressly exempts municipal garbage disposal systems and sewage systems, but has been held to apply to cattle lots, poultry businesses, and meat processing plants depending on the circumstances of the case.[12] It is apparently enforced by both law enforcement and health authorities, and violations are misdemeanors, punishable by a fine of $50-$200 and/or imprisonment of up to six months.[13]

• The second nuisance provision declares it a nuisance to "in anywise pollute or obstruct any watercourse, lake, pond, marsh or common sewer, or continue such obstruction or pollution, so as to render the same unwholesome or offensive."[14] This provision, enforced by local law enforcement officials, carries a maximum $100 fine per violation; these officials also may seek to abate the nuisance.[15]

Note that under the Wyoming Right to Farm and Ranch Act, farm or ranch operations cannot be held to be a public or private nuisance if they "conform to generally accepted agricultural management practices" and existed prior to a change in land use on the adjacent land.[16] Likewise, proof of compliance with feedlot regulations (discussed below) is an absolute defense against any nuisance action brought by a person whose property ownership is subsequent in time to the date of establishment of the feedlot, if those feedlot activities are also subject to local or DEQ regulation.[17]

Fish/Fisheries Laws

• The Public Health and Safety Code contains a general provision that prohibits manufacturing and industrial works from "throw[ing] or deposit[ing] in, or in any way permit[ting] to pass into any natural stream or lake ... wherein are living fish, any sawdust, chemicals, mill-tailing, or other refuse matter of deleterious substance or poisons ...that will or may tend to the destruction or driving away from such waters any fish...or that will or may tend to pollute, contaminate, render impure for domestic, irrigation, stock or other purposes."[18]

• Similarly, the Fish and Game Code states that "[n]o person shall allow any refuse or substance to pass into any public water: (i) [w]hich drives away or is injurious to fish, or wildlife; or (ii) [w]hich obstructs the natural flow, channels, or condition of any stream or body of water."[19]

Both of these provisions are enforced by the Health Department and the Department of Fish and Game; violation of either of them is a misdemeanor, punishable by fines of $50-$100 and imprisonment of 30 days to six months.[20] Neither of the provisions applies to slag from smelters, or to operations that construct settling ponds.[21]

OPERATIONAL REQUIREMENTS

Forestry Requirements

State forestry laws do not appear to contain enforceable provisions relating to nonpoint source discharges.

Agriculture Requirements

Wyoming law regulates feedlot operations and pesticide management practices that might contribute to nonpoint source water pollution. In addition, soil conservation districts are authorized to prescribe best management practices to combat erosion, and may provide financial incentives for landowners to adopt these BMPs.

• In a chapter titled "Livestock Feedlot Operations," the Wyoming Statutes authorize the Department of Environmental Quality to issue regulations governing livestock feedlots and to establish schedules for compliance with the rules.[22] Operations that are in compliance with the regulations have an absolute defense against a nuisance action brought by a person whose property ownership is subsequent in time to the date of establishment of the feedlot, if the feedlot activities are subject to other local or DEQ regulation.[23] Feedlot operators are also required to comply with applicable local zoning requirements.[24] Until recently, there appears to have been little, if any, regulatory activity under this chapter of the Statutes.

In February 1997, the legislature amended the Environmental Quality Act to require DEQ to promulgate "standards for housed facilities where swine are confined, fed and maintained for a total of forty-five (45) consecutive days or more in any twelve (12) month period and the feedlot or facility is designed to confine an equivalent of one thousand (1,000) or more animal units."[25] The new standards must include financial assurance for facility cleanup and closure; waste management plans; setback requirements that facilities be sited at least one mile from homes, schools and towns and 1/4 mile from domestic water wells and streams; and notice-and-comment provisions for any new permits.[26] If any county adopts a land use plan or zoning law with stricter setback standards, those will prevail over the statute.[27]

• Wyoming also has enacted a general pesticide control regime, which largely consists of registration and labeling requirements and requires that pesticides be applied in accordance with the labeling.[28] It includes a general prohibition against discarding, transporting or storing pesticides or containers "in such a manner as to cause injury to humans, vegetation, crops, livestock, wildlife, beneficial insects or to pollute any waterway in a way harmful to any wildlife therein."[29] The board of certification may promulgate rules governing discarding and storage of pesticides and pesticide containers, and is authorized to enter and inspect premises for enforcement of the pesticide law.[30] Violations of the law are misdemeanors, subject to a fine of up to $500 and/or imprisonment of up to one year for the first offense, and $1,000 and/or imprisonment of up to one year for subsequent offenses; actions for injunctive relief are also possible.[31]

• Finally, the Wyoming Statutes establish soil conservation districts and authorize them to conduct research, demonstration projects, improvement projects, and so on.[32] The districts may develop and publicize comprehensive plans that specify best management practices for soil conservation, but these do not appear to be enforceable.[33] However, the district's provision of loans, grants, and other benefits to private landowners may be conditioned on implementation of best management practices.[34]

Development and Other Earth-Disturbing Activities

• Under the Land Use Planning Act,[35] the state land use commission is authorized to develop a state land use plan, which may include "areas of critical or more than local concern."[36] These are defined as "areas...where uncontrolled or incompatible large scale development could result in damage to the environment, life, or property, where the short or long term public interest is of more than local significance," and can include, inter alia, "fragile or historic lands, natural hazard lands, renewable resource lands."[37] However, enforceability of the Act is doubtful unless local regulations are enacted; the statewide plan apparently is intended to serve as a "guideline" for the development and adoption of local land use plans and zoning regulations. Even in "areas of critical or more than local concern," the state land use commission is authorized only to "establish developmental guidelines" and to "assist local governments" in planning for these areas.[38]

THE ENVIRONMENTAL LAW INSTITUTE

For a quarter century, the Environmental Law Institute has played a pivotal role in shaping the fields of environmental law, management, and policy domestically and abroad. Today, ELI is an internationally recognized, independent research and education center.

Through its information services, training courses and seminars, research programs, and policy recommendations, the Institute activates a broad constituency of environmental professionals in government, industry, the private bar, public interest groups, and academia. Central to ELI's mission is convening this diverse constituency to work cooperatively in developing effective solutions to pressing environmental problems.

The Institute is governed by a board of directors who represent a balanced mix of leaders within the environmental profession. Support for the Institute comes from individuals, foundations, government, corporations, law firms, and other sources.

Water Environment Federation

The Water Environment Federation is a not-for-profit technical educational organization that was founded in 1928. Its mission is to preserve and enhance the global water environment. Federation members are more than 42 000 water quality specialists from around the world, including environmental, civil, and chemical engineers, biologists, chemists, government officials, treatment plant managers and operators, laboratory technicians, college professors, researchers, students, and equipment manufacturers and distributors.

American Society of Civil Engineers

The American Society of Civil Engineers (ASCE) offers civil engineering professionals many opportunities for technical advancement, networking, and leadership and technical skill training. Also available to members are major savings on educational seminars, conferences, conventions, and publications. On the local level, chapters (called Sections and Branches) act as advocates in the public interest on local issues and present seminars and programs relevant to the needs of the local community. For more information, call 800-548-2723 (ASCE) or visit ASCE's web site, http://www.asce.org.

Manuals of Practice

(As developed by the Water Environment Federation)

The Water Environment Federation (WEF) Technical Practice Committee (formerly the Committee on Sewage and Industrial Wastes Practice of the Federation of Sewage and Industrial Wastes Associations) was created by the Federation Board of Control (now Board of Directors) on October 11, 1941. The primary function of the committee is to originate and produce, through appropriate subcommittees, special publications dealing with technical aspects of the broad interests of the Federation. These manuals are intended to provide background information through a review of technical practices and detailed procedures that research and experience have shown to be functional and practical.

ASCE Manuals and Reports on Engineering Practice

(As developed by the ASCE Technical Procedures Committee July 1930 and revised March 1935, February 1962, and April 1982)
A manual or report in this series consists of an orderly presentation of facts on a particular subject, supplemented by an analysis of limitations and applications of these facts. It contains information useful to the average engineer in his/her everyday work, rather than the findings that may be useful only occasionally or rarely. It is not in any sense a "standard," however, nor is it so elementary or so conclusive as to provide a "rule of thumb" for non-engineers.

Furthermore, material in this series, in distinction from a paper (which expresses only one person's observations or opinions), is the work of a committee or group selected to assemble and express information on a specific topic. As often as is practicable, the committee is under the general direction of one or more of the Technical Divisions and Councils, and the product evolved has been subjected to review by the Executive Committee of that Division or Council. As a step in the process of this review, proposed manuscripts are often brought before the members of the Technical Divisions and Councils for comment, which may serve as the basis for improvement. When published, each work shows the names of the committee by which it was compiled and indicates clearly the several processes through which it has passed in review so its merit may be definitely understood.

In February 1962 (and revised in April 1982), the Board of Direction voted to establish a series entitled "Manuals and Reports on Engineering Practice" to include the Manuals published and authorized to date, future Manuals of Professional Practice, and Reports on Engineering Practice. All such Manual or Report material of the Society would have been refereed in a manner approved by the Board Committee on Publications and would be bound, with applicable discussion, in books similar to past Manuals. Numbering would be consecutive and would be a continuation of present Manual numbers. In some cases of reports on joint committees, bypassing of Journal publications may be authorized.

Preface

The quality of urban stormwater was largely ignored in the design of urban drainage systems until approximately 1980. Previously, the focus was on efficient surface drainage and flood control, namely the effects of relatively large storm events. However, a number of engineers and scientists were becoming aware that runoff from the smaller, frequently occurring storm events was the cause of many observed negative effects in the nation's streams, lakes, estuaries, wetlands, and other receiving water systems downstream of, and within, the urban and urbanizing areas. Stream banks experienced accelerated erosion, stream habitat was degraded or lost, lakes and estuaries eutrophied at a faster rate, and the water quality in the receiving waters showed noticeable degradation during and sometimes after wet weather events.

Although many of the observed negative effects could also be attributed to causes other than stormwater runoff from urban areas (for example, nutrient- and sediment-laden runoff from agricultural areas, runoff from industrial areas, and unpermitted point sources), a general concern about the effects of uncontrolled urban growth on the nation's waterways began to take hold. In 1982, Florida became the first state to pass a law requiring that the urban runoff from the first inch of rainfall be treated to remove pollutants. Maryland and Delaware followed suit shortly thereafter. In 1988, the U.S. Environmental Protection Agency (U.S. EPA) promulgated its first draft regulations for the nationwide control of urban runoff quality and, in 1990, published final regulations governing municipalities with populations of more than 100 000 people.

Guidance for designing controls for urban runoff quality management has been published in the literature by many individuals; however, most of these publications are oriented toward a specific geographic region of the country, and guidance for application in other areas is not addressed. Also, many of these publications discuss the design of individual controls but not the subject of planning for urban runoff quality management on a watershed-wide basis.

This manual comprises a holistic view of urban runoff quality management. For the beginner, who has little previous exposure to urban runoff quality management, the manual covers the entire subject area from sources and effects of pollutants in urban runoff through the development of management plans and the design of controls. For the municipal stormwater management agency, guidance is given for developing a water quality management plan that takes into account receiving water use objectives, local climatology, regulation, financing and cost, and procedures for comparing various types of controls for suitability and cost effectiveness in a particular area. This guidance will also assist owners of large-scale urban development projects in cost-effectively and aesthetically integrating water quality control to the drainage plan. The manual is also directed to designers who desire a self-contained unit that discusses the design of specific quality controls for urban runoff.

Chapter 1 provides information on the sources and effects of chemical constituents in urban runoff. The chapter discusses chemical constituents found in urban runoff, with indications of the frequencies and concentrations in which these constituents are found. The effects of urban runoff on receiving waters are also addressed, including effects on water quality and ecology. The chapter also presents a section on environmental resource protection, which looks at urban runoff quality management from the more holistic receiving water management point of view, rather than the narrower and more traditional pollution minimization approach.

Chapter 2 is directed primarily at municipal agencies, who must develop and implement, or regulate, a plan of urban runoff quality management. The chapter addresses the development of such a plan from two perspectives: meeting U.S. EPA requirements of the 1990 regulations and achieving the objective of environmental resource management. Master-planning considerations take into account the type of receiving water, designated and desired beneficial uses, permitting requirements, financing, and integration of quality management with quantity management.

Chapter 3 addresses monitoring, bioassessment, and modeling. Information in this chapter supports the planning activities in Chapter 2 and the monitoring of control practices or devices that have been constructed.

Chapters 4 and 5 provide guidance on the design and implementation of source controls and treatment controls, respectively, for urban runoff quality management. Guidance is provided at the beginning of each chapter on how to evaluate tradeoffs between the various controls addressed. However, if guidance on the design of a specific control is all that is desired, the user may go directly to that section in the chapter and develop the design from the guidance given there. Familiarity with other parts of the manual is not required if the performance requirements of the control are known, or if a particular control is required by ordinance.

The user of this manual should understand that while established scientific practice underlies the treatment controls addressed here, considerable professional judgment is involved in the application. For this reason, the designer should be knowledgeable in aquatic chemistry and aquatic ecology—in addition to hydrology and hydraulics—or seek the advice of someone who is. Designers are advised to use their own common sense in applying the design criteria to a specific situation, combining theoretical concepts with experience in the joint application of the principles embodied in these four disciplines.

Finally, there is no way to separate quality management from quantity management of urban runoff. This manual deals with urban runoff quality;

the quantity aspects of urban runoff management are addressed only in a general way. For more details on quantity concerns, the reader is referred to *Design and Construction of Urban Stormwater Management Systems*, published by the American Society of Civil Engineers and the Water Environment Federation in 1992 (ASCE Manuals and Reports of Engineering Practice No. 77; WEF Manual of Practice No. FD-20), which is the companion manual on urban runoff quantity.

MATERIAL ADDRESSED IN THIS MANUAL

URBAN RUNOFF EFFECTS AND CONTROL REQUIREMENTS. This manual focuses on the protection and enhancement of urban water resources through control of the transport of constituents into urban waterways by urban stormwater runoff. The manual emphasizes control of constituent discharges, reflecting the fact that chemical and particulate constituents in urban stormwater runoff play a key role in determining the negative effects of that runoff.

To provide a context for control requirements, receiving waters of potential concern are addressed, primarily in Chapters 2 and 3. Of these, streams tend to be the water body primarily affected by urbanization, and they are given special focus later in this introductory chapter. It is noted that the discussion of control addresses both traditional and developing approaches to control. Traditionally, control requirements have often been set without regard to the specific intended use of the receiving water. More recently, there have been attempts to improve the methods for measuring and assessing how constituents of stormwater runoff affect designated beneficial uses (see Chapters 1 and 3).

BEST MANAGEMENT PRACTICES. Best management practice, or BMP, as applied to urban runoff management was a term adopted in the 1970s to represent actions and practices that could be used to reduce the flow rates and the constituent concentrations in urban runoff. It reflects the developing and somewhat empirical engineering that applies to this area of practice and differentiates it from the more highly developed and predictable engineering associated with traditional wastewater treatment facility design.

R0017342

A variety of urban BMPs are considered in Chapters 4 and 5. Source control practices and "passive" BMP systems (those not requiring active operational control or adjustment beyond routine maintenance) are described in some detail. Design considerations for "active" treatment technologies (those that are not passive, such as ultraviolet irradiation for bacteria [Craig and Tracy, 1993] or chemical precipitation for phosphorus) are not included in this manual. However, planning approaches, which might lead to the need for such systems, are discussed in Chapter 2. Design objectives for BMPs, and processes by which objectives can be established, are discussed in Chapter 2. It is noted that objectives can be stated in terms of technology (by specifying a particular control device) or in terms of quantitative effect (for example, by specifying a required degree of control or a maximum allowable effect). Because quantitative objectives can be defined for both hydrological parameters and constituent removal performance parameters, both of these are discussed. Examples of objectives based on hydrological parameters include peak flow rate and retention of a defined water volume for a specific period of time, while objectives based on chemical parameters include percent removal of specific chemical constituents and effluent concentration or mass discharge targets.

The understanding of the role of BMPs in reducing the potential toxicity of stormwater runoff is evolving. Data characterizing toxicological properties of urban runoff are sparse, and the scale-up of event-type phenomena to receiving water effects is not well understood. However, significant advances are being made in understanding this issue (see Chapters 1 and 3).

Best management practice technology is imperfect; for example, BMPs may not have a significant effect on the removal of soluble toxic substances. Therefore, pollution prevention (source control) and public education (also inherently a source control) are discussed in Chapter 4 as ways of providing some added improvement to effluent quality.

WATER QUALITY PARAMETERS. Water quality parameters addressed most in this manual are total suspended solids (TSS) and nutrients (nitrogen and phosphorus); this reflects current common practice in BMP design. In fact, TSS and nutrients are the primary constituents of stormwater runoff that can be controlled by the passive BMPs considered in this manual. It is noted that focus on these parameters is not a complete oversight of other parameters, because most other constituents of concern (for example, metals, hydrophobic organics) are reduced by the processes used to remove TSS, and most biochemically removable constituents will be reduced by processes that remove nutrients. Moreover, the two most widely documented effects of urban runoff on receiving waters are associated with sediment and nutrient enrichment.

Benefits do accompany the removal of other substances, such as metals (for example, copper, zinc, iron, and lead) if they are primarily particulate, hydrophobic organics, detritus, and bacteria. However, it is difficult to develop design criteria to control these substances because their removal depends on physiochemical factors that are intractable in design. All things considered, it is not unreasonable that present common practice focuses on particulate removal, and this approach is adopted in this manual.

It is noted that water quality parameters described in this manual typically use the total mass per unit volume (total concentration) as a basis for discussion. This is because the reference quantity used in many water quality standards is the total concentration. It is nevertheless recognized that the ecological significance of total concentration is the subject of much debate. This debate arises because in flowing water, the soluble form of substances (for example, in the case of copper) is the form that most directly causes toxicity to biota. However, the chemistry of the water, the substrate, and other factors make toxicity determination based on chemical speciation a complex process. This level of assessment is considered to be outside the present scope of practice targeted by this manual. References dealing with the details of aquatic toxicity may be sought in the literature.

DEFINITIONS OF TERMS

Constituents, pollutants, and contaminants are terms often used interchangeably in discussions of urban stormwater runoff. This section presents definitions for these and other commonly used terms in this manual. Definitions of various types of constituents of urban stormwater runoff are also presented. These latter definitions have been adapted from a technology-transfer publication of the University of Connecticut (1994):

- Site runoff coefficient—the ratio of direct runoff volume to rainfall volume, calculated over the duration of an event from beginning of rainfall to end of runoff resulting from that rainfall.
- Site imperviousness—the fraction of land surface that does not allow infiltration of rainfall at the start of a rainfall event.
- Constituent—a substance found in dissolved, colloidal, or particulate form in water that can be measured as a concentration.
- Pollutant—(a) a substance discharged at a rate that causes the receiving water ecosystem to become degraded or (b) a constituent in stormwater runoff that has a concentration and discharge rate (mass/time) that causes an impairment of designated beneficial uses of the receiving water. (The basis of a designated beneficial use [such as aesthetics, potability, recreational contact or noncontact, aquatic food consumption, or aquatic ecosystem protection] and its application in setting management objectives for urban stormwater runoff are presented in Chapter 2.)
- Contaminant—a term often used interchangeably with "pollutant" or to represent substances such as trace metals and synthetic organic

chemicals that have not historically been found in aquatic systems at present levels and that have been introduced by anthropogenic activities such as the processing of geological materials (such as lead from lead sulfide ores) or the release of new compounds not previously found in nature (such as pesticides).

- Water quality parameter—a physical, chemical, or biological characteristic, property, or representation of the quality of water. The parameter may be stated in qualitative terms (for example, an aesthetic property such as the presence or absence of trash) or in quantitative terms (for example, the concentration of a constituent in water).
- Pathogens—disease-causing microorganisms such as bacteria, viruses, and protozoan cysts that come from the fecal waste of humans and animals. Pathogens wash off the land from animal and pet waste. A more significant source of pathogens, especially in older urban areas, is the illegal connection of sanitary sewers to "separated storm sewers."
- Nutrients—substances that stimulate plant growth, such as nitrogen and phosphorus. Nutrients in polluted runoff can come from fertilizers, home lawn-care products, plant excretion, and yard and animal wastes. Other sources include cross connections and atmospheric inputs (for example, nitrous oxide emissions from automobiles).
- Sediments—sand, dirt, and gravel eroded by runoff that typically end up in stream beds, ponds, or shallow coastal areas. Poorly protected construction sites, roadways, suburban gardens and other unvegetated areas, and winter maintenance (sanding operations) can be significant sources of sediment. Soil erosion is more severe in areas under construction than in mature urban areas, which are stabilized by vegetation, pavement, houses, and sidewalks.
- Potentially toxic contaminants—substances that can harm the health of aquatic systems or human life. Toxins are created by a wide variety of human practices and products and include heavy metals (such as copper and lead), pesticides, and organic compounds. Oil, grease, and gasoline from roadways and some chemicals used in homes, gardens, and yards are toxic contaminants. An evolving area of knowledge is the role of automobile wear and tear (copper products, brake linings, oil drippings, and crankcase and radiator leaks), corrosion, and emissions and changes in vehicle technology and fuel constituents (for example, the removal of lead from gasoline) in contributing to these substances in urban runoff.
- Debris—trash, or solid waste, that often starts as street litter and is carried by runoff to waterways.

Of special note in further defining a pollutant are the terms "balanced" and "unbalanced," which have been used to describe oxygen concentrations in streams (Streeter and Phelps, 1925) and, in particular, eutrophication, which is associated with the excessive input of nutrients to the receiving water system. In the concept of balance, there are two significant *in situ* processes involved in a biological cycle: planktonic growth (that is, reduction of minerals and synthesis of organic materials) and bacterial degradation (that is, oxidation or decomposition of organic matter to liberate nutrients). When these two processes are in balance, the rate of eutrophication is minimal (Oswald and Golueke, 1966).

Therefore, pollution is a result of processes becoming out of balance, and the degree of pollution is a function of the degree of imbalance (for example, stimulation of planktonic growth or bacterially induced deoxygenation). Furthermore, concepts such as desired and designated beneficial uses have evolved to include other considerations such as human-health–related issues, consumptive uses, recreational uses, aesthetic values, and other water resource considerations.

STUDIES OF NONPOINT SOURCE POLLUTION AND REGULATORY BACKGROUND

The study of urban nonpoint source runoff in the U.S. has evolved from initial research into chemical constituents in dustfall and rainout conducted by the U.S. Geological Survey in the 1960s (Carter, 1961, and Leopold, 1968). The discovery that significant quantities of nutrients, pesticides, herbicides, and heavy metals were contained in urban runoff caused the U.S. Environmental Protection Agency (U.S. EPA) to require that regional urban planning agencies in the U.S. conduct planning studies regarding ways to reduce pollution from urbanized areas under Section 208 of the Clean Water Act. The studies, which came to be known as the "208 nonpoint source planning area studies," were conducted throughout significant metropolitan areas across the U.S. during the 1970s. The 208 studies were not successful because the profession had little experience in how to measure and quantify runoff quality or in the effectiveness of control measures in a dynamic system subject to the vagaries of urban hydrology. The unsuccessful 208 programs prompted U.S. EPA to fund the National Urban Runoff Program (NURP) of the early 1980s. While early studies aimed to define the magnitude of nonpoint source pollution relative to point sources and the significance of urban nonpoint sources (such as combined sewer overflows and separated storm drainage systems) relative to rural sources (such as agricultural land uses; wooded lands; and arid, sparsely vegetated lands), recent studies have focused on confirming the levels of pollution and effectiveness of pollution control efforts. A similar study path has been followed in Europe and Canada (Marsalek *et al.*, 1993), in which the focus on characterizing the relative importance of nonpoint sources has changed to the implementation of BMPs in agricultural and urban areas.

R0017346

Best management practice, which has the roots of its definition in agricultural practice, refers to management practices and "soft engineering" methods to control pollutants in runoff. Agricultural management practices include leaving stubble in harvested fields to reduce wind erosion, fertilizer management to reduce costs, and crop rotation to increase yields; soft engineering controls include contour plowing, establishment of buffer zones between working fields and receiving waters, and check dams in drainage ditches to reduce sediment production. In an urban setting, BMPs are of two types: source controls (sometimes called "nonstructural" controls) and treatment controls (sometimes called "structural controls"). Source controls, which are described in detail in Chapter 4, are practices that keep chemical constituents from entering the runoff. Examples are covering chemical storage areas and/or diverting runoff away from such areas, street sweeping, and household hazardous waste recycling programs. Treatment control BMPs refer to devices that remove pollutants from the runoff. Examples are vegetated swales and buffers strips, infiltration, detention, and retention. Chapter 5 addresses treatment controls in detail.

After two decades of emphasis by U.S. EPA on the treatment of point source pollution as part of the Federal Clean Water Act (CWA) of 1972, remaining pollution problems now stem predominantly from diffuse and minor point sources. According to U.S. EPA, nonpoint source pollution represents more than half of the remaining water quality problems in the U.S. Through more recent legislation, U.S. EPA has developed a multifaceted approach to controlling runoff quality from these sources. Largely implemented through state agencies, this approach consists of overlapping programs covering general state strategies for nonpoint sources, municipal and industrial runoff quality, national estuary protection, protection of the U.S. Great Lakes, coastal zone protection, total maximum daily loads, and combined sewers. Runoff quality requirements have also indirectly been established through other federal and local environmental programs, such as environmental impact statements, endangered species programs, and wetlands preservation programs.

The CWA, as amended in 1987, and subsequent U.S. EPA regulations governing National Pollution Discharge Elimination System (NPDES) permits for stormwater discharges are the principal vehicles for controlling stormwater pollutants at the federal level. The 1987 amendments to CWA added Section 402(p), which established a framework for regulating municipal and industrial stormwater discharges as part of the NPDES program. In addition, in November 1990, U.S. EPA published regulations that established application requirements for stormwater NPDES permits.

U.S. EPA's application requirements for municipal discharges consist of two parts. Part 1 requires the discharger to collect existing information regarding stormwater dischargers, receiving waters, management programs, fiscal resources, and associated elements. In Part 2, a municipality is expected to take this information and formulate a stormwater management program designed to reduce the discharge of pollutants to the "maximum extent practicable."

Other laws/programs that directly or indirectly affect the control of stormwater pollutants are discussed in Chapter 2.

HYDROLOGICAL CHARACTERISTICS OF URBAN STORMWATER RUNOFF

HYDROLOGICAL CHANGES IN AN URBAN CATCHMENT. In general, urbanization can change a hydrologic cycle by

- Reducing the degree of infiltration and increasing the volume of runoff because of development of surfaces (changing slope, form, or cover);
- Changing the amount of depression storage because of regrading;
- Changing evapotranspiration because of removal of vegetative cover; and
- Reducing the travel time to a receiving body of water because of the construction of efficient sewer systems.

In extreme cases, small streams may be completely replaced by pipes and open channels after urbanization, resulting in streams and open channels that are completely dry between storms.

Imperviousness and Runoff. The relationship between imperviousness and runoff is worth considering in some detail. Figure 1.1 provides a good representation of the way the site runoff coefficient typically relates to site imperviousness. The figure was developed from more than 40 runoff monitoring sites throughout the U.S. (Schueler, 1994). The runoff coefficient (event runoff volume divided by event rainfall volume) ranges from 0 to 1, representing no runoff at one extreme and no infiltration at the other.

The first significance of the figure is that the runoff coefficient is closely correlated with the percentage of impervious cover, except at very low imperviousness. At low levels, other factors (soils and slopes) become important and imperviousness is a less perfect predictor of runoff coefficient.

It is interesting to note that the total runoff volume for a 100% paved parking lot is approximately 20 times that produced by an undeveloped meadow. This is indicative of the degree to which runoff volume can increase as sensitive lands are developed. Peak discharge, velocity, and time of concentration of stormwater runoff would also increase to a large degree in such a situation (see Table 1.1).

Another example of this is the calculated effect on a catchment's hydrol-

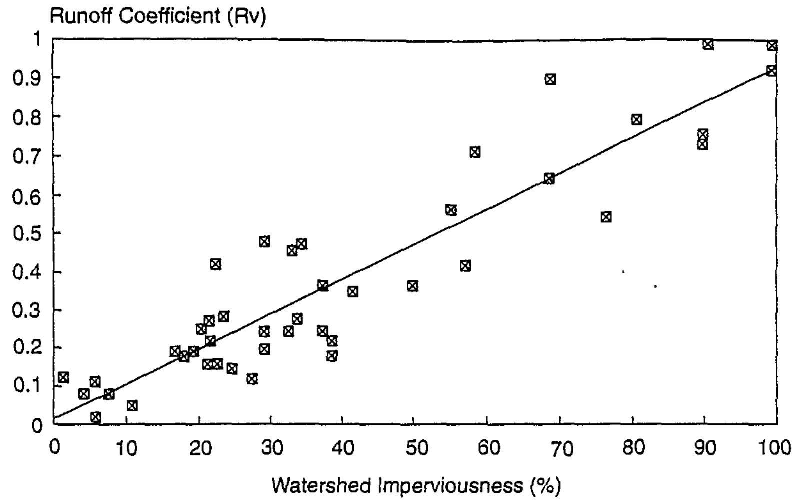

Figure 1.1 Watershed imperviousness and the storm runoff coefficient.

Table 1.1 Comparison of 1 ac (0.4 ha) of parking lot versus 1 ac (0.4 ha) of meadow in good condition (from Schueler, T.R. [1994] *Watershed Protection Techniques: a Quarterly Bulletin on Urban Watershed Restoration and Protection Tools.* Center for Watershed Protection, Silver Spring, Md., 1, 1, with permission).

Runoff or water quality parameter	Parking lot[a]	Meadow[b]
Curve number	98	58
Runoff coefficient	0.95	0.06
Time of concentration, minutes	4.8	14.4
Peak discharge rate, cfs,[c] 2/year, 24-hour storm	4.3	0.4
Peak discharge rate, cfs, 100-year storm	12.6	3.1
Runoff volume from 1-in. storm, cu ft[d]	3 450	218
Runoff velocity at 2-year storm, ft/sec[e]	8	1.8
Annual phosphorus load, lb/yr/ac[f]	2	0.50
Annual nitrogen load, lb/yr/ac	15.4	2.0
Annual zinc load, lb/yr/ac	0.30	—

[a] Parking lot is 100% impervious, with 3% slope; 200-ft (61-m) flow length; type 2 storm, 2-year, 24-hour storm = 3.1 in. (79 mm); 100-year storm = 8.9 in. (226 mm); hydraulic radius = 0.3; concrete channel; and suburban Washington "C" values.
[b] Meadow is 1% impervious, with 3% slopes, 200-ft (61-m) flow length, good vegetative condition, "B" soils, and earthen channel.
[c] cfs × 0.028 32 = m^3/s.
[d] cu ft × 0.028 32 = m^3.
[e] ft/sec × 0.304 8 = m/s.
[f] lb/yr/ac × 1.121 = kg/ha·a.

Table 1.2 **Effect of urbanization on distribution of May to November water budget for forested and urban areas.**[a]

Item	Forested areas		Urban areas with 40% impervious land			
			No infiltration		With infiltration

May to November rainfall	515	100	515	100	515	100
Interception storage and depression storage on impervious areas	342	66.5	235	45	235	45
Infiltration	155	30	100	20	200	40
Runoff	18	3.5	180	35	80	15

[a] Sandy soils assumed.

ogy because of a change in land use from a forested area to a typical single-family residential area. The results show a decrease in infiltration, depression storage, and interception storage (see Table 1.2). This results in a tenfold increase in the volume of runoff that reaches the receiving stream. Other observed changes in urban hydrology include the ratio of urbanized to nonurbanized peak flows. Data for three sites are provided in Table 1.3 (Urbanos and Roesner, 1992).

Table 1.3 **Ratio of peak runoff rates before and after development at three single-family residential sites.**

Return period, years	Post/preurbanization ratios of runoff peaks		
	New Jersey site[a]	Denver, Colorado, site[b]	Canberra, Australia, site[c]
2		57.0	9.0

15	3.0		
100		1.85	1.9

[a] 33-in. (840-mm) annual precipitation; based on modeling pre- and postdevelopment conditions using SCS TR-55 model and type II storm distribution.
[b] 15-in. (380-mm) annual precipitation; based on 8-year rainfall–runoff data record and 73-year simulation of pre- and postdevelopment conditions.
[c] 22-in. (550-mm) annual precipitation; based on statistical analysis of similar size adjacent developed and undeveloped tracts of land.

Effect of Imperviousness on Groundwater Recharge. As runoff volume increases with imperviousness, infiltration reduces. Groundwater recharge may be expected to reduce accordingly, which should, in turn, tend to cause lower dry weather stream flows. This is an effect that has been associated with urbanization; however, there are actual data that suggest this effect is not universal. An analysis of 16 North Carolina (U.S.) watershed areas could not find any statistical difference in low stream flow between urban and rural watersheds (Schueler, 1994). Nevertheless, other studies support the conclusion that the phenomenon exists. For example, dry weather flows dropped 20 to 85% after development in several urban watersheds in Long Island, New York (U.S.) (Schueler, 1994). And, in contrast, by evaluating low-flow statistics for urban streams in Toronto, Ontario (Canada), Belore (1991) found that low-flow rates (over a 7-day moving average and 10-year return period) increased during a 30-year urbanization period. One explanation offered for this counterintuitive result is that the additional water discharged to storm sewers from sources such as lawn irrigation and sanitary sewer exfiltration was sufficient to affect mass balances.

The net result of these studies is a mixed picture concerning the effects of urbanization on groundwater infiltration as inferred from base flow in streams. Therefore, it may be useful to critically evaluate these and other new studies case by case, paying particular attention to infiltration estimates distinct from base flow trends.

IMPERVIOUSNESS AS AN INTEGRATING CONCEPT. It is difficult to provide a measure of effect that simultaneously reconciles the needs of various scientists, engineers, and other stakeholders who must deal with the effects of urbanization. Nevertheless, some such common measure is needed if results are to be consistent when these individuals make decisions regarding individual development sites or the watershed as a whole.

One suggested index of effect is the amount of imperviousness on a given site or watershed. Imperviousness is the percent, or decimal fraction, of the total catchment covered by the sum of roads, parking lots, sidewalks, rooftops, and other impermeable surfaces of an urban landscape. Operationally, for mature urban areas, watershed imperviousness can be defined as the fraction of watershed area that is unvegetated.

Another way to describe imperviousness is that it represents the imprint of land development on a landscape, which, in simplistic terms, consists of two primary components: rooftops under which humans live, work, or shop and a transportation system consisting of roads, driveways, and parking lots. Increasingly, the "transportation system" often exceeds the rooftop component in terms of total impervious area created. For example, transportation-related imperviousness composed 63 to 70% of total impervious cover in 11 residential, multifamily, and commercial areas in the city of Olympia, Washington (U.S.) (Schueler, 1994, and City of Olympia, 1994).

Because imperviousness is a useful indicator for measuring the varying effects of land development on receiving waters and their aquatic systems, it can be viewed as providing a unifying theme in urban watershed protection (Schueler, 1994). It should be recognized that this is a convenient approximation only, not necessarily a realistic measure.

CONSTITUENTS IN URBAN STORMWATER RUNOFF

Two general approaches have developed in the literature for estimating contribution to chemical constituents in stormwater runoff: approaches based on human activities (such as pesticide application) and those based on general land-use categories (such as suburban downtown). Presently, land-use category approaches dominate the field of urban stormwater management to predict constituent concentrations. Primary land-use contributors are streets, roads, and highways; residential areas; commercial areas; industrial areas; and sites under development.

Historical case studies have provided alternative ways of estimating constituent loadings from urban areas or helped in developing methods for predicting pollutant levels based on urban characteristics (such as street accumulation or curb length). Implications for monitoring these studies are provided later in this chapter.

RESULTS FROM THE NATIONAL URBAN RUNOFF PROGRAM. National Urban Runoff Program research (U.S. EPA, 1983), which includes data from 28 urban sites throughout the U.S., is a compilation and evaluation of urban runoff data. The NURP study was funded and guided by U.S. EPA from 1978 to 1983, and although conducted at 28 local sites, it was reviewed, coordinated, and managed centrally.

One objective of the study was to characterize the water quality of discharges from separated storm sewers that drain residential, commercial, and light areas. The majority of samples collected in the study (see Table 1.4) were analyzed for eight conventional parameter sets. However, the study did not rigorously address issues such as the significance of elevated constituents' concentrations in urban runoff as they relate to the designated beneficial uses of receiving waters. This issue and the assessment/measurement of effects have been primary focuses of research and monitoring in similar studies of the 1990s.

The NURP study found that geographic location, land-use category, runoff volume, and other factors appeared to be of little use in explaining overall site-to-site or event-to-event variability. The NURP study determined that the best general characterization to predict characteristics of urban runoff at unmonitored sites is obtained by pooling site data from all sites (other than the open/nonurban ones). Pooled data for water quality characteristics from the NURP study are given in Table 1.4. In the absence of better

Table 1.4 **Overall water quality characteristics of urban runoff (U.S. EPA, 1983).**

Constituent	Typical coefficient of variation	Site median EMC[a] For median urban site	Site median EMC[a] For 90th percentile urban site
TSS, mg/L	1–2	100	300

[a] Event near concentration.

information, the NURP study recommended the values given in Table 1.4 for planning purposes as the best description of the expected quality of urban runoff.

The event mean concentration (EMC) and the site mean concentration (SMC) are approaches to reporting the concentration of constituents in urban stormwater runoff and are used in Table 1.4 and subsequent chapters. Event mean concentration is the total mass of the constituent in the runoff event divided by the total volume of runoff during that event. Site mean concentration is the mean (from an arithmetic probability distribution) or median (from a log-normal distribution) value of all EMC values measured for a particular monitoring site.

In addition to assessing water quality characteristics, a portion of the NURP study also involved monitoring 120 "priority pollutants" in stormwater discharges (Thon, 1992). The study detected 77 priority pollutants in samples of stormwater discharges from the study sites, including 14 inorganic and 63 organic substances. Representative detection frequencies included lead (94%), zinc (94%), copper (91%), chromium (58%), arsenic (52%), pesticides (in particular, endosulfan, chlordane, and lindane) (15 to 19%), pentachlorophenol (19%), phthalates (22%), and fluoranthene (16%).

CONCENTRATIONS ESTABLISHED IN RECENT DATA SETS. **Representative Concentrations from One Urban Area.** The NURP database includes a limited number of water quality parameters. Where resources permitted, more parameters were monitored and SMC estimates were developed to determine the concentrations of other constituents (see Tables 1.5

Table 1.5 Comparison of concentrations measured in Toronto waterfront studies with various water quality criteria (separated urban stormwater system discharge to Lake Ontario).

and 1.6 and papers published in Torno *et al.* [Eds.], 1994, for recent data). These data sets provide several advantages. A data set from the same site improves the assessment of water quality because it is often difficult to find an internally consistent set of data that includes most parameters. New statistical techniques for detection-limit data now permit estimation of the SMC, even if 80% of the EMC data from a site are below analytical detection limits. Moreover, new analytical equipment and improved sampling and analytical methodologies have resulted in lower detection limits and more rigorous quality assurance/quality control.

Concentrations measured in separated urban storm sewers for dry weather and wet weather conditions are given in Tables 1.5 and 1.6 and are compared to various water quality targets. Catchments that are drained by these storm sewers serve low-density suburban areas (that is, drainage areas ranging from

R0017356

10 to 100 ha) of Metropolitan Toronto along the Toronto waterfront (D'Andrea *et al.*, 1993). For many conventional parameters and trace metals, observed concentrations (see Table 1.5) exceeded relevant receiving water standards and even targets established for discharges to storm drains. For a variety of other compounds (see Table 1.6), either urban source concentrations were below water quality targets or water quality targets were not established.

In general, these and similar literature data sets (Cooke *et al.*, 1995) can be used to define exclusionary criteria for parameter selection, provided that additional criteria, such as a knowledge of what constituents have the potential to be in the water, are used to define the parameters to be excluded.

GENERAL LITERATURE. The following is a list of references for individual sources of constituents in urban stormwater runoff:

- Atmospheric deposition, general levels (Halverson et al., 1982; Harrison and Johnston, 1985; Ng, 1987; and Novotny and Chesters, 1981).
- Atmospheric deposition by land-use type (Novotny and Kincaid, 1982; Pitt and Barron, 1989; and Randall *et al.*, 1982), geology (Pitt, 1979), wet fall–dry fall (Bannerman *et al.*, 1984), and dry deposition (Department of City Development, 1981).
- Street refuse deposition (see U.S. EPA, 1984, for particles greater than 60 μm).
- Vegetation (Halverson *et al.*, 1984, and Heaney and Huber, 1973).
- Traffic (Harrison and Johnston, 1985; Pitt, 1979; Sartor and Boyd, 1972; Shaheen, 1975; and Strecker *et al.*, 1987).
- Deicing chemicals, when applied (Field *et al.*, 1974; Lord, 1988; Oberts, 1986; and Zariello, 1990).
- Impervious and pervious surfaces:
  - Accumulation on impervious surfaces—buildup (Heaney and Huber, 1973; HEC, 1975; Huber, 1986; James and Boregowda, 1986; U.S. EPA, 1971; and Whipple *et al.*, 1978);
  - Retrainment from impervious surfaces (Cowherd *et al.*, 1977, and Pitt, 1979);
  - Winter accumulation (Bannerman *et al.*, 1984);
  - Washoff (Sartor and Boyd, 1972; Sartor *et al.*, 1974; and Zison, 1980); and
  - Losses with snow melt processes (Bengtsson, 1982; McComas *et al.*, 1976; Novotny, 1987 and 1988; Oberts, 1986 and 1990; and Westerström, 1990).
- Cross connections and illicit discharges (Pitt *et al.*, 1990a and 1990b, and Schmidt and Spencer, 1986).
- Grain size distribution (Sartor et al., 1974).

The following is a list of references for other substances in urban runoff (see Marsalek and Torno [Eds.], 1993; Torno *et al.* [Eds.], 1994; and historical references cited below):

- Microorganism (Glenne, 1984, and Olivieri *et al.*, 1977 and 1989);
- Pesticides and herbicides (U.S. EPA, 1984);
- Plasticizers (U.S. EPA, 1984);
- Polychlorinated biphenyls (Marsalek, 1986);
- Petroleum hydrocarbons (Hoffman, 1985, and Hoffman *et al.*, 1984);
- Polyaromatic hydrocarbons (Fam *et al.*, 1987; Forster, 1990; Hoffman *et al.*, 1984; and Marsalek, 1990);
- Toxicity (Pitt and Barron, 1989); and
- Atmospheric acidity and its influences (Forster, 1990, and Novotny and Kincaid, 1982).

Measurement of Other Chemicals. There are more than 60 000 chemicals used in the U.S. In relative terms, only a few are analyzed in a typical extended suite of analysis (approximately 100 to 150) or are regulated in terms of having receiving water standards. More recent studies (Waller *et al.*, 1995) have identified pesticides such as diazinon, which is a toxicant that is not typically tested for in water quality monitoring programs, in runoff in the southern U.S. Therefore, a designer should be encouraged to consider potential unknown factors about chemicals used in watersheds to establish a water quality management or monitoring program.

CONCENTRATIONS IN RUNOFF FROM OTHER STORMWATER SOURCES. Combined Sewer Overflows. Representative constituent levels for combined sewer overflows (CSOs) based on late 1970s monitoring have been established by U.S. EPA (1978). Although CSOs have been scrutinized by researchers and U.S. EPA and a large number of data sets on their use have been compiled, a statistical analysis comparable to NURP studies is only now evolving. Therefore, only ranges and mathematical averages have historically been reported. Some analysis has emphasized EMCs for CSOs (Driscoll and James, 1987).

The significance of CSOs, relative to secondary wastewater treatment plant (WWTP) discharges to surface waterways, was demonstrated in a U.S. EPA nationwide assessment conducted in 1978. For example, for the same land area, loadings from CSOs relative to loadings from secondary WWTPs had the following relationships: biochemical oxygen demand (BOD), equal; lead and suspended solids (SS), CSOs were 15 times larger; and total nitrogen and phosphorus, CSOs were one-quarter to one-seventh. The relative significance of CSOs and separated storm sewers in a watershed is site specific. For initial screening for planning purposes on a watershed basis, consideration of the relative volumes of runoff from different types of land areas (for example, separated storm drains, highways, or CSOs) and EMCs for these land areas is an appropriate approach. Where data for CSOs are not available, an EMC can be estimated from the relative volume of stormwater flow and sanitary sewer flow in the "overflow event" and the stormwater EMC and sanitary wastewater concentration (estimated as the dry weather flow concentration or the average wet weather concentration in the WWTP inflow).

Industrial Sources. Data for concentrations in runoff from industrial sources are evolving under the NPDES program. A designer is encouraged to contact local agencies and trade associations for relevant data.

Highway Sources. The U.S. Federal Highway Administration (FHWA) maintains a national database for highways similar to the NURP database. In the FHWA database, sites were sampled during the same time period (early 1980s) as the NURP database and were summarized by Driscoll *et al.* (1990) using similar statistical techniques (such as EMCs and reduction to approximately log-normal distributions).

The FHWA database contains concentration data (see Watershed Planning section) for 10 water quality parameters. The database has been summarized for urban areas and rural areas for two highway traffic densities: greater than and less than 30 000 average daily traffic (ADT). (Traffic density is the total number of vehicles that drive past a specific point in both directions in all lanes expressed on a daily basis.) Investigators such as Strecker *et al.* (1990) have provided probabilistic representations of the data (see Watershed Planning section). Recent synthesis documents (for example, Young *et al.*, 1996) stress that the categories of "urban/rural" and "less than/greater than" continue to be the accepted approach for estimating pollutant concentrations in highway runoff. However, some question still exists about the use of the database—most of the urban sites had an ADT of greater than 30 000, whereas most of the rural sites had an ADT of less than 30 000. This led Young *et al.* (1996) to summarize the data for two categories, urban areas (ADT > 30 000) and rural areas (ADT < 30 000), and to not provide data for the opposite categories of urban areas (ADT < 30 000) and rural areas (ADT > 30 000). Other studies that focus on data from only one site (such as Kerri *et al.*, 1985; Barrett *et al.*, 1995; and Thomson *et al.*, 1995 and 1997) have found additional predictive factors for constituent concentrations, such as ADT during the storm and interevent periods.

In the absence of site-specific data, these values are useful for planning and other purposes.

LESSONS LEARNED FROM PREVIOUS WATER QUALITY MONITORING

STATISTICAL CONCEPTS FOR URBAN RUNOFF WATER QUALITY EVALUATION. The NURP studies focused on evaluating EMCs. In most cases in these studies, the total load from the runoff event was more important than the individual concentrations within the event because the nature of the effect (for example, loadings to a receiving water) on the receiving water did not occur instantaneously but, rather, during an extended period of time.

Evaluation of the NURP database (U.S. EPA, 1983) and European data (Harremöes, 1988) revealed that the probability distribution of EMCs followed a probability distribution reasonably represented as log-normal. Additional studies (Driscoll and James, 1987) have also demonstrated that concentration data for other sources, such as CSOs, WWTP influent and effluent streams, and agricultural runoff, can be taken to have log-normal distributions.

The representation of the fundamental probability distribution of EMCs as log normal has a number of benefits (U.S. EPA, 1983, and Marsalek, 1991), including the following:

- Concise summaries of highly variable data can be developed;
- Comparisons of results from different sites and events are convenient and are more easily understood;
- Conclusions can readily be made concerning frequency of occurrence (one can express how often values exceed various magnitudes of interest);
- A more useful method of reporting data than the use of ranges is provided (one that is less subject to misinterpretations);
- A framework is provided for examining "transferability" of data in a quantitative manner;
- Data below the detection limit can be extrapolated; and
- Loadings can be obtained by multiplying the EMC by the total volume of runoff.

Another important statistical concept is the analysis of detection-limit data from knowledge of the probability distribution function. For many parameters, 20 to 80% of the sample values from a sample set are below detection limits. This can pose a problem in determining the true population mean and variance. An effective approach is to use a probability distribution estimation technique for this left-censored data set.

The variance structure of the term "loadings" also influences the method for reporting water quality data. To allow comparison of data between sites, investigations of the 1960s and 1970s reported data using units of unit loads (loadings per unit area of catchment). This is in contrast to recent data, which emphasize concentrations. Because unit loads include variance (because of both hydrological and concentration components), the concentration approach is emphasized in this manual.

PREDICTIVE RELATIONSHIPS OF URBAN RUNOFF QUALITY. Several potential predictors of constituent concentrations in runoff were evaluated in the NURP studies (U.S. EPA, 1983). The results are summarized in the following sections.

Land-Use Effects. The nationwide analysis in the NURP studies did not detect a significant statistical correlation of EMCs to the geographical locations of the sites studied throughout the U.S. In addition, three typical land uses, "residential, mixed, and commercial," were not found to be statistically different. Only open land uses and nonurban land uses were found to be significantly different (using statistical criteria) from these three land uses.

Runoff Volume Effects. A total of 67 sites from 20 of the NURP projects were examined for possible correlation between volume and EMC for nine constituents. The NURP study concluded that there is no significant linear correlation between EMCs and runoff volume.

Other Watershed Factor Effects. Factors such as slope, soil types, and rainfall characteristics are all potentially important. However, in a statistical sense, these factors did not have any consistent significance in explaining observed similarities or differences among individual sites.

IMPLICATIONS FOR MONITORING PROGRAMS. Monitoring programs for characterizing the quality of stormwater runoff, defining the effectiveness of BMPs, and developing relationships between runoff quality and various factors require increasingly onerous amounts of data and numbers of monitoring locations. Therefore, results from existing monitoring programs can be used to provide reasonably clear direction for typical stormwater quality monitoring issues in the 1990s. These issues include

- Defining differences in the concentration of stormwater chemical constituents over time at a site (for example, lead concentrations have declined because of their removal from gasoline);
- Defining a structured approach to measuring site-specific environmental effects and the implications of stormwater toxicity measurements (Herricks *et al.*, 1994);
- Applying scale-dependent factors (such as time and space) to a monitoring program design (for example, in a watershed in which BMPs have been completely implemented); and
- Defining the amount and type of monitoring data required to show significant differences between inflow and outfall loadings from a BMP facility (for example, one might establish 20% differences with an 80% level of confidence [a minimal statistical test] in a monitoring program).

Moreover, the issue of monitoring data to show differences between inflow and outfall of a BMP can be further addressed by analyzing NURP data, data from specific sites (see Torno *et al.* [Ed.] [1994] for examples of urban sites, and Thomson *et al.* [1995] for an example of a highway site), and data collected from a study of 18 sites in Austin, Texas (U.S.) (Cheng *et al.*, 1994).

Stormwater quality monitoring is sufficiently well developed today that direction can be given to new monitoring programs. Monitoring the environmental effects of stormwater runoff is a combination of art and science and requires hypothesis testing, evaluation of what "effects" are measurable, and an adaptive approach to program design (Hollings [Ed.], 1978).

National Urban Runoff Program research (U.S. EPA, 1983) and the FHWA database (Driscoll *et al.*, 1990), which were gathered in the early 1980s, are still considered the definitive studies available to characterize the concentration of substances such as SS, nutrients, metals, and oxygen-demanding substances (for example, chemical oxygen demand and BOD).

Recent NPDES monitoring data typically are consistent with these constituent concentrations except for lead, which displays lower levels because of its removal from gasoline. However, more recent data should be used to characterize many parameters, such as synthetic organic chemicals and polynuclear aromatic hydrocarbons (PAHs), because of the use of lower detection limits and better quality assurance/quality control. In addition, because of different levels of detection limits for parameters such as PAHs, some of these programs have varying degrees of utility.

As shown in NURP data, concentration (EMC) and runoff volume are independent (such that there is no significant correlation). The influence of other factors, such as interevent period and event duration, may be influential at a particular site (Barrett *et al.*, 1995, and Thomson *et al.*, 1997).

Studies have suggested that a minimum of 15 to 20 (Thomson *et al.*, 1995) or 18 to 30 (Cheng *et al.*, 1994) samples per site are required to provide an unbiased estimate of an SMC. In earlier studies, such as one conducted in Austin, Texas, approximately 40 monitoring sites were thought to be needed to show differences between two types of land uses and three sizes of watersheds to obtain four to eight mean concentration values for each combination of land use and watershed scales (Cheng *et al.*, 1994).

Furthermore, a practical measurement program can be used to specify the minimum number of flow-proportioned samples necessary to obtain a reasonable estimate of SMC, where the minimum number is a compromise between the number of samples suggested by a thorough statistical analysis and economic and resource considerations. For example, for sites typical of the temperate climates of the northeastern U.S., a reasonable minimum number would be 8 to 10 events, while a larger number of events may be needed for extremely left-censored data. For such a minimum number, obtaining two to three samples per site to address site-specific questions is not useful. Aggregation of two to three samples per site and data from several sites in an urban area may provide useful data for establishing SMCs; however, the additional variance introduced by this process should be evaluated.

Additionally, although first-flush phenomena have been observed in relatively small catchments (see Thomson *et al.*, 1995, for a Minnesota highway example), the existence of first-flush phenomena in large catchments is less clear.

Finally, performance assessment data from existing BMP databases can be used to define the amount of data required to evaluate the performance of new BMPs. For example, for a wet detention pond BMP (see Chapter 5), the following performance (removal of constituents) might be observed: SS, 70%; lead, 70%; total phosphorus, 50%; and total zinc, 20%. Compilations of performance-monitoring data (Schueler *et al.*, 1992) are rapidly accumulating; one method for decreasing the range of observed performance (for example 30 to 90% for TSS) is the use of standardized BMP data reporting protocols (Urbonas, 1994).

Clear monitoring guidance cannot be given for several biological and ecological properties of stormwater. The database characterizing the toxicological properties of urban runoff is sparse, and the scale-up of event-type phenomena to receiving water effects is not well known (see Herricks *et al.*, 1994). The role of BMPs in minimizing or reducing the potential toxicity of stormwater runoff is an evolving science. However, significant advances are currently being made in developing an understanding of this issue, as discused at the conclusion of this chapter and in Chapter 3.

EFFECTS OF URBANIZATION ON RECEIVING ENVIRONMENTS

Urbanization affects all components of the environment, such as air quality, surface water, groundwater, soil quality, and the habitats for animals, including humans. The quality of the existing local environment, which may range from pristine to degraded, is influenced by the form and characteristics of the existing development within the watershed. New development, redevelopment, and retrofitting provide opportunities for changing the characteristics of the receiving environment. The form of new development, together with the existing quality of the local environment, determines whether these projects will cause further degradation or improve the local environment.

The alteration of the hydrological cycle in an urban watershed was described earlier in this chapter. This section describes the effects of these alterations on receiving environments. Effects from the alteration of the hydrological cycle are presented in an integrated way to assist designers in developing appropriate solutions for specific conditions. This section discusses effects on streams, wetlands, lakes, groundwater, and the biological habitats supported by these aquatic systems. Emphasis is given to streams because the relative distribution of surface waters affected by urban areas has been estimated by Herricks (1991) as follows:

- Receiving streams and rivers: 85%. More than 80% had an average annual flow less than 8 500 L/s (300 cfs), with many having a flow of less than 8.5 L/s (0.3 cfs).

- Receiving lakes: 5%.
- Small ponds, shallow backwater areas: less than 0.1%.
- Estuaries and oceans: 10%.

Not captured in this survey is the large number of headwater streams affected by urbanization.

EFFECTS OF STORMWATER RUNOFF ON STREAM ECOSYSTEMS. Effects in urban streams can be loosely grouped into four categories: changes to stream hydrology, stream form, water quality, and aquatic ecology (Schueler, 1992). The extent of an alteration is a function of the climatic regime (wet or dry) and change in land use.

The example presented in this section for streams is based on the urbanization of a forested headwater watershed in a relatively wet, temperate area on the eastern seaboard of the U.S. Therefore, a designer should consider the hydrologic characteristics of other climatic areas and an individual stream's morphological setting to assess the potential effect of hydrological alterations on particular receiving streams.

Changes in Stream Hydrology. The net effect of conventional development practices on an urban stream is a dramatic change in the hydrologic regime of the stream. Effects include

- An increase in the magnitude and frequency of runoff events of all sizes;
- Delivery of more of the stream's annual flow as surface storm runoff rather than base flow or interflow; and
- Increases in velocity of flow during storms.

Changes in Urban Stream Morphology. Stream channels in urban areas respond and adjust to the altered hydrologic regime that accompanies urbanization. The severity and extent of stream adjustment is a function of the degree of watershed imperviousness. Examples of stream adjustments and their consequences include

- Increased stream cross-sectional area to accommodate higher flows;
- Significant downcutting of the stream channel (unless the bottom is heavily armoured), where widening is prevented by road or pipeline crossings;
- Increased sediment loads in the stream because of increased stream bank erosion and upland construction site runoff;
- Modification of the streambed (typically, the grain size of channel sediments shifts from coarse-grained particles to a mixture of fine- and coarse-grained particles); and
- Modification of the stream through straightening and/or lining by humans to "improve" drainage and reduce flooding risks in intensively

urbanized areas (headwater streams tend to suffer disproportionately from enclosure).

Additionally, stream crossings by roads and pipelines change such stream plan-form characteristics as location and meander pattern. These structures may be heavily armored to withstand the downcutting power of stormwater.

A critical issue is the level of development at which stream morphology begins to change significantly. Research models developed in the Pacific Northwest (U.S.) suggest that a threshold for urban stream stability exists at approximately 10% imperviousness of a watershed (see Figure 1.2) (Booth, 1991, and Booth and Reinelt, 1993). Watershed development beyond this threshold consistently results in unstable and eroding channels. The rate and severity of channel instability appears to be a function of subbankful floods, the frequency of which can increase by a factor of 10 even at relatively low levels of imperviousness (Hollis, 1975; Macrae and Marsalek, 1992; and Schueler, 1994).

Changes in Stream Water Quality. Changes in stream water quality are associated with two phases of urbanization. During the initial phase of development, an urban stream can receive a significant pulse of sediment eroded from upland construction sites, even if erosion and sediment controls are

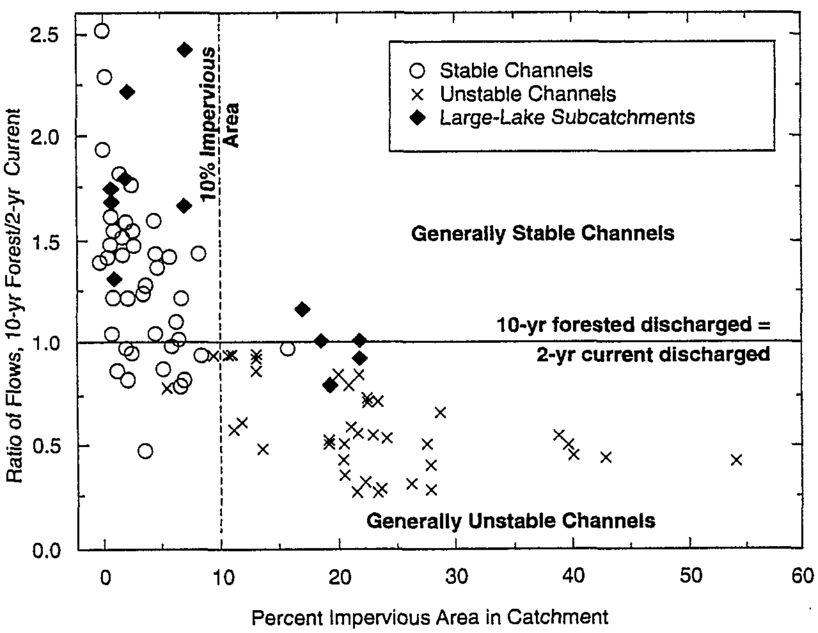

Figure 1.2 **Channel stability as a function of imperviousness (Booth and Reinelt, 1993).**

R0017365

used. Sediment contributions from the land surface typically decline to less than predevelopment contributions after upland development stabilizes and is replaced by increased stream-bank erosion. In the second phase of urbanization, the dominant source is the washing off of accumulated deposits from impervious areas during storms (Schueler, 1992).

In general, constituent concentrations in urban streams are one to two orders of magnitude greater than those reported in forested watersheds (see earlier section, Constituents in Urban Stormwater Runoff). Their degree of loading has been shown to be a direct function of the percentage of watershed imperviousness (Schueler, 1987). In urban streams, higher loadings can cause water quality problems such as turbid water, nutrient enrichment, bacterial contamination, organic matter loads, toxic compounds, temperature increases, and increased instances of trash or debris.

Changes in Stream Habitat and Ecology. The ecology of urban streams is shaped and molded by extreme shifts in hydrology, geomorphology, and water quality that accompany the development process. Stresses on the aquatic community of urban streams are often manifested as

- A shift from external (leaf matter) to internal (algal organic matter) stream production;
- A reduction in diversity in the stream community; and
- A destruction of freshwater wetlands, riparian buffers, and springs.

Structure of These Changes. Stream hydrology, stream form, water quality, and stream habitat and ecology, in order of importance, provide a structure for a designer to develop an integrated picture of the effects of hydrologic alteration on receiving environments (Snodgrass *et al.,* 1996). This structure can also be used to assist in defining environmental and BMP monitoring (Chapter 3) and stream protection (Schueler, 1992) strategies.

EFFECTS OF URBANIZATION ON OTHER RECEIVING ENVIRONMENTS. Effects of Urbanization on Wetland Systems. Neglecting direct intrusion, sound, and other effects outside the sphere of urban hydrology, the effects of urbanization on wetlands can be broadly categorized into physical/geochemical and biological effects. Primary physical/geochemical effects include

- Changes in hydrology and hydrogeology;
- Increased nutrient and other contaminant loads;
- Changes in atmospheric inputs (through increased air emissions to the urban airshed); and
- Compaction and destruction of wetland soil.

Primary biological effects associated with urban stormwater discharges are

- Changes in wetland vegetation;
- Changes in or loss of habitat;
- Changes in the community of organisms (diversity, kind, density);
- Loss of particular biota; and
- Permanent loss of wetlands.

In addition, socioeconomic changes may result, such as decreased passive recreational use. However, through the proper application of BMPs, much of this effect can be mitigated and a healthy ecosystem can be promoted.

Effects of Stormwater Runoff on Lakes. Compared to streams, lakes have at least three inherent differences that cause different reactions to stormwater runoff. These differences are as follows:

- Lakes, because of their volume, respond primarily to the mass of constituents and volume of flow rather than constituent concentration and peak flow rate. The response time is on the order of days or weeks, whereas a stream responds within hours or days.
- After visible refuse and damage, nutrient enrichment and the resulting increase in primary productivity is the most visible sign of urbanization.
- Lakes do not flush as quickly as streams and are net-depositional environments. As such, they act as sinks for sedimented materials and take longer to recover from contamination than do streams.

Heavy metals that adsorb onto sediment particles in urban runoff may not pose an immediate threat to lake ecosystems if the bottom is aerobic. But, if the bottom eventually becomes anaerobic, or is seasonally anaerobic, metals may solubilize in sufficient quantity to be toxic to benthos or pelagic species that swim through the area.

A common effect of urban runoff on lake ecosystems is that the sediment load in the inflowing stream(s) drops out near the inlet and impacts the biota living on the bottom. Depending on the areal extent of the deposition, a sufficient percentage of the natural benthos might be destroyed to alter the food chain, hence the lake organism assemblage.

Another common effect on lakes is that floatables carried into the lake by the runoff stream are blown onto the shore or into small pocket embayments, impairing the aesthetic value of the water body.

A third common effect is increased algae production by the lake if a formerly forested watershed is urbanized. Eventually, summer populations get sufficiently high to create blooms that are aesthetically displeasing. At this point, a lake's value as a drinking water source is also compromised. Blooms may deplete lake oxygen supplies sufficiently to cause fish kills, but ecologically the most significant effect is that the increased primary productivity results in an aquatic environment with decreased diversity and increased "trash" fish populations. Once this occurs, a simple stopping of the source of nutrients will have a limited short-term effect on biota—a polluted lake may take decades to recover naturally.

The broader effects of urbanization on lakes include inputs from storm sewers, CSOs (where they exist), and wastewater treatment plants. Perceptions about increased algal production after urbanization are caused more often by WWTP discharges than by storm sewer discharges. Well-developed loading estimates from the different sources on a watershed basis are needed to adequately distinguish the relative importance of the different influences of urbanization.

Effects of Urbanization on Groundwater. Urbanization affects both groundwater flow and groundwater quality, although, as noted previously, the effects on flow do not always follow expected norms. The primary effects of urbanization on groundwater quality are caused by leaking or leaching of toxic or hazardous substances from significant industrial operations (such as landfills or specific manufacturing sites), gasoline stations, and leaching of previously contaminated soils by infiltrating rainwater. These sources are often the main focuses for soil quality and groundwater quality management in urban areas but are beyond the scope of this manual.

A principal focus of this manual is the way groundwater quality is affected by infiltrating stormwater runoff and BMP facility water. The effects of these sources can be subdivided into perceptions and documented data. The perception of many individuals working in urban stormwater management is that the constituent concentration levels in stormwater runoff (see Tables 1.4 and 1.5) should affect groundwater by increasing the concentration of constituents such as heavy metals, pesticides, and herbicides. Limited data for heavy metals (such as copper, iron, and zinc) suggest that they are sorbed by soils in the bottom of BMP facilities, provided the sediments remain aerobic and have high redox potential (Yousef *et al.*, 1985) and, therefore, do not migrate in a significant way. Hydrophobic organic compounds, such as polychlorinated biphenyls and PAHs, typically do not migrate because of their highly sorptive properties.

However, highly soluble substances such as chlorides and nitrates will move with infiltrating water and not be sorbed. Some evidence is evolving to suggest that groundwater below cities such as Toronto, which uses deicing chemicals, may attain chloride levels between 500 and 800 mg/L (Howard *et al.*, 1991).

Effects of Stormwater Runoff on Estuaries. Because of the relative size of receiving environments, attributing effects to stormwater is more likely in cases of discharges to creeks (rivers) than in discharges to estuaries. To date, few studies have focused solely on the effects of urban runoff to estuaries (Odum and Hawley, 1986, and Jones, 1986). One reason for this is that, in large estuaries, urban runoff effects are inexorably and synergistically associated with the effects of dredging, chemical spills, point source contaminants, and other serious alterations. Therefore, separating the effect of urban runoff is difficult and perhaps artificial.

The effect of urban runoff is also discontinuous. Because episodes of heavy runoff with high pollutant levels are interspersed with long periods of little or no runoff, erosion of near-shore sediments during runoff events is followed by tranquil periods when biological communities can reestablish themselves. In addition, tidal processes spread discharges in multiple directions.

However, there are some definable and measurable effects of urbanization on estuaries. These include

- Sedimentation in estuarial streams;
- Changed hydroperiod of saltwater wetlands, which results from larger, more frequent pulses of fresh water and longer exposure to saline waters because of reductions in base flow; and
- Short-term salinity swings in small estuaries caused by the increased volume of runoff; this affects the local ecosystem, which may be a "delicate" or key reproduction area.

Research studies, hypothesis of effect (Hunsaker and Carpenter [Eds.], 1990), and careful segregation of scale may provide the database necessary for systematically documenting effects. Alternatively, generalized land-use relationships between the lands of urban areas and adjoining estuaries in specific ecozones may be the scale at which effects are documentable. At such a scale, the cumulative effects of urban land development, including stormwater discharges, are related to receiving water characteristics, although the specific effects of stormwater discharges are not measured.

EVOLVING ISSUES

ECOSYSTEMS AND WATERSHED BASIS FOR MANAGEMENT. Water quality management has historically focused on the control of specific pollutants. Control of BOD discharged to streams and estuaries to maintain satisfactory oxygen levels has been evaluated using assimilative capacity models (Streeter and Phelps, 1925). Discharges of phosphorus to lakes are managed to maintain a specific trophic status for lakes (Reckhow and Chapra, 1983). However, some constituents discharged to a receiving water cannot be assimilated and are exported to adjacent ecosystems through cycles of water and elements.

Ecological limits posed by the biosphere and the pollution of specific aquatic systems are leading to attempts to use ecological targets (endpoints) as approaches for defining objectives for urban stormwater quality management. In simple terms, the biosphere is the life-supporting system on the surface of the earth that provides energy, fresh air, potable water, uncontaminated food, and the recycling of wastes. Water and chemical elements cycle through various biological niches and hydrological and geological reservoirs in the biosphere. However, urbanized human populations exert severe stress on specific local biota and natural resources. In addition, the elemental and hydrological cycles cause stress to be exported to adjacent lakes, streams, estuaries, and ecosystems.

Therefore, the ecosystem has become the focus for management of the environment. This requires an understanding of what is meant by the term "ecosystem" and an approach for using the ecosystem as the basis for urban stormwater quality management.

These broad concepts are applied to urban stormwater management issues in the following sections, which consider the overall effects of urbanization on the environment, watersheds, application of ecosystem principles to BMP planning, and impact assessment.

EVOLVING APPROACHES TO STORMWATER QUALITY MANAGEMENT. Urban stormwater quality management is subject to analysis through several different approaches, namely, environmental resource protection planning, comprehensive urban runoff quality management, and comprehensive stormwater management. As it applies in this manual, the term "urban" includes developed and urbanizing areas. In broader terms, evolving approaches to stormwater quality management in North America include

- Water-quality-based mandates for stormwater releases (that is, stormwater effluent quality levels developed by an impact assessment methodology or for a design storm by the stipulation of a defined concentration target for stormwater releases);
- Best management practice plans for stormwater runoff from a specific facility or subwatershed;
- A comprehensive stormwater quality protection strategy that includes BMP plans;
- A comprehensive receiving water protection strategy; and
- Watershed-based approaches.

The comprehensive stormwater quality protection strategy includes pollution prevention (also called source control), pollution control, land-use planning, and regulatory control.

Pollution control, in the form of treatment-type BMPs, has been a primary focus of recent efforts. Because most BMPs are passive in nature, protection strategies have expanded to include pollution prevention and regulatory control approaches. However, the effectiveness of pollution prevention efforts are often not known quantitatively. With the development of data that link percent imperviousness thresholds to stream degradation in headwater areas (see Figures 1.2 and 1.3), the potential for using land-use planning as a tool has commonly been proposed.

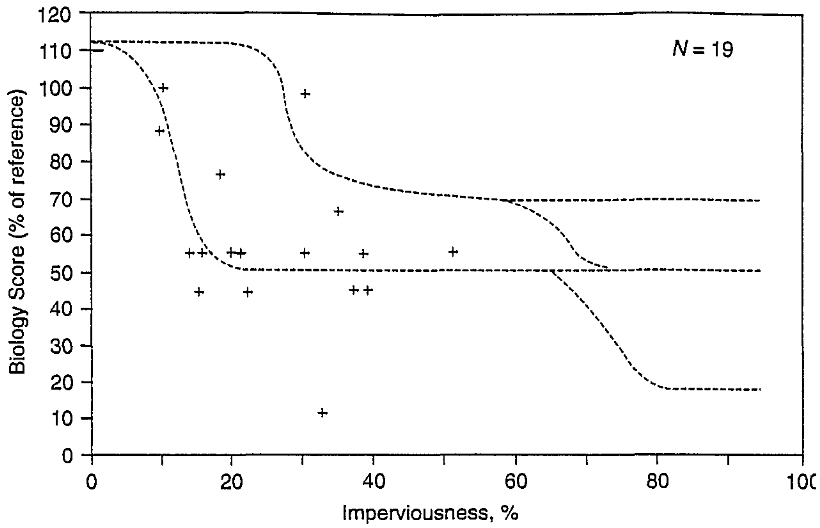

Figure 1.3 Effect of watershed imperviousness on biologic integrity within the Northern Piedmont ecoregion of Delaware, 1993.

Both pollution prevention and pollution control are cornerstone approaches for stormwater quality management. They are addressed in this manual in Chapters 4 and 5, respectively. Watershed approaches historically have been used for flood control and erosion control. Future direction will come from ecosystem analysis on a watershed basis and attempts to integrate these concepts with flood control, erosion control, and water quality management.

THE WATERSHED AS NATURAL BIOPHYSICAL BOUNDARY. An ecosystem approach to planning requires that boundaries for examining relationships between the natural environment and human activities be based on biophysical rather than political issues. To this end, watersheds and subwatersheds provide a biophysical basis for planning and management.

A watershed uses the hydrologic cycle as the pathway that integrates the physical, chemical, and biological processes of the basin ecosystem. It provides a fundamental unit with real boundaries of ecological significance. This unit provides a quantitative reference frame to make inferences on ecological stress, instream flow, and the cumulative effects of land-use development. A watershed basis has been the natural approach for water-quantity-related issues (such as flood control or erosion control) and, more recently, for water quality issues (for example, dissolved oxygen control in streams and phosphorus loadings to streams).

The ecosystem approach assists in balancing economic, social, and environmental needs. The approach purposefully links aquatic, terrestrial, and human life within the watershed as a healthy self-sustaining ecosystem. The benefits of this are numerous and long term. Watershed planning becomes an integral part of an ecosystem and land-use planning process, set within the context of environmental sustainability.

WATERSHED PLANNING. Watershed planning (U.S. EPA, 1993), described further in Chapter 2, involves at least the following three phases:

- Background review and definition of management goals;
- Analysis and development of a plan (strategies including an impact assessment); and
- Implementation of a plan.

Watershed planning is an essential element for environmental resource protection because it identifies ecological components requiring protection, systematically analyzes relationships between urban land uses and these ecological components, and develops a plan that is ecosystem based. The pertinent steps for watershed planning are outlined in Table 1.7; methods for developing an overall watershed approach are described in Chapter 2.

Representative products (or deliverables) expected from a watershed study, a subwatershed study, and a BMP facilities study are given in Table 1.8. An ecosystem approach requires that a master environmental plan be developed in addition to "and integrated with" a master drainage plan. A fundamental problem, however, is how to implement an ecosystem approach to planning on a watershed basis. An ecosystem approach forces a designer to look not only at air, water, land, and living things but also at the interrelationships of these components. Furthermore, the study of these interrelationships includes both "quality" and "quantity" aspects.

Traditionally, science has taken a reductionist approach by studying the individual components of a system. In the context of a watershed, this would mean studying streams, groundwater, aquatic communities, and other environmental components of interest. It also includes studying municipal WWTP discharge, industrial waste sources, CSOs, sanitary sewer overflows, and stormwater discharges. However, ecological planning requires an understanding of how these components interact. This study of interrelationships and the whole is known as "integration."

USE OF AN ECOSYSTEM APPROACH FOR PLANNING. Best management practice planning occurs on both a watershed scale and a site scale (see Table 1.9). Watershed-level plans are more suited to incorporating ecosystem-based geographic boundaries, multiple project influences and effects, and the setting of ecosystem health objectives with the assistance of public input.

However, application of an ecosystem approach for individual development projects and BMP facilities is more difficult because it is harder to understand the relationship of a specific project to the surrounding ecosystem

Table 1.7 Steps in watershed planning.

Phase I background information
Define study goals
Inventory watershed and establish VECs/human uses
Design/initiate necessary field work
Public participation
Define present land uses and pollution sources
Define present state of the environment
Define future causes of environmental degradation (land-use changes, population growth, emission sources)
Define management goals for aquatic systems/human uses
Phase II analysis and development of plan
Define ecosystem framework
Define impact hypothesis (modes of impact, exposure pathways, environmental changes)
Define ecological/environmental endpoints and targets (evaluation criteria)
Define by screening studies, magnitude of impact
Define potential ecosystem protection/mitigating measures (such as BMPs, conservation practices)
Prioritize analysis
Define and apply prediction techniques
Establish alternative management strategies
Review effectiveness, uncertainties, cost, benefits, risks, implementation
Assess whether management goals/environmental targets can be met
Public and institutional review
Select and develop recommended watershed plan
Define uncertainties
Financing
Phase III implementation plan
Define implementation strategy
Define uncertainties and necessary research
Define lead agency for implementing different components of plan
Define funding sources
Define approval mechanisms
Define direction for subwatershed and BMP plans
Define schedule and phasing
Establish implementation committee/task force and terms of reference
Define long-term monitoring program

Table 1.8 Outline of deliverables expected from watershed planning.

Deliverables expected from watershed study
Inventory of resources and establishment of management objectives
Statement of environment endpoints and quality targets
List of BMPs and mitigating measures and location in watershed
List of impact statements and uncertainties to be addressed in future monitoring programs.
Deliverables expected from subwatershed study
Detailed evaluation of watershed information
More detailed analysis of environmental quality targets (defined in watershed study) and land-use densities and mitigating measures required to achieve the targets
Detailed hydrology and hydraulic modeling (as required) to define sizes of BMP facilities required for hydrological aspects
BMP selection
Deliverables expected from BMP facilities study
Confirmation of critical hydrological/hydraulic assumptions used previously
Selection of ecosystem features at BMP facility
Conceptual followed by detailed layout of BMP/BMPs for upstream, site, and downstream aspects
Detailed design

and it is difficult to assess the cumulative effects that are involved. Therefore, for individual projects in which watershed plans have not been developed, an ecosystem approach should include

- Establishing ecological objectives based on desired beneficial uses;
- Considering effects beyond the vicinity of the facility site but within the watershed (another definition is to "look upstream," "downstream," and "at the point of release" of the stormwater);

Table 1.9 Proposed hierarchy based on geographic/geomorphic scaling considerations.

System level	Linear spatial scale, m	Aerial spatial scale, m^2	Time scale of continuous potential persistence, years	Time scale of persistence under human disturbance patterns, years
Watershed	10^5	10^{10}	10^6–10^5	10^4–10^3
Subwatershed	10^4	10^8	10^4–10^3	10^2–10^1
Reach	10^2–10^1	10^5	10^2–10^1	10^1–10^0
Site	10^1–10^0	10^2	10^0	10^0–10^{-1}
Habitat element	10^0–10^{-1}	10^1	10^0–10^{-1}	10^{-1}–10^{-2}

- Establishing the boundaries of the study to include off-site areas with functional linkages on site, sometimes by facilitating cooperation among landowners to include stream corridors, wildlife management areas, and local groundwater aquifers;
- Increasing collaboration among the team members dealing with biology, surface water, and hydrogeology;
- Illustrating ecosystem functions and linkages in "pathway diagrams" for project effects such as air, noise, litter, and water quality and using these to scope the assessments;
- Systematically considering interactions among components of the environment (for example, the effects of surface water and groundwater on biology);
- Describing existing and past conditions, including both the functions of the ecosystem components and their interactions with one another (for example, past construction of a storm sewer has dried up a wetland or the construction of barriers has reduced stream flow); and
- Systematically considering environmental effects of other existing and future facilities or projects in assessing the net effects of the undertaking.

The first four points are often considered in watershed evaluations; the other points represent the evolving practice toward an "ecosystem" approach.

ENVIRONMENTAL MONITORING AND IMPACT ASSESSMENT

Methods for conducting an impact assessment include evolving methodologies such as a stress-response framework (Hunsaker and Carpenter [Eds.], 1990), risk assessment approaches (Suter, 1993, and Warren-Hicks *et al.*, 1988), environmental effects monitoring (Hollings [Ed.], 1978, and Hunsaker and Carpenter [Eds.], 1990) and other methodologies detailed in Chapter 3.

Furthermore, watershed studies, research studies, and experience now permit desired environmental quality goals to be stated in physical, biological, and chemical terms. However, cause–effect methodologies for relating BMP performance to biotic changes are only now evolving. Therefore, impact assessment methodologies presented in Chapter 3 are stated in terms of hydrological performance (using hydrological models); loadings of constituents to receiving environments; and bioassessment, biocriteria, and inferences that can be gathered from field data rather than from deterministic cause–effect relationships.

EVOLVING APPROACHES TO BIOLOGICAL IMPACT ASSESSMENT. Environmental Endpoints. The term "environmental endpoint" has evolved from the field of ecological risk assessment (U.S. EPA, 1992, and Warren-Hicks *et al.*, 1988) to include both "ecological entities" and human uses/concerns (such as human health and safety and property protection). An environmental endpoint can be defined as

- A component of the environment (for example, air or soil quality) that is valued by the public and represents a significant attribute of the environment;
- A part of the environment that can be measured (often using various biological, chemical, or physical parameters) or calculated/modeled;
- An entity that is affected by urbanization or a specific proposed project; or
- An intermediate or final compartment along a series of environmental pathways that are affected by the project.

The following environmental endpoints and methods are presently being applied in the field of impact assessment:

- *In situ* properties of receiving environments:
  - Hydrological characteristics (such as flow and velocity);
  - Physical and chemical constituents of surface water;
  - Physical and chemical characteristics of sediments (Livingston *et al.*, 1995);
  - Water column communities (such as algae, zooplankton, and fish);
  - Benthic communities;
  - Human health characteristics (such as fecal coliforms and viruses);
  - Other biological and toxicity characteristics (for example, BOD); and
  - Morphometric properties (particularly in streams).
- Laboratory-based measurements:
  - Aquatic toxicity,
  - Genotoxicity,
  - Sediment toxicity, and
  - Chemical concentrations of field samples.
- *In situ* probes and biomonitors:
  - Algal organisms to measure bioaccumulation or *in situ* toxicity,
  - Attached algae that sorb particular contaminants, and
  - Young-of-year fish that migrate limited distances in stream.
- Stormwater and BMP discharge:
  - Chemical constituents, and
  - Biological properties (BOD, fecal coliforms, toxicity).

The category "*in situ* probes" involves putting organisms in place for brief periods of time to measure phenomena not measured by typical chemical procedures or using special *in situ* organisms to detect effects.

Biologically Based Effects Monitoring. These types of environmental endpoints represent a shift away from a chemical concentration approach for measuring environmental quality and toward a biologically based effects approach (for example, bioassessment or biocriteria). This change is occurring because biological measurements provide more meaningful data for characterizing environmental quality. However, data obtained are often difficult to interpret. Moreover, while water quality standards for many parameters provide a reference by which to compare water characteristics, water quality objectives for many biomonitors are not known. By installing biomonitors above and below stormwater discharges in an urban area, an increase in body burden for a particular chemical parameter can be measured, although its environmental meaning is unclear.

An environmental effects monitoring program can be thought of as having the following structure in its biological and chemical components:

- Concentrations of constituents and whole water toxicity of the BMP-discharged water;
- Sediment accumulation and toxicity;
- Bioaccumulation (for example, contaminant burden in organism tissue or human consumptive concerns); and
- Trophic-level effects (such as subcellular, cellular, community level, and population level).

The development of monitoring systems during the next decade may be aimed at formulating a balance between chemical- and biological-monitoring approaches in this evolving science. A set of principles and approaches for monitoring the effectiveness of stormwater quality BMP and receiving water effects is provided in Chapter 3.

Focus in This Manual. In the evolving field of environmental monitoring, the following physical and chemical factors are particularly relevant monitoring components (Urbonas, 1994) as they apply to information presented in this manual:

- Hydrological alterations/mitigations to stormwater runoff from an urban catchment provided by the BMP;
- The treatment efficiency provided by the BMP for SS and attached contaminants;
- Nutrient removal provided by the facility; and
- Temperature properties of discharged waters.

These monitoring components are presently carried out at many sites and are discussed in detail in Chapter 3 in relation to monitoring BMPs and their receiving waters.

In addition to physical and chemical factors, important environmental monitoring factors for biological components include

- Toxicological properties of runoff water (as a laboratory procedure) and scale-up to receiving water consequences;
- Bioaccumulation of contaminants in the food chain; and
- Alteration of the benthic community because of the physical stress of runoff water.

A key technical issue of monitoring is to determine the relative importance of flow alterations (physical, morphological changes that degrade the benthic community) and chemical effects (through toxicity and bioaccumulation) on determining the primary cause of effects on receiving water ecosystems. Presently, emphasis is placed on the structure and abundance of water column and benthic communities in receiving environments rather than on cause–effect relationships. If either the physical or chemical effects of urban stormwater runoff were clearly shown to be the primary causes of degradation of urban receiving water ecosystems, improvement in the rationale for stormwater BMP design could be achieved.

ISSUES OF SCALE. This section examines the influence of scale on the response time of streams to urbanization and the receiving water scale on which monitoring can be expected to detect changes because of the installation of one BMP facility or a set of facilities within a watershed.

Physical and Temporal Response of Streams. The geomorphological alteration of streams caused by altered urban hydrology has one of the longest response times of all receiving water attributes. In terms of the scale of a stream reach, at least a decade may be required for a stream ecosystem to respond to altered hydrology.

Scale for Monitoring the Response of Streams. Research has suggested that a threshold effect is observed in the relationship between imperviousness of a watershed and a stream's morphology and ecosystem. The relationship between imperviousness and benthic organism density, presented in Figure 1.3, shows a significant change in watersheds having 10 to 20% imperviousness. Shaver *et al.* (1995) hypothesized that installations of BMPs might protect the stream and change the threshold to 30 to 50% (see Figure 1.3).

Because the streams shown in Figure 1.3 are largely unprotected with BMPs, validation of this hypothesis should be sought by comparing subwatersheds fully protected by BMPs to equivalent watersheds without BMPs.

In developing such a monitoring program, additional points should be considered. Benthic organisms, if used as the response variables, integrate the effects of hydrologic control and water quality protection provided by BMPs. As discussed above, a monitoring program that seeks to separate the effects of water quality improvement from those of hydrologic control requires a special design. Secondly, many of the streams represented in research drain small watersheds (typically containing first- and second-order streams). Therefore, different threshold effects may be measured in larger streams.

TOTAL EFFECTS METHODOLOGIES. Broader based planning methodologies and environmental assessment are evolving to account for the total impacts of urbanization on the environment. Best management practice impact assessment methodologies may need to consider such new issues especially in multifaceted watershed studies.

Other Ecosystem Boundaries. The watershed boundary is an appropriate ecological boundary for managing stormwater runoff from catchments discharged to receiving environments (surface waters and their contained ecosystems, and groundwater). But, other boundaries may need to be considered.

The watershed boundary is not the only boundary used in ecosystem analysis and planning. In fact, there is no single, all-inclusive ecosystem approach to analysis and planning. Rather, there are several approaches in existence, such as landform based (such as the Appalachian mountains), ecological land classification based (ecoregions and ecozones) (see Livingston *et al.*, 1995), landscape and natural heritage, groundwatersheds, and airsheds. Human concerns include urban regions and commutersheds. An important points is that we are the ones identifying the boundaries of ecosystems as a geographical basis for management. However, ecosystems function regardless of our efforts to compartmentalize and spatially define them. The ecosystems that we map are simply "constructs" to facilitate our understanding and management. The chosen boundaries are seldom "absolute," but, rather, should be regarded as "diffuse" and as an approximation of what is appropriate for a given concern, theme, and chosen scale.

Total Impacts of Urbanization. This chapter has concentrated on the environmental impacts of urbanization caused by stormwater runoff and the mitigation provided by urban BMPs. However, stormwater runoff does not account for all the environmental impacts of urbanization. This section outlines the broader issues to assist the designer in understanding other evolving issues that may influence their decisions related to stormwater management. The broader issues include direct spatial effects involving loss of lands; indirect impacts through pathways, especially hydrological and ecological alterations; and cumulative effects.

DIRECT SPATIAL EFFECTS. Loss of lands and direct alteration of stream channels (direct spatial effects) have historically been among the largest effects of urbanization on surface waters and their contained ecosystems. In fact, a permanent feature of urban development is the loss of natural features, valued land forms, groundwater recharge/discharge areas, and wildlife habitats if development occurs on lands occupied by these land uses. In some literature, these effects are called "form effects" or "spatial impacts," in the geographical information system sense of "spatial analysis."

Spatial impacts resulting from urbanization include reconstruction, encroachment, and intrusion by humans. For receiving environments such as stream corridors and valleys, direct effects have historically been caused by enclosing streams in pipes or open channels, channel realignments, and stream crossings by infrastructure. Stormwater impacts are not easily addressed under this topic because they are an indirect effect.

PATHWAYS. Pathway-based methodologies are used in fields such as ecological and human health risk assessment. Pathways involve the movement of water or contaminants from industrial, residential, commercial, or agricultural areas through atmospheric, surface water, or groundwater routes (indirect impacts through pathways) to affect biota in the various ecosystems where they live, breed, and raise their offspring. These ecosystems units are called habitats. The pathways may be physical or biological in nature. Pathways relevant to urbanization issues include hydrological pathways, biological pathways, and air pathways.

Stormwater runoff is one pathway used to analyze the impacts of urbanization and is considered in this manual. As summarized above, the main effects of urbanization on hydrological pathways include increases in surface water flow, reduction in infiltration to groundwater, increased risk of water quality degradation, increases in flooding and erosion potential, and habitat degradation and even destruction.

The main effects of biological pathways include the bioaccumulation of toxic elements through the food chain. The main effects on air pathways include increased emissions of various contaminants to air from fuel consumption for heating residences, industrial and commerical buildings, transportation, and industrial operations. These latter pathways are generally not considered in this manual.

CUMULATIVE EFFECTS. Cumulative effects assessment is an additional factor required in recent planning and monitoring studies. The current system for reviewing planning applications, particularly in rural areas within the urbanizing fringe, is primarily oriented to site-specific analysis and, therefore, does not anticipate the broader, longer term environmental implications of permitting many individual sites to be developed. In some planning circles, these are known as cumulative environmental effects (for additional discussion, see Constant and Wiggins, 1991).

Watershed studies and ecosystem-based planning are examples of cumulative effects analyses. They allow one to examine the effect of all development on loadings of contaminants to surface waters and groundwater; changes in groundwater and surface water flow; changes in an instream or lacustrine fishery habitat caused by changes in surface water flow or water quality; and changes in other ecosystems or their habitat because of the introduction of contaminants through air or water pathways.

However, few studies have been carried out to date to measure (monitor) the cumulative effects of implementing urban BMPs throughout a watershed, a deficiency that needs to be addressed in future research.

Historically, municipal management of stormwater has focused on runoff quantity—primarily through the control of peak runoff rates during land development to limit susceptibility to flood-related damage. However, considerable emphasis has also been placed on municipal management of stormwater quality—pollutant removal from stormwater before discharge to receiving waters. This emphasis primarily is because of

- Regulations prepared by the U.S. Environmental Protection Agency (U.S. EPA) that control the quality of stormwater discharges under the National Pollutant Discharge Elimination System (NPDES) permitting program;
- Water quality regulatory programs at local and state levels; and
- Specific cases in which there is a clear mandate to treat stormwater before discharge, regardless of whether there is a regulatory need to do so.

Although there is legitimate debate on many aspects of stormwater quality management, there is a general consensus that urban stormwater quality needs to be managed. This section presents a six-step decisionmaking process for developing a stormwater management program, as follows:

- Step 1—define objectives,
- Step 2—assess existing conditions,

- Step 3—establish program framework,
- Step 4—select near-term best management practices,
- Step 5—implement near-term program, and
- Step 6—evaluate effectiveness.

The first three steps establish a long-range strategy for the stormwater management program. These steps are described below:

- Establish stormwater management objectives—convene a committee of "stakeholders" in the program to define what the program aims to achieve and the critical factors that will determine its success.
- Assess pollutant sources and existing controls—use readily available information to perform an initial assessment of factors affecting stormwater quality management (for example, development patterns, known pollutant sources, and observations of illicit discharges). Implement a long-term assessment plan to provide decisionmakers with a better understanding of water quality issues, pollutant sources, and best management practice (BMP) effectiveness.
- Establish a management program framework—a long-term strategy should include a management program framework outlining the scope of the program and a list of priorities appropriate to the objectives and current conditions.

Steps 4 and 5 involve selection and implementation of a complementary and integrated set of BMPs. Chapters 4 and 5 of this publication describe BMPs.

The last step in this decision process, assessing the effectiveness of implemented BMPs, may involve monitoring, modeling, and BMP performance auditing. This step is introduced in this chapter, with evaluation techniques defined in Chapter 3.

ESTABLISHING STORMWATER MANAGEMENT OBJECTIVES

An effective management program should focus on desired beneficial uses of receiving waters and must relate to significant pollutant sources within the entire watershed of that receiving water. Often, the cause–effect relationships of pollution control and beneficial use protection are uncertain. Therefore, near-term goals should focus on obvious, localized problems and should establish an appropriate scientific and administrative structure for addressing long-term beneficial use protection in a cost-effective manner.

PROTECTING BENEFICIAL USES. A stormwater quality control program should protect beneficial uses of receiving waters. These beneficial uses typically include aesthetic resources, aquatic habitat, water supply, and recreation. While state regulatory agencies have designated beneficial uses for most major receiving waters, beneficial uses of many urban streams and lakes may not be currently designated. In addition, beneficial uses of urban streams and lakes should reflect their municipal drainage functions and consider any previous or required future alterations for flood or stream bank erosion control.

After being designated, the stormwater management program should implement only those stormwater management measures necessary to mitigate urban runoff effects on beneficial uses. While this conclusion is obvious, there are significant gaps in our understanding of these effects, their causes, the relative effects of other pollutant sources, and the effectiveness of available management measures. The municipal stormwater management program should participate in confirming or designating beneficial uses of waters receiving urban runoff. Each receiving water "user" will have definite views on what these beneficial uses should be (for example, swimming, surfing, fishing, boating, aquatic life habitats, or aesthetics) and the local areas of concern. Certain waters will be seen as more valuable than others.

The attainment of seemingly obvious beneficial uses may carry significant cost burdens. If the attainment of goal 4 in Table 2.1 were selected as the goal of the stormwater management program, enormous costs would be incurred and current technology might be insufficient to meet existing standards for several constituents. Therefore, it is imperative to understand the implications of various goals and the costs associated with obtaining these goals. Technical studies are necessary to determine whether beneficial use attainment is achievable at a reasonable cost and to quantify long-term pollution control goals necessary to attain designated uses. Detailed discussion of appropriate study techniques is found in Chapter 3.

DEVELOPING A WATERSHEDWIDE APPROACH. The need to use a watershedwide approach to managing stormwater is obvious—stormwater flows and constituent loads at any location are generated to some degree by all points tributary to that location. However, every watershed is composed

Table 2.1 Beneficial use attainment guide.

	Performance standards	
Attainment goals	**Loadings**	**Water quality**
1. No significant degradation	Reduce increase	Reduce deterioration
2. No degradation	No increase	No deterioration
3. Improved water quality	Lower than existing	Better than existing
4. Meet numeric water quality standards during storm events	Significantly lower than existing	Better than existing

of many smaller watersheds, and each watershed is a portion of a larger watershed. Therefore, focus management programs on the watersheds of receiving waters with observable beneficial use impairment or valuable beneficial uses warranting protection.

Next, establish watershed management responsibilities. Smaller watersheds may be entirely urban with no significant sources of pollution other than stormwater. Typically, these watersheds can be managed exclusively by the urban stormwater management agency. However, other watersheds may span several jurisdictions or contain a wide variety of pollutant sources. Watershed management in these larger watersheds requires intergovernmental coordination and cooperation to establish

- Objectives that will benefit the watershed,
- Measurable criteria to demonstrate that the implemented practices are effective, and
- Clear lines of responsibility for watershed management among all jurisdictions in the watershed.

Finally, establish watershed management objectives. At a minimum, objectives for a small urban watershed should address the needs of its local receiving water. In addition, a small watershed's objectives should reflect its relative contribution to beneficial use impairment to receiving waters of the larger watersheds. The larger watershed may have different pollution control objectives than its smaller component watersheds, objectives that may be difficult to define in the near term because of size and complexity. Therefore, near-term stormwater management programs typically should focus on managing the watersheds of small urban streams because their needs are easier to define and solve. Near-term stormwater management programs should also address impairment to larger receiving waters only where the source is obvious, the cost is low, or the program establishes the foundation for long-term control (for example, public education).

INVOLVING STAKEHOLDERS. A stormwater management program should be developed with the involvement of one or more qualified committees of interested and affected organizations, agencies, elected officials, or citizens within the watershed. The purpose of these committees is to address technical, monetary, and policy issues associated with a regional stormwater management program. It is important to establish these committees early in the planning process. Perhaps more importantly, the committee will develop a sense of the commitment on the part of the participating agencies.

Participating committee members must include any agencies that will be affected by the stormwater management program. The composition of a typical committee is shown in Figure 2.1. Key members of the committee include representatives from regulatory agencies and environmental groups to address health and safety aspects of specific stormwater management early in

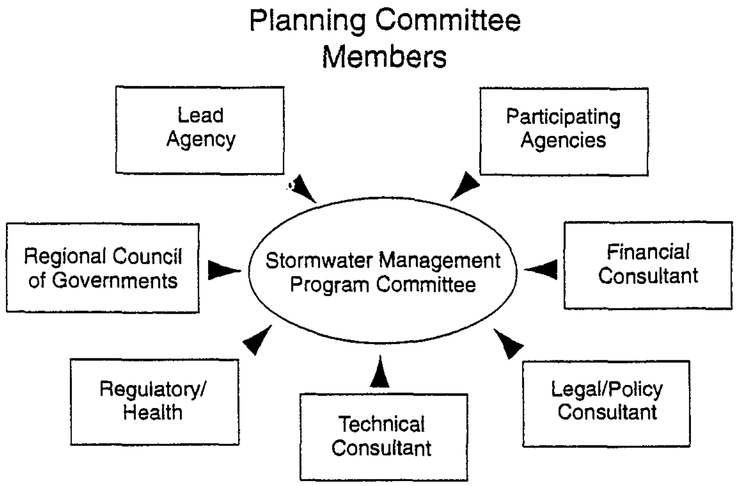

Figure 2.1 Stormwater management program.

the planning process. The committee also must include experienced individuals in the areas of aquatic chemistry, aquatic ecology, and urban hydrology.

The stormwater planning committees must ensure that watershed planning is conducted in the spirit of cooperation and good faith. The priorities of each participating agency need to be fully disclosed and discussed. Even a hint of a "hidden agenda" can prolong any real progress of a project.

MEETING REGULATIONS. In the final analysis, the stormwater management program pollution reduction goals are set by the regulatory requirements. This section describes types of regulatory programs concerned with urban runoff pollution.

Federal. *NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM PERMITTING.* Section 402(p) of the Clean Water Act established NPDES permitting requirements for municipal stormwater systems and two goals for these permits:

- Eliminate nonstormwater discharges from storm drains. Nonstormwater discharges typically are intermittent, unpredictable, widely dispersed, and difficult to detect. They may be physically connected to storm drains or may result from dry weather water use that entrains constituents as it runs off.
- Reduce stormwater pollution to the maximum extent practicable. According to U.S. EPA NPDES permitting regulations in the Code of Federal Regulations, the local entities and regulatory agency should define the maximum extent practicable (MEP) through a comprehensive planning process. The process should consider the magnitude of

the problem, constraints on its resolution, the effectiveness and track record of available BMPs, and costs. Recent practice is to define MEP using a combination of source control BMPs and treatment control BMPs. The MEP is not a fixed target but should be reexamined and, if necessary, revised to incorporate current knowledge about sources of pollution and the demonstrated effectiveness of BMPs.

COASTAL NONPOINT POLLUTION CONTROL PROGRAM. The Coastal Zone Act Reauthorization Amendments of 1990 require states with approved coastal zone management programs to develop a Coastal Nonpoint Pollution Control Program for approval by U.S. EPA and the National Oceanographic and Atmospheric Administration. The purpose of the program is to work closely with other state and local authorities to develop and implement management measures for nonpoint source pollution (including urban runoff) that restore and protect coastal waters. Coastal stormwater control programs are not intended to supplant existing coastal zone management programs. Rather, they are to serve as an update and expansion of existing nonpoint source management programs and are to be coordinated closely with the existing nonpoint source management programs (U.S. EPA, 1991).

NATIONAL ESTUARY PROGRAM. U.S. EPA administers the National Estuary Program under Section 320 of the Clean Water Act. This program focuses on all pollutant sources in geographically targeted, high-priority estuarine waters. Through this program, U.S. EPA assists state, regional, and local governments in the development of comprehensive management plans that recommend priority corrective actions to restore estuarine water quality, fish populations, and other designated uses of the water (U.S. EPA, 1991).

State. States have evolved a variety of statewide stormwater pollution control strategies. A few states initiated controls in response to the perceived needs of their states. Many more developed strategies in response to U.S. EPA requirements that have sometimes lapsed into oblivion, lacking any obvious immediate necessity or federal sanction. The general objective of controlling stormwater pollution is accepted as important not only by environmental interests but by water resource analysts as well. Development of stormwater pollution control programs is proceeding but is moving slowly.

CASE STUDY—STATE OF MARYLAND. Maryland has a well-developed program for the control of stormwater pollution, with particular interest in the restoration and protection of the Chesapeake Bay and its tributaries. Eutrophication of the Chesapeake Bay causes serious declines in water quality and fishery productivity. A water quality model of the Chesapeake Bay demonstrated the relationship between nutrient input, eutrophication, and deoxygenation. Accordingly, a target was set in 1987 to reduce the total input of nitrogen and phosphorus by 40% by the year 2000. A current reevaluation will examine the progress made toward the 40% goal and recommend adjustments to the program.

Maryland enacted legislation from 1984 to 1986 to establish a 305-m (1 000-ft) critical area around the edge of the bay and create the Chesapeake Bay Critical Area Commission to establish criteria for development in the critical area. Within intensely developed areas of the critical area, storm runoff pollution loads for new development must be reduced at least 10% below predevelopment levels or offsets must be provided. In limited development areas, no more than 20% of woodland or forest may be developed, and the impervious area created in any development site is limited to a maximum of 15% of the total site. In resource conservation areas, additional residential development can only be allowed at a density not exceeding one house per 8 ha (20 ac). State grants have been available to support the necessary local planning.

More than 5 000 stormwater management facilities have been installed on new developments in Maryland between 1985 and 1989. The general goal of Maryland's stormwater management program is that both the quantity and quality of runoff from developed land will be as close as possible to the runoff characteristics of the predeveloped condition. Implementation of management stormwater controls for existing urban areas is carried out with local jurisdictions through the Stormwater Pollution Control Program. This state program provides grants of up to 75% of the project's cost to counties and towns. Although more than 50 projects have been constructed, progress statewide has been slow.

Interstate. Many watersheds encompass areas within more than one state. For example, the Delaware Estuary Management Plan, sponsored by U.S. EPA and the states of Delaware, New Jersey, and Pennsylvania, is part of the National Estuaries Program. The Delaware Estuary, as a whole, is still relatively unpolluted. Thus, the plan focuses primarily on land use management programs in each state designed to prevent the major increases of stormwater pollution that otherwise would accompany future development and the protection of sensitive habitat (for example, a primary national flyway).

The plan establishes a "primary zone of influence" where controls would be mandated based on time of travel (that is, the time for runoff to reach the estuary). A time of travel of 40 hours at mean flow conditions was used to establish the tentative boundary for the primary zone of influence.

The estuary program is bringing attention to some striking differences in handling stormwater pollution control in the three states. Delaware has a recently developed program requiring water quality control of storm runoff from new developments statewide. New Jersey has well-developed, but nonmandatory, standards of water quality control in stormwater management in which application is left to municipal discretion. Pennsylvania has no such standards except for streams draining into lakes and for the control of nutrients in the Susquehanna River Basin related to the Chesapeake Bay estuary study. Clearly, interstate programs present numerous implementation issues.

Regional. Several states have adopted regional approaches to managing stormwater runoff. In Florida, rapid growth during the late 1970s and throughout the 1980s placed numerous demands, both in water quantity and quality, on the state's vulnerable and limited water resources. To reduce degradation from the rapid growth and extensive land-use changes, a wide variety of laws and regulations have been implemented by the state and local governments.

California's Porter-Cologne Act requires the development of basin plans for the various watersheds. The basin plans are implemented through the NPDES permitting program, which is administered by the nine regional water quality control boards under supervision of the State Water Resources Control Board. Areawide municipal stormwater NPDES permits have been granted to 12 urban counties and all cities within these counties. In the San Francisco Bay watershed, the Bay Area Stormwater Management Agencies provide watershedwide coordination of the NPDES-permitted stormwater management programs, other nonpermitted municipal stormwater management programs, and San Francisco's combined sewer overflow program. Additionally, statewide Stormwater Quality Management Task Force meetings of municipalities, industries, regulatory agencies, and consultants help coordinate stormwater management programs throughout the state.

ASSESSING EXISTING CONDITIONS

A common question asked while developing a stormwater management program is "What is the stormwater quality problem?" While this is a logical question, a firm scientific answer is sometimes difficult and costly to give. To move the program forward, municipalities should conduct a quick assessment of obvious local receiving water problems, significant pollutant sources, and existing control programs based on visual observations and readily available data. This assessment should apply monitoring, modeling, and performance auditing methods discussed in Chapter 3 for watershedwide evaluations of pollutants and their effects. Local staff members with pragmatic knowledge of the "lay of the land" are an asset when assessing existing conditions. The four primary areas that should be explored when assessing existing conditions are receiving water characterization, watershed characteristics, pollutant sources, and existing programs.

RECEIVING WATER CHARACTERIZATION. The main receiving water effects associated with stormwater are

- Receiving water hydromodification because of increased runoff from urban areas;
- Water quality degradation from changes in the chemical/bacteriological constituents in runoff; and
- Losses in the assimilative capacity of the urban drainage system.

Schueler (1993) classifies urban runoff effects as changes in stream hydrology, morphology, water quality, habitat, and ecology. An effective stormwater management program needs to consider receiving water characteristics and effects of urban runoff on the receiving water. However, significant gaps remain in our understanding of and ability to define these characteristics and effects. Therefore, the near-term stormwater management program should begin to define receiving water characteristics and effects to establish near-term stormwater pollution control targets.

Typically, the beneficial use effects of stormwater on specific receiving waters have not been examined in detail. The traditional method of defining beneficial use effects are based on numerical and narrative water quality standards and effluent limits for chemical constituents. This traditional method must be supplemented by other approaches (for example, hydrologic modeling, bioassessment, and habitat assessment) to address the full range of urban runoff effects and develop appropriate control strategies. Chapter 3 discusses these traditional and alternative approaches to characterizing receiving waters and the effects of urban runoff.

POLLUTANT SOURCES. The stormwater management program should direct control measures at pollutants that impair the beneficial uses of the receiving water. For example, pollution control in the watershed of a eutrophic receiving water should be directed at significant sources of the limiting nutrient (such as phosphorus or nitrogen). Concentrated sources of pollutants can be effective early targets for the stormwater program because their cleanup is both observable and measurable. These sources might include old commercial and industrial areas and old core urban areas where polluting non-stormwater connections to the storm drain system are most likely to be found. Also, stormwater pollution controls are often easier to implement if directed at related problems recognizable to the community. For example, a business or resident using "bad housekeeping practices" outdoors is often considered to be an eyesore to neighbors (if not in violation of local regulations).

Visual observation is the best way to begin targeting pollutant sources in the near term. After the most concentrated sources are addressed, long-term monitoring programs may begin providing insight to more widely dispersed pollutant sources. Computer models then can be used to project existing and future pollutant loads based on the land uses of the watershed and characteristic concentrations of runoff from each land use (see Chapter 3 for details). Research into the composition of materials may also help reveal the source of critical pollutants.

Pollutant load estimates define the relative loading of pollutants from different parts of the watershed. Knowledge of pollutant characteristics helps reveal proper pollution control strategies. For example, can nonstructural controls, especially for currently existing development, significantly address water quality needs before structural controls are even considered? What will be gained if structural controls are retrofit in an area, and can the cost be justified?

WATERSHED CHARACTERISTICS. The basic objectives of this step include becoming familiar with the watershed, focusing on those factors that will influence the nature of stormwater management, and collecting all information necessary to select BMPs. Characteristics should include the following:

- Land use: What is the existing land use and impervious area of the watershed? What will land use/imperviousness be at buildout? What is the proximity of intensive land uses to sensitive receiving waters?
- Physiology: Are slopes steep, moderate, or flat? Are soils erosive? Are they permeable? What is the depth to bedrock? To groundwater?
- Climate: What is the rainfall intensity/duration/frequency for small storms?
- Habitat: What habitat thrive in this area? How has urbanization irrevocably altered this habitat?
- Drainage system: What impervious surfaces are connected to the drainage system? What is the extent of the closed storm drain system? Where do curb and gutter systems exist? Are open storm drains improved or natural?
- Community profile: What are the makeup and activities of the residents and businesses in the watershed (for example, demographics, community organizations, and business climate)?

EXISTING PROGRAMS. An effective stormwater management program consists of a number of specific components, each targeted at specific types of pollutant sources. However, not all components need to be new components focused exclusively on stormwater management. Every municipality conducts a wide variety of programs that can be integrated to a community-wide stormwater management program. This section presents examples of existing municipal programs that have objectives similar to those of stormwater management.

Existing Regulatory Programs. Table 2.2 lists a number of regulatory programs that have a bearing on the selection of BMPs or implementation of a stormwater management program. The prudent selection of BMPs will serve to comply with the objectives of both the stormwater program and other regulatory programs. The following paragraphs describe various federal, state, and local programs as they relate to stormwater control.

Table 2.2 **Existing regulations for stormwater pollution control.**

Regulation	Activity	Potential
Federal Clean Water Act 401 and 404 permits	Permits dredging and filling in "waters of the United States"	Erosion control, sediment control, long-term sediment balance, and reduce pollutants Vegetative controls to preserve riparian areas
Federal 1601 and 1603 Stream Bed	Alterations to creek and stream beds	Pollutant controls and prevent loss of habitat
State General Plan Act	Municipal development objectives Adoption of ordinances	Stormwater management controls, for example, pollutants control, watershed protection
State Environmental Quality Act	Environmental review of projects	Mitigation measures for reduction of pollutants
State Subdivision Map Act	Adoption of ordinances	Standard/regulations for grading, erosion protection, detention/retention design, and dust control
State air quality management plans	Emission	Sediment and dust controls
Local flood plain management and drainage ordinances	Control of velocity Detention/retention Bank stabilization and outlet controls	Control of erosion Control of sediment, pollutants, and quantity Erosion and sediment controls
Local zoning ordinances	Cluster development Hillside development Landscape/open space	Reduce runoff and impervious areas Slope and erosion restriction; may include revegetation or stabilization Vegetative best management practice perimeter controls reduction of runoff
Local sewer use ordinance	Control of illicit connections	Pollutant controls
Local uniform building code	Chapter 70—excavating and grading	Reduce erosion and sedimentation Standards for stable cut and fill slopes
Local uniform plumbing code	Prevention of illicit connection Various chapters on materials and application/use	Pollutant controls Pollutant controls
Local fire code	Storage of materials	Pollutant controls

PESTICIDE PROGRAM. U.S. EPA administers the pesticide program under the Federal Insecticide, Fungicide, and Rodenticide Act. Among other things, this program authorizes U.S. EPA to control pesticides (sometimes found in stormwater) that may threaten groundwater and surface water (U.S. EPA, 1991). Potential actions carried out in this program include national requirements on labels, training, development of state management plans, and national prohibition of certain domestic uses of designated chemicals.

HAZARDOUS MATERIAL/WASTE CONTROL PROGRAMS. There are numerous laws (primarily the Resource Conservation and Recovery Act and the Emergency Planning and Community Right-to-Know Act) and regulations regarding the control of hazardous material and waste. Hazardous materials storage and emergency response programs regulate hazardous materials storage and emergency response planning. A company's annual business plan must include a hazardous material inventory, estimates of hazardous waste amounts, and emergency response planning. Under workers' right-to know programs, the employee is advised, through the use of material safety data sheets, material labeling, and employee training, of the potential for contact with hazardous substances. Also, under hazardous waste source reduction and management review programs, hazardous waste generators must look at source reduction as the preferred method for managing waste. The industry must prepare a source reduction evaluation review and plan that identifies all hazardous waste streams and potentially viable source reduction approaches.

AIR QUALITY PROGRAMS. Source control of atmospheric contributions of stormwater pollution (such as automobile and industrial emissions) should be coordinated with state and local air quality programs. As an example, some states require counties with a metropolitan population greater than 100 000 to form a Congestion Management Agency (CMA). This agency, which typically is a joint power authority, coordinates the development of a Congestion Management Program. This program addresses the effects of land-use decisions on regional transportation systems, trip reduction ordinances, and public transit services. Consequently, close cooperation between the CMA and the municipality would benefit each entity's efforts to reduce pollutants in the environment.

SPILL PREVENTION AND CLEANUP PLANS. Federal regulations require on-shore facilities engaged in operations that could reasonably be expected to discharge oil in harmful quantities to prepare Spill Prevention Control and Countermeasure (SPCC) Plans. National Pollutant Discharge Elimination System regulations for some industrial activities also require SPCC plans as part of the facility's BMP program.

Existing Municipal Programs. An effective stormwater management program should instill stormwater management concepts to the activities of other municipal programs. Several examples of integrating stormwater management to existing programs follow:

- Integrated pollution prevention programs–in many cases, a single pollutant prevention measure can meet more than one environmental regulation (for example, household hazardous waste collection, waste minimization, landfill management, or pesticide use).

- Integrated water resource management–extending flood control policies to address more frequent storms, prevent streambank erosion, and promote percolation of runoff to control the peak and volume of runoff will also control pollutants in runoff.
- Growth management policies–how and where land is developed may significantly change the effect of stormwater pollution on receiving waters. Directing intensive land uses away from sensitive receiving waters has been proven to be an effective source control BMP for new development projects.
- Multiuse open spaces–many communities incorporate treatment control BMPs to parks and recreation areas through proper planning, design, and landscaping. These types of "multiuse" facilities provide a cost-effective way of meeting stormwater management plan goals.

ESTABLISHING A MANAGEMENT PROGRAM FRAMEWORK

STRUCTURING THE PROGRAM. A stormwater management program must address a wide variety of individuals, businesses, organizations, and agencies that contribute to the stormwater pollution problem and its solution. Such a program should be planned carefully to have the following important characteristics:

- Comprehensive—the program should have adequate resources to address all aspects of stormwater quantity and quality in the watershed that affect beneficial uses of receiving waters.
- Integrated—maximum effectiveness is achieved by an integrated program of regulation, education, and municipal action.
- Balanced—each responsible party must be defined, and specific direction must be given to each party. Direction for each party should be commensurate with its share of the problem and equitable to its share of the solution.
- Continuous and dynamic—meaningful stormwater control, particularly in developed areas, will take a long time, certainly longer than a single 5-year NPDES permit term. Therefore, stormwater management programs should be implemented in a manner that addresses the dynamics of an evolving, long-term program.

The program's organizational framework should capture the full breadth of the problem and its solution. It is not appropriate for this publication to recommend an ideal stormwater management program structure. Each program must do this based on the assessment of the existing conditions described in the previous section. Typically, however, each program should address the three broad areas listed below:

- Land development is one of the most typically regulated aspects of stormwater management in North America and, thus, is the area where the most experience lies. This aspect of the program typically addresses land-use planning considerations, incorporating treatment controls to development projects, and controlling construction-related effects.
- Municipal drainage system management typically involves cleaning channels, detention basins, pipes, inlets, catch basins, streets, and impervious areas connected to the drainage system. In some cases, it may be feasible to retrofit treatment controls to the drainage system to improve the ability to capture stormwater pollutants or ease their removal.
- Residents and businesses also contribute stormwater pollution, largely by conducting outdoor activities in a manner that allows pollutants to enter the drainage system. Municipalities can use a combination of education and regulation to address this aspect of stormwater pollution.

SETTING PRIORITIES. The next step in developing and implementing the stormwater management program is to set priorities and establish phases for meeting the established objectives. Priorities and phasing should be soundly based on the existing condition assessment. Priorities should be established by the committees that have defined the program objectives. Many decision-making techniques exist for establishing priorities. It is not the intent of this publication to discuss these techniques. At a minimum, priorities should reflect common sense, using questions like those listed below:

- How much can we afford?
- Do we think it will work?
- What are we already doing?
- Can we show that it works?
- Where are the worst problems?
- Can we learn something new?
- What are the easiest solutions?
- Is this the right direction?
- What has been successful for others?
- Will beneficial use impairment decrease?

SELECTING MANAGEMENT PRACTICES

The basic objective of stormwater management is watershedwide improvement in water quality and enhanced beneficial use of the receiving water bodies. The current practice is to presume that a cost-effective, practicable set of BMPs (that is, restrictions, techniques, or treatment facilities that are required under given conditions) will provide some progress in protecting water quality. For example, individuals can conclude that used motor oil should be recycled rather than discarded without site-by-site analysis or sampling. This approach typically will be used, at least in the near term, because the cause–effect relationships between pollutants in the watershed and beneficial use impairment in the receiving water are not always understood, the urban stormwater management agency often does not have complete jurisdiction over a complete watershed, or regulatory requirements can be met through BMPs.

MULTILEVEL STORMWATER QUALITY MANAGEMENT STRATEGY. A municipality's stormwater management strategy must cost-effectively address program objectives using existing information to address priority needs within the context of an overall program framework. An effective strategy uses multiple BMPs, including source controls (see Chapter 4) and treatment controls (see Chapter 5). A single BMP typically cannot provide significant reductions in stormwater pollutant loads because these pollutants come from many sources within the municipality. However, multiple BMPs can provide complementary water quality enhancement to achieve desired results. A multilevel BMP approach, schematically depicted in Figure 2.2, deals with the many pollutant and runoff sources throughout the watershed and shows that, whenever feasible, combining most effective BMPs in a series can be an effective strategy to reduce pollutant loads being transported to the receiving waters by stormwater (UDFCD, 1992).

SELECTING STANDARD AND SPECIAL BEST MANAGEMENT PRACTICES. There are hundreds of different BMPs appropriate for the different sources of pollution and the varieties of receiving waters to be protected. In practice, a large degree of simplification will be necessary, especially in starting a program. Typically, there should be a set of standard BMPs appropriate for general application to a particular geographical or political area, supplemented by special BMPs for application where a greater degree of pollution control may be desirable. These would be further refined by establishing standard and special BMPs for the protection of groundwater and surface water, respectively. For example, control of nitrates and volatile organics is more important for groundwater than for rivers unless they drain into a reservoir, lake, or estuary. Therefore, special BMPs for those substances might be applicable for percolation to groundwater but not for drainage to rivers. In addition to specifying either standard or special degrees of protection, additional measures may be added as particular circumstances require, and, of course, there are some cases where no control of stormwater pollution is necessary.

It is apparent that the selection of BMPs must consider the potential harmfulness of the land use, the sensitivity of the receiving waters, and the prox-

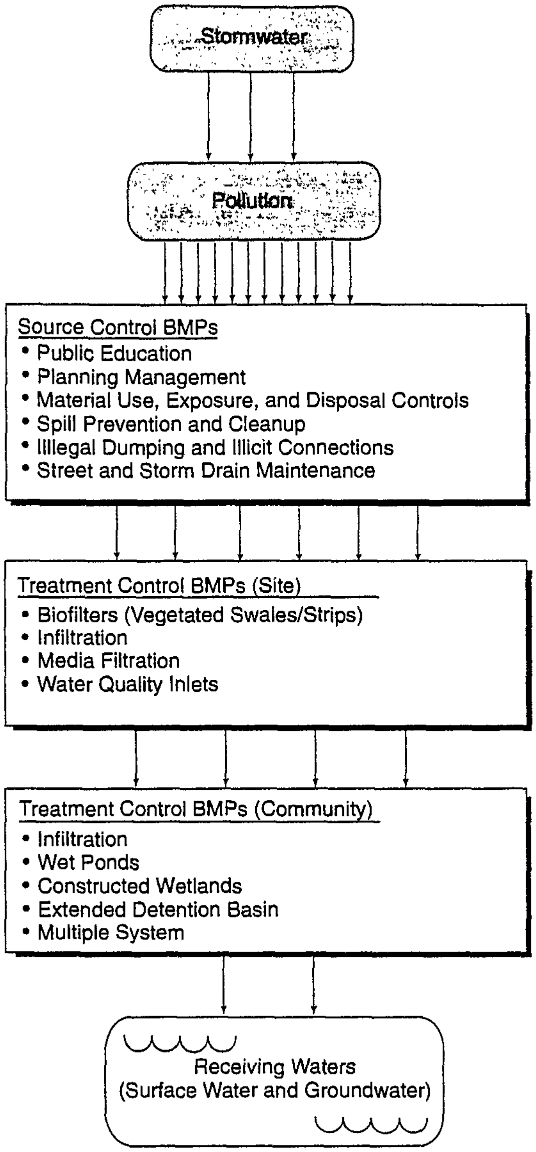

Figure 2.2 Multilevel strategy for stormwater management program (UDFCD, 1992).

imity of the land use to the sensitive portion of the receiving water. One BMP selection method uses numerical indices of harmfulness and sensitivity (see Figure 2.3). These indices can be evaluated with a matrix approach to show whether special or standard BMPs will be required for a given situation or whether, through land-use controls, that kind of development should be prohibited in the location proposed. However, best results can be obtained if the approach described previously provides for the level of BMP control

Areal Priorities: Designate areas GW where extra protection is warranted for groundwater and SW for surface waters warranting extra protection:

Class 1 Any officially designated highest priority protection areas, such as habitat of threatened or endangered species, exceptional resource wetlands. Also, delineated well head protection areas (GW).

Class 2 Aquifers usable for water supply, including important recharge areas (GW). Delineated buffer zones around water supply reservoirs. The area immediately adjacent to the reservoir should be protected against either groundwater or surface water pollution, the balance of the buffer against surface pollution only (SW).

Class 3 The remainder of the watershed to be protected.

Class 4 Any area that does not warrant protection against water pollution from stormwater (typically GW).

Harmfulness Index of Stormwater: Unless otherwise demonstrated in specific situations, the following classifications are in descending order of pollutant loading, the most intense being first:

Class 1 From industrial and waste management sources.

Class 2 From multiple-family housing, commercial facilities such as gas stations and shopping centers, highways, urban areas, and single-family housing with lot sizes smaller than one-third acre per housing unit.

Class 3 From single-family housing developments, with lot size one-third acre or larger per housing unit, and from lesser roads.

Class 4 Undeveloped land or unfertilized vegetation.

In addition, there are other categories of stormwater pollution that are highly variable in their pollutant loading. These include agriculture and road salts, which must be appropriately classified depending on the circumstances.

Stormwater Best Management Practices: If a proposed land use is rated Class 1 harmfulness index (as indicated above), it should not be located in a Class 1 area. If located in a Class 2 or 3 area, special provisions for quality control of runoff are appropriate. If the proposed development is Class 2 harmfulness index, special BMPs are appropriate if the development is located in a priority 1 area. (Class 1 developments may not be allowed in such areas.) If the proposed Class 2 development is not located in a priority 1 area, but its runoff drains into it, it may still require special BMPs for runoff control. A decision is required as to how far upstream such controls should extend. Otherwise, standard BMPs are appropriate for Class 2 harmfulness, except for priority 4 areas.

Figure 2.3 Best management practice numerical selection guide (ac $\times$ 4 047 = m^2).

Infiltration Best Management Practices:

a. In Class 1 protected areas, such as well heads, buffer areas adjacent to protected habitat, and habitat of endangered species, facilities involving infiltration may not be allowed at all. If they are allowed, infiltration of Class 1 runoff will be acceptable only with special water quality provisions for processing the runoff. Infiltration of processed Class 2 runoff will be acceptable if processing of runoff follows standard BMPs.

b. In Class 2 areas, including aquifers, Class 1 runoff that has been processed through standard water quality systems such as water quality detention basins or filter strips may be approved for infiltration to aquifers. Infiltration of Class 3 runoff should be encouraged, after processing with standard water quality provisions, unless special circumstances indicate existence of potential contamination.

Conditions for Infiltration

Areal Priority	Harmfulness Class 1	Harmfulness Class 2
1	No infiltration except after special water quality process	No infiltration except after standard water quality processing
2	No infiltration except with a positive showing of no adverse effect or after standard water quality processing	Infiltration encouraged unless potential harm indicated
3	Allowed	Allowed
4	Allowed	Allowed

Figure 2.3 Best management practice numerical selection guide ($ac \times 4\,047 = m^2$) (continued).

needed for an entire watershed and addresses BMPs that can be applied throughout the watershed. A detailed watershed-planning process should be used where the type and level of BMPs at each site may differ because of technical, financial, or jurisdictional issues.

SELECTING BEST MANAGEMENT PRACTICES FOR LAND DEVELOPMENT. Land development changes both the hydrologic regime of a watershed and the chemical constituents in the runoff. These changes are best controlled at the point of origin by land-use planning. Next best are source controls because land-use controls are often difficult to implement. To the extent that land-use controls and source controls are not sufficiently effective to prevent pollution, treatment controls should be used to address the problem. These controls may include detention and retention facilities, other measures classified as treatment, or, occasionally, diversion of runoff to a less sensitive environment. Both source controls and treatment controls may be included as conditions of a permit, as indicated further below.

Land-Use Controls. Land-use controls involve adoption of a comprehensive and integrated set of environmental restrictions to govern the development process. The greatest level of beneficial use protection is afforded when a single development ordinance is adopted by a community and administered by a single planning authority. In short, the ordinance mandates a minimum level of environmental site planning during development and can include, but is not limited to, the following items:

- Stream buffer requirement—development is not allowed within a variable width buffer strip on each side of ephemeral and perennial stream channels. As an example, in Baltimore, Maryland, the minimum width of the buffer strip is 15 m (50 ft) for low-order headwater streams but expands to as much as 60 m (200 ft) in larger streams (Baltimore County, 1989). The stream buffer further expands to include floodplains, steep slopes, wetlands, and open space areas to form a contiguous system, according to prescribed rules.
- Floodplain restrictions—development is restricted within the boundaries of the postdevelopment, 100-year floodplain.
- Steep slope restriction—no clearing and grading are permitted on steep slopes, for example in excess of 25%.
- Nontidal wetland protection—no development is permitted within nontidal wetland areas and a perimeter buffer area.
- Protection of environmentally sensitive areas—development is not allowed within unique habitat areas/plant communities or protective perimeter buffers identified through watershed master planning.
- Upland and riparian tree cover requirements—an allotted percentage of upland predevelopment tree cover must be maintained after site development. In addition, the riparian tree cover (which should be entirely contained within the stream buffer system) must also be retained or reforested if no tree cover currently exists.
- Waterway disturbance permits—forms of development such as roads and utilities must, by their very nature, cross through the stream buffer system. Linear developments must be scrutinized to locate them in the narrowest portions of the buffer system and ensure they do not form barriers to either fish migration or riparian wildlife migration.
- Community open space requirements—after the stream buffer system has been delineated, consider preserving additional open space at the site to accommodate the residents' future requirements for parks, playgrounds, ball fields, and other community needs.
- Cluster development—the objective here is to reduce the impervious surfaces at the site and cluster development into centralized areas where stormwater can be effectively treated. The best tools include

transferable development rights, cluster zoning, site "fingerprinting," planned unit development, and flexible site and road width layout (Yaro *et al.*, 1988).

Selecting Source Controls. A source control program for a land development project should

- Identify possible postconstruction outdoor activities that may use or generate concentrated or high-risk pollutants at the site;
- Prohibit these outdoor activities where practical;
- Designate specific areas for those activities that must be conducted outdoors;
- Install structural source controls (for example, covers, enclosures, containment systems, or connections to sanitary sewers) in these designated areas; and
- Place conditions on the development project for maintaining these areas.

Outdoor activities may include material storage, waste handling, material loading or unloading, vehicle and equipment maintenance, and myriad specific work tasks typically conducted outdoors. Source controls are selected as described in Chapter 4 of this publication.

Selecting Treatment Controls. An effective system of treatment controls addresses dispersed sources of pollutants throughout the watershed that affect beneficial uses but cannot be effectively controlled at the source (for example, automobiles and air deposition). When coupled with proper land-use controls, they can be integrated to the landscaping, drainage and flood control system, and other open spaces of development projects. When properly designed, they become amenities rather than interferences to development projects. When preceded by effective source controls, they do not cause other environmental problems (such as groundwater pollution or hazardous sediments). For example,

- A grass-lined channel can be designed to effectively convey flood waters and, by incorporating certain design techniques, reduce pollutant loads.
- Ponds can be designed to attenuate peak discharges to desired levels and reduce pollutant load before discharge. Pollutants are reduced by detaining "first-flush" runoff from large storms and all runoff from small storms long enough for sediments to settle and biological processes to act on degradable materials.
- Many well-designed treatment controls integrate with recreational facilities, provide wildlife habitat and groundwater recharge, preserve open space in urban settings, and increase the value of adjoining land.

Integrating treatment controls to multiuse facilities of this type promotes cost effectiveness and other benefits by reducing capital costs (by reducing the number of facilities needed in the first place); saving land; reducing operation, maintenance, and replacement costs; reducing planning and design time; and stimulating integrated, comprehensive planning. Chapter 5 presents an integrated approach to selecting and designing treatment controls that achieves desired water quality and quantity objectives in an effective and efficient manner.

SELECTING BEST MANAGEMENT PRACTICES FOR EXISTING MUNICIPAL DRAINAGE SYSTEMS. In most cases, the urban drainage system includes street gutters, inlets, catch basins, storm drain pipes, constructed ditches, channels, and urban streams. These streams often are severely altered, either by humans or by the changed hydrologic regime. Two categories of BMPs are appropriate for urban drainage systems:

- Various techniques for cleaning drainage system components or preventing nonstormwater discharges to the drainage system in the first place (source controls); and
- Various devices that can be retrofit to the drainage system to slow the rate of runoff or remove and assimilate pollutants (treatment controls).

Typically, all available source controls for municipal drainage systems should be used to some degree. Selection of BMPs for existing municipal drainage systems involves establishing an appropriate cleaning frequency for each component and an inspection frequency for nonstormwater investigations. Chapter 4 describes the source controls for municipal drainage systems and presents guidelines for determining cleaning/inspection schedules.

Feasible retrofit strategies typically involve an urban stream restoration program and feasible retrofitting of existing flood control basins. The primary purpose of stream restoration is to enhance the aquatic habitat and ecological functions of urban streams that have been lost or degraded during the urbanization process. Stream restoration also "builds back" the assimilative capacity of these urban streams, allowing them to better remove pollutants before discharging to larger downstream receiving waters. A comprehensive stream restoration program incorporates several of the following steps, where geomorphological/land-use opportunities permit:

- Watershed assessment of restoration opportunities—stream restoration opportunities are best assessed though systematic biological surveys throughout the stream system and its upland watershed. These surveys should determine the dominant effects that have degraded the aquatic community and identify feasible opportunities for restoring stream habitat or water quality.

- Retrofitting of flood control basins—the best restoration opportunities often involve the improvement of existing flood control basins. For example, in the Washington, D.C., metropolitan area, retrofitting typically has involved converting older, dry stormwater ponds to extended wet pond–marsh systems (Herson, 1989).
- Construction of additional urban best management practices—retrofit of new urban BMPs in the urban landscape is not an easy task, given the typically limited amount of space available. Innovative retrofit techniques include the peat–sand filter (Galli, 1989), oil–grit separator inlets, and extended detention lake/wetland systems (Schueler and Helfrich, 1988).
- Reforestation programs—the buffer zone along urban streams and upland areas can be reforested gradually within a matter of years at a relatively low cost through cooperative community tree planting programs according to a long-term watershed plan. These volunteer programs are most effective when local governments arrange the logistics, assemble the sites, and secure the plant stock.
- Instream fish habitat improvement—the degradation of stream habitat structure (most notably the loss of pools, riffles, and clean spawning areas) can be reversed by adapting habitat improvement techniques such as boulder and log deflectors, log drop structures, brush bundles, willow wattles, boulder placement, and imbricated riprap.
- Urban wetland creation/restoration—active creation, restoration, and management of urban wetlands partially substitute for the lost ecological functions of the destroyed or degraded wetland system in many urban areas.
- Identification and removal of fish barriers—possible barriers to fish migration can be detected through systematic upstream/downstream fish collections at suspected structures during spring runs (Cummins, 1988) or, in some cases, by visual surveys. In many cases, urban fish barriers are created by structures in the stream that can be rather easily modified to allow migration.
- Stream stewardship—citizens often take an active and personal interest in maintaining urban stream quality. Local governments can encourage them to adopt a stream; remove debris; and report oil spills, sediment control violations, pollution problems, and sewer overflows.
- Natural urban parks—urban parks, centered about the stream valley and riparian vegetation zone, provide a tool for managing land use and human access while protecting key vegetative communities in core stream areas.

SELECTING BEST MANAGEMENT PRACTICES FOR RESIDENCES AND BUSINESSES. Most of the urban landscape consists of private property containing residences and businesses. An effective municipal stormwater management program must include BMPs for these residences and businesses. Typically, the near-term program will focus on source control in these areas, achieved through a combination of public education and municipal regulation. Chapter 4 of this publication describes feasible source control strategies for existing residences and businesses.

It is unlikely that treatment controls will be retrofit to existing development on private property in the near future unless the runoff is significantly polluted, the property discharges to a highly sensitive receiving water, source controls are ineffective, or the property is subject to an industrial NPDES stormwater permit. Retrofitting other treatment controls on private property will be expensive and controversial without additional proof of direct water quality effects for each property's runoff.

IMPLEMENTING THE PROGRAM

IMPLEMENTATION STRATEGIES. Three options exist for implementing the stormwater management program: incorporating stormwater management concepts into an existing program, starting a new program, and conducting further planning and study. The following sections describe each of these strategies.

Incorporate Stormwater Concepts to an Existing Program. Programs that partially achieve stormwater pollution control are already in place for many areas. These may be municipal programs, programs sponsored by overlapping jurisdictions, or private initiatives. Typical existing programs include household hazardous waste collection, hazardous spill response units, hazardous material storage rules, Resource Conservation and Recovery Act and landfill management and closure regulations, litter control programs, and erosion and sedimentation control requirements. For many existing programs, all that may be required is better documentation and effective communication about their conduct and effectiveness at achieving stormwater pollution control. Other existing programs may be compatible with stormwater pollution control but require some redirection. In this category, the objective should be to incorporate effective stormwater management concepts to the program. Water quality management plans that have been developed by local governments to satisfy the requirements of Section 208 of the Clear Water Act typically refer to nonpoint source effects and controls. These need to be reviewed and, in most cases, redirected to focus on stormwater quality aspects rather than on point sources only. Existing programs that may be redirected include detention/retention requirements for new development, construction site and building permit inspection programs, drainage system maintenance activities, and transportation and land-use planning programs.

Start a New Program. There are two instances where new programs are favored in the near future:

- The program will directly and measurably benefit the beneficial uses of the receiving water (for example, an illicit discharge control program).
- The program will begin educating the community at large about how stormwater systems operate, how their actions can pollute receiving waters through storm drains, and how the community can be involved in stormwater pollution control.

Conduct Further Planning and Study. Some activities warrant additional study in the short term to achieve cost-effective BMP selection:

- Watershedwide master plans are often used to select BMPs for land development activities and new, enlarged flood control facilities as described previously in this chapter.
- Pilot studies are an interim step aimed at gaining practical knowledge on which to base long-term implementation decisions. They should be directed toward a representative microcosm of the watershed and should be considered where watershedwide implementation is expected to be cost prohibitive in the near term. Possible pilot studies may include street sweeping programs, school curriculum on stormwater pollution control, stormwater pollution control initiatives directed at small businesses, innovative treatment technologies, and illicit connection detection programs.

Pilot studies are most appropriate for source control BMPs where a high level of community involvement may be required, implementation may be labor intensive, effectiveness is largely unmeasured, or effective implementation may be site specific. While a large body of research and practical field experience already exist for treatment control BMPs, pilot studies of these BMPs may still be necessary to account for local climatic, physical, and institutional conditions.

TREATMENT CONTROL OPERATION AND MAINTENANCE. Regular inspection and maintenance of treatment BMPs is an absolute necessity if these controls are to perform consistently to expectations. Sediment removal and removal of debris from BMP inlets and outlets are important requirements to maintain consistent performance. Access to detention ponds is necessary for excavating equipment, trucks, mowers, and personnel for routine maintenance and erosion repair and for the removal of sediment and trash accumulation. Where access is particularly difficult or impractical, ponds should be overdesigned to allow for additional sediment accumulation.

Chapter 5 of this publication presents an overview of maintenance requirements. Further information is also contained in *Design and Construction of Urban Stormwater Management Systems* (ASCE and WEF, 1992). Each municipal stormwater management program should determine specific maintenance practices for treatment controls implemented in their community, clearly define what the municipality will maintain, and develop enforceable agreements with private parties responsible for facilities the municipality does not maintain.

FINANCING STORMWATER MANAGEMENT PROGRAMS. Revenue Alternatives. The stormwater management program needs a reliable source of revenue for general administration, operation, maintenance, and capital improvements. This section reviews revenue alternatives for the funding and financing of the stormwater management program. Funding refers to sources of revenues used to pay for annual operating expenditures, including maintenance and administrative costs; to pay for improvements directly out of current revenues; and to repay debt issued to finance capital improvements. Financing is defined as the initial source of funds to pay for planned capital improvements or equipment.

Five funding alternatives and nine financing alternatives are reviewed in this section. Several important characteristics are discussed to provide a general background for comparing alternatives. Legal provisions for the selection and use of the revenue alternatives presented may vary from state to state, depending on state statutes or regulations.

Funding Options. Annual funding requirements of a local stormwater management program may include administration, permitting, design, planning, operation, system maintenance, meeting the system's annual debt service obligations, and other financial requirements.

GENERAL GOVERNMENT TAX RECEIPTS. Stormwater management operation and maintenance costs can be funded by general government tax receipts. With this option, the funds required could be generated by any revenue source accrued in the general fund. Revenue from the general fund primarily is derived from *ad valorem*-based levies on taxable property. A significant advantage to consumers is that these costs are tax deductible. The primary disadvantage is that the general fund is not a dedicated source, and stormwater management needs would have to compete for limited funding with other programs. As a result, this funding mechanism is subject to fluctuations and typically is unreliable for implementing a long-term capital improvement program. In addition, *ad valorem* funding is less equitable because tax-exempt property does not pay and charges are based on property values rather than the effects associated with stormwater runoff or services provided.

BENEFIT AREA OR SPECIAL ASSESSMENTS. Property owners within a stormwater benefit area typically are assessed a levy or charge to fund stormwater systems within the benefitted area. In addition, if different land uses within the benefit area receive substantially different levels of stormwater benefits, the assessment of levies from subarea to subarea should vary in proportion to the benefits received.

The following criteria typically are applied when a benefit area or special assessment is developed:

- Assessment levies should not exceed the amount of the benefit received by any particular property;
- The assessment should be properly allocated to the benefitted properties; and
- Property owners typically are allowed by law to have an opportunity to comment on how the assessments are allocated to their properties.

The goal is to show that assessed levies are used to cover costs of facilities or services benefitting each property and that the benefits to each property are at least equal in value to the assessment levy. Constitutional standards typically require that property owner benefits funded by such assessments be special benefits that typically are not shared by the community as a whole.

STORMWATER MANAGEMENT UTILITY. A dedicated funding source that has gained recent acceptance is the establishment of a stormwater management utility (SMU). The premise of this method is that developed property can be charged a user fee in proportion to the contribution to the need for stormwater facilities or services. Utility customers are the properties that add runoff to the stormwater system, and individual charges can be calculated using an appropriate billing unit formula. The charge per billing unit can be set to generate the level of annual funding desired by the community.

The careful development of a rate structure has been found to be critical to the successful implementation and operation of an SMU. Also, feasible procedures for preparing billing records and database management requirements should be defined early.

The basis for determining the fee a customer pays for stormwater management services typically is the amount of runoff generated by property improvements. The runoff potential is a function of many variables and is often best determined by measuring the area of impervious surfaces. Because all improved property, including tax-exempt property, can be charged in proportion to its effect on or need for the stormwater management system, SMU fees have been proven to be an equitable and fair method of paying for stormwater management services.

INSPECTION FEES. The costs of evaluating permit applications and inspecting ensuing construction activities can be recovered through fees assessed to the developers or applicants who create the need for this service. These fees can be used with other funding options to recover the costs of providing user-specific stormwater management services.

OTHER FUNDING. Funding mechanisms could include other taxes such as fuel or utility taxes. The availability of other options will depend on state and local statutes that must be evaluated on a case-by-case basis.

Financing Options. This section reviews options available for initial financing of stormwater system capital improvements or equipment purchases. Several of the options discussed involve the issuance of bonds, which is one approach to obtaining lump sums of revenue to pay for significant capital improvement or equipment expenditures. A bond is an instrument by which an agency borrows money and guarantees repayment of the loan principal and interest with revenues generated from a specified source.

PAY AS YOU GO. This approach seeks to establish a revenue flow that is accumulated in a sinking fund. Planned facilities would be constructed or equipment would be purchased after the sinking fund contains enough revenue to pay for the purchases. Revenue deposited in the sinking fund can be derived from a number of sources, including tax revenues, user charges, in-lieu-of charges, or system development charges (impact fees).

GENERAL OBLIGATION BONDS. A general obligation bond is a loan that is secured by the full faith and credit of a local government. This means that the local government pledges its general fund revenues, primarily property taxes, as the source of revenue for loan repayment. This type of bond is easy to administer and widely used to finance various types of capital improvements. Because of the high level of security associated with the pledge of tax revenues for these bonds, the interest rates can be lower.

Both the amount of general obligation debt that a local government may issue and the total property taxes that may be assessed are limited. Because general obligation bonds are repaid through property taxes, the distribution of costs typically is not considered equitable. Costs are distributed to property owners in proportion to the value of their property, rather than to the amount of stormwater runoff generated by their land use. Tax-exempt properties do not pay for these improvements.

REVENUE BONDS. A utility enterprise typically can fund capital improvement projects or purchases by issuing bonds that will be repaid by the revenues from an enterprise operation. With revenue bonds, the utility obtains the funds needed to start and complete significant improvements and repays them over the long term with revenue collected from those who benefit from the improvements, such as the utility's users or rate payers. Provided the utility has a rate structure designed to equitably recover costs, this form of financing is better suited for use on stormwater projects than general obligation bonds. Interest rates, thereby the interest expenses, typically are somewhat higher for revenue bonds than for general obligation bonds.

SPECIAL ASSESSMENT BONDS. Special assessment bonds may be issued if the planned stormwater construction project will benefit a specific area or watershed. These bonds are secured by non-*ad valorem* tax assessments to the landowners in that area. The initial cost of implementing this option typically is high because the local government must establish stormwater benefit areas or tax assessment districts for each individual project. This bond is then relatively easy to administer because the debt service is recovered through non-*ad valorem* assessments to the properties in the district.

User acceptance and equity can be good for a properly designed program because a clearly identified area directly benefits from the stormwater improvements. User equity also can be high because tax assessments must be distributed in direct proportion to the benefits received.

DEVELOPER-CONSTRUCTED IMPROVEMENTS. As a condition of approving a proposed new development, the local government could require a developer to construct improvements to control stormwater runoff. Typically, these are on-site improvements; however, the local government occasionally may require some off-site improvements. The ease of administering this option may be difficult because developers may object to or oppose the required construction. Equity typically is considered to be good because the new development likely to generate the runoff will incur the cost of controlling or alleviating the problems arising from that runoff.

IN-LIEU-OF CHARGES TO DEVELOPERS. An alternative to requiring developers to construct on-site stormwater management facilities is to require them to pay a front-end charge for off-site capital improvements needed to serve their development. Payment would be a condition of development approval and would recover the cost of the off-site improvements to manage the development's runoff or its proportionate share of the cost of a regional facility serving a larger area.

This technique frequently is used where a small-scale facility is not necessarily advisable (that is, assumption of responsibility for the operation and maintenance costs for the planned improvements), and the local government wants developer participation in a larger facility designed to control drainage on a regional basis.

Conceptually, this option can be equitable because it can be designed to recover the cost of the improvements in proportion to the runoff generated by the users of the system. However, equity may be difficult to implement if the costs paid by each developer are negotiated separately. Therefore, in-lieu-of charges should not change over time or reflect factors other than user runoff contribution.

Developers may resist these assessments if they can identify improvements that are less expensive than their proportionate share of the planned regional facilities. Administrative costs for this option may also be high.

SYSTEM DEVELOPMENT CHARGES. System development charges (or impact fees) are fees or charges collected from new developments to recover the cost of increasing the capacity of a stormwater or other system to meet the needs of new customer growth. These fees frequently are used to repay debt service on capital improvements and thus could be considered an annual funding option. System development charges are discussed as a financing option because their primary purpose is to generate funds for capital improvements that provide the capacity to serve new development.

Stormwater impact fees are designed to reflect the stormwater contribution of new development and the costs incurred to provide enough additional control facilities in the system to meet those needs. These charges are set in a fee schedule uniformly applied to all new development and are often based on impervious area. In this way, all new development contributes on a consistent basis to the costs of the regional stormwater system rather than to specific regional facilities to serve the individual development. This provides an equitable way, from a regional viewpoint, to recover these costs.

System development charges shift the burden of payment to new residents for facilities sized to serve future growth, rather than imposing these costs on existing customers. These revenues may be used to reimburse existing customers for costs they have incurred to provide capacity for future users. Revenues from these fees may be used to retire a debt issued to finance regional facilities or as part of a pay-as-you-go financing plan. Revenues will fluctuate with the amount of new construction.

COMMUNITY DEVELOPMENT BLOCK GRANTS. This is a federal grant program to aid local governments in constructing various types of public improvements that cannot be financed by any other available source. This program is intended to benefit low-income groups or communities. These grants may be difficult to administer because they originate and are supervised by a federal agency—the Department of Housing and Urban Development. Funds available are also limited.

INTERNAL BORROWING. Another source of revenue for financing the construction or purchase of capital improvements involves borrowing money from other local departments or utilities. The borrowed money must be repaid with interest.

Implementation Process. The evaluation and selection of appropriate revenue alternatives available to implement a stormwater management master plan typically can be accomplished by the following steps:

- Define level of service goals. Categories of problems should be identified and specific performance criteria defined to address the problems.
- Identify program components. Watershed evaluations should be performed to identify and prioritize specific problem areas, including the development of program facility components or activities to comply with the level of service goals.
- Establish program costs. Based on the program components, a schedule of funding and financing requirements can be prepared.
- Identify revenue alternatives. Available revenue alternatives, as discussed in this section, should be reviewed to identify existing and potential sources.
- Develop funding and financing plans. Combine results of the program cost and revenue alternative evaluations to develop specific funding and financing plans.

The process to accomplish these tasks can require several iterations to match level-of-service goals with achievable funding and financing plans.

EVALUATING EFFECTIVENESS

Chapter 3 of this publication provides detailed guidance on assessment, monitoring, and modeling approaches to evaluating program effectiveness. Assessing the program effectiveness means demonstrating that the BMPs adequately protect beneficial uses of the receiving waters. Doing this correctly can be complex, and specific procedures need to be defined for assessment. The assessment typically consists of the following three methods:

- Ecological monitoring evaluates the habitat in the receiving water, determines stresses on the habitat, and defines habitat that reasonably can be supported in the receiving water.
- Water quality monitoring can take place in either the receiving water where the stormwater discharges or in the stormwater discharges before the receiving water.
- Nonconventional monitoring is the enumeration of some quantity other than direct water quality data to infer pollution reduction or water quality improvement. There are many different kinds of indirect measures that can be devised to estimate the success of a particular BMP program. For example, public surveys may show increases in environ-

mental awareness. Another example would be monitoring the amount of used oil collected.

In either case, it is important to establish the specific objective of the monitoring program. There are primarily three distinctly different objectives to consider:

- Characterize the stormwater discharge. Here, the monitoring program basically is set up to provide water quality data for comparison with other databases (for example, to determine if a pollutant warrants special attention in the stormwater management plan).
- Characterize the receiving water during and after stormwater discharges. A monitoring program carried out under this objective could include "biological surveys" and water quality sampling.
- Assess the effectiveness of the stormwater management plan in reducing pollutants. To accomplish this objective, a carefully laid out program is required. Because of the wide variability in stormwater quality, this monitoring program should be complemented with a targeted BMP. Pilot studies provide an excellent opportunity for evaluating targeted BMPs in a well-defined area or watershed.

The management of urban stormwater quality requires accurate and detailed information about sources and possible effects of stormwater-related pollution. Monitoring, modeling, and performance auditing activities typically are part of a program that is structured to address specific issues, such as permit compliance, pollutant source identification and removal efficiency, or impact assessment. Therefore, a stormwater management program requires coordinated and detailed monitoring procedures, which include planning, data collection, data analysis, and result interpretation and use. Modeling can supplement and, in some cases, replace monitoring efforts with simulations that allow prediction of both discharge and receiving water quality. Auditing performance is a specific application of monitoring (and, in some cases, modeling) that demands standardization of the physical, chemical, climatic, geological, biological, and meteorological parameters reported as part of the audit. This chapter reviews methods for data collection, analysis, and interpretation in monitoring programs; the selection and use of models; and information on parameters that are essential in assessing the performance of best management practices (BMPs).

MONITORING

Monitoring has been an essential element of management programs. Since the adoption of Public Law 92-500 in 1972, holders of National Pollutant Discharge Elimination System (NPDES) permits have been responsible for self-monitoring. Self-monitoring must meet specific frequency and quality criteria, and contain information about discharge quality, toxicity, and receiving water conditions. In 1991, the U.S. Environmental Protection Agency (U.S. EPA) adopted an NPDES permitting program for urban runoff, and in late 1992, U.S. EPA published a draft policy statement on combined sewer overflows. Stormwater NPDES permit monitoring requirements have included the development of sampling programs and the assessment of both discharges receiving water conditions. Further, U.S. EPA has placed a high priority on controlling nonpoint source pollution through clarification of the requirements of Section 303(d) of the Clean Water Act. Dischargers are now faced with total maximum daily load analyses within a water-quality-based toxics control program (U.S. EPA, 1991).

The result of these developments in regulatory programs is an increasing emphasis on monitoring physical, chemical, and biological conditions of receiving water. Holders of NPDES permits, environmental quality managers, consultants, and others must now deal with a regulatory environment that requires monitoring beyond the analysis of chemical water quality parameters in effluents. Different data collection procedures and integrated monitoring efforts are now required to meet the typical objectives of management programs.

This section of the publication has been developed to provide the reader with a summary of the steps that lead to effective and efficient monitoring programs. The design process starts with developing a clear statement of objectives, followed by identifying data needs, data collection procedures, and methods of data analysis. Further, to develop a context for monitoring stormwater, it is necessary to connect storm events with stormwater runoff and recognize that the complex interaction of physics and chemistry on the land as well as in the channel will have an equally complex effect on receiving waters. In short, a watershed approach is essential in stormwater monitoring.

FUNDAMENTAL DESIGN ISSUES. Study Design Assurance. Monitoring efforts in stormwater management programs typically are initiated based on a general need to identify sources, quantities, and effects of pollutants. Unfortunately, this need is often expressed as a general direction for studies, not sufficiently detailed objective statements that will direct monitoring efforts. For example, a general statement might specify "assess water quality." That assessment could include water quality sampling and analysis, toxicity testing, or biosurveys. The toxicity testing might include laboratory or *in situ* testing. The biosurvey could sample algae, macroinvertebrates, or fish, including single samples or long-term assessments. Any of these efforts will require different personnel and have different costs. Further, water quality analyses, toxicity testing, or biosurveys may answer different questions about receiving waters and support management decision making in a different way. The first step in a monitoring program will be the careful development of a statement of objectives, which will direct specific data collection efforts.

A monitoring design approach proposed by Schaeffer *et al.* (1984) and Herricks and Schaeffer (1987), termed study design assurance (SDA), provides a workable process to ensure that the monitoring conducted fully meets an agreed objective. The SDA process recognizes that the first step in monitoring program implementation is the review of stated study objectives. If an objective is general (such as the determination of environmental impact), then specific monitoring program objectives (such as the determination of the effects of fish, macroinvertebrates, and water supplies) must be developed to guide data collection. An effective, specific objective is clear and testable, similar to hypotheses that are used to test a general theory in many scientific experiments. This development of specific objectives is an iterative process where the initial objective is used to specify the data needed to meet the objective. Then, the data needs are evaluated and a "hypothetical" database is developed. At this stage, it is possible to determine if sufficient resources (both fiscal and scientific/technical) are available to collect the data needed to meet the stated objective. If resources are limited, the initial general objective is then modified. This modification will produce a more specific objective that reflects the limits in available resources while still addressing the stated objective. A hypothetical database is again identified and evaluated against available resources. At this time, it may be apparent to both the managers and the scientists and technicians that initial management expectations are unrealistic, and management expectations are then modified with the stated objective. The process of objective development, evaluation, and more specific objective development may require many iterations.

Critical to the SDA process is the effective communication of monitoring "realities" to managers and the corresponding resource "limits" to monitoring specialists. Therefore, in the SDA process, managers come to recognize that monitoring realities may constrain initial expectations, leading to a more realistic understanding of how monitoring data can be used in their decision making. The scientific and technical staff benefit from the SDA process because they clearly identify how the data can be used before costly data collection efforts are initiated. Matching expectations to what actually can be achieved with a specific data collection program avoids a typical problem where data limitations fail to meet management needs, and potentially useful information from a monitoring effort is discredited.

The organization of the SDA process calls for iterative analysis at all stages in the management process, formalizing data collection to meet specific decision requirements. Adoption of SDA procedures can ensure that a rigor similar to that imposed by the scientific method in experimentation is applied to monitoring.

Monitoring Program Implementation. Implementation of a monitoring program can be considered a five-step process that includes identification and acquisition of existing data, design of the assessment program, collection of the data, analysis of the data, and presentation of the data/information developed.

IDENTIFY AND ACQUIRE EXISTING DATA. The first step of any monitoring design is to identify and review available data. Obtaining access to existing data will have a number of benefits. First, it is relatively inexpensive; when involved in the development of a monitoring program, fiscal issues will often be the most significant constraint. It may even be possible to use existing data to meet management objectives, and scarce resources can be applied to other needs in the management program. Second, existing data will guide the monitoring design by providing critical information on existing conditions. It will be possible to evaluate "watershed" or other influences on the monitoring site, identify problem areas or areas of significant interest, and, as part of the SDA process, use existing data to better define specific objectives and expectations for monitoring data use. Finally, existing data provide a basis for early comparison of results, supporting mid-course corrections typical in any data collection effort.

PREPARE THE MONITORING DESIGN. Monitoring programs must emphasize information development, not simply data acquisition. Further, the SDA process has, at its foundation, the analysis of cost versus information. Thus, the monitoring program design must clearly identify sampling locations, sampling variables, and frequency of sampling to identify not only the information to be acquired but also the cost of that information. The typical sampling design will identify a reference location, a site in the area of maximum effect, and a location where effects have moderated and the receiving waters have recovered. Sampling variables should include sufficient water quality data to characterize water quality and assist in the interpretation of the results of biological sampling. Biological variables should be selected on the basis of expected effect—benthic macroinvertebrates are often used because they are not mobile, while fish may provide information connected directly to public interests and existing (fisheries) management programs. Sampling frequency will vary, but most bioassessment programs will require seasonal sampling. Finally, added to these design elements are the quality assurance/quality control (QA/QC) program requirements, which include both field and laboratory elements.

COLLECT THE DATA. Although data collection is often identified as one of the primary functions of monitoring design, if the existing data are identified and acquired, needed data may be acquired from existing sources rather than requiring new data collection efforts. The final sampling program design should recognize that any data collection effort in natural systems must deal with conditions that are constantly changing. The data collection program should be flexible enough to allow modifications as these receiving system changes occur. A common problem in many data collections programs should be avoided. In many programs, data collection is often assigned the most junior, lowest-cost, and least-experienced member of the team. Because any analysis will only be as sound as the data on which it is based, good analysis will depend not only on a good QA/QC program, but also on competent staff. Elements of a good data collection program are

- Assignment of competent staff,
- Maintenance of design flexibility,
- Rapid processing of data so that results can be used for continuous improvement in design, and
- Maintenance of a QA/QC program.

ANALYZE THE DATA. Data analysis is a process that requires both specific skills and the benefit of experience. Identifying small anomalies in a data set, developing connections between disparate types of data, and extracting the maximum amount of information from a data set are skills that grow with practice but may develop into standard analysis procedures for longer term monitoring efforts. As mentioned in the discussion of data collection, the analysis of data will often depend on and be constrained by the quality of the collection effort. The process of data analysis includes

- Evaluation of the QA/QC program and its results;
- Analysis of independent factors (parameter-specific trends and identified problems with the data set);
- Analysis of the relationships among independent factors (this analysis typically will involve arrangement of data sets, such as ranking and correlation—it is extremely important to maintain flexibility in this analysis step and not get locked into a limited set of analysis procedures that may not be appropriate for the data collected);
- Comparison of new data with historical data or other data collected as a part of the current monitoring program;
- Creation of an archive; and
- Maintenance of the established QA/QC program.

PRESENT THE DATA. The actual presentation of the data is possibly the most important step in monitoring program implementation because design, collection, and analysis quality are all represented in this program step. In the presentation, one should

- Present the facts simply and in an understandable format;
- Meet the objectives and goals initially set for the monitoring program;
- Translate monitoring complexity (including elements of analysis) without losing meaning; and
- Provide a basis for future use, specifically relating the presentation to the data archive.

Quality Assurance and Quality Control. In the monitoring program implementation steps presented, one of the consistent elements of monitoring activities is the development and implementation of the QA/QC program. The QA/QC program is initiated with the application of the study design process and followed by specific quality control activities suited to data collection, analysis, or interpretation. Quality control procedures can be applied to any data collection effort or monitoring program, but it must be recognized that studies with different objectives involve different approaches to data collection and will have different quality control elements. What should be sought is an internal statistical quality control and an external quality control, proficiency testing, or laboratory evaluation. Both product quality and production processes must be evaluated.

In programs designed to assess receiving system effects of urban stormwater, it will be necessary to consider QA/QC elements specific for biological monitoring. Biological monitoring can be separated into two types of analysis: toxicity testing and biosurveys, or bioassessments. Toxicity tests are laboratory-based analyses that incorporate rigorous experimental protocols operating under strict environmental control to expose selected organisms to toxicants for a defined time period. Guidance for QA/QC programs is provided in *Standard Methods for the Examination of Water and Wastewater* (APHA *et al.*, 1995) and ASTM publications. Bioassessments are field-based analyses that lack strict experimental controls and may range from the description of organisms present in a community or ecosystem to the measurement of a range of ecosystem properties and processes. Bioassessments may include the use of experimental manipulation of contaminants, habitat, and ecological relationships in ecosystems, but bioassessments depend on uncontrolled reference areas to assess the consequence of the manipulation. The QA/QC procedures for biosurveys and bioassessments begin with adherence to quality assurance procedures for field and laboratory analyses of chemical and biological data (U.S. EPA, 1973a, and USGS, 1993). Quality assurance procedures for database development and management, including entry error checking, range checking, and statistical/graphical detection of outliers, should follow current practices for research databases (Gurtz, 1986).

Physical, Chemical, and Biological/Ecological Measurements

Because the actual selection of measurements needed in a monitoring program is objective and often site specific, a full discussion of measurements useful in the assessment of urban runoff effects is not possible in this publication. Nonetheless, it is possible to reference a number of government publications that provide detailed information on measurements typically made in monitoring programs. Publications listed in the Reference and Suggested Readings sections provide specific guidance on measurement and assist in setting the context for analysis and interpretation.

PHYSICAL PARAMETER SELECTION. Changes in physical conditions because of urban runoff include both change in hydrology and modification of channels in the receiving systems. Typical hydrological data measured in monitoring programs include analysis of discharge volume and distribution. From these data, it is possible to develop information about storm runoff peaks, runoff volumes, or storms and base flow. General hydrologic parameters that should be measured or calculated from discharge information include

- Runoff volume parameters during the monitoring season:

  V_R = volume of the average runoff event in the watershed, mm (in.);
  V_{50} = volume of the 50th percentile runoff event in the watershed, mm (in.);
  CV_{VR} = coefficient of variation in the volumes of runoff events ($V_{SD\text{-}R}/V_R$), in which $V_{SD\text{-}R}$ = standard deviation of runoff volumes;
  V_B = volume of the seasonal dry weather base flow in the watershed, mm (in.);
  Q_P = average runoff peak rate, m^3/s (cu ft/sec); and
  CV_{QP} = coefficient of variation of flow peaks.

- Time-variable parameters of storms during the monitoring season.
- Storm runoff interevent (separation) time:

  T_S = average separation period between the end of a storm runoff hydrograph and the beginning of the next one, hours;
  T_{S50} = the 50th percentile of storm runoff event separation periods, hours; and
  CV_{TS} = coefficient of variation in storm runoff event separation periods ($T_{SD\text{-}S}/T_S$), in which $T_{SD\text{-}S}$ = standard deviation of storm runoff event separation periods.

- Storm runoff duration:

  T_D = average duration of storm runoff, hours;
  T_{D50} = the 50th percentile value of storm runoff duration, hours; and
  CV_{TD} = coefficient of variation in storm runoff duration ($T_{SD\text{-}D}/T_D$), in which $T_{SD\text{-}D}$ = standard deviation of storm runoff duration.

The modification of channels should focus on analysis of

- Stream channel widening and downcutting;
- Changes in stream bank erosion;
- Changes in channel features, including bar location and sediment size composition;
- Changes in pool/riffle characteristics; and
- Stream relocation/enclosure or channelization.

Unlike hydrology, where a long history of practice has produced well-defined measurement and analysis methods, the process of monitoring changes in channel morphology is evolving. Accordingly, rather than make definitive statements in this publication, two types of data collection are recommended—indicators of change and establishment of data on stream channel stability (Rhoads, 1995).

Key parameters for change in channel morphology include

- Meander geometry,
- Width:depth ratio, and
- Frequency of full-bank flow.

Systems for classifying the morphology of streams are less well defined. One system, the Rosgen system, is receiving wide application. Other approaches are energy based (unit stream power) or ecosystem based (habitat suitability index modeling). The basic data needed for classification include

- Watershed position (stream order),
- Riparian zone condition (for example vegetation or encroachment),
- Watershed and local geology and land use,
- Channel morphology,
- Channel profile, and
- Substrate and sediment characteristics.

WATER QUALITY PARAMETER SELECTION. In urban runoff, two aspects of water quality are often the focus of monitoring programs. The first is the concentration of contaminants in the runoff, particularly the changes in concentration that occur through time. The second is the eventual loading to the receiving system, which integrates concentration and discharge flow. The parameters selected for monitoring include general parameters such as temperature, alkalinity, hardness, conductivity, and pH and site-specific parameters that will include analyses for conservative and nonconservative pollutants. The actual selection of parameters should be based on expected sources of contamination or should be guided by water quality standards, which are the foundation for any water quality regulation. Of particular importance are contaminants that may bioaccumulate.

Because the presence and concentration of contaminants change rapidly in urban runoff, a critical element of water quality analyses is sampling. For selected general parameters (temperature, dissolved oxygen, pH, and conductivity), continuous monitoring using multiparameter "sonde" units is recommended. Measurement frequency of these general background parameters should be selected based on expected storm hydrograph characteristics, and the duration of the monitoring should reflect pre- and poststorm conditions. Sampling for specific parameters should be accomplished by grab sampling. Automatic samplers are available that can collect sequential grab samples during an event; mix sequential grab samples to provide an event composite sample; or provide flow-weighted or time-weighted single, or multiple, sample composites. Flow-weighted composite sampling is essential for contaminant-loading determinations.

Analysis of water quality parameters should follow standard methods, and QA/QC programs should be in place for both sample collection and sample analysis. Two interpretation issues typically associated with urban runoff analysis are detection limits and outliers. Analyses below detection limits should not be reported as zero values. General guidance suggests that water quality data should not be censored by detection limits; whenever possible, report actual concentration (positive or negative) regardless of whether it is below detection limits (Gilbert, 1987). Care must also be exercised in dealing with outliers. Although excursions well beyond other analytical results are often attributed to analytical error, the nature of urban runoff sampling suggests that these outliers may be "real" measures of short-term events and should be preserved in reported data.

BIOLOGICAL MONITORING. Although guidance for biological monitoring is provided in numerous published sources, the most typically applied procedures are rapid bioassessment protocols (RBPs), which are directed to macroinvertebrate and fisheries sampling. The following discussion of RBP procedures provides guidance for biological monitoring of urban runoff.

RAPID BIOASSESSMENT PROTOCOLS. In 1989, U.S. EPA published a set of protocols for bioassessments in *Rapid Bioassessment Protocols for Use in Streams and Rivers—Benthic Macroinvertebrates and Fish* (U.S. EPA, 1989). The implementation framework first describes the development of an empirical relationship between habitat quality and biological condition. As additional information is obtained from systematic monitoring, a relationship between habitat and biological potential is developed and the effect of water quality alteration can be objectively determined from either habitat change or measures of biological integrity.

Five rapid bioassessment protocols have been developed, three for benthic invertebrates and two for fish. The appropriate bioassessment approach depends on the study objectives. Rapid bioassessment protocols I and IV are screening tools to help determine if biological impairment exists. Benthic RBP I and fish RBP V are more rigorous and provide more objective and reproducible evaluations than RBPs I and IV. Rapid bioassessment protocols II, III, and V are semiquantitative and use an integrated analysis technique to provide continuity in evaluation impairment among sites and seasons. Each of the RBPs is summarized briefly.

- Rapid bioassessment protocol I—benthic macroinvertebrates, and rapid bioassessment protocol IV—fish. These RBPs provide a screening mechanism to identify biological impairment. They are neither intended to quantify the degree of impairment nor provide definitive data to establish cause-and-effect relationships. They allow a cursory assessment, using cost and time efficiencies to evaluate a large number of sites, identify major water quality problems, and help plan and develop management strategies.

- Rapid bioassessment protocol II—benthic macroinvertebrates. This RBP provides information to rank sites as severely or moderately impaired so that additional study or regulatory/management action can be planned. Like RBP I, this protocol can be used as a screening tool and allows agencies to evaluate a large number of sites with relatively little time and effort. The more documented procedures and integrated metrics of RBP II promote better consistency and allow better comparison among sites.
- Rapid bioassessment protocol III—benthic macroinvertebrates, and rapid bioassessment protocol V—fish. These two RBPs provide a consistent, well-documented biological assessment. Like RBP II, they provide information for ranking site impairment and a way to compare repeatable results over time (trend monitoring). These RBPs include taxonomic identifications to the lowest practical level, thereby providing information on population as well as community-level effects. They include an integrated assessment of metrics and can be used to develop biocriteria.

AN INTEGRATED ASSESSMENT APPROACH. An integrated assessment of urban runoff effects should include a watershed-based analysis that connects physical, chemical, and biological/ecological analysis activities in an effective, well-focused monitoring program. An integrated effort initially may focus on water quality, toxicity, physical dynamics, or general system health as program elements, but these analyses eventually must be brought together in a watershed context. Because spatial relationships are critical in an integrated approach to understanding and management of water resource problems caused by urban runoff and nonpoint sources, integrated management requires careful consideration of the spatial framework for the monitoring program. Traditionally, we have relied on spatial frameworks based on political boundaries, watersheds, hydrologic units, or physiographic regions. However, these areas do not correspond to patterns in vegetation, soils, land surface form, land use, climate, rainfall, or other characteristics that control or reflect spatial variations in surface water quality or aquatic organisms. An alternate approach is based on ecoregions. Omernik (1987) proposed using spatial frameworks based on ecological regions (ecoregions) to assess the health of aquatic systems. Ecoregions reflect similarities in the type, quality, and quantity of water resources and the factors affecting them. Therefore, regional patterns of environmental factors reflect regional patterns in surface water quality.

MODELING

URBAN MODELING OBJECTIVES AND CONSIDERATIONS. Studies and projects involving urban stormwater runoff quality can relate to many problems. In the broadest sense, water quality studies may be performed to protect the environment under various state and federal legislation. In a narrower sense, a study may address a particular water quality issue in a particular receiving water, such as the bacterial contamination of a beach or the release of oxygen-demanding material to a stream or river. Many of these studies can be supported or completed through modeling. By no means should it be assumed that every water quality problem requires a water quality modeling effort. Some problems may be mostly hydraulic in nature, for example, problems with basement flooding. That is, the solution may often reside primarily in a hydrologic or hydraulic analysis in which the concentration or load of pollutants is irrelevant. In some instances, local or state regulations may prescribe a nominal "solution" without recourse to water quality analysis. For example, stormwater runoff in the state of Florida is considered "controlled" through retention or detention with filtration of the runoff from the first inch of rainfall for areas of 40 ha (100 ac) or less. Other problems may be resolved through the use of measured data without the need to model. In other words, many problems do not require water quality modeling at all.

If a problem does require modeling, some objectives are better met through modeling than others. Models may be used for objectives such as the following:

- Characterize the urban runoff as to temporal and spatial detail, and concentration/load ranges;
- Provide input to a receiving water quality analysis (for example, drive a receiving water quality model);
- Determine effects, magnitudes, locations, and combinations of control options;
- Perform frequency analysis on quality parameters (to determine return periods of concentrations/loads); and
- Provide input to cost–benefit analyses.

The first two objectives characterize the magnitude of the problem and the last four objectives are related to the analysis and solution of the problem. Computer models allow some types of analysis, such as frequency analysis, to be performed that could rarely be performed because the history of water quality measurements in urban areas is often poor. It should always be recognized, however, that the use of measured data is typically preferable to the use of simulated data, particularly for the first two objectives, in which accurate concentration values are needed. Typically, models are not good substitutes for good field-sampling programs. On the other hand, models can sometimes be used to extend and extrapolate measured data and enhance field-sampling results.

Careful consideration should be given to providing input to a receiving water quality analysis. The model output needed to drive a receiving water quality model is related to the objective of the analysis program. Modeling can also follow a modified SDA process. If the focus in a monitoring effort is toxicity, the model should produce concentration versus time predictions for short intervals (5 to 15 minutes). In fact, the first urban runoff quality model incorporated the concept of simulation of detailed intrastorm quality variations, for example, the production of a "pollutograph" (concentration versus time) at 5- or 10-minute intervals during a storm for input to a receiving water quality model. If the objective of the receiving water quality modeling effort is to assess general effect, the modeling effort should be supported by a bioassessment program and the model need not predict short-term variations in concentration. The total storm load will be sufficient to determine the receiving water response.

Differences in detail require differences in model complexity, as seen in Table 3.1. The most complex models are needed to predict concentration versus time at high frequencies. If only the total storm loads are needed, this presents a much easier modeling task.

In any modeling effort, data requirements are critical. Such requirements may be as simple as a constant concentration, or they may include detailed time-related changes in concentration or flow. Data may be obtained from existing studies or require extensive field monitoring. For some model objectives, it may not be possible to actually measure fundamental input parameters, which are obtained through model calibration. Acquisition of the high-quality data needed to support modeling efforts, either through literature reviews or field surveys, will affect the level of effort and costs associated with the management program. Details on data requirements for model appli-

Table 3.1 Required temporal detail for receiving water analysis.

Type of receiving water	Key constituents	Frequency
Lakes, bays	Nutrients and toxics	Weeks, seasonal, years
Estuaries	Nutrients, oxygen demand, bacteria, toxics	Tidal cycle, days, weeks
Large rivers	Oxygen demand, nitrogen, toxics	Minutes, days (event based)
Streams	Oxygen demand, nitrogen, bacteria, toxics	Minutes, hours, days (event based)
Ponds	Oxygen demand, nutrients, toxics	Hours, weeks
Beaches	Bacteria	Hours (event based)

cation in urban areas will be deferred until modeling techniques are described.

OVERVIEW OF AVAILABLE MODELING OPTIONS. Several quality modeling options exist for the simulation of quality in urban storm and combined sewer systems. These have been reviewed by Huber (1985 and 1986) and range from simple to involved, although some "simple" methods (such as U.S. EPA statistical methods) can incorporate quite sophisticated concepts. The principal methods available to the contemporary engineer are outlined generically below, in a rough order of complexity. Their data requirements are summarized again in a following section.

- Constant concentration or unit loads,
- Spreadsheet,
- Statistical,
- Rating curve or regression, and
- Buildup/washoff.

Constant Concentration or Unit Loads. As its name implies, constant concentration means that all runoff is assumed to have the same constant concentration at all times for a given pollutant. At its simplest, an annual runoff volume can be multiplied by a concentration to produce an annual runoff load. However, this option may be coupled with a hydrologic model, wherein loads (product of concentration and flow) will vary if the model produces variable flows. This option may be useful because it may be used with any hydrologic or hydraulic model to produce loads simply by multiplying by the constant concentration. In many instances, it may be most important to get the volume and timing of such overflows and diversions correctly and simply estimate loads by multiplying by a concentration.

An obvious question is which constant concentration to use. Early (pre-1977) concentration and other data are summarized in publications such as Lager *et al.* (1977) and Manning *et al.* (1977). U.S. EPA Nationwide Urban Runoff Program (NURP) studies (U.S. EPA, 1983) have produced a large and invaluable database from which to select numbers, but the 30-city coverage of NURP will most often not include a site representative of the area under study. Nonetheless, a large database does exist from which to review concentrations. Another option is to use measured values from the study area. This might be done from a limited sampling program.

Unit loads are perhaps an even simpler concept. These consist of values of mass per area per time (typically pounds per acre per year or kilograms per hectare per year) for various pollutants, although other normalizations such as pound/curb-mile are sometimes encountered. Annual (or other time unit) loads are thus produced by multiplying mass per time by the contributing area. Such loadings are site specific and depend on both demographic and hydrologic factors. A unit load must be based on an average or "typical" runoff volume and cannot vary from year to year, but loading can be subject to reduction by BMPs if the BMP effect is known. Although early U.S. EPA references provide some information for various land uses (McElroy *et al.*, 1976; U.S. EPA, 1973b; and U.S. EPA, 1976a), unit loading rates are variable and difficult to transpose from one area to another. Constant concentrations can sometimes be used for this purpose because mg/L $\times$ 0.226 5 = lb/ac per inch of runoff. Thus, if a concentration estimate is available, the annual loading rate may be calculated by multiplying by the inches per year of runoff.

The universal soil loss equation (Heaney *et al.*, 1975, and Wischmeier and Smith, 1958) was developed to estimate tons per acre (kilograms per square metre) per year of sediment loss from land surfaces. If a pollutant may be considered as a fraction ("potency factor") of suspended solids concentration or load, this offers another option for the prediction of annual loads. Lager *et al.* (1977), Manning *et al.* (1977), and Zison (1980) provide summaries of such values.

Spreadsheets. Microcomputer spreadsheet software is now ubiquitous in engineering practice. Extensive and sophisticated engineering analysis is routinely implemented on spreadsheets, and water quality simulation is no exception. The spreadsheet may be used to automate and extend the constant concentration or unit load determinations. In the typical application of the spreadsheet approach, runoff volumes are calculated simply, typically by multiplying runoff coefficient times rainfall depth. The coefficient may vary according to land use, but the hydrology is inherently simplistic in the spreadsheet predictions. The runoff volume is then multiplied by a constant concentration to predict runoff loads. Alternatively, unit loads are input directly and then multiplied by corresponding land-use areas. The spreadsheet approach is best suited to estimation of long-term loads, such as annual or seasonal, because simple prediction methods typically perform better over a long averaging time and poorly at the level of a single storm event.

The advantage of the spreadsheet is that a mixture of land uses (with varying concentrations or loads) may easily be simulated, and an overall load and flow-weighted concentration can be estimated for the study area (Walker *et al.*, 1989). A study area may range from a single catchment to an entire urban area, and delivery ratios can be added to simulate loss of pollutants along drainage pathways between the simulated land use and receiving waters. The relative contributions of different land uses may be easily identified, and handy spreadsheet graphics tools may be used for displaying the results.

As an enhancement, control options may be simulated by application of a constant removal fraction for an assumed BMP. Although spreadsheet computations can be complex, BMP simulation is rarely more complicated than a simple removal fraction because anything further would require simulation of the dynamics of the removal device (for example, a wet detention pond), which typically is beyond the scope of the hydrologic component of the spreadsheet model. Nonetheless, the spreadsheet can be used to estimate the effectiveness of control options. Loads with and without controls can be estimated, and problem areas can be determined by separate analysis of contributing basin and land-use characteristics. Because most engineers are familiar with spreadsheets, such models can be developed in house.

Again, the question arises of what concentrations or unit loads to use, this time potentially for multiple land uses and subareas. Again, the NURP database will typically be the first one to turn to, with the possibility of local monitoring to augment it.

Statistical Method. The so-called "U.S. EPA Statistical Method" is somewhat generic and until recently was not implemented in any off-the-shelf model or implemented well in any single report (Hydroscience, 1979, and U.S. EPA, 1983). A FHWA study (Driscoll *et al.*, 1989) partially remedies this situation. The concept is straightforward, namely that of a derived frequency distribution for estimated mean concentration (EMC). This idea has been used extensively for urban runoff quantity (Howard, 1976; Loganathan and Delleur, 1984; and Zukovs *et al.*, 1986) but not as much for quality predictions.

The U.S. EPA statistical method uses the fact that EMCs are not constant but tend to exhibit a log-normal frequency distribution. When coupled with an assumed distribution of runoff volumes (also log-normal), the distribution of runoff loads may be derived. When coupled again to the distribution of stream flow, an approximate (log-normal) probability distribution of instream concentrations may be derived (Di Toro, 1984)—a useful result, although assumptions and limitations of the method have been pointed out by Novotny (1985) and Roesner and Dendrou (1985). Further analytical methods have been developed to account for storage and treatment (Di Toro and Small, 1979, and Small and Di Toro, 1979). The method was used as the primary screening tool in U.S. EPA NURP studies (U.S. EPA, 1983) and has also been adapted to combined sewer overflows (Driscoll, 1981) and highway-related runoff (Driscoll *et al.*, 1989). This latter publication offers a concise explanation of the procedure and assumptions and includes spreadsheet software for easy implementation of the method.

A primary assumption is that EMCs are distributed log-normally at a site and across a selection of sites. The concentrations may thus be characterized by their median value and by their coefficient of variation (*CV*—standard deviation divided by the mean). There is little doubt that the log-normality assumption is good (Driscoll, 1986), but similar to the spreadsheet approach, the method typically is then combined with weak hydrologic assumptions (for example, the prediction of runoff using a runoff coefficient). (The accuracy of a runoff coefficient increases as urbanization and imperviousness increase.) However, because many streams of concern in an urban area consist primarily of stormwater runoff during wet weather, the ability to predict the distribution of EMCs is useful for the assessment of levels of exceedance of water quality standards. The effect of BMPs can again be estimated crudely through constant removal fractions that lower the EMC median, but it is harder to determine the effect on the coefficient of variation. Overall, the method has been successfully applied as a screening tool.

Inputs to the method discussed by Driscoll *et al.* (1989) include statistical properties of rainfall (mean and coefficient of variation of storm event depth, duration, intensity, and interevent time), area, and runoff coefficient for the hydrologic component, plus EMC, median, and coefficient of variation for the pollutant. Generalized rainfall statistics have been calculated for many locations in the U.S. Otherwise, the U.S. EPA SYNOP model (Hydroscience, 1979; U.S. EPA, 1976b; U.S. EPA, 1983; and Woodward-Clyde Consultants, 1989) must be run on long-term hourly rainfall records. If receiving water effects are to be evaluated, the mean and *CV* of the streamflow are required plus the upstream concentration. A lake impact analysis is also possible based on phosphorus loadings.

As with the first two methods discussed, the choice of median concentration may be difficult, and the statistical method requires a coefficient of variation as well. Fortunately, from NURP and highway studies, *CV* values for most urban runoff pollutants are fairly consistent, and a value of 0.75 is typical. If local and/or NURP data are not available or inappropriate, local monitoring may be required.

Regression—Rating Curve Approaches. With the completion of the NURP studies in 1983, there are measurements of rainfall, runoff, and water quality at more than 100 sites in more than 30 cities. Some regression analysis has been performed to try to relate loads and EMCs to catchment, demographic, and hydrologic characteristics (Brown, 1984; McElroy *et al.*, 1976; and Miller *et al.*, 1978), the best of which are results of the U.S. Geological Survey (USGS) (Driver and Tasker, 1988, and Tasker and Driver, 1988) and are described briefly in this section. Regression approaches have also been used, with limited success, to estimate dry-weather pollutant deposition in combined sewers (Pisano and Queiroz, 1977). What are termed "rating curves" in this discussion are a special form of regression analysis in which concentration or loads are related to flow rates or volumes.

A rating curve approach is most often applied using total storm event load and runoff volume, although intrastorm variations can sometimes also be simulated (for example, Huber and Dickinson, 1988). It is typically observed (Driscoll *et al.*, 1989; Huber, 1980; and U.S. EPA, 1983) that concentration (EMC) is poorly correlated or not correlated with runoff flow or volume, implying that a constant concentration assumption is adequate. Because the load is the product of concentration and flow, load typically is well correlated with flow regardless of whether concentration correlates well. This instance of spurious correlation (Bensen, 1965) is often ignored in urban runoff studies. If load is proportional to flow to the first power (that is, linear), then the constant concentration assumption holds; if not, some relationship of concentration with flow is implied. Rating curve results can be used by themselves for load and EMC estimates and can be incorporated to some models.

Rainfall, runoff, and quality data were assembled for 98 urban stations in 30 cities (NURP and others) in the U.S. for multiple regression analysis by USGS (Driver and Tasker, 1988, and Tasker and Driver, 1988). Thirty-four multiple-regression models (mostly log-linear) of storm runoff constituent loads and storm runoff volumes were developed, and 31 models of storm runoff EMCs were developed. Regional and seasonal effects were also considered. The two most significant explanatory variables were total storm rainfall and total contributing drainage area. Impervious area, land use, and mean annual climatic characteristics also were significant explanatory variables in some of the models. Models for estimating loads of dissolved solids, total nitrogen, and total ammonia plus organic nitrogen (total Kjeldahl nitrogen) typically were the most accurate, whereas models for suspended solids were the least accurate. The most accurate models were those for the more arid Western U.S., and the least accurate models were those for areas that had large mean annual rainfall.

These USGS equations represent some of the best generalized regression equations available for urban runoff quality prediction. Note that these equations do not require preliminary estimates of EMCs or local quality monitoring data. except of verification of the regression predictions. Regression equations only predict the mean and do not provide the frequency distribution of a predicted variable, a disadvantage compared to the statistical approach. (The USGS documentation describes procedures for calculation of statistical error bounds, however.) Finally, regression approaches, including rating curves, are difficult to apply beyond the original data set from which the relationships were derived. That is, they are subject to potential errors when used to extrapolate to different conditions. Thus, the usual caveats about use of regression relationships continue to hold when applied to prediction of urban runoff quality.

Buildup and Washoff. In the late 1960s, a Chicago study by the American Public Works Association (1969) demonstrated the (assumed linear) buildup of "dust and dirt" and associated pollutants on urban street surfaces. During a similar time frame, Sartor and Boyd (1972) demonstrated buildup mechanisms on the surface and an exponential washoff of pollutants during rainfall events. These concepts were incorporated to an early hydraulic model (Metcalf and Eddy, Inc., *et al.*, 1971) as well as to the other models to a greater or lesser degree (Huber, 1985). "Buildup" is a term that represents all of the complex spectrum of dry-weather processes that occur between storms, including deposition, wind erosion, and street cleaning. The idea is that all such processes lead to an accumulation of solids and other pollutants that are then "washed off" during storm events.

Although ostensibly empirically based, models that include buildup and washoff mechanisms use conceptual algorithms because the fundamental physical foundations are related to principles of sediment transport and erosion that are sometimes poorly understood. Furthermore, the inherent heterogeneity of urban surfaces leads to the use of average buildup and washoff parameters that may vary significantly from conditions in isolated locations such as a street gutter. Thus, except in rare instances where actual measurements of accumulations of surface solids are available, the use of buildup and washoff formulations involve a calibration exercise against measured end-of-pipe quality data. In the absence of accumulation measurements, inaccurate predictions can be expected.

Different models offer different options for conceptual buildup and washoff mechanisms. In fact, with calibration, good agreement can be produced between predicted and measured concentrations and loads with such models, including intrastorm variations that cannot be duplicated with most of the methods discussed earlier. (When a rating curve is used instead of buildup and washoff, it is also possible to simulate intrastorm variations in concentration and load.) A survey of linear buildup rates for many pollutants by Manning *et al.* (1977) is a source of generalized buildup data, and some information is available in the literature to aid in selection of washoff coefficients (Huber, 1985, and Huber and Dickinson, 1988). However, such first estimates may not even get the user in the ballpark (that is, quality—not quantity—predictions may be off by more than an order of magnitude); the only way to be sure is to use local monitoring data for calibration and verification. Thus, as for most of the other quality prediction options discussed in this section, the buildup–washoff model may provide adequate comparisons of control measures or ranking of loads, but it cannot be used for prediction of absolute values of concentrations and loads (for example, to drive a receiving water quality model without adequate calibration and verification data).

It is relatively easy to simulate potential control measures, such as street cleaning and surface infiltration, using this modeling approach. When intrastorm variations in concentration and load must be simulated (as opposed to total storm event EMC or load), buildup and washoff offers the most flexibility. This is sometimes important for the design of storage facilities in which first-flush mechanisms may be influential.

The data for buildup and washoff modeling are sparse (Manning *et al.*, 1977), and the needed measurements are seldom made as part of a routine monitoring program. For buildup, normalized loadings, such as mass/day per area, mass/day per curb-length, or just mass/day, are required, along with an assumed functional form for buildup versus time, such as linear or exponential. For washoff, the relationship of washoff rate (mass/time) runoff rate must be assumed, typically in the form of a power equation. When end-of-pipe concentration and load data are all that are available, all buildup and washoff coefficients end up being calibration parameters.

Related Mechanisms. In the discussion above, washoff rate is assumed proportional to the runoff rate, as for sediment transport, but erosion from pervious areas may be proportional to the rainfall rate. One model includes this mechanism in its algorithms for erosion of sediment from pervious areas. Another includes a weaker algorithm based on the Universal Soil Loss Equation (Heaney *et al.*, 1975, and Wischmeier and Smith, 1958).

Many pollutants, particularly metals and organics, are adsorbed to solid particles and are transported in particulate form. The ability of a model to include "potency factors" or "pollutant fractions" enhances the ability to estimate the concentration or load of one constituent as a fraction of that of another, such as solids (Zison, 1980).

Groundwater contribution to flow in urban areas can be important in areas with unlined and open-channel drainage. The precipitation load may be input to some models, typically as a constant concentration. Point source and dry-weather flow (base flow) loads and concentrations can also be input to some models to simulate background conditions. Other quality sources of potential importance include catch basins and snowmelt.

Scour and deposition within the sewer system can be important in combined sewer systems and some separate storm sewer systems. The state of the art in simulation of such processes is poor (Huber, 1985).

SUMMARY OF DATA NEEDS. In the application of most models, there are two fundamental types of data requirements. First, there are data needed simply to make the model function, that is, input parameters for the model. These typically include rainfall information, area, imperviousness, runoff coefficient, and other quantity prediction parameters, plus quality prediction parameters such as constant concentration, constituent median and *CV*, regression relationships, and buildup and washoff parameters. In other words, each model will have a fundamental list of required input data.

The second type of information is required for calibration and verification of more complex models, namely, sets of measured rainfall, runoff, and quality samples with which to test the model. Such data exist (for example, Driver *et al.*, 1985; Huber *et al.*, 1982; and Noel *et al.*, 1987) but seldom for the site of interest. If the project objectives absolutely require such data (for example, if a model must be calibrated to drive a receiving water quality model), then monitoring may be necessary to produce needed data.

SELECTING URBAN RUNOFF QUALITY MODELS. This summary will relate primarily to quality prediction and will not represent a comprehensive statement of data needs for quantity prediction. However, because rainfall and runoff are required for virtually every study, certain quantity-related parameters are also necessary.

Modeling Fundamentals. Modeling caveats and an introduction to modeling are presented by several authors, including Huber (1985 and 1986), James and Burges (1982), and Kibler (Ed.) (1982), and summarized in *Combined Sewer Overflow Pollution Abatement* (WPCF, 1989). Space does not permit a full presentation here; a few items are highlighted in the following bullets.

- Have a clear statement of project objectives. Verify the need for quality modeling. (Perhaps the objectives can be satisfied without quality modeling.)
- Use the simplest model that will satisfy the project objectives. Often, a screening model, such as regression or statistical, can determine whether more complex simulation models are needed.
- To the extent possible, use a quality prediction method consistent with available data. This would often rule against buildup–washoff formulations, although these might still be useful for detailed simulation, especially if calibration data exist.
- Only predict the quality parameters of interest and only over a suitable time scale. That is, storm event loads and EMCs typically will represent the most detailed prediction requirement, and seasonal or annual loads will sometimes be all that are required. Do not attempt to simulate intrastorm variations in quality unless necessary.
- Perform a sensitivity analysis on the selected model and familiarize yourself with the model characteristics.
- If possible, calibrate and verify the model results. Use one set of data for calibration and another independent set for verification. If no such data exist for the application site, perhaps they exist for a similar catchment nearby.

Operational Models. Implementation of an off-the-shelf model or method will be easiest if the model can be characterized as "operational" in the sense of the following:

- Documentation—this should include a user's manual, explanation of theory and numerical procedures, data needs, and data input format. Documentation most often separates the many computerized procedures found in the literature from a model that can be accessed and easily used by others.
- Support—this is sometimes provided by the model developer but often by a federal agency such as U.S. EPA.
- Experience—every model must be used a "first time," but it is best to rely on a model with a proven track record.

Models described below are operational in this sense. New methods and models are constantly under development and should not be neglected simply because they lack one of these characteristics, but the user should be aware of potential difficulties if any characteristic is lacking.

Surveys of Operational Urban Runoff Models. Several publications, though somewhat out of date, provide reviews of available models. Some models have persisted for many years and are included in both older and newer reviews, while other models are more recent. Reviews that consider surface runoff quality models include Barnwell (1984 and 1987), Bedient and Huber (1988), Huber (1985 and 1986), Huber and Heaney (1982), Kibler (Ed.) (1982), Viessman *et al.* (1989), WPCF (1989), and Whipple *et al.* (1983).

URBAN RUNOFF QUALITY SIMULATION MODELS AND METHODS. Several models are often considered the best choices for full-scale simulation for urban areas. Other models have been adapted and given modified names. Still other models have been used for water quality simulation for a specific project (Noel and Terstriep, 1982), but such modifications and quality procedures remain undocumented, and the quality model cannot be considered operational. A number of models have been developed in Europe and applied extensively in a number of situations. One of these models includes modules for generation of runoff from rainfall using either a time–area method or a nonlinear reservoir model. The model handles six pollutants, and the emphasis is production of statistics for both extreme and annual loads. Finally, there are many models well known in the hydrologic literature that are useful in the hydrologic modeling in water quality studies but do not simulate water quality directly.

BIOLOGICAL AND ECOLOGICAL MODELING. In many respects, biological and ecological modeling have lagged far behind physical, chemical, and hydrologic modeling, and there are few examples of general application of biological and ecological models in urban runoff. It is possible to connect other modeling efforts with a prediction of biological and ecological receiving system effects through a general application of concentration and time of exposure analysis, which allows assessment of toxicity and supports general predictions of effect.

RECEIVING WATER MODELS

To assess the effects of runoff loads on receiving water quality, it is often necessary to use computer models. Measurements of receiving water quality parameters are preferable for impact assessment, but such data typically are sparse. Also it is difficult and costly to obtain sufficient data for model calibration, let alone for evaluation of effects. And if alternative pollution control options are to be evaluated, models are the only option with which to assess "what if" management strategies, at least as far as effects on *in situ* concentrations are concerned. It sometimes may be possible to evaluate water quality control strategies on the basis of hydraulic or surface runoff quality criteria alone, without receiving water quality modeling—an advantage.

Do not model if it is not necessary. However, if comparison with water quality standards is a requirement, modeling typically is the only option.

Receiving water quality models are available for streams, lakes (and reservoirs), estuaries, and bays. Groundwater models will not be discussed here, although several models are available. Segments of coastal ocean areas can also be modeled with more difficulty (because of the necessity of two- and three-dimensional formulations). Such models are driven by transient or steady-state point and nonpoint source loadings, typically entering the water body at multiple locations. Nonpoint source loads are often generated by surface runoff loading models discussed previously. Thus, there typically is a coupling of surface runoff models with receiving water models for determination of nonpoint source effects. The output from such models typically is a transient or steady-state prediction of water quality constituent concentrations at multiple locations throughout the receiving water, although some methods (such as simple eutrophication models) provide only an average concentration in space and time.

Most receiving water quality models require information about flows, velocities, volumes, and stages—that is, a description of quantity (hydrodynamic) processes. Some models compute flows and quality concentrations, whereas other models require a separate model or data for input of such information. Data input for the former is correspondingly more demanding. This discussion will focus only on quality modeling because of the vast complexity of two- and three-dimensional quantity modeling. Simulation of quantity processes will thus be mentioned only incidentally if it is included as an option for a particular model.

Most of the caveats and general modeling fundamentals provided previously while discussing surface runoff models also apply to receiving water quality modeling, for example clear objectives, desirability of simplicity, and the need for data. Receiving water quality models should be calibrated and verified similar to surface runoff models because of the many influential processes at work in natural waters. A similar statement can be made for receiving water quality modeling as for surface runoff quality modeling: calibration/verification data (that is, measured *in situ* concentrations) are essential for accurate predictions of concentrations. Without such data, only relative comparisons can be made. Of course, accurate concentrations are important for comparison of predicted concentrations with water quality standards.

The models discussed below are all "far-field" models, that is, models for which transport is influenced only by the hydrodynamics of the receiving waters. "Near-field" models consider the effects of plumes and jets at the discharge location and may be used for mixing zone calculations and are not considered herein. These dilution calculations are hydrodynamic in nature and discussed by Fischer *et al.* (1979) and Holley and Jirka (1986). Another category of models not included below is simple eutrophication models for lakes. Procedures for analyzing lakes in a spatially lumped manner for eutrophication screening are described, for example by Mills *et al.* (1985), Reckhow and Chapra (1983), and Thomann and Mueller (1987).

LINKAGE WITH SURFACE RUNOFF MODELS. Nonpoint source loadings used to "drive" the receiving water model typically are obtained from surface runoff models. A time series of loads (and flows) must be supplied as input to the receiving water model. This interface may be more or less difficult depending on the models used. The user should determine the nature of the interface requirements to ensure compatibility between the surface and receiving water models. For instance, the surface runoff model should be able to output a file containing the load and flow time series, and it should be possible to manipulate this file to produce the required format for the receiving water model. Obviously, the receiving water model documentation should specify this format. It can thus be seen that the interfacing of different models may be more or less difficult, depending on the models and their documentation. Use of surface and receiving water models from the same agency may alleviate this problem to a large extent.

SURVEY OF RECEIVING WATER QUALITY MODELS. Modeling is such a dynamic process that reviews and surveys are rapidly outdated. Typically, it is best to contact an agency or model distributor directly for current information. However, useful summaries are provided by Ambrose and Barnwell (1989), Ambrose *et al.* (1988), and Feldman (1981). Principles of fate and transport are discussed in references such as Bowie *et al.* (1985), Fischer *et al.* (1979), French and McCutcheon (Eds.) (1989), Holley and Jirka (1986), Krenkel and Novotny (1980), Mills *et al.* (1985), and Thomann and Mueller (1987).

SOURCES OF RECEIVING WATER MODELS. Models are available from federal agencies and private vendors. For water quality formulations (as opposed to detailed hydrodynamic components), the predominant federal source is the U.S. EPA Center for Exposure Assessment Modeling at Athens, Georgia. Additional federal sources include the U.S. Army Corps of Engineers, Waterways Experiment Station in Vicksburg, Mississippi, and the U.S. Army Corps of Engineers, Hydrologic Engineering Center, in Davis, California. The USGS has performed numerous receiving water quality studies, including development of two- and three-dimensional transient hydrodynamic/quality models. Most of these efforts are for a particular project, and local centers should be contacted for information about particular model availability. Similar remarks can be made about the National Oceanic and Atmospheric Administration for estuary/bay modeling and for the Tennessee Valley Authority for river/reservoir modeling. Still other federal agencies may perform quality modeling as a part of other studies.

BEST MANAGEMENT PRACTICE DATA REPORTING AND MONITORING

Auditing and monitoring BMPs are important applications of monitoring and modeling. This section proposes a standardized set of BMP data for reporting purposes and equipment considerations for monitoring specific BMP facilities based on Urbonas (1995a and 1995b).

NEED FOR STANDARDIZED REPORTING. There is a need to develop an approach for reporting data on the physical, chemical, climatic, geological, biological/ecological, and meteorological parameters in the assessment of the performance of BMPs used to enhance urban runoff quality. Transferability of performance results and consistency or lack of it in the performance of various BMPs have been ongoing problems. By defining a standardized approach it is expected that over time this standardization will conserve the resources being expended by various field investigations and will lead to improvements in the selection and design of various BMPs. Further, this standardization provides a workable listing of parameters that are the focus of monitoring and modeling efforts.

FACILITIES COVERED FOR REPORTING. A standard reporting format is provided for the following BMP technologies:

- Retention basin (dry pond, wet pond),
- Extended detention basin,
- Wetland basin,
- Wetland channels,
- Sand filters,
- Oil–grit separators (traps), and
- Infiltration and percolation facilities.

For facilities that contain more than one type of BMP in a BMP train, the analyst should report data for the overall unit, if performance assessment occurs on this basis, and for specific BMPs, if monitoring is done on this basis.

PARAMETERS FOR RETENTION PONDS. Retention ponds always have some surcharge detention storage above the permanent pool water surface. There are several pollutant removal mechanisms at work within a retention pond. These include sedimentation during runoff events and between runoff events and other physical, chemical, and biological processes. As a result, more information needs to be reported for these types of facilities than for facilities that remove pollutants primarily though physical processes. The following parameters emerge as important reporting points to assess retention pond removal efficiency.

Surface area and pond layout parameters:

A_P = surface area of the permanent pool, m^2 (sq ft);
A_L = surface area of the littoral zone (zone ≤ 0.5 m [1.5 ft] deep), m^2 (sq ft);
A_D = surface area of the top of the surcharge detention basin, m^2 (sq ft);
L_P = length of the permanent pool or flow path, m (ft);
L_D = length of the surcharge detention basin, m (ft);
A_F = surface area of the forebay, m^2 (sq ft); and
L_F = length of the forebay, m (ft).

Basin volume parameters:

V_P = volume of the permanent pool, m^3 (cu ft);
V_D = design volume of the surcharge detention basin above the permanent pool's water surface, m^3 (cu ft); and
V_F = volume of the forebay, m^3 (cu ft).

Emptying time parameters:

T_E = time needed to empty 99% of V_D assuming no inflow takes place while the surcharge pool is emptying, hours; and
$T_{0.5E}$ = time needed to empty the upper one-half of V_D assuming no inflow takes place while the surcharge pool is emptying, hours.

PARAMETERS FOR EXTENDED DETENTION BASINS. Extended detention basins use sedimentation as their primary pollutant removal mechanism. As a result, extended detention basins have to be viewed somewhat differently than retention ponds. In a retention pond, sediments that settle below the overflow outlet level are essentially trapped within the permanent pool and are less likely to be discharged through the outlet. The trapped sediment continues to settle to the bottom of the pond even after the surcharge volume is drained off. In an extended detention basin, stormwater empties through an outlet located on the bottom. As the sediments settle to the bottom, they concentrate within the lower levels of the ever-shrinking pool and discharge through the outlet. Unless they are scoured out, only the sediments that deposit on the bottom can be trapped within the basin.

The list that follows reflects most of the parameters of importance for an extended detention basin. Many of the same parameters that were recommended for retention ponds are repeated.

Surface area and plan layout parameters:

A_D = surface area of the extended detention basin, m^2 (sq ft);
L_D = length of the extended detention basin, m (ft);
A_B = surface area of the bottom stage (that is lower basin), m^2 (sq ft); and
L_F = length of the forebay, m (ft)

Basin volume parameters:

V_D = total volume of the extended detention basin, m^3 (cu ft);
V_B = volume of the bottom stage only of the basin, m^3 (cu ft); and
V_F = volume of the forebay, m^3 (cu ft).

Time variables: Use the same emptying time parameters as defined for the retention pond.

PARAMETERS FOR WETLAND BASINS. Some wetland basins are similar in their operation to retention ponds, while others resemble extended detention basins. The difference between the two is whether or not the wetland basin has standing water or a wetland meadow as its bottom. The pollutant removal mechanisms are probably similar to those found in retention ponds and in detention basins, except that stormwater comes in contact with wetland flora and fauna. This contact and the physical structure of the wetland provide pollutant removals through adsorption and biochemical processes and possibly through reoxygenation of the sediments and detoxification of the water column—processes that may or may not be available in retention ponds and that are not available in detention basins.

Each performance monitoring program should report parameters that are particular to the wetland studied. Most currently available wetland monitoring data rarely contain such information, often not even reporting many of the parameters typically reported for other BMPs. Because the quantification of wetland performance as a BMP is relatively new, little information can be found in the literature, and it is difficult to suggest parameters to report when reporting the performance data of wetland basins. Table 3.2 and the follow-

Table 3.2 Additional general parameters to report for wetlands.

Type of wetland	Cattail marsh, northern peat land, meadow, palustrine, southern marshland, hardwood swampland, brackish marsh, high-altitude riverine, freshwater riverine, constructed or natural wetlands
Rock filter?	Is there a rock filter media present in the wetland bottom?
Dominant plant species	Lists the dominant plant species in the wetland and the age of these plants (that is, the time since their original planting or replanting)

ing list suggest the parameters that appear to be most important, many of which are identical to those recommenced for retention ponds.

Surface area and layout plan parameters:

- A_P = surface area of permanent wetland pool, if any, m^2 (sq ft);
- A_M = surface area of the meadow wetland, if any, m^2 (sq ft);
- $P_{0.30}$ = percent of permanent pool less than 0.30 m (12 in.) depth;
- $P_{0.60}$ = percent of the permanent pool more than 0.60 m (24 in.) depth;
- A_S = surface area of the surcharge detention basin's top, m^2 (sq ft),
- L_S = length of the wetland surcharge/detention pool or flow path, m (ft);
- A_F = surface area of the forebay, m^2 (sq ft); and
- L_F = length of the forebay, m (ft).

Basin volume parameters:

- V_P = volume of the permanent pool, if any, m^3 (cu ft);
- V_D = design volume of the surcharge/detention basin, m^3 (cu ft); and
- V_F = volume of the forebay, m^3 (cu ft).

Time variables: Use the same emptying time parameters as defined for the retention pond.

PARAMETERS FOR WETLAND CHANNELS. Channels can be designed to have a wetland bottom that is designed to flow slowly. When properly designed, the channel's bottom is covered by wetlands, with only the sideslopes having terrestrial vegetation. The flow velocity is controlled by transverse berms, check dams, or an outlet at the downstream end of a given channel's reach. In the last case, the channel is essentially a long and narrow wetland basin. Figure 3.1 shows a profile of an idealized wetland bottom channel.

The pollutant removal mechanisms in wetland bottom channels are similar to those found in wetland basins, except that contact time of stormwater with the wetland vegetation is likely to be less. Because of the flowing channel nature of this BMP, the following parameters should provide some of the information needed to compare the performance of different installations:

- $V_{2\text{-yr}}$ = average channel velocity during a 2-year runoff event, m/s (ft/sec);
- A_D = surface area of the wetland bottom, m^2 (sq ft);
- L_D = length of the wetland channel, m (ft); and
- Prt = describe any pretreatment provided ahead of the channel (such as detention).

There are no emptying time parameters to report for wetland channels.

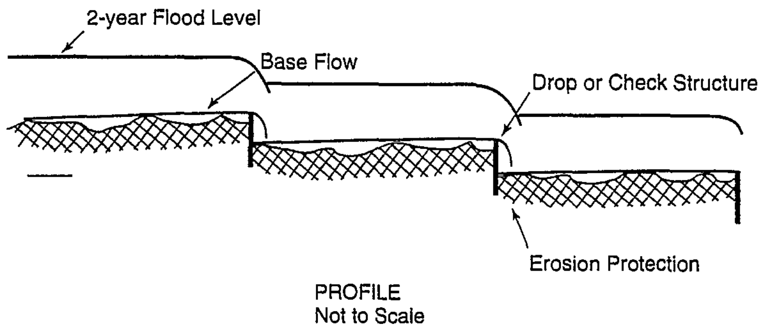

Figure 3.1 **Profile of an idealized wetland bottom channel (UDFCD, 1992).**

PARAMETERS FOR SAND FILTERS. Sand filters can be installed as basins or as sand filter inlets. Figures 3.2 through 3.4 illustrate typical sand filter designs. These installations will have a detention basin or a retention pond (or tank) upstream of the filter to remove the heavier sediment and, if properly designed, some of the oil and grease found in stormwater. However, such a pretreatment basin is not always present. All of the parameters required for a retention pond or for an extended detention basin should also be reported, along with the information about the sand filter whenever the filter is preceded by a pretreatment basin. For example, a filter inlet is often equipped with an underground tank, which helps to remove some of the sediment, oil, and grease before stormwater is applied to the filter. Such a tank is similar to a retention pond, and all of the parameters associated with a retention pond, such as volume, surface area, length, and surcharge volume, should be reported.

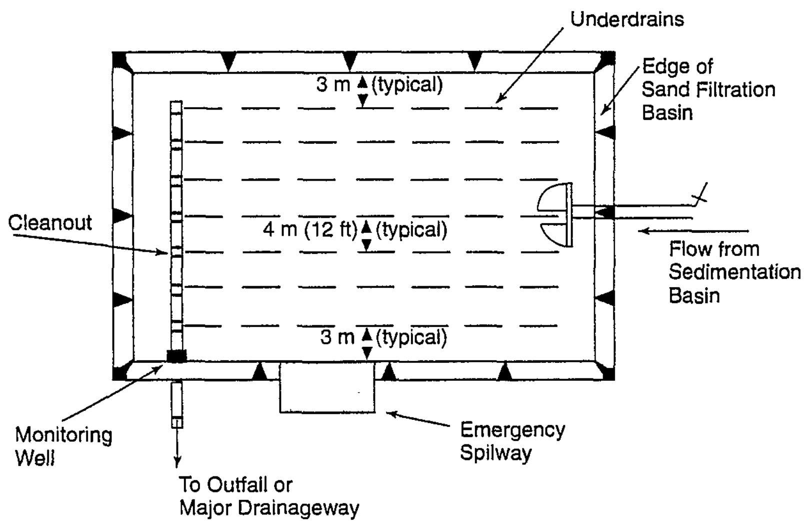

Figure 3.2 **Plan of an idealized sand filter basin.**

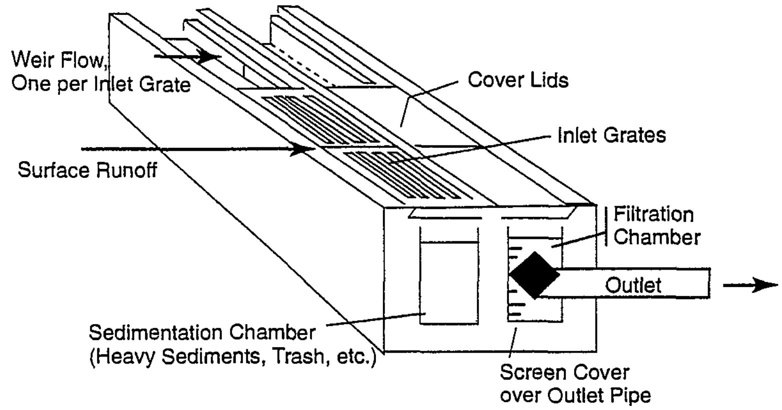

Figure 3.3 An idealized sand filter inlet.

In addition to the parameters of the pond or basin associated with the filter, provide the following:

- Dimensions of the installation;
- Depth of various filter material layers;
- Type of filter media, its median particle size (D_{50}), and its coefficient of uniformity;
- Maintenance frequency; and
- All associated drainage and flooding problems attributed to the installation because of its configuration size and maintenance practices.

Use the same parameters for *emptying time* as defined for the retention pond.

PARAMETERS FOR OIL, GREASE, AND SAND TRAPS. An oil, grease, and sand trap is an underground tank, similar to the one illustrated in Figure 3.4. It is nothing more then a special configuration of a retention pond. As a result, all parameters listed for a *retention pond* should be reported for these installations. Typically, these installations have a forebay and an outlet basin. In addition to reporting the parameters for a pond, pro-

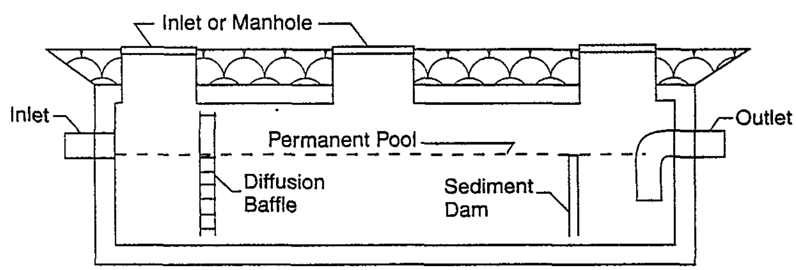

Figure 3.4 An idealized oil, grease, and sand trap.

vide the dimensions of the installation, details of its design (including skimmers, sorbent pillows, lamella plates, and baffles), and the maintenance provided during the testing period. Because these traps are much smaller than a surface pond, the flow-through velocity is of concern because it can cause trapped oil, grease, and sediment to be remobilized and flushed out of the trap. As a result, provide the average flow velocity that can be expected to occur in this device during a 2-year storm. This velocity can be used as an index for comparing the performance among a variety of installations. Use the same *emptying time* parameters as defined for a retention pond.

PARAMETERS FOR INFILTRATION AND PERCOLATION FACILITIES. For percolation trenches and for infiltration basins, report all of the parameters suggested for the extended detention basin. In addition, report the following:

- Depth to high groundwater and impermeable layers below the infiltrating surface of the basin or below the bottom of the percolation trench;
- The hydraulic conductivity of soils adjacent to percolation trenches and the saturated surface infiltration rates of soils underlying infiltration basins;
- Dimensions of the installation;
- Maintenance needs and associated drainage and flooding problems attributed to the installation; and
- Failures to empty out the captured water completely within the design emptying time.

Use the same *emptying time* parameters as defined for a retention pond.

SUMMARY

In summary, in the reporting of various BMP parameters and the field testing data on their performance, we can find a model for the selection of parameters useful in both more general monitoring programs and modeling. Table 3.3 lists the parameters identified in standardized procedures for BMP performance monitoring.

Table 3.3 Summary of reportable best management practice site parameters.

Parameter	Ret. pond	Ext. det. basin	Wet-land basin	Wet-land channel	Sand filter	Oil/ sand trap	Infilt. & perc.
Tributary watershed area—A_T	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Total % trib. watershed is impervious—I_{IT}	Yes	Yes	Yes	Yes	Yes	Yes	Yes
% of impervious area hyd. connected—I_{IC}	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Gutter/sewer/swale/ditches in watershed?	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Average storm runoff volume—V_R	Yes	Yes	Yes	Yes	Yes	Yes	Yes
50th percentile runoff volume—V_{R50}	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Coeff. var. of runoff volumes—CV_{VR}	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Av. daily base flow volume—V_B	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Average runoff interevent time—T_S	Yes	Yes	Yes	Yes	Yes	Yes	Yes
50th percentile interevent time—T_{S50}	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Coeff. var. of interevent times—CV_{TS}	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Average storm duration—T_D	Yes	Yes	Yes	Yes	Yes	Yes	Yes
50th percentile storm duration—T_{D50}	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Coeff. var. of storm durations—CV_{TD}	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Water temperature	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Alkalinity, hardness, & pH	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Sediment settling velocity dist.—V_{SD}	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Type and frequency of maintenance	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Inlet and outlet dimensions and details	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Solar radiation	Yes	No	Yes	Yes	No	No	No
Volume of permanent pool—V_P	Yes	No	Yes	No	Yes	Yes	No
Perm. pool surface area—A_P	Yes	No	Yes	No	Yes	Yes	No
Littoral zone surface area—A_L	Yes	No	No	No	No	No	No
Length of permanent pool—L_P	Yes	No	Yes	No	Yes	Yes	No
Detention (or surcharge) vol.—V_D	Yes	Yes	Yes	No	Yes	Yes	Yes
Detention basin's surface area—A_D	Yes	Yes	Yes	No	Yes	Yes	Yes
Length of detention basin—L_D	Yes	Yes	Yes	No	Yes	Yes	Yes
Brim-full emptying time—T_E	Yes	Yes	Yes	No	Yes	Yes	Yes
1/2 Brim-full emptying time—$T_{0.5E}$	Yes	Yes	Yes	No	Yes	Yes	Yes
Bottom stage volume—V_B	No	Yes	No	No	No	No	No
Bottom stage surface area—A_B	No	Yes	No	No	No	No	No
Forebay volume—V_F	Yes	Yes	Yes	No	Yes	Yes	Yes
Forebay length—L_F	Yes	Yes	Yes	No	Yes	Yes	Yes
Wetland type, rock filter present?	No	No	Yes	Yes	No	No	No
% of wetland surface at $P_{0.3}$ & $P_{0.6}$ depths	No	No	Yes	Yes	No	No	No
Meadow wetland surface area—A_M	No	No	Yes	Yes	No	No	No
Plant species and age of facility	Yes	Yes	Yes	Yes	No	No	No
Two-year flood peak velocity	No	No	No	Yes	No	Yes	No
Depth to groundwater or impermeable layer	No	Yes	Yes	No	No	No	Yes

Source controls are practices that prevent pollution by reducing potential pollutants at their source before they come into contact with stormwater, as opposed to treatment controls that remove pollutants from stormwater. A comprehensive urban runoff quality management program requires that certain source control best management practices (BMPs) be implemented on existing development. In addition, some source controls will be applied in developing areas after the new development has been completed. Twenty-two source control BMPs are described in this chapter.

Typically, source controls for urban areas can be grouped into the following seven categories:

- Public education—this is an institutional practice intended to change the way the general public manages many of the constituents that wind up in stormwater runoff. How the public uses and disposes of automotive fluids, fertilizers, pesticides, herbicides, and many other household products can have a profound effect on the quantities of these materials that come into contact with stormwater and the amounts of these substances that are eventually discharged to the receiving waters. Although this promises to be a cost-effective way of affecting stormwater quality, the effectiveness of public education on the actual reductions of the target constituents in receiving waters has yet to be definitively demonstrated.

- Planning and management of developing areas—these practices by local governments can be aimed at reducing runoff and the discharge of pollutants through stormwater from new developments and are most effective when applied during the site-planning phase of new development. Examples include the adoption of zoning ordinances and subdivision regulations aimed at stormwater quality management. These ordinances may require buffers and setbacks from all streams, lakes, and natural wetlands and may include provisions to reduce impervious areas that are connected directly to the formal stormwater drainage system.
- Materials management—these practices include controlling the use, storage, and disposal of chemicals that could pollute runoff. The objective is to reduce the opportunity for rainfall or runoff to come into contact with these chemicals. This BMP includes the following three categories of activities:
  - — Material use controls,
  - — Material exposure controls, and
  - — Material disposal and recycling controls.
- Spill prevention and cleanup—this category includes programs that reduce the risk of spills during outdoor handling and the transportation of chemicals and other materials and the development of plans and programs to respond, contain, and rapidly clean up spills when they do occur so that they do not enter the storm drain system.
- Illegal dumping controls—this category comprises ordinances, public education programs, and enforcement aimed at keeping individuals and businesses from dumping various waste products onto the urban landscape and the drainage system.
- Street/storm drain maintenance—this applies to the removal of pollutants from paved areas and the maintenance of runoff quality controls that exist within the drainage system. Examples include street sweeping, catch basin cleaning, road and bridge maintenance, and maintenance of structural controls in the system for runoff quality management. This group also includes the use of good housekeeping measures whenever performing pavement maintenance such as asphalt overlays or seal and chip procedures.
- Illicit connection controls—this group of controls is directed at preventing, by ordinance, and eliminating, by discovery and removal, connections to the storm drainage system that discharge any material except stormwater runoff. Bans on connection of floor drains, washdown areas, septic tank overflows, and the like to the stormwater conveyance system are all a part of this BMP category.

General Guidance for Selection of Stormwater Best Management Practices

Selecting the proper stormwater quality controls or BMPs is often driven by the following:

- Federal, state, and local regulations;
- Real or perceived receiving water problems or beneficial uses to be protected; or
- The cost of the BMPs being considered.

The reduction of pollutants in stormwater discharges to the maximum extent practicable (MEP) is the statutory requirement of stormwater regulations. Ultimately, however, the goal is to reduce the effects of urban stormwater runoff on the receiving water. Despite the best of intentions, the cost of the selected BMPs is a major consideration, especially when considering retrofitting treatment control BMPs in developed areas. Retrofitting any treatment control BMP is expensive and often unfeasible on a citywide basis. For this reason, source controls are often the only affordable option.

There is no single BMP that will prevent all of the effects on receiving waters caused by urban runoff. However, through the use of a combination of BMPs, both source controls and treatment controls, the greatest benefits will be gained. Figure 2.2 illustrates a multilevel strategy suggesting that urban runoff quality management begins with source controls, followed by on-site treatment controls. These can be further supplemented, where required, by regional, subregional, or communitywide control facilities. This so-called "treatment train" (Livingston *et al.*, 1988) can use the numbers and types of controls that best serve the community or the watershed. Land availability, capital, and operation and maintenance (O & M) costs, balanced against the benefits of pollutant removal, should be the bases for determining the nature of such a treatment train at each site.

SELECTING SOURCE CONTROLS. Table 4.1, with locally defined selection criteria for various factors, contains a worksheet that can be used to assist a municipality in selecting source controls. Several municipalities have used this system or a similar one to select BMPs (City of Stockton, 1993, and County of San Bernardino, 1993). Some of the locally defined selection criteria may include

Table 4.1 **Worksheet for evaluating municipal source control practices (Camp Dresser & McKee *et al.,* 1993).**

Worksheet 1
Source control practices

Program activities: (such as residential/commercial), See Table 4.2
Program element: (such as roadway and drainage facility maintenance), see Table 4.2

Practice	Meets regulatory requirements (1–5)	Effectiveness of pollutant removal (1–5)	Public acceptance (1–5)	Implementable (1–5)	Institutional contraints (1–5)	Costs (1–5)	Total (30 maximum)

- Ability to meet regulatory requirements,
- Effectiveness of the practice to remove pollutants of concern,
- Public acceptance of the practice,
- Ability to implement,
- Institutional constraints, and
- Costs.

Selection criteria provide for a sliding scale of 1 to 5 and can be used to rank the practices in how well they meet the factors or concerns represented by the criteria. To use the Table 4.1 worksheet, first determine which proposed stormwater program elements are addressed by the various management practices or source control BMPs previously listed. Table 4.2 provides an example of how this can be done. For each BMP identified, the municipality ranks it according to its ability to meet selection criteria.

After the worksheets are completed for each program element and the ratings are scored, the municipality will have a ranking of BMPs. It should be kept in mind that the ranking is only a tool for comparing BMPs and provides the information for the municipality to decide which BMPs should be implemented immediately, which BMPs should be targeted for pilot-scale study, and which BMPs should be phased for later implementation. Such ranking may also serve the purpose of defining MEP as required under stormwater regulations.

Selection criteria and the scoring system presented in this chapter are similar to other qualitative selection processes developed to screen and rank alternatives for stormwater management programs. The user may wish to modify the selection process to accommodate local requirements. Modification of the following selection process attributes may be considered:

- Criteria—the user may want to redefine some of the criteria or add or subtract criteria.
- Scores—likewise, the user may want to modify the scoring to a simple +, 0, and/or 1, 2, and 3.
- Weighing—in addition, it may be appropriate to group the criteria into tiers reflecting their relative importance to solid waste management practice goals. By multiplying the scores of the highest tier by some factor (for example, ×2) the first-tier scores could be weighted more heavily than the others to reflect this importance.
- Fatal flaw—scoring the BMPs should provide for some fatal flaw (for example, the BMP is illegal or its implementation is unacceptable to the public) that would make implementation impossible. Scoring a fatal flaw as a "0" is one way of highlighting the flaw. Any BMP scoring a "0" against a criterion would be eliminated from consideration, regardless of its overall ranking.

Ranking Criteria. A suggested criteria for ranking source control BMPs follows.

MEETS REGULATORY REQUIREMENTS. Does the BMP comply with federal stormwater regulations or a state permit condition? For the most part, the selected BMP will address the requirements of the stormwater regulations. In certain situations, the state agency may require a specific BMP, in which case it will become a mandated best management practice.

Rating score:
5 = Meets specific state requirements.
3 = Meets federal storm water regulations.
1 = Does not meet regulatory requirements.

EFFECTIVENESS OF POLLUTANT REMOVAL. Does the BMP have a high likelihood of reducing pollutants of concern? This is probably one of the hardest questions to answer, especially for source control BMPs. As of 1996, the knowledge required to make this assessment is lacking. Consequently, most source control BMPs will receive a low rating, not so much because they are not effective in removing pollutants, but because the ability to quantify the removal is not available. It is more likely that the ratings of source control BMPs will be relative to each other. Also, some BMPs are more suited to removing a specific pollutant than others.

Table 4.2 **Application of source control practices to stormwater management plan program elements (Camp Dresser & McKee *et al.*, 1993).[a]**

	Source control practice							
Required elements of solid waste management program	**Planning management**	**Material use control**	**Material exposure controls**	**Material disposal and recycling**	**Spill prevention and cleanup**	**Illegal dumping controls**	**Illicit connection controls**	**Street/storm drain maintenance**
For residential/commercial activities:								
Roadway and drainage facility maintenance		X						X
Best management practice planning for new development and redevelopment projects	X							X
Retrofitting existing or proposed flood control projects with best management practices								

Municipal waste handling and disposal operations	X	X	X	X	X	
Pesticide, herbicide, and fertilizer use controls	X	X	X	X	X	
For improper discharge activities:						
Prevention, detection, and removal of illegal connections to storm drains						X
Spill prevention, containment, and response	X	X	X	X	X	
Promote proper use and disposal of toxic materials	X	X	X	X	X	
Reduce stormwater contamination by leaking/overflowing separate sanitary sewers				X	X	

Rating score:

5 = Highly effective in removing pollutants with sufficient data to support such a claim.

3 = Expected to provide moderate level of pollutant removal.

1 = Ineffective in removing pollutants or insufficient data are available to make an assessment.

PUBLIC ACCEPTANCE. Does the BMP have public support? Some source control BMPs will carry more public support than others (for example, stream cleanup versus tighter land-use controls). The successful implementation of source controls depends, to a large extent, on the amount of public support. Such support can be identified by knowing the community interests. Without the public support (which should include understanding the issues and problems), the BMP will be ineffective.

Rating score:

5 = Public understands the problem and supports the BMP implementation.

3 = Likely that the public will support the BMP once it understands the problem but presently does not know the issues.

1 = Public does not support the BMP.

IMPLEMENTABLE. Can the BMP be implemented through existing programs or departments? The ability of the municipality to implement a BMP will, to a certain extent, depend on whether existing programs can be used or expanded. Obviously, the likelihood of a BMP being implemented is greatest if it can be incorporated to an existing program (or department). Another issue to be considered under this criterion is the availability of staff (or necessity of additional staff) and equipment. Also, the municipality should consider how the BMP will affect interdepartmental coordination and communication. (Is there overlap? Will there be "turf battles"?)

Another issue to consider under implementation is whether the BMP should be implemented in a specific area or a larger watershed area. Some BMPs will be more appropriate for a specific target group within a limited area (for example, the industrial illicit connection program), while others need to be implemented areawide (for example, the elimination of motor oil dumping). Those BMPs that apply to the larger watershed should receive higher consideration.

Rating score:

5 = Existing program or department can be used and adequate personnel and equipment are available; applies to larger watershed area.

3 = Existing program will need to be expanded with either more staff or equipment.

1 = Existing program or department does not exist to implement BMPs.

INSTITUTIONAL CONSTRAINTS. Are there any institutional constraints that limit the ability to implement the BMP? Typical institutional constraints would include legal and intergovernmental coordination. Many of the source control BMPs can be implemented under existing ordinances or regulations. A new ordinance will be required in some situations. Source control BMPs may also require interjurisdictional coordination, to be effective. This coordination, whether it is through complementary watershed protection ordinances, common public education programs, or shared maintenance duties, is critical to selecting BMPs.

Rating score:

5 = Existing ordinances and intergovernmental agreements are in place to implement BMP.

3 = New ordinances and intergovernmental agreements will need to be developed; however, there is consensus among the parties that the BMP is important.

1 = New ordinances and intergovernmental agreements will need to be developed. Such ordinances and agreements will require extensive time and cost to develop a consensus.

COST. How much is the BMP going to cost initially and over the long term, and does the municipality have adequate financial means to fund its implementation? Many source control BMPs do not require significant capital investments (such as storm drain stenciling), while others do (such as the purchase of vacuum street sweepers). Also, it is important to look at the means for generating the funds required for the BMP (or for the stormwater program in general). Is the existing funding mechanism (for example, user fees or general funds) adequate for funding the BMP, or does a new mechanism need to be developed (such as a utility fund)? Additionally, the municipality may want to consider the cost to the community at large, although this may be a difficult task.

Rating score:

- 5 = Low-cost BMPs that can be funded with the existing municipal funding mechanism.
- 3 = Moderate-cost BMPs that will require an adjustment to the city's funding mechanism for support.
- 1 = High-cost BMP or a BMP that will require a major restructuring of the municipal funding mechanism.

There are a few points to remember about selection processes:

- Have several people or a stormwater committee conduct the selection independently to get a broad perspective on the relative merits of each BMP and to help reach consensus.
- The validity and accuracy of any scoring system is only as good as the available information.
- Keep the selection system as simple as possible and use "best professional judgment" to interpret and conduct a reality check on the total scores. Differences of a few points in the total score are probably not significant.
- The final rankings may be used to plan and prioritize the stormwater management program. For example, those BMPs with the highest scores may be implemented in the first year of a new program, while low-scoring BMPs may need time for development, relegating their implementation to later years or to further study.
- The exercise of working through this selection will provide the necessary data to promote the stormwater program to other departments, political leaders, regulatory agencies, and the public.

PUBLIC EDUCATION AND PARTICIPATION

Public education and participation, like an ordinance or piece of equipment, is not so much a BMP as it is a method by which to implement BMPs. The Clean Water Act and the 1990 stormwater regulations require public participation and the establishment of public education programs. This section highlights the importance of integrating elements of public education and participation to a municipality's overall plan for urban runoff quality management. Public education and participation are vital components of many of the individual source control BMPs that follow in this chapter.

A public education and participation plan provides the municipality with a strategy for educating its employees, the public, and businesses about the importance of protecting stormwater from improper use, storage, and disposal of pollutants. Municipal employees must be trained, especially those who work in departments not directly related to stormwater but whose actions affect stormwater. Residents must become aware that a variety of hazardous products are used in the home and that their improper use and disposal can pollute stormwater. Businesses, particularly smaller ones that may not be regulated by federal, state, or local regulations, must be informed of ways to reduce their potential to pollute stormwater.

The specific public education and participation aspects of each of the source controls are highlighted in the sections for each BMP discussed in this chapter. The focus of this section includes the overall objectives and approaches for ensuring public involvement in local stormwater management programs.

OBJECTIVES. The public education and participation plan should be based on five objectives:

- Promote a clear identification and understanding of the problem and the solutions;
- Identify responsible parties and efforts to date;
- Promote community ownership of the problems and the solutions;
- Change behaviors; and
- Integrate public feedback to program implementation.

APPROACH. The approach to public education and participation is detailed in the following bulleted items:

- Pattern a new program after the many established programs from municipalities around the state and country. Whenever possible, integrate stormwater public education and participation to existing programs from other departments at the municipality.
- Implement public education and participation as a coordinated campaign in which each message is related to the last.
- Present a clear, consistent message and image to the public regarding how they contribute to stormwater pollution and what they can do to reduce it.
- Stick to the program. There is a lag in the public's response to anything new, so it is important to stick with the message long enough to get the bulk of the audience. The point in time when municipal staff are ready to "move on" to another message is probably about the time that most of the audience is just starting to get the original message.
- Expand the definition of "public" to include small businesses that often possess the same limited levels of awareness of the problems, regulations, and solutions as the general public. As a result, small busi-

nesses need the same level of technical assistance (education) and participation in the process as the general public.

- Use a multimedia approach to reach the full range of audiences.
- Translate messages to the foreign languages of the community to reach the full spectrum of the populace and avoid misinterpretation of messages. Account for cultural differences in translating messages and concepts. Outreach in a non-English language is not just a matter of transcription.
- Create an awareness and identification of the local watershed.
- Involve focus or advisory groups in the development of a public education and participation plan. This will create a more effective plan and promote ownership of the plan by those involved.
- Use everyday language in all public pieces. Use outside reviewers to highlight and reduce the use of technical terminology, acronyms, and jargon.
- Make sure all statements have a sound, up-to-date technical basis. Do not contribute to the spread of misinformation.
- Break up complicated subjects into smaller, more simple concepts. Present these concepts to the public in a simplified and organized way to avoid "overloading" and confusing the audience.
- Choose quality over quantity. One good message or outreach piece is more effective than many poor attempts.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. Because most of the BMPs discussed in this publication require some public education and participation, a qualified public education specialist can be critical to the success of source control programs.

EXAMPLES OF EFFECTIVE PROGRAMS. There are a number of communities with effective public education and participation programs. The most proactive include the Alameda Countywide Clean Water Program, the City and County of San Francisco, the Santa Clara Valley Nonpoint Source Pollution Control Program, and the City of Palo Alto, California; the Municipality of Metropolitan Seattle (Metro), Washington; and the Unified Sewerage Agency of Washington County, Oregon. In addition, large businesses, such as utility companies, have used inserts in their bill mailings to educate their customers.

LAND-USE PLANNING AND MANAGEMENT

This BMP presents an important opportunity to reduce the pollutants in stormwater runoff by using a comprehensive planning process to control or prevent certain land-use activities in areas where water quality is sensitive to development. It is applicable to all types of land use and represents one of the most effective pollution prevention practices. Land-use planning and management are critical to watershed management.

APPROACH. The land-use planning process need not be complex. A basic schematic model involves six basic phases as follows:

- Phase 1—goals: clear-cut water quality goals are determined.
- Phase 2—study: activities of this phase are identifying planning area, gathering pertinent data, and writing a description of the planning area and its associated problems.
- Phase 3—analysis and synthesis: the water quality goals are determined and prioritized as they relate to land use.
- Phase 4—recommendations: future courses of action are developed to address the identified problems and needs.
- Phase 5—adoption: recommendations are presented to a political body for acceptance and implementation.
- Phase 6—implementation: recommendations adopted by the local government are implemented by the community.

COST CONSIDERATIONS. The majority of the cost for this BMP is associated with establishing a comprehensive land-use plan that addresses the quality of stormwater runoff after projects are completed.

REGULATORY CONSIDERATIONS. Ordinances typically are required to implement and enforce land-use plans, including those relating to stormwater runoff quality. Several federal initiatives influence land-use planning, including the National Environmental Policy Act, the Clean Water Act, and the Clean Air Act.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. Site plans or environmental impact documents for projects must be reviewed for compliance. Additional staff may be required to implement a site plan review and inspection program. Also, interdepartmental and decisionmaker cooperation is crucial.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. To gain the necessary support for land-use policies, public participation is a necessity. The public should be educated regarding the positive environmental effects of land-use management, including the improvement to stormwater runoff quality. To increase public awareness, public education materials should be as specific as possible about the effects of land-use policies on watersheds and water quality. Geographic information systems can be a dynamic and effective tool to illustrate water quality effects.

LIMITATIONS. Land-use planning and management frequently address sensitive public issues. Restrictions on certain land uses required to mitigate stormwater pollution may not be politically feasible. Zoning ordinances that are not reinforced by a comprehensive planning process typically are less effective because they are often applied illogically for pollution prevention and are more easily circumvented politically.

EXAMPLES OF EFFECTIVE PROGRAMS. The city of Austin, Texas, has chosen to manage the effects of new development in two fundamental ways: through treatment control requirements and through impervious area minimization requirements. The city of Olympia, Washington, studied the feasibility of a 20% reduction in impervious surfaces throughout northern Thurston County, Washington, and found the goal achievable through policy changes, new standards, and education. In Virginia, the Chesapeake Bay Preservation Act requires no net increase in pollutants in stormwater runoff from previously undeveloped sites. Runoff from redeveloped sites must contain 10% fewer pollutants than before redevelopment.

HOUSEKEEPING PRACTICES

The promotion of efficient and safe housekeeping practices (storage, use, cleanup, and disposal) when handling potentially harmful materials such as fertilizers, pesticides, cleaning solutions, paint products, automotive products, and swimming pool chemicals can be an effective source control BMP. Good housekeeping practices include storing hazardous products securely, safely, and in original containers; reading and following product instructions; working in well-ventilated areas; and properly disposing of products.

Related information is provided in source control BMPs for safer alternative products, household hazardous waste collection, used oil recycling, and spill prevention and cleanup.

APPROACH. The following housekeeping practices may be effective:

- Pattern a new program after the many established programs from municipalities around the state and country. Integrate this BMP as much as possible with existing programs in the municipality.
- This BMP involves three key audiences: municipal employees, the general public, and small businesses.
- Implement this BMP in conjunction with the safer alternative products BMPs.

COST CONSIDERATIONS. The primary cost for good housekeeping practices is for staff time. More information follows under the heading Administrative and Staffing Considerations.

REGULATORY CONSIDERATIONS. There are no additional regulatory requirements to this BMP. Existing regulations already require municipalities to properly store, use, and dispose of hazardous materials and waste. This source control also focuses on materials and waste that may not be hazardous in the regulatory sense but are deleterious to water quality and organisms. Housekeeping practices of the general public are addressed through education rather than regulation.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. Staff are needed to train municipal employees and coordinate public education efforts. Municipal employees who handle potentially harmful materials should be trained in good housekeeping practices.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. Public awareness is a key to this BMP. The continued use or switch to good housekeeping practices is a behavior, and behavior is based on awareness.

LIMITATIONS. There are no major limitations to this BMP.

EXAMPLES OF EFFECTIVE PROGRAMS. There are a number of communities with effective programs. The most proactive include Santa Clara County, the city of Palo Alto, and the city and county of San Francisco, California, and the Municipality of Metropolitan Seattle (Metro), Washington. These programs are characterized by high-profile, comprehensive efforts to reach all audiences (that is, the general public, small businesses, and agency employees) using a variety of tools.

SAFER ALTERNATIVE PRODUCTS

Promoting the use of less harmful products can reduce the amount of toxic and deleterious substances that enter stormwater and ultimately reach receiving waters. Alternatives exist for most product classes, including fertilizers, pesticides, cleaning solutions, and automotive and paint products. There are natural alternatives to most garden products and less toxic alternatives to home and automotive repair products.

Related information is provided in source control BMPs for housekeeping practices, household hazardous waste collection, used oil recycling, and spill prevention and cleanup.

APPROACH. Pattern a new program after the many established programs from municipalities around the country. Integrate this BMP as much as possible with existing programs at the municipality. This BMP has three key audiences: municipal employees, the general public, and small businesses. Implement this BMP in conjunction with the housekeeping practices BMP.

COST CONSIDERATIONS. The primary cost of this BMP is for staff time. More information is available in the following sections.

REGULATORY CONSIDERATIONS. This BMP has no additional regulatory requirements. Existing regulations already require municipalities to reduce the use of hazardous materials. Safer alternatives for use by the general public are presented through education rather than required by regulation.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. Staff are needed to educate municipal employees and coordinate public education efforts. Municipal employees who handle potentially harmful materials should be trained in the use of safer alternatives. Purchasing departments should be encouraged to procure less hazardous materials.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. Awareness is the key to this BMP. It promotes a willingness to try alternatives and modify old behaviors.

LIMITATIONS. Safer alternative products may not be available, suitable, or effective in every case.

EXAMPLES OF EFFECTIVE PROGRAMS. There are a number of communities with effective programs promoting safer alternative products. The most proactive include Santa Clara County, the city of Palo Alto, and the city and county of San Francisco, California, and the Municipality of Metropolitan Seattle (Metro), Washington. The Bio-Integral Resource Center in Berkeley, California, conducts research and produces brochures and a newsletter on integrated pest management.

MATERIAL STORAGE CONTROL

Material storage controls can prevent or reduce the discharge of pollutants to stormwater from material delivery and storage areas. This can be done by reducing the storage of hazardous materials on site, storing materials in a designated area, installing secondary containment, conducting regular inspections, and training employees and subcontractors.

This BMP primarily concerns material delivery and storage for municipal and commercial operations. For material storage related to the general public (for example, the storage of pesticides), refer to the Housekeeping Practices section of this chapter.

APPROACH. The key is to design and maintain material storage areas that reduce exposure to stormwater by

- Storing materials inside or under cover on paved surfaces;
- Using secondary containment, where needed;
- Minimizing storage and handling of hazardous materials; and
- Inspecting storage areas regularly.

Keep an ample supply of spill cleanup materials near the storage area.

COST CONSIDERATIONS. Costs will vary depending on the size of the facility and the necessary controls.

REGULATORY CONSIDERATIONS. The storage of reactive, ignitable, or flammable liquids must comply with the Uniform Fire Code and the National Electric Code. The storage of reactive, ignitable, or flammable liquids and chemicals is regulated by Superfund Amendments and Reauthorization Act Title III, in excess of the minimum quantities set forth in the act.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. Accurate and up-to-date inventories should be kept of all stored materials. Employees should be well trained in proper material storage. Employee education is paramount for successful BMP implementation.

LIMITATIONS. Storage sheds often must meet building and fire code requirements.

VEHICLE-USE REDUCTION

Reducing the discharge of pollutants to stormwater from vehicle use can be achieved by highlighting the stormwater effects from vehicle emissions, promoting the benefits to stormwater of alternative transportation, and integrating initiatives with existing or emerging regulations and programs.

APPROACH. The following practices may be successful in implementing vehicle-use reduction BMPs:

- Build alliances with air quality agencies to identify common challenges and opportunities.
- Integrate this BMP as much as possible with efforts being developed and implemented by government agencies and businesses to reduce vehicle use and improve air quality, including the designation of high-occupancy vehicle or carpool lanes in most major cities in America. Integration will help avoid redundant or conflicting programs and will be more effective and efficient.

- Establish trip reduction programs at government offices or large businesses.

COST CONSIDERATIONS. The primary cost is for staff time.

REGULATORY CONSIDERATIONS. Support efforts to pass reasonable regulations at the state and local level (land-use plans and zoning ordinances) aimed at reducing vehicle use and developing transit-oriented communities. Also, support development of regional governing bodies to address the issue in a comprehensive way.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. This BMP requires at least one staff person to track, review, and comment on emerging legislation and programs.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. Educate the public and municipal employees about the water quality benefits of reduced vehicle use. Also, help coordinate public participation in ride-sharing programs.

LIMITATIONS. The limitations for this BMP include

- The possible lack of cooperation and integration between departments and programs, and
- The fact that the use of alternative transportation may be dependent on its convenience and relative cost.

STORM DRAIN SYSTEM SIGNS

Stenciling of the storm drain system (inlets, catch basins, channels, and creeks) with prohibitive language and graphic icons discourages the illegal dumping of unwanted materials.

APPROACH. Create a volunteer workforce to stencil storm drain inlets, and use municipal staff to erect signs near drainage channels and creeks. Enlist the aid of city code enforcement staff to stencil curb inlets that show signs of being used for dumping.

COST CONSIDERATIONS. The following bulleted items should be considered for this BMP:

- A volunteer workforce serves to lower program cost.
- Stenciling kits require procurement of durable and disposable items.
- The storage and maintenance of stenciling kits requires planning.

- The program should aid in the cataloging of the storm drain system.

REGULATORY CONSIDERATIONS. Develop, implement, and enforce an ordinance that requires inlets, catch basins, channels, and creeks to be fitted with antidumping, pollution prevention signs.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. The primary staff demand is for program setup to provide marketing and training. Ongoing/follow-up staff time is minimal because of volunteer services. A minimum of two persons is required for stenciling in high-traffic areas and commercial and industrial zones with appropriate safety measures in use (for example, reflective vests, flag person, and signage). Additional staff may be required at program headquarters for emergencies or to answer questions.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. Promote volunteer services (individual and business) through radio, television, and mail-out campaigns. Encourage public reporting of improper waste disposal by a hotline number stenciled onto the storm drain inlet. Training sessions of approximately 10 to 15 minutes will cover stenciling procedures, including how to stencil, recordkeeping, and problem drain notation. Also, consider proper health and safety protocols (such as the buddy system, traffic, and health concerns).

LIMITATIONS. The following limitations may apply.

- Private property access limits stenciling to publicly owned areas.
- This program is dependent on volunteer response.
- Storm drain inlets that are physically blocked will be missed or require follow-up.
- High-traffic, commercial, or industrial zones will be the responsibility of city staff.

EXAMPLES OF EFFECTIVE PROGRAMS. The city of Palo Alto, California, has a combined volunteer/contractor program that greatly facilitates storm drain stenciling. The city used the Conservation Corps to paint approximately 75% (2 000) of its storm drains, leaving the 25% (700) of its drains in more residential areas to be done by volunteers. This strategy speeds up the stenciling, reduces the city's liability, supports a worthwhile program, and still allows plenty of storm drains for volunteers.

The Association of Bay Area Governments in Oakland, California, has sponsored a nine-county stenciling effort on Earth Day since 1992. This association has up-to-date information on stencil and program development.

The city of Huntington Beach, California, has a stencil that includes the municipal code section number for illegal dumping to facilitate incident reporting and enforcement.

HOUSEHOLD HAZARDOUS WASTE COLLECTION

Household hazardous wastes (HHWs) are defined as waste materials that typically are found in homes or similar sources and exhibit characteristics such as corrosivity, ignitability, reactivity, and/or toxicity or are listed as hazardous materials by the U.S. Environmental Protection Agency (U.S. EPA). This source control also focuses on the collection of deleterious chemicals that sometimes are disposed of in a manner that threatens stormwater quality.

APPROACH. Integrate efforts with a municipal solid waste program that likely has already been established. Optimize collection method(s) (for example, permanent, periodic, mobile, and curbside) and frequency (for example, monthly and quarterly) based on waste type, community characteristics, existing programs, and budgets.

COST CONSIDERATIONS. The following cost considerations may apply to this BMP:

- Both collection and disposal can be expensive and are partly a function of the frequency of collection, which depends on the collection program implemented.
- Trained operators are required.
- Laboratory and detection equipment are necessary.
- Extensive recordkeeping is required including dates, types, and quantities.
- Many communities have deferred HHW programs because of the high cost.
- Cost depends on the type of program chosen and available disposal costs.

REGULATORY CONSIDERATIONS. Federal regulations (such as the Resource Conservation and Recovery Act; the Superfund Amendments and Reauthorization Act; and the Comprehensive Environmental Response, Compensation, and Liability Act) and state regulations regarding the disposal of hazardous waste apply to this BMP. Local ordinances to discourage improper disposal may be necessary. Municipalities may be required to have HHW elements within their integrated waste management plans.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. This BMP may require a minimum of six highly trained persons per collection site or event to handle traffic, waste drop-off, characterization, and disposal.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS.
The following considerations may be applicable for this BMP:

- Educate the public about hazardous materials in the home and consequences of improper use or disposal.
- Identify and promote the use of nonhazardous alternatives.
- Identify proper storage and disposal methods.
- Promote HHW reuse and recycling.
- Promote participation in local HHW collection programs.
- Distribute posters, handouts, and educational efforts aimed at local schools.
- Use public service announcements on local television, radio, and newspapers.
- Try utility bill inserts.
- Make video or slide presentations to community organizations.
- Develop a "speakers bureau" made up of local environmental professionals and recycling experts.

LIMITATIONS. This BMP maybe limited to areas with convenient access to hazardous waste disposal facilities and recycling facilities because of the cost associated with transport. This BMP can be a high-cost option compared to other source controls. There are significant liability issues involved with the collection, handling, and disposal of household hazardous waste.

EXAMPLES OF EFFECTIVE PROGRAMS. There are a number of communities, using a variety of approaches, with established and effective HHW collection programs. Seattle/King County, Washington, uses a mobile collection program that was initiated in 1989. One of the oldest (1988) and most convenient permanent collection centers in the country is in San Francisco, California. The Regional Water Quality Control Plant in Palo Alto, California, hosts a periodic program on the first Saturday morning of each month.

USED OIL RECYCLING

Used oil recycling is a responsible alternative to improper disposal practices, such as dumping oil in the sanitary sewer or storm drain system, applying oil to roads for dust control, placing used oil and filters in the trash for landfill disposal, or simply pouring used oil on the ground.

APPROACH. The following approaches may be effective for used oil recycling:

- Integrate efforts with a municipal solid waste program that likely has already been established.

- Set up a municipal collection center funded by the city.
- Contract out the collection and hauling of used oil to a private hauler or recycler.
- Use the automobile service industry (for example, service stations and fast-oil-change businesses) for the collection of used oil.
- Work with automotive parts supply stores and their parking lots, where consumers often change their automotive fluids improperly.

COST CONSIDERATIONS. A collection facility or curbside collection may result in significant costs. Using commercial locations (such as automobile service stations and fast-oil-change businesses) as collection points eliminates hauling and recycling costs for a municipality.

Staffing costs are minimal when using commercial locations as collection points; staffing costs are higher if the city performs collection services.

REGULATORY CONSIDERATIONS. Some states have enacted legislation requiring the state agency to pay a recycling incentive to curbside collection programs and certified used oil collection centers. Municipalities must comply with all applicable state and federal regulations regarding storage, handling, and transport of petroleum products. The municipality may be required to have a used oil recycling element within its integrated waste management plan.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. Staffing requirements are minimal if collection and recycling are contracted out to a used oil hauler or recycler or required at commercial locations.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. Create procedures for collection, such as collection locations and schedules, acceptable containers, and maximum amounts accepted. Promote public participation through the use of posters, handouts, brochures, and announcements in the print and broadcast media; provide a list of commercial recyclers. Also, develop incentive programs (such as a return deposit) for commercial locations and used oil haulers or recyclers.

LIMITATIONS. The availability of reliable, licensed used oil haulers and recyclers may be limited. The program requires frequent public education/notification messages. The used oil/hazardous waste separation requirement under federal law may also be a limitation. Meeting zoning, fire, and health and safety laws associated with collecting used oil may not be possible at all locations.

EXAMPLES OF EFFECTIVE PROGRAMS. There are numerous locations throughout the country that accept used oil. As is the case with HHW, communities have used different methods to collect and recycle used oil. Examples of effective programs include the permanent Household Hazardous

Waste Collection Facility in San Francisco, California, and curbside collection programs in Sacramento and Palo Alto, California. Statewide programs include California Integrated Waste Management Boards's program in which businesses that accept used oil from the public are listed as "Certified Oil Collection Centers" and receive payment for those collections. Another nationally recognized used oil program is Project R.O.S.E. (Recycled Oil Saves Energy), operated by the University of Alabama and funded by the Science, Technology, and Energy Division of the Alabama Department of Economic and Community Affairs.

VEHICLE SPILL CONTROL

Methods for preventing or reducing the discharge of pollutants to stormwater from vehicle leaks and spills include reducing the chance for spills by preventive maintenance, stopping the source of spills, containing and cleaning up spills, properly disposing of spill materials, and training employees. This BMP covers only prevention and cleanup of spills from vehicles; it does not contain information on underground storage tanks.

APPROACH. Vehicles will leak and spill fluids. The key is to reduce the frequency and severity of leaks and spills and, when they do occur, prevent or reduce the environmental effects. The following approaches to vehicle spill control may be effective:

- Perform fluid removal and changes inside or under cover on paved surfaces.
- Properly store hazardous materials and waste.
- Have spill cleanup supplies readily available.
- Clean up spills and leaks immediately.
- Use dry cleanup methods.
- Prepare a written contingency plan between local agencies that outlines responsibilities for major spills from tanker trucks.

COST CONSIDERATIONS. The prevention of leaks and spills is inexpensive. Treatment and disposal of contaminated soil or water can be expensive. Keep ample supplies of spill control and cleanup materials at municipal facilities, near storage and maintenance areas. Also, update spill cleanup materials as changes occur in the types of chemicals stored on site.

REGULATORY CONSIDERATIONS. The federal government and most states have specific laws concerning oil, oil filters, and batteries.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. This BMP has no significant administrative or staffing requirements. Training is crucial to reduce the frequency, severity, and effects of leaks and spills.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. The following considerations may be useful for vehicle spill control:

- Encourage the general public to regularly inspect and maintain their vehicles.
- Educate car repair shops to identify leaks and advise the vehicle owner.

LIMITATIONS. For larger spills, a private spill cleanup company or hazardous materials team may be necessary.

EXAMPLES OF EFFECTIVE PROGRAMS. Typically, more advanced HHW and used oil collection programs include educational outreach to do-it-yourselfers (DIYs) who do their own oil changes. Using state grant funds, San Mateo County, California, developed a DIY program that links used oil disposal with stormwater quality. The Santa Clara Valley and Alameda countywide stormwater programs joined the Palo Alto Regional Water Quality Control Plant to develop and distribute "Keeping It All in Tune," a car care brochure in multiple languages for DIYs.

ABOVEGROUND TANK SPILL CONTROL

Prevention or reduction of the discharge of pollutants to stormwater from aboveground storage tanks can be done by installing safeguards against accidental releases, installing secondary containment, conducting regular inspections, and training employees in standard operating procedures and spill cleanup techniques.

APPROACH. Integrate efforts with existing aboveground petroleum storage tank programs through the local fire and health departments and with area business emergency response plans through the city, county, or fire district. Use engineering safeguards to reduce the chance for spills. Perform regular maintenance. Also, keep ample supplies of spill control and cleanup materials at municipal facilities. Update spill cleanup materials as changes occur in the types of chemicals stored on site.

COST CONSIDERATIONS. Costs will vary depending on the size of the facility and the necessary controls.

REGULATORY CONSIDERATIONS. Consider requiring smaller secondary containment areas (less than 60 m [200 sq ft]) to be connected to the sanitary sewer and prohibiting any hard connections to the storm drain.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. This BMP has no significant administrative or staffing requirements. However, employees should be trained in spill prevention and cleanup.

LIMITATIONS. For larger spills, a private spill cleanup company or hazardous materials team may be necessary.

ILLEGAL DUMPING CONTROL

The use of measures to detect, correct, and enforce against the illegal dumping of pollutants in gutters and streets and into the storm drain system and creeks can have a significant effect on stormwater quality. This BMP includes controls of indirect sources (for example, overwatering after pesticide use on a lawn) and direct sources.

The remedial focus of this BMP contrasts with the preventive focus of the material disposal and recycling BMPs in this chapter. Illegal discharges through physical connections are addressed in the section on illicit connection BMPs.

APPROACH. Public awareness is the key to this BMP. Train municipal employees and educate the general public to recognize and report illegal dumping. Deputize municipal staff with the authority to write environmental tickets. Establish a system for tracking incidents. Consider indirect sources to be as important and typical, if not more so, than direct sources.

COST CONSIDERATIONS. The primary cost is for staff time. The cost depends on how aggressively a program is implemented. Additionally, a database is useful for defining and tracking the magnitude of the problem.

REGULATORY CONSIDERATIONS. Municipal codes should include sections prohibiting the discharge of soil, debris, refuse, hazardous wastes, and other pollutants to the storm sewer system. State laws may authorize the confiscation or impoundment of vehicles involved in illegal dumping.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. This BMP requires technical staff to detect and investigate illegal dumping violations and coordinate public education. Legal staff members are required to pursue prosecution. The training of technical staff in identifying and documenting illegal dumping incidents is also required.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. Educate the public about antidumping ordinances (fold into existing household hazardous waste program). Awareness of the issue accomplishes two things: the receiver of the information understands the issue and, therefore, is unlikely to cause a problem, and the public's awareness often helps detect other violations.

LIMITATIONS. The elimination of illegal dumping depends on the availability, convenience, and cost of alternative means of disposal. Some communities encourage homeowners and commercial establishments to rake yard or green waste into the street for pickup. For the most part, the general public does not know when they are using the storm drain system, which leads to a large volume of indirect discharges.

STREET CLEANING

Some reduction in the discharge of pollutants to stormwater from street surfaces can be accomplished by conducting street cleaning on a regular basis.

APPROACH. The following approaches may be effective in implementing and maintaining the street-cleaning BMP:

- Prioritize cleaning to use the most sophisticated sweepers, at the highest frequency, and in areas with the highest pollutant loading.
- Optimize cleaning frequency based on interevent times (for example, the dry period between storms).
- Increase sweeping frequency just before the rainy season.
- Keep in mind that proper maintenance and operation of sweepers greatly increases their efficiency.
- Keep accurate operation logs to track program.

COST CONSIDERATIONS. Any street-cleaning program for water quality improvement requires a significant capital and O & M budget. Sweeper costs range from $65 000 to $120 000 per machine, depending on the type. There is a definite cost–benefit relationship between increased sweeping efficiency/frequency and pollutant removal that a municipality should understand before making significant changes to its existing street-sweeping program.

REGULATORY CONSIDERATIONS. Densely populated areas or heavily used streets may require parking regulations to clear streets for cleaning.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. The following considerations may apply to the street-cleaning BMP:

- Sweeper operators and maintenance, supervisory, and administrative personnel are required.
- Traffic control officers may be required to enforce parking restrictions.

- Skillful design of cleaning routes is required for a program to be productive.
- Arrangements must be made for disposal of collected wastes.
- Operators must be trained in proper sweeper operation.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. The general public should be educated about the need to obey parking restrictions and participate by using litter receptacles to reduce street litter.

LIMITATIONS. The following limitations may apply to this BMP:

- No currently available conventional sweeper is effective at removing oil and grease.
- Mechanical sweepers are not effective at removing fine sediment.
- Parked cars are the primary obstacles to effective street sweeping.
- Effectiveness may also be limited by street condition, traffic congestion, presence of construction projects, climatic conditions, and condition of curbs.

EXAMPLES OF EFFECTIVE PROGRAMS. In San Francisco, California, 90% of the streets are swept at least once per week, and some sections are swept two to three times per week. San Francisco is also converting as much of its fleet as possible to vacuum sweepers. The effects of these actions are less clear in separate sewer areas, but there are examples of other effective programs. These include the city of Beverly Hills, California, which sweeps all streets in the commercial district six times per week and all streets in the residential area at least once per week.

CATCH BASIN CLEANING

Catch basin and stormwater inlet maintenance should be done on a regular basis to remove pollutants, reduce high pollutant concentrations during the first flush of storms, prevent clogging of the downstream conveyance system, and restore the catch basin's sediment-trapping capacity.

APPROACH. Catch basins should be cleaned regularly enough to reduce the possibility of sediment and pollutant loading from the flushing effect of stormwater inflow. A catch basin that becomes a source rather than a sink for sediments is not being cleaned frequently enough. Prioritize maintenance to clean catch basins and inlets in areas with the highest pollutant loading and in areas near sensitive water bodies. Keep accurate operation logs to track the program.

COST CONSIDERATIONS. A catch basin cleaning program requires a significant capital and O & M budget because of the typically large number of catch basins in any given area and the high cost of labor and specialized equipment to do the work. Except for small communities, with relatively few catch basins that may be cleaned manually, most municipalities will require mechanical cleaners such as eductors, vacuums, or bucket loaders.

REGULATORY CONSIDERATIONS. There are no regulatory requirements for this BMP. Municipal codes should include sections prohibiting the disposal of soil, debris, refuse, hazardous waste, and other pollutants into the storm sewer system.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. The following administrative and staffing considerations may apply to this BMP:

- Two-person teams are required to clean catch basins with vacuum trucks.
- Arrangements must be made for the proper disposal of collected wastes.
- Crews must be trained in proper maintenance, including recordkeeping, disposal, and safety procedures.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. For this BMP to be successful, educate contractors (cement, masonry, painting) and utility employees (telephone, cable, gas, and electric) about proper waste disposal.

LIMITATIONS. The metal content of the decant and solids cleaned from a catch basin should be periodically tested to determine if the decant violates limits for disposal to the wastewater treatment plant or if the solids would be classified as a hazardous waste.

VEGETATION CONTROLS

Vegetation control typically involves a combination of mechanical methods and careful application of chemicals (herbicides). Mechanical vegetation methods are discussed herein; vegetation control by herbicides is addressed in the housekeeping practices BMP described earlier in this chapter. Mechanical vegetation control includes leaving existing vegetation, cutting less frequently, hand cutting, planting low-maintenance vegetation, collecting and properly disposing of clippings and cuttings, and educating employees and the public.

APPROACH. The following are areas of concern:

- Steep slopes,
- Vegetated drainage channels,

- Creeks,
- Areas adjacent to catch basins, and
- Detention/retention basins.

These areas are of less concern to stormwater quality:

- Flat or relatively flat vegetated areas,
- Areas not adjacent to drainage structures, and
- Areas screened from drainage structures by vegetation.

COST CONSIDERATIONS. Additional costs will result from upgrading certain mowing equipment for bagging and hiring additional laborers involved in cutting by hand and picking up clippings.

REGULATORY CONSIDERATIONS. Local municipal antidumping ordinances can be used to ensure that when vegetation is controlled by cutting or removal the waste is disposed of properly. Grading ordinances often prescribe controls and limits on exposure of soil after removal of vegetation. In an effort to meet solid waste reduction goals, many municipalities require or encourage composting yard waste instead of landfill disposal.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. Additional labor may be needed to hand cut and pick up clippings from areas where mechanical cutting and collection are not practical.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. Educate the public about careful use of or alternatives to herbicides, proper disposal of clippings and cuttings, and the effect of erosion from exposed soil.

LIMITATIONS. The public may not find existing, natural, or low-maintenance vegetation as attractive or desirable as ornamental or higher maintenance vegetation in some situations.

STORM DRAIN FLUSHING

A storm drain is "flushed" with water to suspend and remove deposited materials. Flushing is particularly beneficial for storm drain pipes with grades too flat to be self-cleansing. Flushing helps ensure pipes convey design flow and removes pollutants from the storm drain system.

APPROACH. Locate reaches of storm drain with deposit problems and develop a flushing schedule that keeps the pipe clear of excessive buildup. Also, consider flushing portions of the storm drain system upstream of the problem area, including gutters and streets, as a preventive measure and an opportunity to remove more pollutants (assuming the collection system is sufficient).

COST CONSIDERATIONS. Unless flushing is done to a dry or wet detention area or the sanitary sewer, the collection of liquid and sediments may be costly in terms of pollutant removal benefits.

The following equipment may be required:

- Water source (water tank truck, fire hydrant),
- Sediment collector (evacuator/vacuum truck, dredge),
- Inflatable bladders to block flow from exiting pipe, or
- Sediment and turbidity containment and treatment equipment, if flushing to an open channel.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. With storm drain flushing, the following considerations should be noted:

- Two-person teams are needed for routine sediment removal and flush water collection.
- Equipment operators are required.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. If large-scale flushing activities are undertaken, local residents should be informed in advance. The public should be educated about the purpose of storm drains and the problems created by illegal dumping.

LIMITATIONS. These limitations may apply:

- Flushing is most effective in small-diameter pipes.
- The availability of sufficient water to do the job must be ensured.
- Personnel may have difficulty finding a downstream area to collect sediments.
- Flushing requires liquid/sediment disposal.
- The disposal of flushed effluent to the sanitary sewer may be prohibited in some areas because of inflow capacity and water quality concerns of the local wastewater treatment plant.

ROADWAY AND BRIDGE MAINTENANCE

Methods to prevent or reduce the discharge of pollutants to stormwater from roadway and bridge maintenance include paving as little area as possible, designing bridges to collect and convey stormwater, using measures to prevent

R0017489

runon and runoff, properly disposing of maintenance wastes, and training employees and subcontractors.

APPROACH. Address stormwater pollution from roadway and bridge maintenance on a site-specific basis. The disposition and subsequent magnitude of pollutants found in road and bridge runoff is variable and affected by climate, surrounding land use, roadway or bridge design, traffic volume, and frequency and severity of accidental spills.

COST CONSIDERATIONS. This BMP is typically low in cost. Additionally, keep ample supplies of drip pans or absorbent materials on site.

REGULATORY CONSIDERATIONS. Consider requiring new bridges to incorporate treatment control BMPs to the design. For more information on treatment control BMPs, see Chapter 5 of this publication.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. This BMP has no significant administrative or staffing requirements. Inspect the activities of employees and subcontractors to ensure that measures to reduce the stormwater effects of roadway and bridge maintenance are being followed. Require engineering staff or consulting firms to address stormwater quality in new bridge designs or existing bridge retrofits.

LIMITATIONS. There are no significant limitations to this BMP.

EXAMPLES OF EFFECTIVE PROGRAMS. The county of Alameda, California, recently wrapped a 56-year old bridge with tarpaulins so that workers could remove lead paint without allowing toxics to fall into the local estuary or blow away in the wind.

DETENTION AND INFILTRATION DEVICE MAINTENANCE

Proper maintenance and sediment removal are required on both a routine and corrective basis to promote effective stormwater pollutant removal efficiencies for wet and dry detention pond and infiltration devices.

APPROACH. These approaches may be beneficial for a detention and infiltration device maintenance BMP:

- Remove silt after sufficient accumulation.
- Periodically clean accumulated sediment and silt from pretreatment inlets.

R0017490

- Infiltration device silt removal should occur when the infiltration rate drops below 13 mm (0.5 in.) per hour.
- Removal of accumulated paper, trash, and debris should occur at least every 6 months or as needed to prevent clogging of control devices.
- Vegetation growth should not be allowed to exceed approximately 4.5 m (18 in.) in height.
- Mow the slopes periodically and check for clogging, erosion, and tree growth on the embankment.
- Corrective maintenance may require more frequent attention.

COST CONSIDERATIONS. Frequent sediment removal is labor intensive and costly. Transport and disposal costs for waste material will vary proportionately with the volume of material. Disposal costs can be high if sediments have high levels of toxics. Other cost considerations are vehicles, dump trucks, bulldozers, backhoes, excavators, mowers, weed trimmers, sickles, machetes, shovels, rakes, and personal protective equipment (goggles, dust masks, coveralls, boots, and, gloves).

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. Two-person teams are needed for routine silt removal and excavation. A program manager is needed to track maintenance activities and provide field assistance. A staff team is needed for corrective maintenance activities. Training in appropriate excavation and maintenance procedures and proper waste disposal procedures is needed.

REGULATORY CONSIDERATIONS. Permits may be required by the U.S. Army Corps of Engineers, U.S. Fish and Wildlife Service, or state parks and wildlife agencies.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. It may be useful to create a public education campaign to explain the function of wet and dry detention pond and infiltration devices and their operational requirements for proper effectiveness. Also, encourage the public to report wet and dry detention pond and infiltration devices needing maintenance.

LIMITATIONS. Dredging sediments in a wet detention pond produces slurried waste that often exceeds the limits for acceptability used by many landfills. Frequent sediment removal is labor and cost intensive. Care should be taken when using monitoring wells so as not to provide a conduit to the unsaturated zone under basins, which might lead to groundwater contamination.

EXAMPLES OF EFFECTIVE PROGRAMS. Because of flat terrain and few water courses, the city of Fresno, California, built almost 100 stormwater retention/recharge basins to dispose of surface runoff and recharge an aquifer. Monitoring confirmed that a variety of organic and inorganic contaminants generated in the catchments are removed by sorption within the top 4 cm of sediment in the recharge basins, making these contaminants available for removal and disposal through routine maintenance. Monitoring results also show that contaminants have not degraded groundwater quality beneath the basins.

STORM CHANNEL AND CREEK MAINTENANCE

Reduction of pollutant levels in stormwater can be achieved by regularly removing illegally dumped items and material from storm drainage channels and creeks. Channel characteristics can be modified to enhance pollutant removal and hydraulic capacity.

APPROACH. The following approaches may be beneficial to storm channel and creek maintenance:

- Identify illegal dumping "hot" spots; conduct regular inspection and cleanup of hot spots and other storm drainage areas where illegal dumping and disposal occurs.
- Post "No Littering" signs with a phone number for reporting a dumping in progress.
- Adopt and enforce substantial penalties for illegal dumping and disposal.
- Modify storm channel characteristics to improve channel hydraulics, increase pollutant removals, and enhance channel and creek aesthetic and habitat value.
- Maintain accurate logs to evaluate materials removed and improvements made.
- Establish buffer zones along creeks.

COST CONSIDERATIONS. The following cost considerations may apply to this BMP:

- The purchase and installation of signs,
- The cost of vehicle(s) to haul illegally disposed items and material to landfills,
- The rental of heavy equipment to remove larger items (for example, car bodies) from channels,
- The purchase of landfill space to dispose of illegally dumped items and material, and
- Capital and maintenance costs for channel modifications.

REGULATORY CONSIDERATIONS. Regulatory considerations include the adoption of substantial penalties for illegal dumping and disposal.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. Larger municipalities should commit at least one full-time staff person; smaller municipalities should commit at least one part-time staff person. Additional staff can be added as needed. Staff will need training in channel maintenance and use of heavy equipment and training in the identification and handling of hazardous materials and wastes.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. The storm channel and creek maintenance BMP may require the following:

- Education on the need for proper disposal of refuse;
- Notification of penalties for illegal dumping and disposal; and
- Promotion of volunteer services to create litter collection groups (such as Adopt-a-Stream).

LIMITATIONS. Cleanup activities may create a slight disturbance for local aquatic species. Access to items and material on private property may be limited. Tradeoffs may exist between channel hydraulics and water quality habitat. Worker and public safety may be at risk in high-crime areas.

ILLICIT CONNECTION PREVENTION

Preventing unwarranted physical connections to the storm drain system from sanitary sewers and floor drains through regulation, regular inspection, testing, and education can remove a significant source of stormwater pollution.

APPROACH. The following steps are components of this BMP:

- Ensure that existing municipal building and plumbing codes prohibit physical connections of nonstormwater discharges to the storm drain system.
- Require visual inspection of new developments or redevelopments during the development phase.
- Develop documentation and recordkeeping protocols to track inspections and catalog the storm drain system.
- Use techniques such as zinc chloride smoke testing, fluorometric dye testing, and television camera inspection to verify physical connections.

COST CONSIDERATIONS. Zinc chloride smoke testing, fluorometric dye testing, and television camera inspection can be cost considerations. Also, there may be additional labor and equipment costs for verification of plumbing connections.

REGULATORY CONSIDERATIONS. Ensure that existing building and plumbing codes prohibit physical connection to the storm drain system of nonstormwater discharges, and establish penalties for such action. Implement procedures to inspect and verify that new construction development does not interface with the storm drain system.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. Building and plumbing inspectors must verify and document that inappropriate discharges are not allowed through connections to the storm drain system. Zinc chloride smoke testing, fluorometric dye testing, or television inspection may be necessary for the verification of illicit connections. Additional staff time is required for verification and documentation of proper connections to the storm drain system.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. Consider a community awareness program (using various media), targeting appropriate audiences (homeowners, businesses, and contractors) to warn against improper connections to the storm drain system and encourage public reporting of illegal connections through a community hot line telephone number. Notify community and local fire departments before testing with zinc chloride smoke testing and fluorometric dye testing in targeted areas.

LIMITATIONS. The following limitations may be applicable:

- Proper connections may be verified on date of inspection but could be altered afterwards by illicit connections.
- The cost for inspection equipment can be high.
- The removal of an illicit connection from the storm drain system to the sanitary sewer may require the approval of the local sewer authority.
- Improper physical connections to the storm drain system can occur in a number of ways, such as the overflow of crossconnects from sanitary sewers and floor drains from businesses such as auto shops and restaurants.

ILLICIT CONNECTION— DETECTION AND REMOVAL

Control procedures for the detection and removal of illegal connections from the storm drain conveyance system should be implemented to reduce or prevent unauthorized discharges to receiving waters. Procedures include field screening, follow-up testing, and complaint investigation.

APPROACH. The approach can involve any or all of the following:

- Field screening program;
- Sampling program, including beach sampling during dry weather;
- Fluorometric dye testing (suspected source testing);
- Zinc chloride smoke testing (suspected source testing);
- Television camera inspection;
- Physical inspection testing;
- Citizens' complaints on a community hotline to report suspected illegal connections; and
- Correction by plugging, disconnecting, or otherwise eliminating the discharge route.

COST CONSIDERATIONS. Considerations for this BMP can include program initialization costs for procuring necessary equipment and training. Explore the possibility of equipment sharing with municipal wastewater treatment departments.

Keep in mind that illegal connection location techniques can be labor and equipment intensive.

The following equipment may be necessary:

- Personal protective equipment such as hardhats, boots, plastic gloves, and coveralls;
- Sampling containers and equipment;
- U.S. EPA-recommended stormwater test kits;
- Fluorometric dye and fluorometer (optional);
- Zinc chloride smoke and dispersal fans;
- Pipeline television camera with videocassette recorder;
- Self-contained breathing apparatus;
- Oxygen/toxic/combustible gas detection meters;
- Vehicle(s); and
- Aboveground communication.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. Administrative and staffing considerations include the following items:

- Two-person teams are required for field screening and sampling activities.
- Larger staff teams (at least one additional member) are required for fluorometric dye and zinc chloride smoke testing or television camera inspection and physical inspection with confined space entry.
- Staffing a community hotline telephone number may be necessary.

- Program coordination is needed for emergencies and recordkeeping.
- Health and safety training required by the Occupational Safety and Health Administration (OSHA) (29 CFR 1910.120), with annual refresher training, may be needed.
- Confined space entry training (federal OSHA 29 CFR 1910.146) may be needed as required by OSHA.
- Procedural training (field screening, sampling, dye or smoke testing, television or other inspection, source training, and corrective and mitigative techniques) of staff may be necessary.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. Encourage public reporting of improper waste disposal or evidence of illicit connections. Community notification, including notifying the local fire department, is required in targeted areas for zinc chloride smoke testing.

LIMITATIONS. Local ordinances must specify access rights to private property to allow for field screening and testing along storm drain system right-of-ways. Additionally, local ordinances may require that the source be suspected for guaranteed rights of entry to conduct verification testing.

EXAMPLES OF EFFECTIVE PROGRAMS. The Fort Worth, Texas, Drainage Water Pollution Control Program is action-oriented and designed to monitor and correct nonstormwater discharges in urban storm drain systems using innovative screening, tracing, and corrective techniques. Staff requirements are one full-time staff member equivalent per year (three part-time staff members are used from other programs) for a total labor cost of $30 000. Equipment, supplies, and services range from $20 000 to $50 000 per year, depending on the level of activity and co-utilization of city services. Costs could be higher for initial start-up and equipment purchases. If another program were unable to use existing city staff, additional costs would be expected.

LEAKING SANITARY SEWER CONTROL

Control procedures should be implemented for identifying, repairing, and remediating infiltration, inflow, and wet weather overflows from sanitary sewers to the storm drain conveyance system. Procedures include field screening, follow-up testing, and compliance investigation.

APPROACH. The approaches listed below may be useful for sanitary sewer control:

- Identify dry weather infiltration and inflow first. Wet weather overflow connections are difficult to locate.
- Locate wet weather overflows and leaking sanitary sewers using conventional source identification techniques, including
  - — Field screening program (including field analytical testing),
  - — Fluorometric dye testing,
  - — Zinc chloride smoke testing,
  - — Television camera inspection,
  - — Nessler reagent test kits for ammonia detection, and
  - — Citizens' hot line for reporting of wet weather sanitary overflows.

COST CONSIDERATIONS. Cost considerations include the following:

- There may be program costs for procuring necessary equipment and training.
- Departmental cooperation is recommended for sharing or borrowing staff resources and equipment from municipal wastewater treatment departments. Infiltration, inflow, and wet weather overflows from sanitary sewers can be labor and equipment intensive to locate.
- The following equipment may be needed:
  - — Personal protective equipment (such as hardhats, boots, plastic gloves, and coveralls);
  - — Sampling containers/equipment;
  - — Stormwater test kits (recommended by U.S. EPA);
  - — Zinc chloride smoke and dispersal fans;
  - — Fluorometric dye and fluorometer (optional);
  - — Pipeline television camera with videocassette recorder;
  - — Self-contained breathing apparatus;
  - — Oxygen/toxic/combustible gas detection meters;
  - — Vehicle(s), and
  - — Aboveground communication.

ADMINISTRATIVE AND STAFFING CONSIDERATIONS. Two-person teams are needed to perform field screening and associated sampling. Larger teams (at least one additional member) are required for fluorometric dye testing, zinc chloride smoke testing, television camera inspection, and physical inspection with confined space entry. Program coordination is required for handling emergencies and recordkeeping.

Health and safety training (required by OSHA, 29 CFR 1910.129), with annual refresher training, is needed. Confined space entry training (federal OSHA, 29 CFR 1910.146) may be needed. Also, procedural training (field screening, sampling, dye/smoke testing, television or other inspection, source training, and corrective/mitigative techniques) of staff may be needed.

PUBLIC EDUCATION AND PARTICIPATION CONSIDERATIONS. Consider a public awareness program through local media to identify the problem of sanitary infiltration, inflow, and wet weather overflows to the storm sewer system.

Establish a community response hotline for reporting observed sanitary infiltration or leaks and wet weather sanitary overflows to the storm sewer system. Finally, remember that public notification, including notifying the local fire department, is required for fluorometric dye or zinc chloride smoke testing in targeted areas.

LIMITATIONS. The local ordinance must specify access rights to private property to allow for field screening and testing along storm drain system right-of-ways. Also, local ordinances may require that the source be suspected for guaranteed rights of entry to conduct verification testing.

EXAMPLES OF EFFECTIVE PROGRAMS. The city of Stockton, California, Municipal Stormwater Discharge Management Program contains a comprehensive program element created to prevent, detect, and eliminate illegal connections to storm sewers.

The city of Fort Worth, Texas, Drainage Water Pollution Control Program is an action-oriented program designed for corrective measures using innovative biotoxicity testing. Staffing requirements are one full-time person per year for a total labor cost of $30 000. Equipment, supplies, and services costs approximately $50 000 per year.

The selection and successful design of selected passive treatment controls often called structural best management practices (BMPs) for stormwater quality enhancement is the cornerstone of stormwater management in newly developing and redeveloping urban areas. It is also possible sometimes to retrofit BMPs in already developed parts of a municipality; however, the costs can be high.

Overall, structural BMPs are most applicable to developing and redeveloping areas. The cost effectiveness of each control has to be considered and measured against the actual environmental benefits realized. One price of urban society is the indelible mark it leaves on the ecology of urban areas. Through the use of structural BMPs, these effects can be, in part, mitigated as new urban centers develop and the old ones redevelop or expand. It is unlikely, however, that all effects of urbanization can be eliminated.

This chapter will address how several known structural BMPs can be evaluated for use at any given site and, after being selected, how each can be sized and configured. The control practices described are those that have a known performance track record. Other practices and types of controls are evolving and may eventually prove to be superior to those described herein. However, this manual is limited to established state of practice at the time of publication. New and evolving practices will be the topic of future updates. Structural BMPs require commitment of resources for initial construction and continuing operation and maintenance. Despite the development of technology mandates that new concepts be tried and tested, the bottom line is that whatever controls are used, the designer, the client, and often the regulator need to have sufficient confidence in their performance before attempting to use them. As a result, the testing of newer concepts is sometimes better left to government agencies or risk takers in industry, who can provide the new design technologies to the stormwater professionals.

This chapter will cover the following topics:

- Stormwater quality hydrology;
- Selection of treatment facilities (that is, structural BMPs);
- Operation and maintenance needs of treatment facilities;
- Swales and filter strips;
- Stormwater infiltration, including minimized connected impervious area;
- Extended detention;
- Retention (wet) ponds;
- Constructed wetlands;
- Media filtration; and
- Oil and water separators.

The above topics can be better understood when the reader has a thorough understanding of the municipal system and its relationship to stormwater quality and quantity management infrastructure. Issues such as community needs and fiscal strength, local priorities and preferences, regulatory demands, other infrastructure needs and fiscal demands, and many other's are part of the equation. Also, this chapter is most useful if the reader has become familiar with the topics discussed in Chapters 1 through 4.

Ideally, structural BMPs should be a part of the treatment train discussed in Chapter 4—namely, source control BMPs. Good housekeeping measures need to be practiced to ensure adequate performance and longevity of structural facilities. For example, if erosion control during construction is not being rigorously practiced within the catchment being served by the structural control facility, the facility will probably be rendered inoperative in a short time. For example, a detention basin, a retention pond, or a constructed wetland will fill with sediment, and infiltration devices will fail. Thus, without implementing source erosion controls, the investment in the structural facilities will be lost, and expensive rehabilitative maintenance or reconstruction of these facilities will then be needed to return them to a working condition.

It is best that the practices described in Chapter 5 be selected through a comprehensive planning process. This could involve systemwide simulation of rainfall and runoff processes, preferably using a continuous model. Some of the selection of practices actually may be based on monitoring, bioassessments, or the understanding of effects on the receiving systems. Chapters 1, 2, and 3 address all of those topics and form the foundation and an introduction to all topics covered in this chapter.

HYDROLOGY FOR THE MANAGEMENT OF STORMWATER QUALITY

In 1990, the U.S. Environmental Protection Agency (U.S. EPA) promulgated National Pollution Discharge Elimination System regulations regarding the permitting of stormwater discharges from municipal storm sewer systems. These rules require the municipalities to reduce the pollutants in urban runoff to the maximum extent practicable (MEP). The definition of MEP for the control of stormwater pollutant discharges has focused primarily on the application of economically achievable management practices. Because stormwater runoff rates and volumes vary from storm to storm, the statistical probabilities of runoff events and their management have to be considered in the development of practices to meet the MEP goal. It is paramount that the hydrology of urban runoff be examined within this context.

The type and size of storm runoff events to use for the design of runoff treatment systems need to be examined. "Treatment systems" are those measures that are often referred to in the literature as "BMPs." Among these are swales; buffer strips; infiltration basins and percolation trenches; extended detention basins; "wet" ponds that retain some or all of one event's runoff until it is displaced by the runoff from a subsequent event; media filters; and a variety of other devices and facilities. Guidelines for the design of these types of facilities can be found in this chapter and elsewhere (Livingston *et al.,* 1988; Roesner *et al.,* 1989; Schueler, 1987; Urbonas and Roesner [Eds.], 1986; and Urbonas and Stahre, 1993).

LONG-TERM RAINFALL CHARACTERISTICS. Hydrologists typically look at the infrequent events: either large storms for drainage and flood protection or drought periods for water supply development. But what characteristics are representative of the storms that produce most rainfall on a long-term basis?

Figure 5.1 presents the cumulative probability distribution of daily precipitation data for 40 years at Orlando, Florida, and Cincinnati, Ohio. These data have been screened to include only precipitation events 2.5 mm (0.1 in.) or greater in Cincinnati and 1.5 mm (0.06 in.) or greater in Orlando. Cumulative occurrence probabilities were computed for values ranging from 2.5 to 51 mm (0.1 to 2.0 in.).

Examination of Figure 5.1 reveals most of the daily values to be less than 25 mm (1 in.) in total depths. In Orlando, which averages 1 270 mm (52 in.) of rainfall per year, 90% of these events produce less than 36 mm (1.4 in.) of rainfall. In Cincinnati, which has 1 016 mm (40 in.) per year of precipitation, 90% of the events produce less than 20 mm (0.8 in.) of rainfall. By contrast,

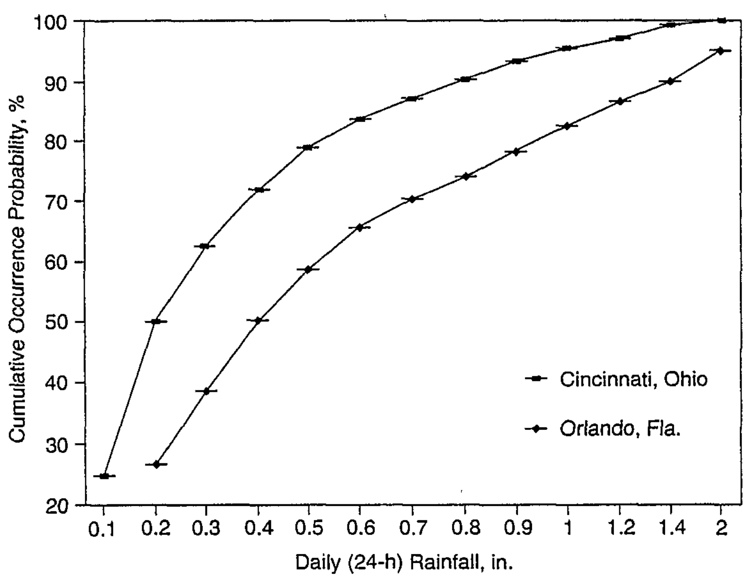

Figure 5.1 **Cumulative probability distribution of daily precipitation for two cities in the U.S. (in. $\times$ 25.4 = mm) (Roesner *et al.*, 1991).**

R0017507

the 2-year, 24-hour storm produces precipitation of 127 mm (5.0 in.) in Orlando and 74 mm (2.9 in.) in Cincinnati. This suggests that capturing and treating runoff from "smaller" storms should capture a large percentage of the runoff events and runoff volume that occur from the urban landscape. Also, a water quality facility capable of capturing these smaller storms would also capture the "first flush" portion of the larger, infrequently occurring runoff events.

CAPTURE OF STORMWATER RUNOFF. To illustrate the terms "smaller" and "most" discussed earlier, long-term simulations of runoff were examined for six U.S. cities by Roesner *et al.* (1991) using the Storage, Treatment, Overflow, Runoff Model (STORM). The six cities were Butte, Montana; Chattanooga, Tennessee; Cincinnati, Ohio; Detroit, Michigan; San Francisco, California; and Tucson, Arizona. The Storage, Treatment, Overflow, Runoff Model is a simplified hydrologic model that translates a time series of hourly rainfall to runoff then routes the runoff through detention storage.

Hourly precipitation records of 40 to 60 years were processed by Roesner *et al.* (1991) for a variety of detention basin sizes for the six cities. These simulations were performed using the characteristics of the most typically occurring urban developments found in each city. Table 5.1 lists the average annual rainfall and the area-weighted runoff coefficient at each of the study watersheds. Runoff capture efficiencies of detention basins were tested using an outflow discharge rate that emptied or drained the design storage volume in 24 hours. This drawdown time was based on field study findings by Grizzard *et al.* (1986) in the Washington, D.C., area. They determined that a detention basin had to be designed to empty out a volume equal to the average runoff event's volume in no less than 24 hours to be an effective stormwater quality enhancement facility. The findings by Roesner *et al.* (1991) are illustrated in Figure 5.2.

One way to define a cost-effective basin size is to represent it as that which is located on the "knee of the curve" for capture efficiency. This "knee" is evident on the six curves in Figure 5.2. Urbonas *et al.* (1990) have

Table 5.1 Hydrologic parameters used at six study watersheds (Roesner *et al.*, 1991).

City	Average annual rainfall, in. (mm)	Runoff coefficient of study watershed
Butte, Montana	14.6 (371)	0.44
Chattanooga, Tennessee	29.5 (749)	0.63
Cincinnati, Ohio	39.9 (1 013)	0.50
Detroit, Michigan	35.0 (889)	0.47
San Francisco, California	19.3 (490)	0.65
Tucson, Arizona	11.6 (295)	0.50

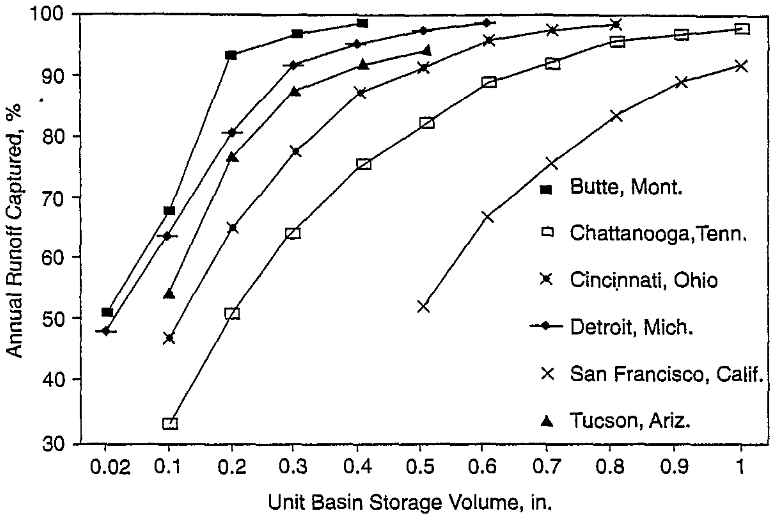

Figure 5.2 **Runoff capture rates versus unit storage volume at six study sites (Roesner *et al.*, 1991).**

defined this "knee" as the "optimized" capture volume and reported on a sensitivity study they performed relative to this volume for the Denver, Colorado, area. Later, Urbonas and Stahre (1993) redefined this "knee" as the "maximized" volume because it is the point at which rapidly diminishing returns in the number of runoff events captured begin to occur. For each of the six study watersheds previously described, the maximized storage volume values are listed in Table 5.2.

The sensitivity investigation by Urbonas *et al.* (1990) also estimated the average annual stormwater removal rates of total suspended sediments using the maximized volume as the surcharge storage above a permanent pool of a retention pond. Estimates of total suspended sediment removals were performed using the procedure reported by Driscoll (1983). Similarly, the runoff

Table 5.2 **Maximized unit storage volume at six study watersheds (Roesner *et al.,* 1991).**

City	Maximized storage volume[a]	
	in. (mm)	ac-ft/ac (m³/ha)
Butte, Montana	0.25 (6.4)	0.021 (63.5)
Chattanooga, Tennessee	0.50 (12.7)	0.042 (127)
Cincinnati, Ohio	0.40 (10.2)	0.033 (102)
Detroit, Michigan	0.30 (7.6)	0.025 (76.2)
San Francisco, California	0.80 (20.3)	0.067 (203)
Tucson, Arizona	0.30 (7.6)	0.025 (76.2)

[a] Based on the ratio of runoff volume captured from all storms.

Table 5.3 **Sensitivity of the best management practice capture volume in Denver, Colorado (Urbonas *et al.*, 1990).**

Capture volume to maximized volume ratio	Annual runoff volume captured, %	Number of storms completely captured	Average annual total suspended sediments removed, %
0.7	75	27	86
1.0	85	30	88
2.0	94	33	90

capture and total suspended sediment removal efficiencies were estimated for capture volumes equal to 70 and 200% of the maximized volume. These findings are summarized in Table 5.3.

Review of Table 5.3 shows that doubling of the maximized capture volume results in a very small increase in the total annual runoff volume captured and an insignificant increase in the average annual removal of total suspended sediments. When 70% of the maximized volume is used, only a moderate decrease occurs in the volume of runoff captured and an insignificant decrease in the annual total suspended sediment load removed. Based on these findings, the Denver, Colorado, municipal area adopted an 80th percentile runoff event (that is, 95% of the maximized event) as the basis for the sizing of stormwater quality BMPs. This 80th percentile runoff event is now considered by the municipalities in this semiarid region of the U.S. as cost effective for stormwater quality management and is viewed as the design event that achieves MEP definition under the Clean Water Act.

Although the MEP event is not clearly defined by the regulations, insight to the appropriate MEP design event can be gained by performing an analysis of local long-term hourly rainfall data similar to those reported in Tables 5.1 though 5.3. These analyses form a basis for making a rational decision in defining sizing criteria for various BMPs. As an example, the maximized unit runoff volume for a watershed in Denver, Colorado, with a runoff coefficient $C = 0.5$, is 7 mm (0.28 watershed in.), or 70 m^3/ha (0.023 ac-ft/ac). This compares well with the maximized storage volumes listed in Table 5.2 for Butte, Montana, and Tucson, Arizona—namely, the two semiarid communities on that list.

As can be seen from Figure 5.2 and Tables 5.2 and 5.3, most runoff-producing events occur from the predominant population of smaller storms, namely, less than 13 to 25 mm (0.5 to 1.0 in.) of precipitation. To be effective, stormwater quality management should be designed based on these smaller events. As a result, detention facilities, wetland basins, infiltration facilities, media filters, and possibly swales need to be sized to accommodate runoff volumes and flows from such storm events to maximize pollution control benefits in a cost-effective manner.

AN APPROACH FOR ESTIMATING STORMWATER QUALITY CAPTURE VOLUME. Estimating a Maximized Water Quality Capture Volume. Whenever local resources permit, the stormwater quality capture volume may best be found using continuous hydrologic simulation and local long-term hourly (or lesser time increment) precipitation records (see Chapter 3). However, it is possible to obtain a first-order estimate of the needed capture volume using simplified procedures that target the most typically occurring population of runoff events.

Figure 5.3 contains a map of the contiguous 48 states of the U.S. with the mean annual runoff-producing rainfall depths superimposed (Driscoll *et al.*, 1989). These mean depths are based on a 6-hour interevent time to define a new storm event and a minimum depth of 2.5 mm (0.10 in.) of precipitation for a storm to produce incipient runoff. After an extensive analysis of a number of long-term precipitation records from different meteorological regions of the U.S., Guo and Urbonas (1995) found simple regression equations to relate the mean precipitation depths in Figure 5.3 to "maximized" water quality runoff capture volumes (that is, the knee of the cumulative probability curve).

The analytical procedure was based on a simple transformation of each storm's volume of precipitation to a runoff volume using a coefficient of runoff. To help with this transformation, a third-order regression equation, Equation 5.1 (Urbonas *et al.,* 1990), was derived using data from more than 60 urban watersheds (U.S. EPA, 1983). Because the data were collected nationwide over a 2-year period, Equation 5.1 should have broad applicability in the U.S. for smaller storm events.

$$C = 0.858i^3 - 0.78i^2 + 0.774i + 0.04 \tag{5.1}$$

Where

C = runoff coefficient, and
i = watershed imperviousness ratio; namely, percent total imperviousness divided by 100.

Equation 5.2 relates mean precipitation depth taken from Figure 5.3 to the "maximized" detention volume. The coefficients listed in Table 5.4 are based on an analysis of long-term data from seven precipitation gauging sites located in different meteorological regions of the U.S. The correlation of determination coefficient, r^2, has a range of 0.80 to 0.97, which implies a strong level of reliability.

$$P_0 = (a \cdot C) \cdot P_6 \tag{5.2}$$

Where

P_0 = maximized detention volume determined using either the event capture ratio or the volume capture ratio as its basis, watershed in. (mm);

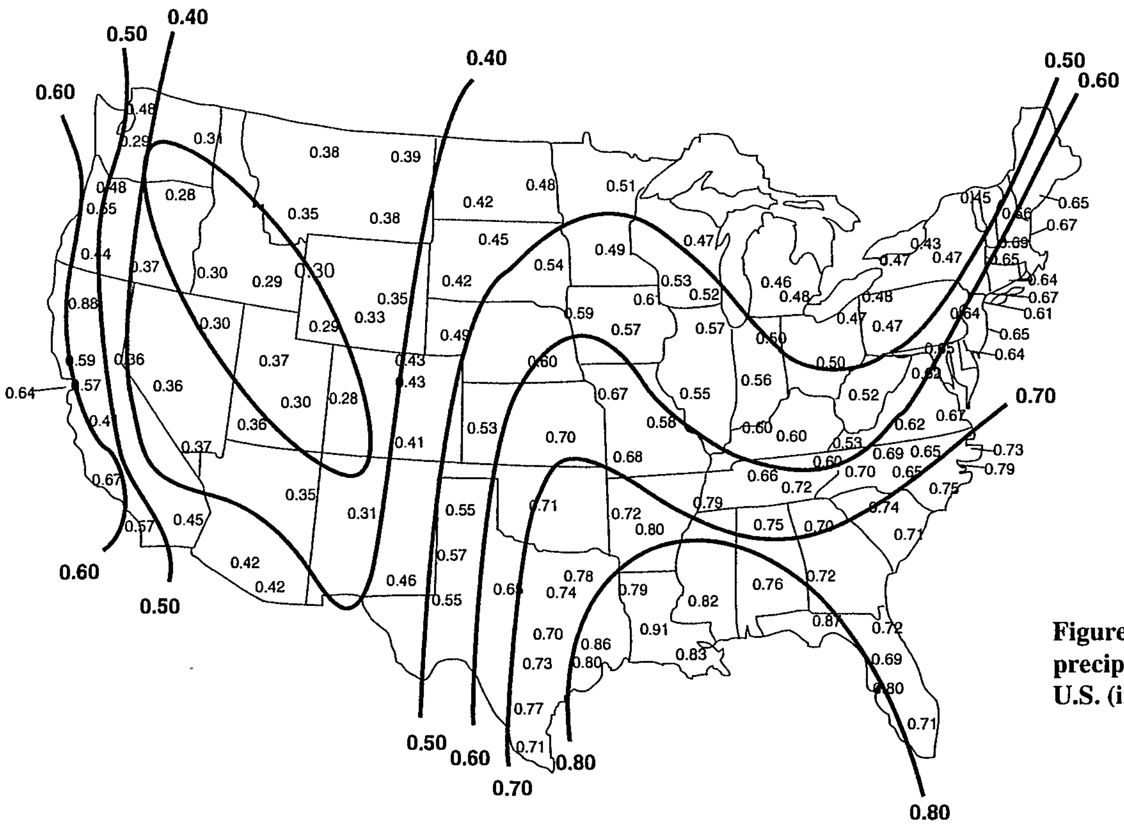

Figure 5.3 Mean storm precipitation depth in the U.S. (in. [in. × 25.4 = mm]).

Table 5.4 **Values of coefficient a in Equation 5.2 for finding the maximized detention storage volume (Guo and Urbonas, 1995).[a]**

		Drain time of capture volume		
		12 hours	**24 hours**	**48 hours**
Event capture ratio	a =	1.109	1.299	1.545
	r^2 =	0.97	0.91	0.85
Volume capture ratio	a =	1.312	1.582	1.963
	r^2 =	0.80	0.93	0.85

[a] Approximately 85th percentile runoff event (range 82 to 88%).

a = regression constant from least-squares analysis;
C = watershed runoff coefficient; and
P_6 = mean storm precipitation volume, watershed in. (mm).

Table 5.4 lists the maximized detention volume/mean precipitation ratios based on either the ratio of the total number of storm runoff events captured or the fraction of the total stormwater runoff volume from a catchment. These can be used to estimate the annual average maximized detention volume at any given site. All that is needed is the watershed's runoff coefficient and its mean annual precipitation.

The actual size of the runoff event to target for water quality enhancement should be based on the evaluation of local hydrology and water quality needs. However, examination of Table 5.3 indicates that the use of larger detention volumes does not significantly improve the average annual removal of total suspended sediments or other settleable constituents. It is likely that an extended detention volume equal to a volume between the runoff from a mean precipitation event taken from Figure 5.3 and the maximized event obtained using Equation 5.2 will provide the optimum-sized and most cost-effective BMP facility. A BMP sized to capture such a volume will also capture the leading edge (that is, first flush) of the runoff hydrograph resulting from larger storms.

Runoff volumes that exceed the design detention volume either bypass the facility or receive less efficient treatment than do the smaller volume storms and have only a minimal net effect on the detention basin's performance. If, however, the design volume is larger and has an outlet to drain it in the same amount of time as the smaller basin, the smallest runoff events will be detained only for a brief interval by the larger outlet. Analysis of long-term precipitation records in the U.S. shows that small events always seem to have the greatest preponderance. As a result, oversizing the detention can cause the most frequent runoff events to receive less treatment than provided by properly designed smaller basins.

Example of a Water Quality Capture Volume Estimate. It is desired to estimate the maximized storage volume for a 223-ha (550-ac) watershed that has 40% of its area covered by impervious surfaces. Assume that this site is located in Houston, Texas (that is, the largest storm region of the U.S.). The detention basin needs to be sized and designed to drain its water quality capture volume in no fewer than 24 hours. Substituting a value of 0.40 (that is 40/100) for the variable I in Equation 5.1 yields a runoff coefficient C = 0.30. Using Figure 5.3 we find the mean storm precipitation depth in Houston: $P6$ = 20.3 mm (0.8 in.). From Table 5.4 we find the coefficient a = 1.299 for the 24-hour drain time. Thus, the maximized detention volume is calculated as follows:

$$P_0 = (1.299 \cdot C) = 0.39 \text{ in. } (0.026 \text{ ac-ft/ac})$$

$$P_0 = 7.9 \text{ mm } (79 \text{ m}^3\text{/ha})$$

The volume of an extended detention basin for this 223-ha (550-ac) watershed needs to be 17 600 m^3 (14.3 ac-ft). It is recommended that this volume be increased by at least 20% to account for the loss in volume from sediment accumulation. The final design then can show a total volume for the basin of 21 200 m^3 (17.2 ac-ft) with an outlet designed to empty out the bottom 17 600 m^3 (14.3 ac-ft) of this volume in approximately 24 hours.

SELECTION OF TREATMENT CONTROL BEST MANAGEMENT PRACTICES

As discussed in Chapter 4, the selection of particular stormwater quality controls (that is, BMPs) is often decided by considerations other than technical issues. These issues, among others, include

- Federal, state, and local regulations;
- Real and perceived receiving water problems;
- Beneficial uses of receiving waters to be protected;
- The cost of the BMPs being considered;
- Subjective and sometimes arbitrary acceptance by the regulators or community groups; and
- Watershed studies.

While reduction of pollutants in stormwater discharges to the MEP is the statutory requirement of the stormwater regulations, the real goal has to be the reduction of effects to urban stormwater runoff on the receiving water. The cost of the BMP is always a major consideration. Recognize that no single BMP is as effective as a "train" (that is series) of practices and controls. The selection and design of structural BMPs is the topic of Chapter 5.

POINTS TO CONSIDER WHEN SELECTING BEST MANAGEMENT PRACTICES. There are several general points that need to be considered whenever selecting and designing any treatment control. The following discussion highlights some of these points.

Source Control. As a first step in the treatment train, source controls should be considered before the more expensive treatment controls are selected. These good housekeeping practices can help to reduce the amount of pollutants coming into contact with stormwater and being transported to receiving waters. Because the structural treatment controls will not remove all pollutants, the use of source controls will supplement, and thereby increase, the efficiency of the total stormwater quality management system.

Local Climate. Many treatment controls rely on the "wet" state where vegetation, biological processes, or the presence of a permanent pool can enhance pollutant removals. In arid and semiarid areas such as the southwest, such treatment controls are not practical unless water losses resulting from evapotranspiration are replaced in part or in total by municipal or irrigation supplies. The state of practice today has emerged from the observations of facilities in climates where the rainfall season is coincident with the growth of vegetation and evaporation losses of pond surfaces. The designer needs to make certain that controls being selected are compatible with local climatology and availability of water to keep these controls functional. For example, a wetland basin in a semiarid climate may not have sufficient water to keep the wetland species alive or healthy unless supplemental irrigation water is provided, which may make this choice economically impractical.

Design Storm Size. The use of design storms for the sizing of water quality controls are not the same as those selected for the design of facilities to control runoff rates for urban drainage. For example, the effect on a receiving water by the pollutant washoff of a 25-year storm is inconsequential compared to the potential hydraulic damage. Of concern for water quality control are the small, frequent events, smaller than the 1-year storm, that carry the vast majority of runoff and pollutants. Stormwater quality hydrology is discussed earlier in this chapter.

Soil Erosion. The success of any BMP control facility is influenced by how rigorously soil erosion protection is being practiced in the tributary watershed. In arid and semiarid climates, native vegetation can be sparse, allowing for greater erosion during storms than in more moist climates. But, irrigated lawns in semiarid climates tend to reduce excessive erosion after the land becomes urbanized. Regardless of climate, higher-than-normal sediment loads will affect the performance and maintenance requirements of treatment controls.

Stormwater Pollutant Characteristics. Potential pollutants can be either in particulate or dissolved form. Some BMPs will only remove particulates. Other BMPs, such as wet ponds, are purported to remove dissolved constituents and particulates. However, the data confirming this premise are limited and sometimes contradictory. Whenever specific pollutants are of particular concern, the designer needs to select treatment controls that are most likely to best remove the constituents of greatest concern.

Multiple Uses. Consider the opportunities for integrating stormwater treatment needs with other community objectives. These include active and passive recreation, enhancing or protecting wildlife habitat, flood control, and groundwater recharge.

Maintenance. None of the treatment controls described herein requires active operation of equipment such as mechanical or chemical systems. Nonetheless, they need to be maintained to operate as designed. The operation and maintenance needs of each facility have to be addressed because their life-cycle costs should be considered.

Physical and Environmental Factors. The most typical physical and environmental factors that need to be considered in the selection of treatment controls are

- Slope—most BMPs are sensitive to the local terrain slope. Certain BMPs, such as swales and infiltration basins, cannot be used in steep terrain, while others, such as detention basins and filters, can be made to work on most reasonably sized land parcels.
- Area required—most BMPs require considerable land area. Some can be placed underground at considerable expense.
- Soil—infiltration systems must be located on porous soils and subsoils. Vegetation requires good soils, while wet ponds require impermeable soils or lining.
- Water availability—the BMPs that rely on vegetation or a permanent water pool for pollutant removal require water, which has to be available in adequate quantity during dry seasons.
- Aesthetics and safety—where visible or accessible to the public, aesthetics and safety are of concern.
- Hydraulic head—some BMPs need a drop in water elevation (for example, an extended detention outlet), which is a site topography issue.
- Environmental side effects—the design process should consider mos-

quito breeding, groundwater contamination, opportunities for aquatic and wildlife habitat, and active and passive recreation.

Regardless of the above factors, in all cases the treatment controls to be used must be compatible with existing drainage or flood control objectives.

To assist the user with the selection of treatment control BMPs in a given watershed, the decision tree shown in Figure 5.4 was developed. This decision tree will lead to treatment control BMPs that are potentially applicable

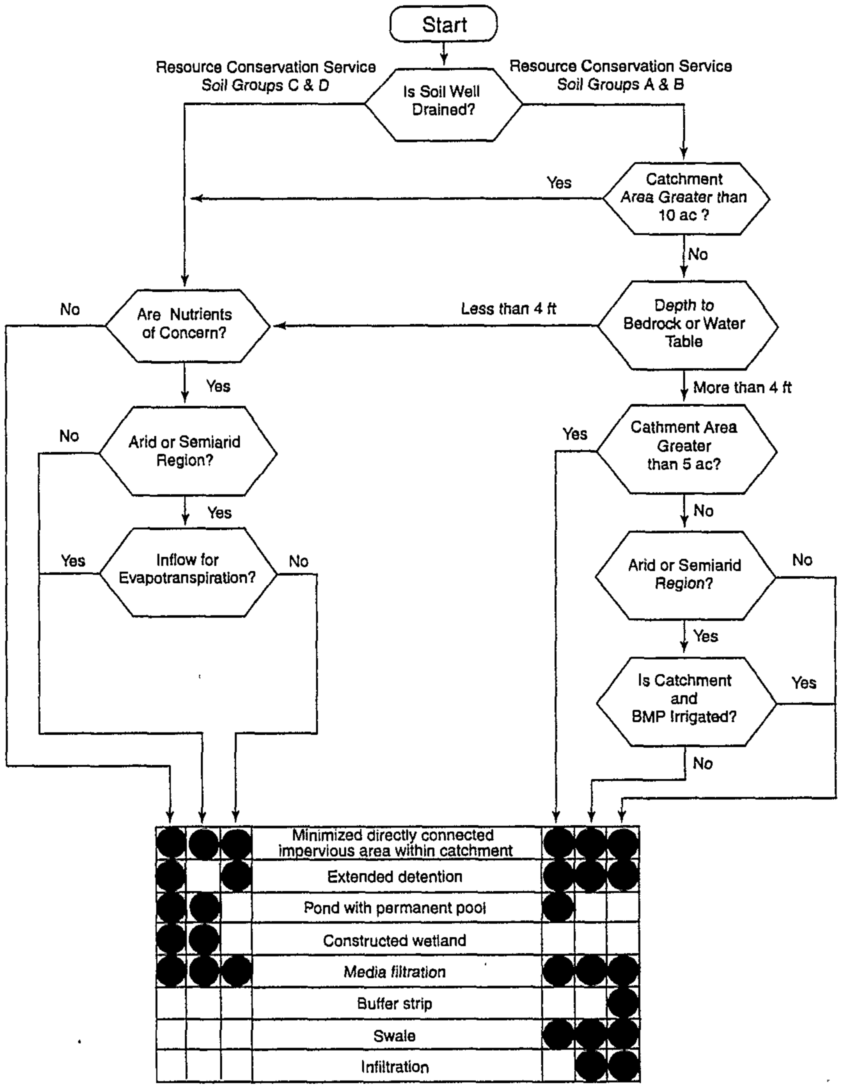

Figure 5.4 **Decision tree for identifying potential treatment controls (ac × 0.404 = ha; ft × 0.304 8 = m).**

R0017517

to a given site/region. Using the site characteristics and the design guidance for the BMPs contained in this chapter, potentially applicable BMPs can be designed and their cost can be estimated. Table 5.5 can then be filled out for the watershed(s) or pollutant(s) of concern to narrow the focus to the most cost-effective BMPs appropriate for the specific site and purpose.

On-Site Versus Regional Controls. Some structural BMPs can be used either as stand-alone, on-site treatment controls or as part of regional controls for stormwater quality enhancement, while others can only be used on site. Swales, filter strips, infiltration and percolation, media filters, oil and water separators, and other controls are not applicable for large-scale, regional controls. Extended detention, wet retention ponds, and wetland basins can be used as regional controls serving large catchments and, if local conditions permit, can also be used as on-site controls. Because large numbers of on-site controls, sometimes exceeding several hundred or even several thousand, can eventually be installed within an urban watershed, it becomes difficult to reliably quantify their cumulative hydrologic effects on receiving waters. Water quality, however, can be improved by both regional and on-site controls, although the degree of improvement for the accumulated effect in numerous on-site controls is less predictable than with regional controls.

Large numbers of on-site controls complicate the quality assurance during design and construction because they are probably designed by a variety of individuals and are constructed by a variety of different contractors under varying degrees of quality control. Further, they may be maintained and operated in a variety of ways impossible to anticipate or to control.

A simple example illustrates what a municipality faces with on-site controls. If the average size of a new land development is 8 ha (20 ac) and only one type of a treatment BMP is installed for each new development, there will be 14 on-site controls per km^2 (32 on-site controls per sq mile). A city or county with more than 260 km^2 (100 sq miles) area would then have to keep track of 3 200 controls. It is not unusual for an on-site control to serve less than 4 ha (10 ac) or even 2 ha (5 ac), and the outlet diameters become small. To ensure maintenance for a large number of such controls, a municipality needs a large, properly trained staff to keep track of their condition. Merely mandating that these facilities be built when land development occurs is not enough.

A more logical approach is to use regional controls serving 32 to 240 ha (80 to 600 ac). This eliminates the uncertainty of large numbers of on-site controls. Large sites need multistage outlets to detain small events. As the watershed becomes larger and the outlets become bigger, runoff from small storms experience little "throttling." To compensate for this, multistage outlets can be used to release small runoff events in 12 to 24 hours and empty the total water quality capture volume in 24 to 48 hours.

Wiegand *et al.* (1989) estimated that regional controls are more cost effective because fewer controls are less expensive to build and maintain than

Table 5.5 **Form for evaluating structural best management practices.**

Worksheet for evaluation of treatment control best management practices								
Pollutant of concern	Best management practice	Area of application, ha	Annual pollutant removed, kg/a	Annual capital costs,[a] $/a	Annual operation and maintenance cost,[b] $/a	Annual administrative costs, $/a	Total annual costs, $/a	Removal cost[c] $/kg

[a] Annual capital costs based on a 20-year design period.
[b] Annual administration costs are best determined by a given community after a citywide program is established.
[c] Removal costs are in units of ($/a)/(kg/a) = $/kg.

a large number of on-site controls. Another benefit is that water quality control outlets are larger and are easier to design, build, operate, and maintain. Also, because regional controls are often maintained by some form of public body, they are more likely to receive ongoing maintenance.

Regional controls can provide treatment for existing and new developments and typically will capture all runoff from public streets, which is often missed by on-site controls. Because regional controls cover large land areas, this permits other compatible uses such as recreation, wildlife habitat, or aesthetic open space to occur within their boundaries.

The two major disadvantages of regional controls are that they require advanced planning and up-front financing. Lack of financing early in the watershed's land development process, before sufficient developer contributions are available, can preclude their timely installation. The use of on-site controls often is the only practical institutional and political alternative.

Overview of Specific Treatment Controls. Treatment controls, often called structural BMPs, can occupy much land area. They often require flat side slopes for access, ease of maintenance, and public safety. Although vertical sides can be used to reduce the needed land area, safety fencing may be needed to reduce the owner's potential liability, which then affects the facility's aesthetics.

The most frequently used treatment controls include swales, buffer strips, infiltration basins and trenches, and extended detention basins and ponds.

SWALES. Swales are shallow sideslope channels with a relatively mild longitudinal slope, typically grassed or vegetated. They are designed for slow velocities during small storms, allowing opportunity for infiltration along the swale bottom and for the trapping of sediment and organic biosolids in the vegetative cover.

FILTER STRIPS. Sometimes called buffer strips, filter strips perform in a manner similar to swales but are not channels. These are mildly sloping vegetated surfaces that are located off, and abut, an impervious surface area. They are designed to slow the velocity of the runoff from the impervious area, increasing the opportunities for infiltration and the trapping of pollutants.

INFILTRATION BASINS AND PERCOLATION TRENCHES. These treatment controls capture runoff generated by small storms from small catchments and, when they work, provide good stormwater treatment by transferring surface runoff to the groundwater regime. This filters out suspended pollutants and provides other treatment processes before water returns to the surface system.

DETENTION CONTROLS. These include extended detention basins (dry), which drain out completely between storm events, and retention ponds (wet), which "retain" some or all of the storm runoff from a given event within its permanent pool until the next storm occurs. Detention basins remove pollutants primarily through sedimentation of solids, while retention ponds remove pollutants through sedimentation and through physical and biochemical processes in the permanent pool during the dry weather periods that follow. Typically, retention ponds are larger than detention basins and can be more efficient than detention basins in the removal of many constituents found in stormwater.

WETLAND BASINS. Wetland basins can be efficient stormwater quality treatment controls. Because of the regulatory protection of wetlands in the U.S., whatever their origin may be, wetland basins for stormwater treatment must be artificially created. Even so, federal or state regulatory agencies can assume control of these artificially "constructed" wetlands, requiring the owners to obtain permits before they can perform needed maintenance. Failure to obtain such permits can become a problem for the owner, individual, or organization performing mechanical cleaning, excavation, or dredging operations within these control treatment facilities.

MEDIA FILTRATION. These controls include sand filters with presettlement to avoid clogging. Other media mixtures of peat, sand, and compost mix and geotextiles are used but with mixed results.

OIL AND WATER SEPARATORS. These controls are designed to remove petroleum compounds, grease, sand, and grit. These devices are designed to remove floatable debris.

Robustness of Design Technology. High robustness of design implies that, when all of the design parameters are correctly defined and quantified, the design has a high probability of performing as intended. In other words, the design technology is well established and has undergone the test of time. Low robustness implies that there are many uncertainties in how the design will perform over time. In the definition used here, it is assumed that the facility will be properly operated and maintained over time as we currently understand its maintenance needs (which are not factors in judging design robustness).

Table 5.6 summarizes the collective opinion of senior professional engineers involved in the field of stormwater quality management about the design robustness of various structural stormwater quality controls. Some of these opinions acknowledge the dependence on local site-specific conditions, such as climates, geology, soil types, and nature of constituents. In some cases, the hydraulic design governs how reliable the design will be and how adequately it will perform. In those cases, even when water quality enhancement performance is known to be excellent when the facility functions properly, its ability to provide water quality enhancement cannot be ensured when its hydraulic design robustness is low. The reverse is also true; namely, a fa-

Table 5.6 Robustness of best management practice design technology.[a]

Type	Hydraulic design	Removal of constituents in stormwater: Total suspended sediments and solids	Dissolved	General Performance
Swale	Moderate-high	Low-moderate	None-low	Low
Buffer strip	Low-moderate	Low-moderate	None-low	Low
Infiltration basin	Moderate-high[a]	High	Moderate-high	Moderate
Percolation trench	Low-moderate[a]	High	Moderate-high	Moderate-high
Extended detention	High	Moderate-high	None-low	Moderate-high
Wet retention pond	High	High	Low-moderate	Moderate-high
Wetland	Moderate-high	Moderate-high	Low-moderate	Low-high[b]
Media filter	Low-moderate	Moderate-high	None-low	Low-moderate
Oil separator	Low-moderate	Low	None-low	Low
Catch basin inserts	Technology unknown	NA[d]	NA	NA
Monolithic porous pavement[b]	Low-moderate	Moderate-high	Low-high[c]	Low-moderate
Modular porous pavement[b]	Moderate-high	Low-high	Low-high[c]	Low-high[c]

[a] Weakest design aspect, hydraulic or constituent removal, governs overall design robustness.
[b] Robustness is site-specific and maintenance dependent.
[c] Low-moderate whenever designed with an underdrain and not intended for infiltration and moderate-high when site conditions permit infiltration.
[d] Not applicable.

cility that has high hydraulic reliability and low water quality enhancement predictability will have a low combined design robustness. In other words, the weakest design link governs the overall reliability of the design.

MAINTENANCE OF TREATMENT CONTROLS

Regular inspection and maintenance of treatment controls (that is, BMPs) are a necessity if these controls are to consistently perform up to expectations. Sediment and debris removal from inlets and outlets are the most important requirements. The following discussion presents an overview of maintenance requirements. Further information may be found in *Design and Construction of Urban Stormwater Management Systems* (ASCE and WEF, 1992). Detailed maintenance requirements for specific treatment BMPs can be found among the references listed in this chapter.

INSPECTIONS. Inspections should be performed at regular intervals to ensure that the BMP is operating as designed. Annual inspection should be considered, with additional inspections following storm events. For the inspection following a major storm, the inspector should visit the site at the end of the specified drawdown period to ensure that any detention or infiltration device is draining properly. Some inspections can be arranged to coincide with scheduled maintenance visits to reduce site visits and ascertain that maintenance activities are performed satisfactorily. Check for accumulations of debris and sediment at the inlets and outlets, and check side slopes for signs of erosion, settlement, slope failure, or vehicular damage. Check emergent vegetation zones to ensure that water levels are appropriate for vegetative growth, that acceptable survival rates are being maintained, and that vegetative cover is above acceptable limits.

ROUTINE MAINTENANCE. Routine or preventive maintenance refers to procedures that are performed on a regular basis to keep the BMP aesthetic and in proper working order. Routine maintenance should include debris removal, silt and sediment removal, and clearing of vegetation around flow control devices to prevent clogging. It is expected that silt removal will have to be performed every 5 to 15 years, as needed.

Routine maintenance also includes the maintenance of a healthy vegetative cover. Dead turf or other unhealthy vegetative areas will need to be replaced after being discovered.

NONROUTINE MAINTENANCE. Nonroutine or corrective maintenance refers to any rehabilitative activity that is not performed on a regular basis. This includes flow control structure replacement or the major replacement and cleaning of aquatic vegetation.

Erosion and Structural Repair. Areas of erosion and slope failure should be repaired and reseeded (or sodded) as soon as possible. Eroded areas near the inlet or outlet may also need to be lined with riprap.

Any major damage to inlet, outlet, or other structures should be repaired immediately. Delay in such repairs can invite structural failure the next time the facility is in operation. When that occurs, it may require total reconstruction of the structure.

Sediment Removal and Disposal. Although considered by some to be routine maintenance, silt and other sediment removal, with few exceptions, is anything but routine. First, it does not occur annually in most treatment facilities. Second, when it is done, it is typically a project that requires mechanized equipment, careful survey, transport and disposal of removed materials, and the reestablishment of the original design grades and sections of the BMP.

Sediment may need to be removed on a regular schedule but rarely on an annual basis. The only exceptions are certain types of oil and grit separators, media filters, and infiltration systems. For most treatment systems, the exact schedule will depend on the annual total suspended sediment load being removed by the facility and the size of the area on which it is being deposited.

Several field observations reported accumulation rates of 6 to 13 mm per year in retention ponds. This rate of accumulation has also been reported to be 10 to 100 times greater whenever construction activities take place in the tributary watershed, especially when effective erosion control practices are not used.

Equation 5.3 (Urbonas, 1994) can be used to estimate the average depth of sediment accumulation within almost any facility that removes total suspended sediments from stormwater:

$$V_P = 1.45 \cdot 10^{-6} \cdot \frac{h \cdot T_{SS} \cdot f_r}{R} \tag{5.3}$$

Where

V_P = average annual depth of bottom sediment deposit, mm;
h = average annual runoff depth from the watershed, mm;
T_{SS} = average annual concentration of total suspended sediments in runoff, mg/L;
f_r = fraction of TSS retained in pond; and
R = (pond's surface area)/(tributary watershed area) ratio.

As an example, estimate the annual accumulation rate within a retention pond with a surface area of 0.53 ha (1.3 ac), a tributary catchment of 223 ha (550 ac) with a runoff coefficient $C = 0.28$, an annual runoff-producing precipitation of 352 mm (12.8 in.), and an average concentration of $T_{SS} = 400$ mg/L in the runoff, of which the retained fraction in the pond is $f_r = 0.80$. First, find the annual runoff depth from the watershed—namely, $h = 0.28 \times 352$ mm $= 99$ mm. Then, the average annual accumulation of sediment is

$$V_P = 1.45 \cdot 10^{-6} \cdot \frac{99 \cdot 400 \cdot 0.80}{0.002\,4} = 19 \text{ mm (0.75 in./yr)}$$

If the pond's original design allowed for a total of 305 mm (12 in.) of sediment accumulation, the pond's bottom will need to be cleaned once every 18 years. This assumes that the bed load fraction is part of the reported TSS concentration and that there are no other sources of sediment, such as construction activities, being delivered to the ponds. Chances are that the actual accumulation rate will be somewhat higher and that more frequent cleanout will be needed.

Accumulation rates of heavy metals such as lead, zinc, copper, or other constituents may be a concern if such accumulations can create hazardous waste. If this is a concern, more frequent removal of sediments and periodic monitoring can be done to avoid these situations. Also, occasional core samples of pond or basin bottom will reveal if buildup of pollutants is occurring. If bottom sediment concentrations approach levels that would restrict disposal on site or in local landfills, site rehabilitation and total cleanout may be required.

Under existing U.S. EPA regulations (40 CFR Part 261), material cleaned from a detention pond should periodically be screened using the toxic characteristics leaching procedure (TCLP). This test should be carried out on accumulated sediment within the pond. If the sediment fails the test, it is subject to Resource Conservation and Recovery Act (RCRA) regulations and must be disposed of in an approved manner at a RCRA-approved facility. If the TCLP test is negative, sediments are subject to state and local solid waste disposal regulations.

If the material has been sufficiently dried to be a "workable material" and can pass a TCLP test, it can also be disposed of off site. This can be done at a landfill or as unclassified fill. However, sediments from any treatment facility can be nutrient-rich soils and, if other characteristics do not disqualify it, can be used in landscaping or as unclassified fill material. Disposing of accumulated sediment as fill or in landscaping avoids depleting landfill volume.

OTHER MAINTENANCE REQUIREMENTS. Mowing. Side slopes, embankments, emergency spillways, and other grassed areas of stormwater controls must be periodically mowed to prohibit woody growth and control weeds. More frequent mowing may be required in residential areas. Mowing can constitute the largest routine maintenance expense.

Debris and Litter Removal and Control. Debris and litter accumulate mostly near the inlet and outlet structures of stormwater controls and need to be removed during regular mowing operations. Particular attention should be paid to floatable debris that can eventually clog the outlet control structure or riser. Trash screens or trash racks can be strategically placed near inflow or outflow points to capture debris and assist with maintenance.

Litter and debris from illegal dumping should also be cleaned up on a regular basis, and an accurate log should be maintained of materials removed and improvements made. Controlling illegal dumping is difficult, but the posting of "no littering" or "no dumping" signs, with a phone number for reporting a violation in progress, may help. Adoption and enforcement of substantial penalties for illegal dumping and disposal could also be a deterrent.

Nuisance Control. Standing water or soggy conditions within a stormwater treatment control facility can create nuisance conditions for nearby residents. Odors, mosquitoes, weeds, and litter can all be potential problems in stormwater controls. However, wetland plants within a littoral zone of a retention pond (wet) provide a habitat for birds, predacious insects, and fish that serve as a natural check on mosquitoes. Also, regular maintenance to remove debris and ensure control structure functionality may also help control potential nuisance problems.

VEGETATED SWALES AND FILTER STRIPS

Biofilters consist primarily of vegetated swales and filter strips. Swales are shallow channels with flow depths often below the height of the vegetation that grows within them. Filter strips are vegetated flat surfaces over which water flows in a thin sheet. Planted vegetation can be turf grasses, emergent wetland, or high marsh plants. Some infiltration occurs through the underlying soil cover, but that is not the primary mode of treatment. Suspended solids are removed by filtering through the vegetation and settling. Dissolved constituents may also be removed through chemical or biological mechanisms mediated by the vegetation and the soil.

PLANNING CRITERIA AND GUIDELINES. Local governments and stormwater professionals should view biofilters as an element of the stormwater management infrastructure and as a part of the treatment train. For example, roadside ditches can be designed as biofilters and as landscaping amenities. Also, when land is limited, surrounding a pond with a biofilter will treat low flows before they enter the pond. Consider retrofitting biofilters in developed areas.

Effective biofiltration depends on proper design, construction, and maintenance. Also, local jurisdictions need to provide for access easements on private land for their inspection, monitoring, and maintenance, and they need to enforce long-term maintenance commitments by private parties to the control facilities owned by private parties.

Every effort should be made to prevent sediment-laden construction runoff, oil, and grease from entering biofilters. Catch basins, detention basins, presettling devices, and oil–water separators can be installed upstream of biofilters to help remove these materials before they reach the biofilter. Any of these devices or controls can improve the performance and the life of a biofilter.

DESIGN AND INSTALLATION CRITERIA AND GUIDELINES. Provisions Applying Equally to Swales and Filter Strips. It is important to maximize water contact with the biofilter vegetation and the soil surface. Graveled and coarse sandy soils are not desirable because they have difficulty sustaining vegetation. Heavy clay soils, materials toxic to vegetation, stones, and debris should also be avoided. When suitable, use on-site materials and scarify and till compacted soils before planting.

Vegetate biofilters uniformly with fine, turf-forming, water-resistant grasses. In arid and semiarid areas, supplemental irrigation will be needed to maintain healthy filter strips. Where biofilters intercept groundwater or where there is little slope for proper drainage, emergent herbaceous wetland vegetation is an acceptable planting alternative. Whenever possible, use vegetation native to the region. It is important to select grass and wetland species that work best for the region, climate, and native soils. Do not assume that information from other regions can be used at every site. Also, if wildlife habitat is being provided, select vegetation accordingly.

Use grass seed and mulch application rates specified by the supplier. If at all possible, do not use animal manure as an amendment and avoid using fertilizers. If fertilizer must be used, apply only the amount needed by the selected plants in the existing soil conditions and use a slow-release fertilizer. Establish grasses when natural moisture is adequate but irrigate if necessary. If wetland plants are used, they may need to be protected from predation with netting during establishment. If possible, divert runoff, other than necessary irrigation, during the period of vegetation establishment.

Vegetate upslope areas to prevent erosion. Use barrier shrubs to reduce intrusion by people and domestic animals. Avoid trees that shade biofilter grasses, and if trees cannot be avoided, space them at least 6.5 m (20 ft) apart. Landscape beds near biofilters should be at a slightly lower elevation than the adjacent ground surface.

Provide for a 1.0 to 2.0% slope in the direction of flow, with 6.0% being the maximum and 0.5% being the minimum. When the longitudinal slope is less than 1.0 to 2.0%, install a perforated underdrain or, if moisture is adequate, establish wetland species. If the slope is greater than 2.0%, use check dams to reduce the effective slope to approximately 2.0%. Install energy dissipating riprap at the toe and for a short distance downstream at the toe of these check dams to control erosion. When the land slopes more than 6%, swales can be installed to traverse the grade at a lesser slope. Grade biofilters carefully to attain uniform longitudinal and lateral slopes and eliminate high and low spots.

If curb cuts are used to distribute the flow over a biofilter, they should be at least 0.3 m (12 in.) wide to reduce clogging. Place the pavement slightly above the adjacent biofilter elevation. Install a flow-spreading device with sediment cleanouts (such as weirs, stilling basins, and perforated pipes) to uniformly distribute flow at an inlet to a swale or across the width of a filter strip. Protect inlet areas from erosion by using stilling basins and riprap pads with rock sized large enough not to be moved by the inflow.

A high-flow bypass is not needed if the biofilter is preceded by a runoff quantity control device designed to release flow at rates that will not cause erosion or scour within the biofilter. When a bypass is used, provide it with an inflow regulating device and use a pipe or a stabilized channel to convey the flow.

Provisions for Swales. At minimum, design for the peak runoff rate during the "maximized" storm. Base this storm depth on the rainfall depth using a runoff coefficient $C = 1.0$ (that is, complete runoff, no infiltration) and a 12-hour "drain time." Relate this "maximized" depth to an approximate intensity-duration curve for the area that can then be used with the rational formula by assuming the storm occurs over 1 or 2 hours. Using the time of concentration for the catchment and its runoff coefficient C, find the design flow rate. Unless larger events will bypass the swale, enlarge its capacity for flood passage of the 10- to 100-year peak flow.

The following criteria are probably most applicable in warm and temperate, non-semi-arid climates and should be met or exceeded during the biofiltration capacity design event:

- "Maximized" runoff hydraulic residence time of 5 minutes or more;
- Maximum flow velocity less than 0.3 m/s (0.9 ft/sec);
- Manning's $n = 0.20$ for routinely mowed swales;
- Manning's $n = 0.24$ for infrequently mowed swales;
- Maximum bottom width of 2.4 m (8 ft);
- Minimum bottom width of approximately 0.6 m (2 ft);
- Maximum depth of flow no greater than one-third of the gross or emergent wetland vegetation height for infrequently moved swales or greater than one-half of the vegetation height for regularly mowed swales, up to a maximum of approximately 75 mm (3 in.) for grass and approximately 50 mm (2 in.) below the normal height of the shortest wetland plant species in the biofilter; and
- Minimum length of 30 m (100 ft).

Use a trapezoidal cross section for ease of construction with side slopes no steeper than 4:1 for ease of maintenance. Terracing needs to be used when side slopes become steeper than 3:1.

Provisions for Filter Strips. Design filter strips to carry the "maximized" storm peak runoff rate described in the section titled Provisions for Swales. Base the flow capacity design to meet or exceed the following criteria during the design storm event. The following specifications may be used:

- Hydraulic retention time of no fewer than 5 minutes;
- Average velocity not greater than 0.3 m/s (0.9 ft/sec);
- Manning's $n = 0.20$ for routinely mowed strips;
- Manning's $n = 0.24$ for infrequently mowed strips;
- Limit filter strip width to achieve uniform flow distribution;
- Average depth of flow no more than 25 mm (1.0 in.); and
- Hydraulic radius taken to be equal to the design flow depth.

In arid and semiarid areas, biofilter strips will need irrigation to maintain a dependable grass cover.

OPERATION AND MAINTENANCE OF BIOFILTERS. To keep biofilters operating properly, keep all inlet flow spreaders even and free of debris. Remove debris for aesthetic reasons. Mow grass-covered biofilters regularly during the growing season to promote growth and pollutant uptake. Remove cuttings and dispose of them properly or through composting. If the objective is to prevent nutrient transport, mow grasses or cut emergent wetland plants to a low height, but still above the maximum flow depth, at the end of the growing season. For trapping floatables and debris pollution control objectives, let the plants stand at a height exceeding the design water depth by at least 50 mm (2 in.) at the end of the growing season.

Remove sediment by hand with a flat-bottomed shovel during the summer months whenever sediment covers vegetation or begins to reduce the biofilter's capacity. Reseed damaged or recently maintained areas immediately with a mix used for initial establishment or use grass plugs from adjacent upslope areas. If possible, redirect flow until new grass is firmly established. Otherwise, cover the seeded areas with a high-quality erosion control fabric.

Inspect biofilters periodically, preferably monthly, especially after heavy runoff. Maintain clean curb cuts to avoid soil and vegetation buildup. Educate local residents about the importance of keeping biofilters free of lawn debris and pet waste. Base roadside ditch cleaning on hydraulic analysis. Remove only the amount of sediment necessary to restore needed hydraulic capacity, leaving as much of the vegetation in place as possible. Eventually, sufficient sediment will be trapped that the entire biofilter will need to be removed with the sediment and reconstructed to begin a new cycle of stormwater quality control.

BIOFILTER DESIGN PROCEDURE. Preliminary Steps. The design procedures for swales and filter strips are almost identical. The design steps described below are for swales, with notes provided for filter strip design when appropriate:

- P1: estimate runoff flow rate for the design event and limit the discharge to approximately 0.03 m^3/s (1.0 cu ft/sec) by dividing the flow among several swales, installing upstream detention to control release rates, or reducing the developed surface area to reduce runoff coefficient and gain space for biofiltration.
- P2: establish the slope of the proposed biofilter.
- P3: select a vegetation cover suitable for the site.

Design for Biofiltration Capacity. This analysis emphasizes biofiltration rather than efficient hydraulic conveyance, thereby promoting sedimentation, filtration, and other pollutant removal mechanisms. Typically, a lower maximum velocity is arrived at than required for slope stability, and the biofilter dimensions typically do not have to be modified after a check for stability.

- D1: estimate the height of vegetation that is expected to occur during the storm runoff season. The design flow depth should be at least 50 mm (2.0 in.) less than this vegetation height and a maximum of approximately 75 mm (3.0 in.) in swales and 25 mm (1.0 in.) in filter strips.

- D2: select Manning's n as discussed.
- D3: typically swales are designed as trapezoidal channels (skip this step in filter strip design). When using a rectangular section, provide reinforced vertical walls. See Figure 5.5 for relationships for estimating cross-sectional area, top width, and hydraulic radius for typical channel geometrics.

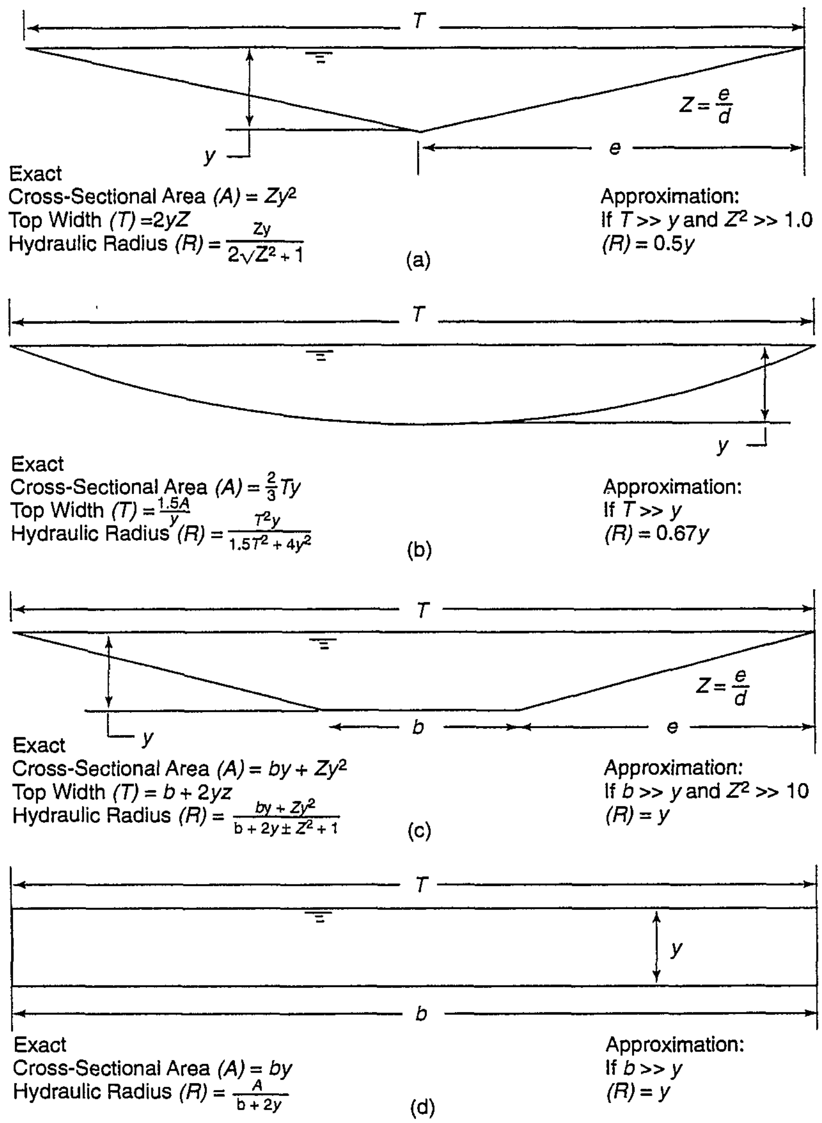

Figure 5.5 **Geometric formulas for common swale shapes: (a) v-shape, (b) parabolic shape, (c) trapezoidal shape, and (d) rectangular shape.**

- D4: use Manning's equation to approximate initial dimensions. For trapezoidal shape, select a side slope that is no steeper than 3:1, with 4:1 or flatter preferred. Set the bottom width to be between approximately 0.6 and 2.5 m (2.0 to 8.0 ft).
- D5: compute cross-sectional area.
- D6: compute the flow velocity for the design flow rate. Limit velocities during the "maximized" design storm to less than 0.3 m/s (0.9 ft/sec). Greater velocities were found to knock grasses from a vertical position in the Pacific Northwest (U.S.), reducing filtration. Experience in other regions may be different. Adjust for local experience. If the flow velocity exceeds the limit value, repeat steps P1 through D6.
- D7: compute the swale length using the design velocity from step D6 and an assumed hydraulic retention time. A suggested retention time value in the Pacific Northwest is 9 minutes. However, it is acceptable to use other accepted regional values, preferably no fewer than 5 minutes. If the computed swale length is less than 30 m (100 ft), increase to 30 m and adjust bottom width.

Check for Stability to Reduce Erosion. The "stability" check is performed for the combination of highest expected flow and least vegetation coverage and height.

- S1: unless runoff will bypass the biofilter, perform the "stability" check for the 10- to 100-year design storm. Estimate the design discharge as in step P1.
- S2: estimate the vegetation coverage (for example, "good" or "fair") and flow depth for conditions that will exist whenever the coverage and vegetation height are the least.
- S3: estimate the degree of retardance using Table 5.7. Because emergent wetland species typically grow less densely than grasses, assume a "fair" coverage.
- S4: establish the maximum permissible velocity (V_{max}) from Table 5.8 to prevent erosion.

Table 5.7 Guide for selecting degree of retardance.

Average grass height, in.[a]	Degree of vegetation coverage	
	"Good"	"Fair"
>30	A. (Very high)	B. (High)
11–24	B. (High)	C. (Moderate)
6–10	C. (Moderate)	D. (Low)
2–6	D. (Low)	D. (Low)
<2	E. (Very low)	E. (Very low)

[a] in. × 25.40 = mm.

Table 5.8 **Recommended maximum velocities for swale stability.**

Cover	Slope, %	Maximum velocity, ft/sec[a] Erosion-resistant soils	Easily eroded soils
Kentucky bluegrass	0–5	6	
Tall fescue			5
Kentucky bluegrass	5–10	5	4
Ryegrass			
Western wheat-grass			
Grass–legume mix	0–5	5	4
	5–10	4	3
Red fescue	0–5	3	2.5
Redtop	5–10	NR[b]	NR[b]

[a] ft/sec × 0.304 8 = m/s.
[b] Not recommended.

- S5: select a trial Manning's n. A reasonable initial choice under poor vegetation cover conditions is $n = 0.04$.
- S6: use Figure 5.6 to help approximate the value for VR (that is the product of velocity and hydraulic radius) using retardation information from step S3 and V_{max} from step S4.
- S7: estimate a new hydraulic radius by dividing (VR) from step S6 by V_{max} from step S4.
- S8: use Manning's equation to solve for the actual VR.
- S9: compare the actual VR from step S8 against the first approximation in step S6. If they do not agree within 10%, repeat steps S5 through S9 until acceptable agreement is reached.
- S10: compute the actual V for the final design conditions and check to be sure that $V < V_{max}$, from step S4.
- S11: compute the cross-sectional area for "stability."
- S12: compare the area computed in step S11 with the area computed from the biofiltration "capacity" analysis (step D5). If less area is required for "stability" than is provided for "capacity," the "capacity" design is acceptable. If not, use area from step S11 and recalculate channel dimensions.
- S13: calculate the depth of flow at the "stability" check design flow rate condition for the final dimensions.
- S14: compare the depth from step S13 to the depth used in the biofiltration "capacity" design. Use the larger of the two and add 0.3 m (1.0 ft) freeboard. Calculate the top width for the full depth. Skip this step in filter strip design.
- S15: make a final check for discharge capacity based on the "stability" check design storm and maximum vegetation height and cover (this

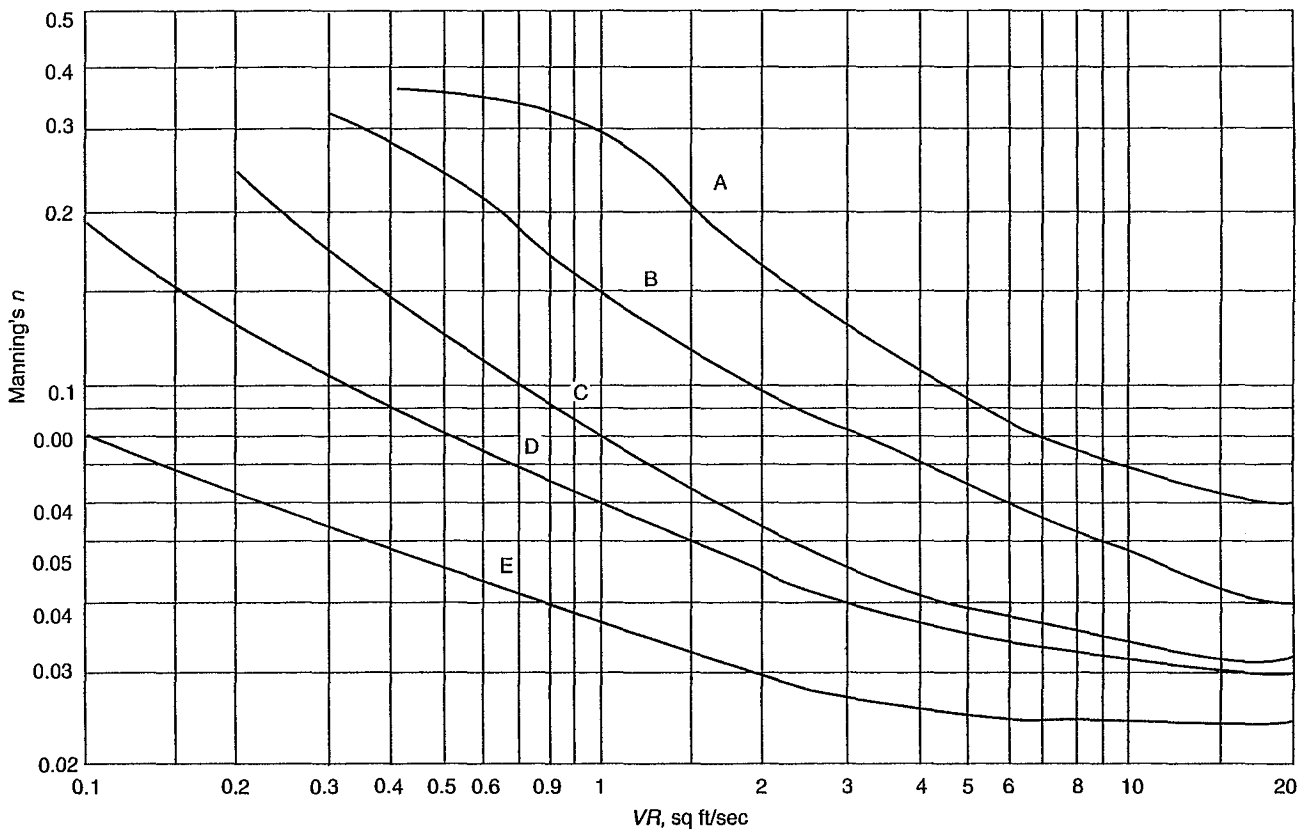

Figure 5.6 Manning's n versus VR versus degrees of flow retardance (note that VR is the product of velocity and hydraulic radius) (sq ft/sec $\times$ 0.092 9 = m^2/s).

check will ensure capacity is adequate if the largest expected event coincides with the greatest retardance). Using Manning's n selected in step D2 and the calculated channel dimensions (including freeboard), and compute the flow capacity of the channel under these conditions. If this flow capacity is less than the "stability," check design storm flow rate, increase the channel cross-sectional area as appropriate, and repeat calculations. Specify the new channel dimensions.

Completion Step. Review guidelines provided in Sections 1, 2, and 3 for biofilter planning, design, installation, and operation, and specify all appropriate features applicable for installation.

STORMWATER INFILTRATION AND PERCOLATION

Whenever site conditions permit, a portion of urban stormwater runoff can be disposed of locally through infiltration. Surface infiltration can be encouraged to occur through the use of grass buffer strips, swales, porous pavement, and dedicated infiltration basins. Stormwater runoff can also infiltrate to the ground near its origin through percolation trenches similar to those used in wastewater septic system leach fields.

Although surface infiltration has received much attention in recent years, it has long been in use and was practiced because good site drainage was lacking. The use of "inefficient" surface runoff in urban areas through the use of permeable vegetated surfaces has gained considerable but not universal acceptance in recent years.

The practice of minimizing directly connected impervious area (MDCIA) is a practice that is most appropriate for sites that are planning to have less than 60% imperviousness with relatively flat terrain. When properly designed and used, effective site drainage can still be provided. Figure 5.7 shows a comparison between traditional and MDCIA land development practices. Note that this is done by reducing the amount of directly connected impervious area, directing all roof downspouts onto lawns instead of to the curb and gutter, using stabilized road shoulders and swales, using modular block porous pavement whenever feasible, and maximizing the lengths of the surface paths leading to formal infiltration areas.

Formal on-site stormwater infiltration is accomplished through the use of infiltration basins and percolation trenches. These facilities need to be designed to also provide good surface and subsurface site drainage. On-site disposal is most successful when used to control runoff from individual building sites and small urban catchments (that is, up to 4 ha [10 ac] of single family residential and up to 2 ha [5 ac] of commercial lands).

Infiltration and percolation facilities are susceptible to early failure. Fail-

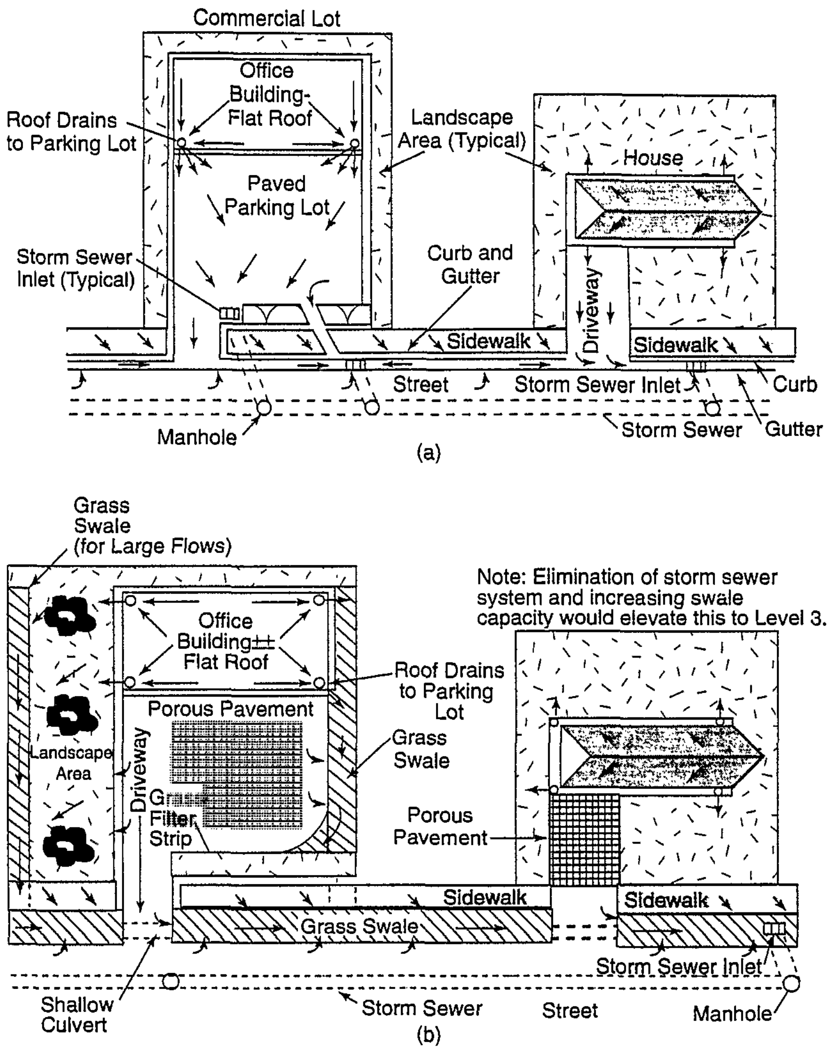

Figure 5.7 **Land development practice: (a) traditional site and street drainage design and (b) limiting directly connected impervious areas (UDFCD, 1992).**

ure is defined when stormwater no longer drains into the ground at design rates. Early signs of failure include excessively long periods of standing water on infiltrating surfaces or within percolation trenches. With failure, downstream stormwater systems and receiving waters experience increased higher runoff rates and greater volumes on a more frequent basis with corresponding pollutant loads.

Infiltration basins and percolation trenches can only be used at sites with porous soils, favorable site geology, and proper groundwater conditions. They should not be used when local institutions cannot ensure their proper installation and long-term maintenance. These infiltration basins and percolation trenches may

- Recharge groundwater,
- Reduce ground settlement in areas of groundwater depletion,
- Help to preserve and enhance local vegetation,
- Reduce pollutant loads transported to receiving waters,
- Reduce runoff volumes and peak flows, and
- Allow the use of smaller storm sewer systems.

Arguments against their use include

- Much of the surface runoff occurs from publicly owned streets and large commercial areas—infiltration and percolation facilities located on individually owned lots may have little effect on runoff rates and volumes experienced downstream;
- Infiltrating surfaces and soils seal as sediment and other solids clog soil pores, causing their failure;
- Individual infiltration and percolation facilities may not receive proper maintenance;
- Local groundwater mounding under these facilities can cause them to fail and may damage adjacent structures and flood basements;
- When they fail, they are expensive to reinstall; and
- They may degrade groundwater quality when used in certain types of industrial and commercial areas.

DESIGN CAPTURE VOLUME. The amount of urban surface runoff arriving at infiltration and percolation facilities is affected by the watershed's size and its imperviousness, local rainfall, snowmelt characteristics, and other factors such as lawn watering, car washing, and hydrant flushing. Of these, stormwater and snowmelt runoff typically are the most significant considerations for design, and the choice of a design is often dictated by local conditions or criteria. It is recommended that infiltration basins and percolation trenches be sized to handle no less than the "maximized" storm runoff volume described earlier in this chapter. Base the design volume for infiltration basins on the coefficients listed for the event capture ratio, 12-hour drain time, and the tributary catchment's runoff coefficient. Estimating the design volume for percolation trenches is somewhat more complex and is described later in this chapter.

SNOWMELT. In some locations, snowmelt can govern the size of infiltration and percolation devices, especially when the tributary catchment has little impervious area and much pervious area. Under extreme conditions, snowmelt rates can equal 4 mm (0.6 in.) of water per hour. Although it is not possible to typify snowmelt runoff rates from across the U.S., the following snowmelt rates may be used to check if snowmelt governs the size of these facilities: impervious surfaces—1.0 mm/h (0.04 in./hr), and pervious surfaces—0.5 mm/h (0.02 in./hr). Use local rates whenever available.

SURFACE INFILTRATION BASINS. Screening for Site Suitability. There are several conditions that can be used to eliminate a site for local stormwater infiltration. These include the following:

- Seasonal high groundwater is less than 1.2 m (4 ft) below the infiltrating surface;
- Bedrock or an impervious soil layer is within 1.2 m (4 ft) of the infiltrating surface;
- The infiltrating surfaces are located on top of fill or compacted soils; or
- The surface and underlying soils are Resource Conservation Service (RCS) hydrologic soil group C or D, or the saturated surface infiltration rate is less than 7.6 mm/h (0.3 in./hr).

If the above conditions do not rule out the new development as a candidate for infiltration, assess its suitability using a point evaluation system suggested by the Swedish Association of Water and Wastewater Works (1983). This assessment technique, when used properly and objectively, has been proven to be effective. It was first described in the U.S. by Urbonas and Stahre (1993) and is based on assessing various site conditions by assigning points for each category listed in Table 5.9.

A site with fewer than 20 points is considered unsuitable, while a site with more than 30 points is considered good. A site with 20 to 30 points is considered to be a fair candidate, with occasional standing water on the infiltration surfaces likely. This preliminary screening technique, however, is not a substitute for detailed site-specific engineering investigations. When the initial screening process finds the site acceptable, the infiltration surface area and the stormwater storage volume above this surface must then be determined. Note that Table 5.9 suggests that the surface area of all infiltration areas within a development (including buffer strips, lawns, and swales) be no less than one-half of the tributary impervious surface areas.

This screening procedure can best be illustrated by an example. For example, an infiltration site is to dispose of stormwater runoff from a roof having a 1.0-ha (2.5-ac) area. The site is a new lawn with a surface area of 1.0 ha (2.5 ac) and a 0.20% slope. The topsoil is normal humus, and the underlying soils are composed mostly of coarse silt. Determine if the site is suitable for infiltration.

Using the evaluation point system presented in Table 5.9, the results are as follows:

- The infiltrating area is 1.6 times larger than the impervious surface (that is, $A_{INF} = 1.6\,A_{IMP}$) = 10 points.

Table 5.9 **Point system for the evaluation of potential infiltration sites (STORMWATER—BEST MANAGEMENT PRACTICES by URBONAS/STAHRE, © 1993. Adapted by permission of Prentice-Hall, Inc., Upper Saddle River, N.J.).**

Site condition	**Evaluation points to award**
Ratio of tributary impervious area (A_{IMP}) to the infiltrating surface area (A_{INF})	
$A_{INF} > 2 \cdot A_{IMP}$ 20 points	10 points
$A_{IMP} < A_{INF} < 2 \cdot A_{IMP}$	5 points
$0.5 \cdot A_{IMP} < A_{INF} < A_{IMP}$	0 points
Urban catchments with pervious surface areas less than one-half of the impervious surfaces are poor candidates	
Surface soil layer type	
Coarse soils with low organic material content	7 points
Normal humus soil	5 points
Fine-grained soils with high ratio of organic matter	0 points
Underlying soils	
If the underlying soils are more coarse than surface soil, assign the same number of points for underlying soils as were given for the surface soil layer soils above	
If the underlying soils are finer grained than the surface soils, use the following points:	
Gravel, sand of glacial till with gravel or sand	7 points
Silty sand or loam	5 points
Fine silt or clay	0 points
Slope (S) of the infiltration basin's site	
$S < 0.007$ ft/ft (m/m)	5 points
$0.007 < S < 0.020$ ft/ft (m/m)	3 points
$S > 0.020$ m/m	0 points
Vegetation cover	
Healthy natural vegetation cover	5 points
Lawn well established	3 points
Lawn new	0 points
No vegetation, bare ground	−5 points
Degree of traffic on infiltration surface	
Limited foot traffic	5 points
Average foot traffic (park, lawn)	3 points
Much foot traffic (playing fields)	0 points

- The top soil layer is of normal humus type = 5 points.
- The underlying soil layers are coarse silt = 5 points.
- The slope of the infiltration surface is 0.002 = 5 points.
- The infiltration surface is a new established lawn = 0 points.
- The lawn is expected to have normal foot traffic = 3 points.
- The total is 28 points for this site. This site is judged to be an above-average candidate, runoff is not likely to puddle frequently, and occasional periods of standing water are likely.

Configuring a Basin. Infiltration basins need to empty through the basin's bottom within a reasonably short period. Otherwise, boggy and undesirable site conditions will occur, and the grasses lining these basins will die. Size the basin's surface area to drain the design capture volume in fewer than 6 hours. Also, design the basin with a shallow maximum ponding depth. An ideal site will not result in water ponding more than 0.3 m (1 ft) deep during the design storm, with the excess volume either overflowing or bypassing the basin. Recognize that the available soil pore volume will amplify each 0.3 m (1 ft) of ponding depth into 0.9 to 1.2 m (3 to 4 ft) of groundwater depth under the basin, which water column then needs to drain off laterally.

There is a strong possibility that unless the underlying soils have high hydraulic conductivity, it will take few runoff events to create a groundwater mound under a basin. In many soils, groundwater mounding drains off laterally slowly and can surface, causing a failure. These failures can be reduced if the development's infiltration is distributed uniformly throughout the development site. Using many infiltration basins distributed throughout the development tends to more closely reproduce the predevelopment condition. Thus, instead of concentrating all site runoff at one infiltration basin, it is better to install many small infiltration basins throughout the development site. Try to fit them into the landscape, even into individual residential or commercial lots.

Vegetate all infiltrating surfaces with grasses that can withstand and survive prolonged periods of inundation, followed by extended dry periods. Healthy vegetation is essential—without it, the surface soil pores quickly seal. Grass roots are needed to reopen them and will help to do so even when considerable deposition of silt has occurred. Eventually, the deposited sediment layer and old grass will need to be removed, the soils rehabilitated, and the basin revegetated.

Sizing Infiltration Basins. An infiltration basin cannot transfer stormwater to the ground as rapidly as stormwater arrives at the basin. As a result, a detention volume is needed above all infiltration surfaces to temporarily store this excess runoff. Table 5.10 contains a list of the infiltration rates for several typical soil groups. It is best, however, to perform several surface infiltration tests at each site and use an average of several of the lowest measured infiltration rates for design purposes. It is also important to recognize that as

Table 5.10 Typical infiltration rates of various soil groups.

Soil conservation service group	Typical soil type	Saturated infiltration rate mm/h	Saturated infiltration rate in./hr
A	Sand	200	8.0
A	Loamy sand	50	2.0
B	Sandy loam	25	1.0
B	Loam	12.7[a]	0.5[a]
C	Silt loam	6.3[a]	0.25[a]
C	Sandy clay loam	3.8	0.15
D	Clay loam and silty clay loam	<2.3	<0.09
D	Clay	<1.3	<0.05

[a] Minimum acceptable infiltration rate is 7.6 mm/h (0.3 in./hr). Sites with soils with lesser rates should not be used.

sediment accumulates on the basin's bottom, the effective infiltration rate will be governed by the sediment layer, which in turn will be affected by the presence or absence of a healthy grass surface. For this reason, it is suggested that when local soils exhibit high surface infiltration rates, the basin's design be based on infiltration rates that do not exceed 50 mm/h (2.0 in./hr). At the same time, when native soils have infiltration rates less than 50 mm/h (2 in./hr), the designer should consider using a somewhat reduced rate to account for the fact that soil infiltration rates will decline as sediment builds up on the bottom of the basin.

The detention volume of an infiltration basin is found using Equation 5.2. Use the "maximized" stormwater capture volume based on a 12-hour drain time. Next, estimate the basin's surface area using a maximum detention depth of 0.3 m (1 ft). The known soil's infiltration rate is then multiplied by the basin's surface area to find the exfiltration rate. Ascertain that the detention volume will drain in 6 hours or fewer. If it does not, increase the surface area until the volume drains in fewer than 6 hours. Last, check if the basin area has to be increased to handle snowmelt.

For example, use a 2.22-ha (5.5-ac) catchment in Minneapolis, Minnesota, located on sandy loam soils with saturated infiltration rate of 25 mm/h (1.0 in./hr). The catchment is 44% impervious (that is, runoff coefficient $C = 0.3$).

Using Equation 5.2 and Table 5.4, the "maximized" volume for a detention basin with a 12-hour drain time is

$$P_0 = 1.109 \times 0.5 \times 0.3 = 4.2 \text{ mm (0.166 watershed in.)}$$

The design volume then is

$$V_{WQ} = (0.166 \div 12) \times 5.5 = 0.076 \text{ ac-ft} = 94 \text{ m}^3 \text{ (3 320 cu ft)}$$

Limiting the ponding depth to 0.3 m (1 ft) establishes the basin's surface area at 308 m^3 (3 320 sq ft). The total exfiltration rate then is

$$Q_{out} = (3\,320 \times 1.0 \div 12) = 7.8\ m^3/h\ (277\ cu\ ft/hr)$$

This exfiltration rate will empty the design volume in 12 hours. Doubling the basin's surface area to 716 m^2 (6 640 sq ft) will empty the design volume in 6 hours at a rate of 15.7 m^3/h (554 cu ft/hr). Note that the resultant basin area occupies almost 3% of the total catchment area.

Next, check to see if the basin will handle prolonged snowmelt periods without overtopping. Using the snowmelt rates listed previously, we find the snowmelt rate for the site is 0.71 mm/h (0.028 in./hr), equal to a 15.8-m^3/h (55-cu ft/hr) runoff rate. This is virtually identical to the design rate of 15.7 m^3/h (554 cu ft/hr), and further adjustment to the basin's size is not justified.

PERCOLATION TRENCHES. Assessing a Site for Suitability. Darcy's law provides a basis for estimating the rate at which water can percolate into the ground through the sides of a percolation trench. It is expressed as Equation 5.4 and forms a basis for judging whether a site is suitable for the installation of a percolation trench:

$$U = k \cdot I \tag{5.4}$$

Where

U = flow velocity, m/s;
k = hydraulic conductivity, m/s; and
I = hydraulic gradient, m/m.

Because the bottom of the facility is above the high seasonal groundwater, assume the hydraulic gradient to be $I = 1.0$. Determine the hydraulic conductivity of the soils adjacent to the percolation trench. Table 5.11 lists ranges in hydraulic conductivity for a variety of typically found soil types. Note that conductivities can vary four orders of magnitude for a single soil group. It is best to perform several site-specific hydraulic conductivity tests and use the

Table 5.11 Hydraulic conductivity of five soil types.

Soil type	Hydraulic conductivity ft/sec	Hydraulic conductivity m/s
Gravel	3.3×10^{-3}–3.3×10^{-1}	10^{-3}–10^{-1}
Sand[a]	3.3×10^{-5}–3.3×10^{-2}	10^{-5}–10^{-2}
Silt	3.3×10^{-9}–3.3×10^{-5}	10^{-9}–10^{-5}
Clay (saturated)	$<3.3 \times 10^{-9}$	$<10^{-9}$
Till	3.3×10^{-10}–3.3×10^{-6}	10^{-10}–10^{-6}

[a] Minimum acceptable hydraulic conductivity for stormwater percolation is 2.0×10^{-5} m/s (6.5×10^{-5} ft/sec).

lowest field measured *in situ* hydraulic conductivities for final design purposes. Even under ideal conditions, soils adjacent to the trench will clog with time. A percolation trench is expensive to construct and more expensive to rebuild. Thus, being conservative in its design is appropriate.

The same factors, except for the use of soil hydraulic conductivity, affect site suitability for a percolation facility as affect a surface infiltration basin. Thus, if the following conditions are discovered or are likely to be at the site, disposal of stormwater by percolation is not recommended:

- Seasonal high groundwater is less than 1.2 m (4 ft) below the bottom of the percolation trench;
- Bedrock or impervious soils are within 1.2 m (4 ft) of the bottom of the percolation trench;
- The percolation trench is located within or on top of fill or recompacted soils; or
- The soils adjacent to the trench are RCS hydrologic group C or D or the field saturated hydraulic conductivity of the soils is less than 2.0×10^{-5} m/s (6.5×10^{-5} ft/sec).

If the above conditions do not rule out the site, the Swedish Association of Water and Wastewater Works (1983) provides design recommendations. This procedure is described by Urbonas and Stahre (1993).

Configuring a Percolation Trench. Percolation trench design uses the pore volume of trench fill media as the detention volume. Table 5.12 lists the porosity of the more typical trench fill materials. The bottoms of these trenches tend to clog first, often shortly after installation. As a result, the bottom of the trench is considered impervious and all water is assumed to percolate out only through its walls. Typically, long and deep trenches are most efficient and require the least amount of porous media. The maximum trench depth is limited by trench-wall stability, seasonal high groundwater levels, and the depth to any impervious soil layer. Trenches 1 m (3 ft) wide and 1 to 2 m (3 to 6 ft) deep seem to be most efficient.

If a percolation trench cannot be made sufficiently large to empty its fully available water storage volume (that is, granular media pore space volume)

Table 5.12 Porosity of commonly used granular materials.

Material	Effective porosity, %
Crushed and blasted rock	30
Uniform sized gravel	40
Graded gravel, 2.0 cm (0.75 in.)	30
Sand	25
Pit run gravel	15–25

within a 24-hour period, it is recommended that a collector pipe be installed near its bottom and the stored water be released slowly through a flow controller (that is, choked outlet). The outlet is designed to supplement the percolation outflow so that both combine to empty out the trench-full volume in 24 hours. This type of installation behaves, in part, like a detention basin.

Most important for percolation trench longevity is to filter all the stormwater entering the trench through a sand layer. Percolation trenches should not be used without first filtering its inflow or if these filter systems will not be adequately maintained. If stormwater is permitted to enter the trench without first being filtered, pore media and adjacent soils will seal with time and the facility will fail.

Figure 5.8 illustrates a percolation trench with a surface sand filter layer

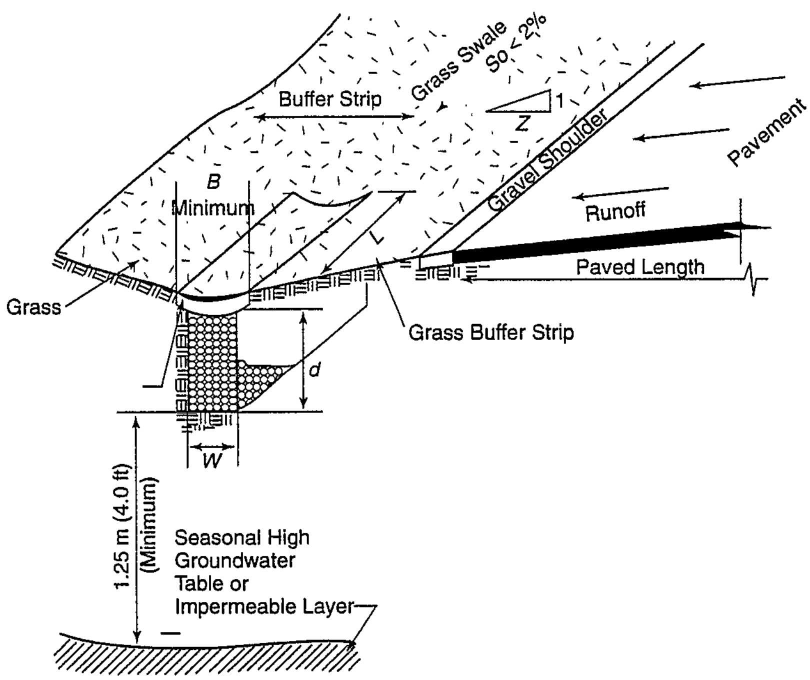

Figure 5.8 **A percolation trench with a sand filter layer for surface inflow (STORMWATER: BEST MANAGEMENT PRACTICES BY URBONAS/STAHRE, © 1993. Adapted by permission of Prentice-Hall, Inc., Upper Saddle River, N.J.). (Notes: Wrap all rock fill in geotextile fabric with coarse pores; buffer strip length > 25% paved length; length $L \leq K/(So/100)$ in which K = 0.3 m (1 ft) and So = slope, %; add trenches as needed to obtain required total length for infiltration; side slope $Z \geq 4.0$; sand or sand–turf filter layer surface area shall be sized to permit inflow to the trench with minimum of ponding; create ponding on sand–turf layer using a berm across the swale; $B > 2d$.)**

on top. This sand filter layer has to have sufficient surface area to permit stormwater to enter the trench with minimal ponding above it. However, some ponding volume will be needed above the sand filter to buffer higher rates of runoff. Such a sand surface filter layer can be a modular porous pavement. Other filter configurations are possible, including inlets with geotextile filter bags within them (Urbonas and Stahre, 1993). All filter devices will need aggressive routine maintenance for acceptable operation.

Unlike the surface infiltration facilities, failure of a percolation trench can be unnoticed for long periods of time because the trench is out of sight. A routine inspection program is needed to discover failed percolation trenches. It is unlikely that someone will randomly observe and report a trench failure during storm periods. One or more observation wells should be provided to facilitate inspections. A record of water in the trench not draining within 2 days after a wet period ends can indicate incipient failure and should be investigated.

Sizing a Percolation Trench. Because a percolation trench is used to limit runoff from a small catchment, rational formula (Equation 5.5) may be used for its design:

$$Q = K_u \cdot C \cdot I_t \cdot A \tag{5.5}$$

Where

Q = average runoff rate for the storm duration t, m^3/s (cu ft/sec);
K_u = unit conversion factor, 1.0 for U.S. standard units (36 for the International System of Units);
C = runoff coefficient, nondimensional;
I_t = rainfall intensity for the design storm at the storm duration t, mm/h (in./hr); and
A = area of the tributary watershed, ha (ac).

Multiplying the average runoff rate, Q, by the design storm's duration, t, results in Equation 5.6, which gives the cumulative runoff volume over time t:

$$V_{\text{in}}(t) = K \cdot 3\,600 \cdot C \cdot \frac{I_t}{1\,000} \cdot t \cdot A \tag{5.6}$$

Where

$V_{\text{in}}(t)$ = total volume of *inflow* over storm duration t, m^3 (cu ft); and
t = storm duration, hour.

Because the water depth in the trench varies during storm runoff, the sides of a percolation trench are not fully inundated during the runoff event. To simplify the sizing process, the designer can assume that the average outflow rate is the result of one-half of the trench depth being inundated. This then allows the designer to find the average effective area of percolation. Also, assume the hydraulic gradient, I, equals 1.0. Thus, Equation 5.7 is derived from

Darcy's law (that is, Equation 5.4):

$$V_{out}(t) = 3\,600 \cdot k \cdot (A_{perc} \div 2) \cdot t \tag{5.7}$$

Where

$V_{out}(t)$ = total volume of water percolated into the ground over time t, m^3;
k = hydraulic conductivity of the soil, m/s (ft/sec);
A_{perc} = total area of the sides of the percolation trench, m^2 (sq ft);
t = duration of the percolation time, hour.

The maximum volume of water stored, V, in the trench is the difference between $V_{in}(t)$ and $V_{out}(t)$, as expressed by Equation 5.8:

$$V = \max\,[V_{in}\,(t) - V_{out}\,(t)] \tag{5.8}$$

Thus, Equation 5.9 is derived by combining Equations 5.5 and 5.7 into Equation 5.8:

$$V = \max\,[3\,600 \cdot K_u \cdot I_t \cdot C \cdot A \cdot t - 1\,800 \cdot k \cdot A_{perc} \cdot t] \tag{5.9}$$

Configure the trench to drain the "maximized" storm volume discussed earlier in the chapter. First, find this volume using Equation 5.2 for the 12-hour drain time and a runoff coefficient $C = 1.0$. The trench is designed to dispose of the runoff from such a storm through percolation through the sides. Because the detention time in the trench is not the issue for water quality enhancement, the maximized depth is used to define the intensity-duration function of a design storm by assuming this rainfall depth occurs within 1 hour.

The next step is to select a cross section for the trench and the type of fill material. Assume a trench length and test it for adequacy. Eventually, through a trial-and-error process, the assumed trench length agrees with the calculated one. This procedure can be reduced to a spreadsheet to facilitate the iterative solution. Figure 5.9 presents an example of such a spreadsheet. After the known parameters are entered, the iterative process begins by entering an assumed trench length and calculating the "needed trench length." New "assumed length" values are entered until a balance is achieved between the "assumed" and "needed" lengths. In this example (that is, Figure 5.8) the needed trench length was found to be 44 m (144 ft).

OTHER INFILTRATION FACILITIES. Buffer Strips and Swales. The design for buffer strips and swales is described earlier in this chapter. Both buffer strips and swales can infiltrate stormwater to the ground. However, the duration of time that runoff actually is in contact with these surfaces is relatively short, and, as a result, the volume of infiltration is limited. Nevertheless, buffer strips and swales can infiltrate significant fractions of the smaller runoff events when they are located on porous soils. Their use is encouraged, Project Title: Percolation Trench Sizing

and they add to the treatment train as stormwater runoff migrates from its origin to the receiving waters.

Porous Pavement. When properly designed and operating, porous pavement can infiltrate, or otherwise treat, the runoff from 70 to 90% of all storm events. It, in effect, reduces the amount of directly connected impervious surface within a catchment.

There are three types of porous pavement: porous asphalt pavement, porous concrete pavement, and modular porous concrete block. Porous asphalt and concrete are constructed similarly to a conventional pavement, except sand and finer fraction of the aggregate are left out of the pavement mix. Such pavement typically is placed on top of a layer of granular base. The modular block pavement is constructed by placing the blocks over a layer of coarse gravel, which in turn is located on a porous geotextile fabric layer.

Whenever the porous pavement is expected to provide local disposal, the seasonal high groundwater and bedrock needs to be at least 0.9 m (3 ft) below the pavement's bottom. Typical porous pavement cross sections are illustrated in Figure 5.10. When the underlying soils, groundwater depth, or bedrock do not qualify the site for stormwater infiltration, porous pavement can be designed to be an underground detention facility. This can be done by installing an impermeable membrane between coarse rock media and the native soil subgrade. The granular base is then drained with the aid of perforated pipes installed at 3- to 8-m (10- to 25-ft) intervals. The release rate is controlled by a flow regulator, such as an orifice, which is designed to empty the pore storage volume within 6 to 12 hours.

Urbonas and Stahre (1993), after discussions with a number of public works departments, concluded that porous concrete and asphalt pavements have a tendency to seal and clog within 1 to 3 years. Also, faster sealing rates were reported in areas where extensive winter salting and sanding occur. One notable exception to surface clogging reports were the concrete pavement installations in the state of Florida (U.S.). Concrete and asphalt pavements need vigorous maintenance and the use of high-power vacuuming, though even then they seem to eventually seal. After sealed, this type of pavement has to be replaced.

Interlocking cellular concrete block pavement seems to seal at a slower rate than concrete and asphalt porous pavement and has a good record of service under a wide range of climatic conditions. After being sealed, the open spaces of modular blocks can be cleaned out by removing the vegetated soil or the sand layer and replacing it with fresh material. Individual blocks can settle and become misaligned, however, and this type of pavement is best suited for nontraffic areas such as parking pads and for overflow parking areas in sport event complexes, shopping centers, churches, and schools.

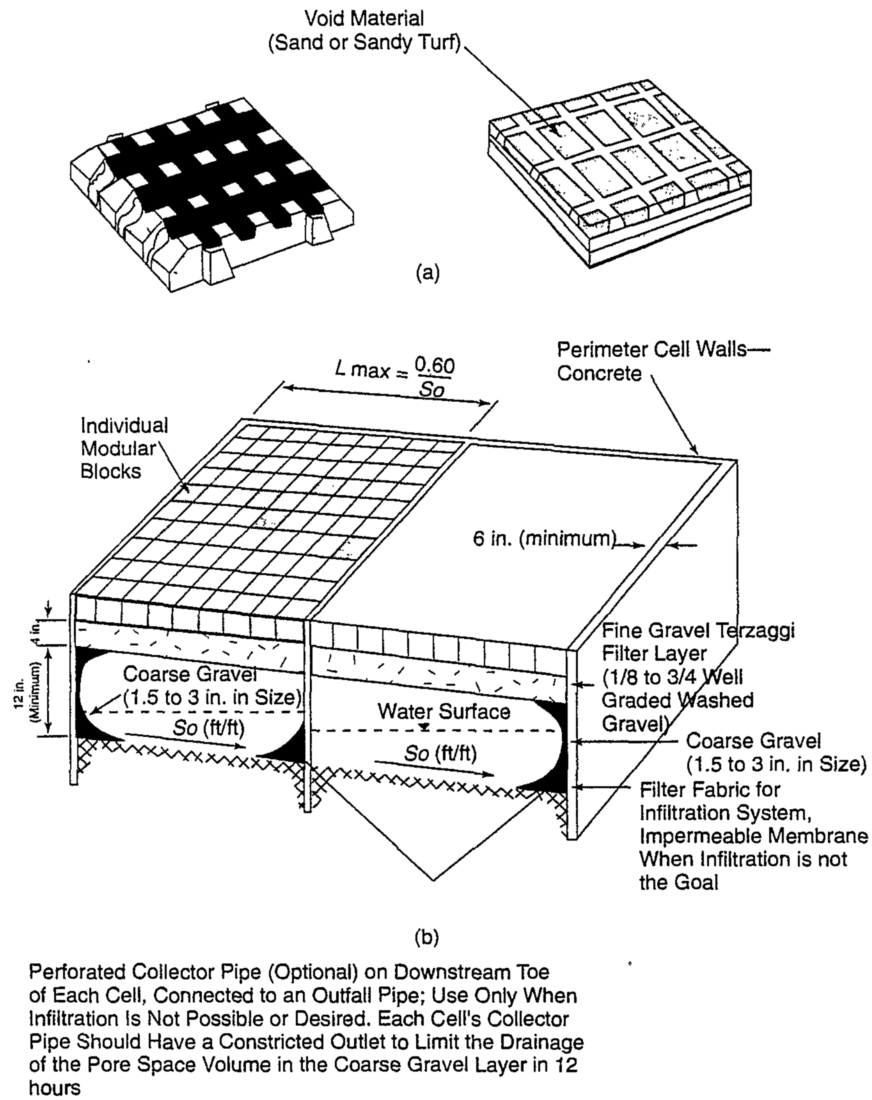

Figure 5.10 **Typical cross sections of porous pavement: (a) two examples of individual concrete modular paving block and (b) perspective of side-by-side modular block cells (ft × 0.304 8 = m; in. × 25.4 = mm).**

EXTENDED DETENTION (DRY) BASINS

Detention of urban stormwater runoff began to appear as an urban stormwater management practice in the early 1970s in North America, Europe, and

Australia to control runoff peaks from new land development sites. This was initially applied to control the 10-, 25-, 50-, or 100-year flow rates. By the mid- and late-1970s, Ontario (Canada) and the state of Maryland (U.S.) mandated detention to control the 2-year peak flow rate for stream bank erosion control purposes (with little success, as was determined later). The use of detention to control stormwater quality began to be used in the early 1980s. By the late 1980s, sufficient empirical data were available to design extended detention basins (that is, dry detention basins) for water quality purposes with reasonable confidence in their performance. Extended detention basins are best at removing suspended constituents. They are not particularly effective in removing solubles. Also, removal rates of solids by retention ponds tend to outperform detention basins. A comparison of constituent removal efficiencies of extended detention basins and retention ponds is described later in this chapter.

SIZING DETENTION BASINS. Using the Maximized Volume. There are several ways to size an extended detention basin. The simplest and most direct way for smaller catchments serving up to approximately 1.0 km^2 (0.6 sq mile) is to use the maximized volume described earlier in this chapter. The volume may be found for locations in the U.S. for basins emptying their entire volume in 24 and 48 hours. If one wishes to use another emptying time, simply interpolate between the results found using the 24- and 48-hour time. It is suggested that the event-capture-ratio–based coefficients in Table 5.4 be used with Equation 5.2 instead of the volume capture ratio coefficients.

The emptying, or drain, time is chosen by the designer or dictated by local authorities. Longer emptying times produce somewhat better removal rates of suspended solids. However, longer drain times tend to produce less attractive facilities, ones that have little or no vegetation on the bottom. Facilities with long emptying times have "boggy" bottoms with marshy vegetation and can be difficult to maintain and clean.

Using Hydrograph Routing. For detention basins that serve areas larger than 1.0 km^2 (0.6 sq mile), the volume can be found using a reservoir routing method. Again, it is recommended that the maximized storm depth be used. It has to be first converted to a design hyetograph, however, to simulate a runoff hydrograph. How this is done will be dictated by the typical design storm temporal distribution in use within the region where the facility is located. It is suggested, however, that the maximized depth be redistributed into a 2-hour design storm hyetograph.

The goal of reservoir routing is to balance inflow rates against outflow rates to find the needed volume. This is accomplished by solving Equation 5.9 with numerical methods or using one of the many available computer programs written for this purpose (see Chapter 3). Referring to Figure 5.11, Equation 5.10 states that the needed storage volume is a time integral of the difference between inflow and outflow hydrographs from the beginning of

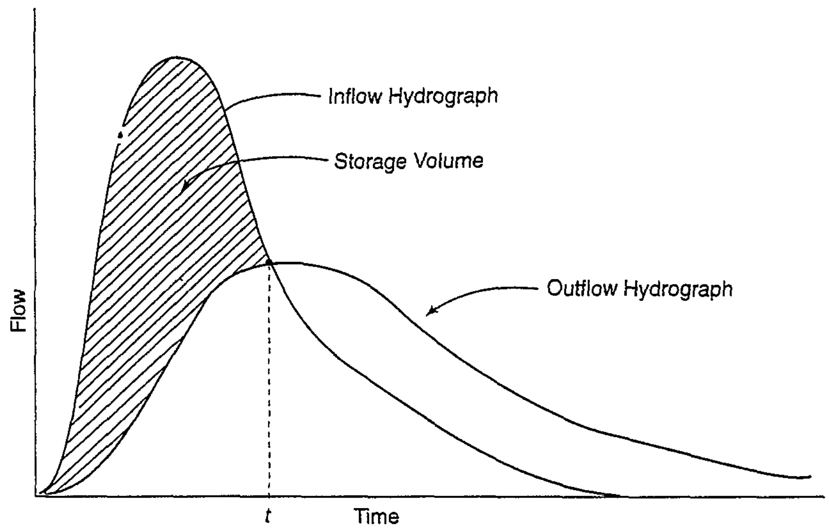

Figure 5.11 Routing a hydrograph through a detention basin.

storm runoff to the point in time where the outflow rate exceeds the inflow rate:

$$V_{max} = \int_0^t (Q_{in} - Q_{out})\, dt \qquad (5.10)$$

Where

V_{max} = storage volume,
t = time from beginning of runoff to a point of maximum storage,
Q_{in} = Q_{out} on hydrograph recession limb,
Q_{in} = inflow rate, and
Q_{out} = outflow rate.

CONFIGURING AN EXTENDED DETENTION BASIN. In configuring an extended detention basin, try to make these facilities an integral part of the community. Consider multiple uses, aesthetics, safety, and the way the facility will fit into the urban landscape. Also, maintainability is an important consideration. Although these basins provide passive treatment with no operational attention, continued successful performance will depend on good maintenance. Always provide adequate maintenance access.

Figure 5.12 shows an idealized layout for an extended detention basin. The individuality of each on-site or regional facility and its place within the urban community make it incumbent on the designer to seek out local input, identify site constraints, identify the community's concerns, and consider a wide array of possibilities during design.

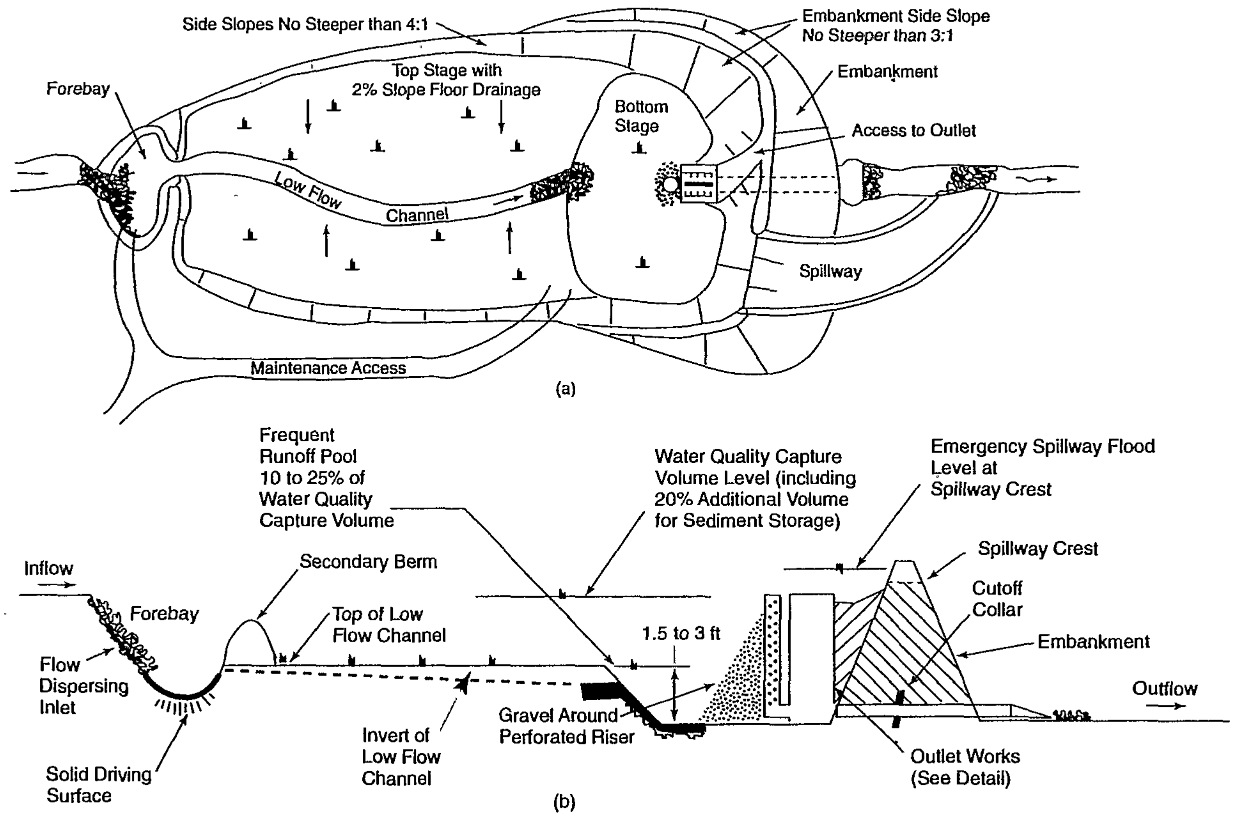

Figure 5.12 **An idealized extended detention basin: (a) plan (not to scale) and (b) section (not to scale) (ft × 0.304 8 = m) (UDFCD, 1992).**

Storage Volume. Provide a storage volume, sometimes called capture volume, equal to the maximized volume described earlier. Add 20% to this volume to provide for sediment accumulation. Randall *et al.* (1982) and Whipple and Hunter (1981) suggest that such detention basins be designed to promote sedimentation of small particles, namely smaller than 60 microns in size, which account for approximately 80% of the suspended sediment mass found in stormwater (Urbonas and Stahre, 1993).

Provide an outlet to empty less than 50% of the design volume in the first one-third of the design emptying period (that is, 12 to 16 hours). This ensures that small runoff events will be detained to remove small suspended solids. The particles, as they settle in a water column, concentrate at the lower levels of the temporary pond. It is this layer that drains through the bottom outlet of a detention basin. A long emptying time–thus the term extended detention–permits smaller particles to attach to the bottom of the basin and become trapped.

Flood Control Storage. Whenever feasible, try to incorporate the extended detention basin within a larger flood control facility. The designer may want to consider combining water quality and flood control functions in a single detention basin.

Basin Geometry. The basin should gradually expand from the inlet and contract toward the outlet to reduce short circuiting. Provide a length-to-width ratio of two or greater, preferably up to a ratio of four.

Two-Stage Design. Whenever feasible, provide a two-stage basin. The lower portion has a micropool that fills often. This reduces the periods of standing water and sediment deposition in the remainder of the basin. The top stage should be 0.6 to 1.8 m (2 to 6 ft) deep, its bottom sloping at approximately 2% toward a low-flow channel. The bottom pool can be 0.5 to 0.9 m (1.5 to 3 ft) deeper and should be able to store 15 to 25% of the capture volume. These recommendations do not necessarily apply to large, regional extended detention basins.

Basin Side Slopes. Basin side slopes need to be stable under saturated soil conditions. They also need to be sufficiently gentle to limit rill erosion, facilitate maintenance, and address the safety issue of individuals falling in when the basin is full of water. Side slopes of 4:1 and flatter provide well for these concerns.

Forebay. Design the basin to encourage sediment deposition to occur near the point of inflow. A forebay with a volume equal to approximately 10% of the total design volume can help with the maintenance of the basin, and the service life of the remainder of the basin can be extended. Equip it with a stabilized access and a concrete or soil cement lined bottom to prevent mechanical equipment from sinking to the bottom.

Basin Inlet. Most erosion and sediment deposition occurs near the inlet. An ideal inflow structure will convey stormwater to the basin while preventing erosion of the basin's bottom and banks, reducing resuspension of previously deposited sediment and facilitating deposition of heaviest sediment near the inlet. With several compromises, many of these design goals can be nearly achieved. Inflow structures can be drop manholes, rundown chutes with an energy dissipator near the bottom, a baffle chute, a pipe with an impact basin, or one of the many other types of diffusing devices.

Low-Flow Channel. Provide a low-flow channel to convey trickle flows and the last of the captured volume to the outlet.

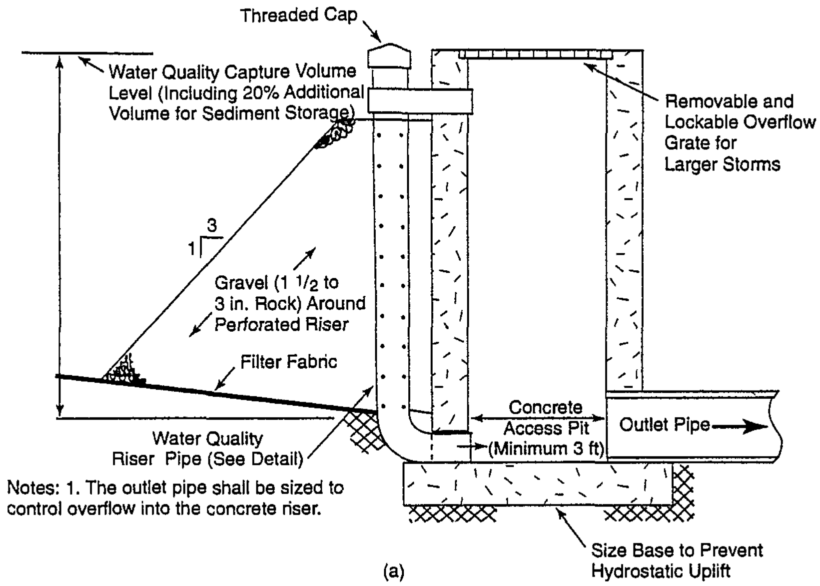
Outlet Design. Use an outlet capable of slowly releasing the design capture volume over the design emptying time. One example is a perforated riser, illustrated in Figure 5.13. Another arrangement of an outlet was suggested by Schueler *et al.* (1992), namely, a hooded perforated riser located in a small permanent pool (that is, a micropool).

Because extended detention basins are designed to encourage sediment deposition and urban stormwater has substantial quantities of settleable and floatable solids, basin outlets are prone to being clogged. This can make the design of reliable outlet structures for extended detention basins difficult. A clogged outlet will invalidate the hydraulic function of even the best design.

ASCE (1985), ASCE (1992), DeGroot (1982), Roesner *et al.* (1989), Schueler (1987), Schueler *et al.* (1992), Urbonas and Roesner (Eds.) (1986), and Urbonas and Stahre (1993) reported many reasons for outlet problems, which include clogging by trash and debris, silting in of the outlet, damage by vandalism, children plugging an outlet, and other factors that modify its discharge characteristics. Each outlet has to be designed with clogging, vandalism, maintenance, aesthetics, and safety in mind.

Trash Rack. If the outlet is not protected by a gravel pack, as shown in Figure 5.13, provide some form of a trash rack. Never wrap a perforated outlet in a geotextile filter cloth that will seal quickly. Figure 5.14 is a chart that provides simple, empirically based guidance for minimum sizes of trash racks for detention outlets.

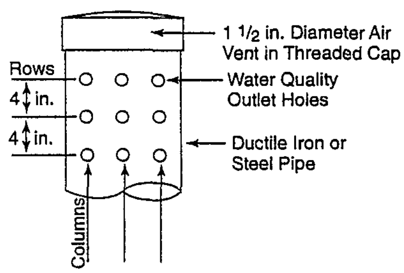
Dam Embankment. Design and build the dam embankment so that it will not fail during storms larger than the water quality design storm. Provide an emergency spillway or design the embankment to withstand overtopping commensurate with the size of the embankment, the volume of water that can be stored behind it, and the potential of downstream damages or loss of life if the embankment fails. Emergency spillway designs vary widely with local regulations. Embankments for small on-site basins should be protected from at least the 100-year flood, while the larger facilities should be evaluated for the probable maximum flood. Always consult the state's dam regulatory agency.



Notes: 1. The outlet pipe shall be sized to control overflow into the concrete riser.

(a)

Notes 1. Minimum number of holes = 8.
2. Minimum hole diameter = 1/8 in. diameter.



Maximum Number of Perforated Columns				
Riser Diameter, in.	Hole Diameter, in.			
	1/4 in.	1/2 in.	3/4 in.	1 in.
4	8	8	±	±

10	20	20	14	10
12	24	24	18	12

Hole Diameter, in.	Area of Hole, sq in.
1/8	0.013
1/4	0.049
3/8	0.110
1/2	0.196
5/8	0.307
3/4	0.442
7/8	0.601
1	0.785

(b)

Figure 5.13 An example of a perforated riser outlet: (a) outlet works (not to scale) and (b) water quality riser pipe (not to scale) (ft × 0.304 8 = m; in. × 25.4 = mm) (UDFCD, 1992).

Embankment slopes should be no steeper than 3:1, preferably 4:1 or flatter. They also need to be planted with turf-forming grasses. Embankment soils should be compacted to 95% of their maximum density at optimum moisture.

Vegetation. A basin's vegetation provides erosion control and enhances sediment entrapment. The basin can be planted with native grasses or with ir-

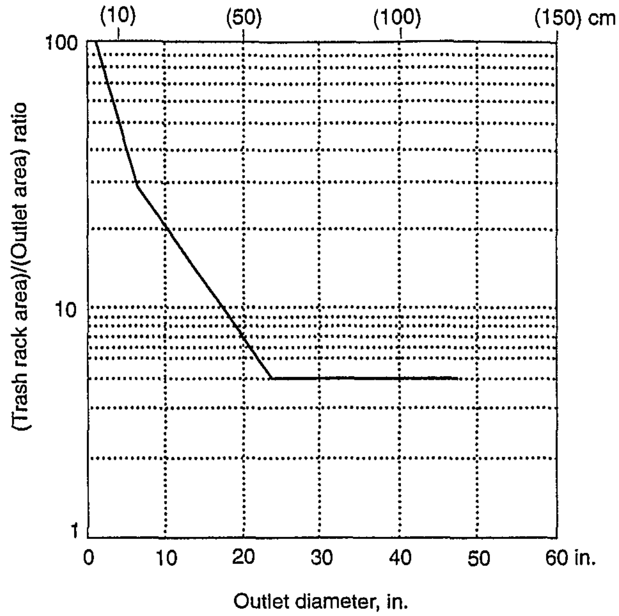

Figure 5.14 **Minimum size of a trash rack versus outlet diameter (note: trash rack area is the net area of all openings between bars, rock packing, and so on) (in. × 25.4 = mm) (UDFCD, 1992).**

rigated turf, depending on the local setting, basin design, and its intended other uses (such as recreation). Sediment deposition, along with frequent and prolonged periods of inundation, make it difficult to maintain healthy grass cover on the basin's bottom. Options for an alternative bottom liner include a marshy wetland bottom, bog, layer of gravel, riparian shrub, bare soil, low-weed species, or other type that can survive the conditions found on the bottom of the basin.

Maintenance Access. Provide for vehicular maintenance access to the forebay and the outlet areas with grades that do not exceed 8 to 10% and have a stable surface of gravel-stabilized turf, a layer of rock, or concrete pavement.

Multiple Uses. Whenever desirable and feasible, incorporate the water quality basin within a larger flood control facility. Also, whenever possible, provide for other uses such as active or passive recreation, wildlife habitat, or wetland. The use of a multiple-stage basin design described earlier can help accommodate multiple uses. The area within an extended detention basin is not well suited for active recreation such as playing fields. These are best located above an extended detention basin's pool level.

Aesthetics. Aesthetics are what the public uses to judge how "successful" or "useful" a detention basin is within the community. Although there are examples of unattractive basins, most new facilities are tastefully integrated to the neighborhood. Aesthetics are important. Using a landscape architect to assist with the design should be considered.

Safety. For larger on-site basins and regional facilities, safety has to also include the structural integrity of the water impounding embankment. As discussed earlier, the embankment should be protected from catastrophic failure. In the U.S., dam failure is almost always judged as an absolute liability of its owner. Always consider this principle of common law when designing detention facilities.

When the facility is in operation, safety concerns need to focus on flow velocities, water depths, and keeping the public from being exposed to high-hazard areas. During dry weather periods, safety is enhanced by reducing the use of high vertical walls and steep side slopes. Outlets and inflow structures and adjacent areas require special attention, and ASCE (1985) suggests the use of thorny shrubs and trash/safety racks at all outlet orifices, pipes, and weirs.

SUMMARY AND CONCLUSIONS. Extended detention basins are viable and effective treatment facilities. When properly designed, reductions of approximately 70% are possible in the total suspended sediment load and of constituents associated with these sediments. Regional facilities often offer economies of scale and greater reliability in capturing stormwater when they are used, while on-site facilities offer institutional and fiscal advantages of implementation as the land is urbanized.

RETENTION PONDS (WET)

A retention pond is a small artificial lake with emergent wetland vegetation around the perimeter, designed to remove pollutants from stormwater. This BMP is also sometimes called a "wet pond" or a "wet detention basin." This manual refers to it as a retention pond to distinguish it from the extended detention basin described in the previous section. A retention pond often is sized to remove nutrients and dissolved constituents, while any pool that may be associated with an extended detention basin is smaller and is provided for aesthetics, for example, to cover solids-settling areas.

Features of a retention pond are shown in Figure 5.15. The permanent pool provides a vessel for the settling of solids between storms and the removal of nutrients and dissolved pollutants. The wetland vegetation bench, called the littoral zone, provides aquatic habitat, enhances pollutant removal, and reduces the formation of algal mats. Figure 5.15 also shows an optional surcharge detention storage volume overlying the permanent pool. This can

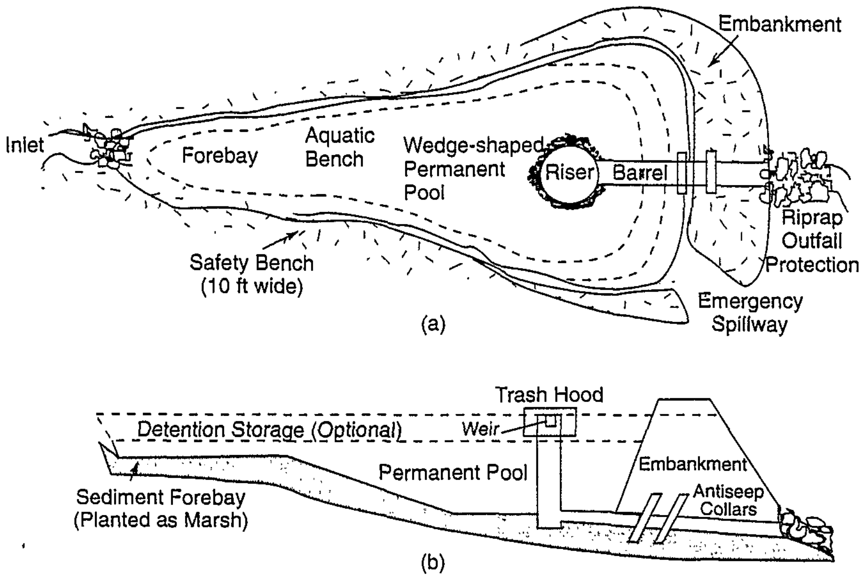

Figure 5.15 **Plan and profile of a retention basin: (a) top view and (b) side view (Schueler, 1987).**

be used for flood control. Some local jurisdictions require that this surcharge storage be designed as extended detention for added pollutant removal efficiency.

STORMWATER MANAGEMENT APPLICATIONS. Control of Nutrient Loadings. Retention ponds can be superior to extended detention basins for the control of nutrients in urban stormwater. While detention basins rely on solids-settling processes, retention ponds remove dissolved nutrients through several physical, chemical, and biological processes in the permanent pool. Table 5.13 shows a comparison of removal efficiencies of

Table 5.13 **Comparison of pollutant removal percentages by well-designed extended detention basins and retention ponds (U.S. EPA, 1983).**

Type of practice	Total suspended sediments	Nitrogen	Phosphorus	Lead	Zinc	Biochemical oxygen demand
Extended detention	70–80	0 (Diss) 20–30 (Total)	0 (Diss) 20–50 (Total)	70–80	40–50	20–40
Retention ponds	70–80	50–70 (Diss) 30–40 (Total)	50–70 (Diss) 50–60 (Total)	70–80	40–50	20–40

properly sized retention ponds and extended detention basins. In addition, petroleum hydrocarbon removals are similar to those of total suspended sediments. Retention ponds are most appropriate where nutrient loadings are of concern, especially in the following situations:

- Watersheds tributary to reservoirs and lakes—retention ponds in the watershed can help achieve eutrophication management goals in downstream reservoirs and lakes.
- Watersheds tributary to tidal embayments and estuaries—nutrient loadings into estuarine systems is a growing concern in coastal areas, including upland areas that drain into tidal waters. Retention ponds can help reduce the nutrient loads.

Removal of nutrients has a price: the permanent pool of a retention pond requires two to seven times more volume than an extended detention basin, depending on local meteorology. The larger volume requires larger structures and more land than detention basins, resulting in costs of facilities that are 50 to 150% more than for extended detention basins. If, however, the facility requires overlying storage for flood control peak-shaving, cost increases become smaller as the flood control volume and benefits get larger. Table 5.14, which summarizes design criteria for a regional stormwater management master plan for Fairfax County, Virginia (U.S.), exemplifies the relative difference in size for retention ponds and extended detention basins for this region of the U.S.

Table 5.14 Comparison of detention storage requirements in Fairfax County, Virginia: permanent pool of retention pond versus extended detention basin.[a]

Land use	Imperviousness, %	Retention pond, in.[b]	Extended detention,[c] in.[b]
Low-density single family	20	0.7	0.1
Medium-density single family	35	0.8	0.2
Multifamily residential	50	1.0	0.4
Industrial/office	70	1.2	0.5
Commercial	80–90	1.3	0.8
Forest/undeveloped	0	0.5	0.0

[a] Retention pond pool volume is based on an average hydraulic retention time of 2 weeks.
[b] In. × 25.40 = mm.
[c] Extended detention volume is based on the capture of first-flush runoff.

Aesthetics. Retention ponds offer a number of aesthetic advantages. They typically are more attractive than extended detention basins and are considered property value amenities in many areas. This is because sediment and debris accumulate within the permanent pool and are out of sight.

Other Siting Considerations. Retention ponds can be designed to require little hydraulic head to operate. While Figure 5.15 shows a dam at the downstream end of the pond, in flat terrain the permanent pool can be excavated below the ground surface, a common practice in the state of Florida (U.S.). Before excavating into the groundwater table, check with local regulatory authorities; however, if the pond is not sited over a gravel or karst formation, it should not adversely affect the quality of the groundwater, although such a possibility may exist in some cases. Most pollutants typically are removed from the groundwater in the first 0.4 to 0.9 m (18 to 36 in.) of soil downgradient of the pond.

Other issues to consider when choosing a retention pond include

- If the tributary catchment is large enough to have sufficient base flow to sustain a permanent pool;
- If the receiving waters immediately downstream are particularly sensitive to increased effluent water temperatures that can result from introduction of the pond;
- If existing wetlands at the site restrict the use of a permanent pool; and
- If water rights available for evapotranspiration are consumptive use in states with a prior appropriation water law system.

DESIGN METHODS. Two different methods are used for the design of permanent pools for a retention pond:

- Solids-settling design method relies on the solids-settling theory and assumes that all pollutant removal is because of sedimentation (Driscoll, 1983, and U.S. EPA, 1983).
- Lake eutrophication model design method provides for a level of eutrophication by accounting for the principal nutrient removal mechanisms (Hartigan, 1989, and Walker, 1987).

Solids-Settling Design Method. The solids-settling method is most appropriate for situations where the control of total suspended sediments and pollutants that attach themselves to the solids is the principal objective. The method relies on rainfall and runoff statistics, pond size, and settling velocities of suspended solid particle size distributions to calculate total suspended sediment removal. This method assumes an approximate plug flow system in the retention pond with all pollutant removal resulting from sedimentation.

Retention pond design curves based on the solids-settling method are shown in Figure 5.16 (U.S. EPA, 1986) for low-density, single-family resi-

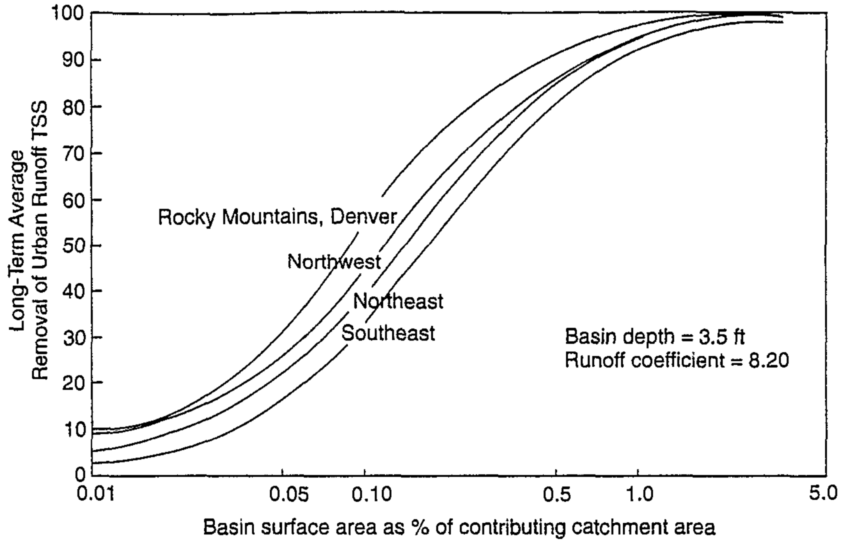

Figure 5.16 **Geographically based design curves for solids settling model (ft × 0.304 8 = m) (U.S. EPA, 1986).**

dential development (runoff coefficient, $RV = 0.2$). Separate design curves must be developed for other land-use patterns. These design curves relate average total suspended sediment removal to the size of the permanent pool. Here, the permanent pool size is expressed as the ratio of its surface area to the tributary catchment area and is based on a mean pool depth of approximately 1 m (3.5 ft). Average removal rates for other constituents may be estimated by multiplying the total suspended sediment removal rate by the average particulate fraction of the constituent of interest.

The total suspended sediment settling model was tested using data from nine retention ponds monitored during U.S. EPA's National Urban Runoff Program (NURP). Based on goodness-of-fit plots, it was concluded that the method did a reasonably good job of predicting removal rates at these nine NURP sites (Driscoll, 1983, and U.S. EPA, 1986).

A drawback to the performance curves shown in Figure 5.16 is that they were developed for only low-density residential land use (that is 20 to 30% imperviousness). However, comparison of this method with facilities designed using the maximized volume based on a 12-hour emptying time has shown nearly identical results, provided a surcharge extended detention volume is given. Thus, it is recommended that the permanent pool volume for the solids-settling method be the maximized volume based on a 12-hour drain time as described earlier in this chapter. It is also recommended that a surcharge extended detention volume be provided above the permanent pool, which is also equal to the maximized runoff volume. The outlet is then designed to draw down, or empty, this surcharge volume in 12 hours. This type of design significantly improves pollutant removal efficiency and virtually eliminates many of the short-circuiting problems often found in ponds without a surcharge extended detention volume above the permanent pool.

Lake Eutrophication Model Design Method. This method assumes that a retention pond is a small eutrophic lake that can be represented by empirical models used to evaluate lake eutrophication effects (Hartigan, 1989, and Walker, 1987). Using this design method, a retention pond can be sized to achieve a controlled rate of eutrophication and an associated removal rate for nutrients. Because retention ponds that achieve nutrient removal also remove other pollutants, typically it is not necessary for the design process to address constituents other than nutrients. Also, as noted earlier, large retention ponds may not be cost effective unless nutrient control is the principal water quality management objective.

The lake eutrophication design model is the phosphorus retention coefficient model developed by Walker (1985 and 1987). Like most input/output lake eutrophication models, this model is an empirical approach that treats the permanent pool as a completely mixed system and assumes that it is not necessary to consider the temporal variability associated with individual storm events. Unlike the solids-settling model, which accounts for temporal variability of individual storms, the Walker model is based on annual flows and loadings.

The model is applied in two parts:

$$K_2 = \frac{0.56 \cdot Q_S}{F \cdot (Q_S + 13.3)} \tag{5.11}$$

Where

K_2 = second-order decay rate, $m^3/mg \cdot a$;
Q_S = Z/T the mean overflow rate, m/a;
Z = mean pond depth, m;
T = average hydraulic retention time, years; and
F = inflow (ortho P)/(total P) ratio.

$$R = 1.0t \frac{1.0 - \sqrt{1.0 + (1.0 + 4N)}}{2N} \tag{5.12}$$

Where

R = total P retention coefficient (that is, BMP efficiency),
N = $K_2 \cdot P_T \cdot T$, and
P_T = inflow total P, μg/L.

Equations 5.11 and 5.12 were developed from a database for 60 U.S. Army Corps of Engineers' reservoirs and were verified for 20 other reservoirs. The model was applied by Walker (1987) to 10 NURP sites and 14 other retention pond systems and small lakes. The goodness-of-fit test yielded an $R^2 = 0.8$, indicating a good job of replicating monitored total P removals.

The permanent pool storage volume, V_B, is calculated for the desired average removal rate for P_t, which is a function of the average hydraulic retention time, T. The value of T (in years) is computed by dividing the permanent pool volume, V_B, by the product of the mean storm runoff, V_R, times the total number of runoff events per year, n, namely, $T = V_B/(V_R \cdot n)$. Field studies indicate that an optimum removal rate for T_P of approximately 50% occurs at T values of 2 to 3 weeks for pools with mean depths of 1.0 to 2.0 m (3 to 6 ft) (Hartigan, 1989). In the eastern U.S., this optimum range for T values corresponds to V_B/V_R ratios of 4 to 6. Ponds with values of T greater than 2 to 3 weeks have a greater risk of thermal stratification and anaerobic bottom waters, resulting in an increased risk of significant export of nutrients from bottom sediments.

State and regional stormwater management regulations and guidelines often address design criteria for the permanent pool storage volume in terms of either average hydraulic retention time, T, V_B/V_R, or minimum total suspended sediment removal rate. For example, the U.S. state of Florida (Florida DER, 1988) requires an average hydraulic retention time of 14 days, equivalent to V_B/V_R of 4; the Urban Drainage and Flood Control District's BMP criteria manual in the Denver, Colorado, area (U.S.) (UDFCD, 1992) specifies that the permanent pool storage volume should be 1.0 to 1.5 times the "water quality capture volume," which is equivalent to V_B/V_R on the order of 1.5 to 2.5. A municipal BMP handbook published by the California State Water Resources Control Board (Camp Dresser & McKee *et al.,* 1993) recommends that retention pond permanent pools be sized for a V_B/V_R of 3. The U.S. state of North Carolina's stormwater disposal regulations for coastal areas and water supply watersheds specify that the permanent pool should be sized to achieve a total suspended sediment removal rate of 85%, which is equivalent to a V_B/V_R in the range of 3 to 4 when no surcharge extended detention is provided. With surcharge extended detention, 85% removal of total suspended sediments has been achieved with a V_B/V_R of 2 or less.

CONFIGURING A RETENTION POND. Depth of Permanent Pool. Mean depth of the permanent pool is calculated by dividing the storage volume by the surface area. The mean depth should be shallow enough to ensure aerobic conditions and reduce the risk of thermal stratification but deep enough to ensure that algal blooms are not excessive and reduce resuspension of settled pollutants during significant storm events. The minimum depth of the open water area should be greater than the depth of sunlight penetration to prevent emergent plant growth in this area, namely, on the order of 2 to 2.5 m (6 to 8 ft).

A mean depth of approximately 1 to 3 m (3 to 10 ft) should produce a pond with sufficient surface area to promote algae photosynthesis and should maintain an acceptable environment within the permanent pool for the average hydraulic retention times recommended above, although separate analyses should be performed for each locale. If the pond has more than 0.8 ha (2 ac) of water surface, mean depths of 2 m (6.5 ft) will protect it against wind-generated resuspension of sediments. The mean depths of the more effective retention ponds monitored by the NURP study typically fall within this range. A water depth of approximately 1.8 m (6 ft) over the major portion of the pond will also increase winter survival of fish (Schueler, 1987).

A maximum depth of 3 to 4 m (10 to 13 ft) should reduce the risk of thermal stratification (Mills *et al.*, 1982). However, in the U.S. state of Florida, pools up to 9.2 m (30 ft) deep have been successful when excavated in high groundwater areas; this is probably because of improved circulation at the bottom of the pond as a result of groundwater moving through it.

Side Slopes along Shoreline and Vegetation. Side slopes along the shoreline of the retention pond should be 4H:1V or flatter to facilitate maintenance (such as mowing) and reduce public risk of slipping and falling into the water. In addition, a littoral zone should be established around the perimeter of the permanent pool to promote the growth of emergent vegetation along the shoreline and deter individuals from wading (see Figure 5.15). The emergent vegetation around the perimeter serves several other functions: it reduces erosion, enhances the removal of dissolved nutrients in urban stormwater discharges, may reduce the formation of floating algal mats, and provides habitat for aquatic life and wetland wildlife. This bench for emergent wetland vegetation should be at least 3 m (10 ft) wide with a water depth of 0.15 to 0.45 m (0.5 to 1.5 ft). The total area of the aquatic bench should be 25 to 50% of the permanent pool's water surface area. Local agricultural agencies or commercial nurseries should be consulted about guidelines for using wetland vegetation within shallow sections of the permanent pool.

Extended Detention Zone above the Permanent Pool. Some state or local regulations require detention of a specified runoff volume as surcharge above the permanent pool. Storage in the surcharge zone is released during a specified period through an outlet structure. This surcharge detention requirement is intended to reduce short circuiting and enhance settling of total suspended sediments. Settling-solids analysis shows that retention ponds sized for nutrient removal with a minimum detention time, T, of 2 weeks and a minimum V_B/V_R of 4 achieve total suspended sediment removal rates of 80 to 90%. Addition of an extended detention zone above the permanent pool is unlikely to produce measurable increases in the removal of total suspended sediments. Still, a surcharge extended detention volume is recommended whenever the V_B/V_R is less than 2.5. Whenever one is used or required, it is suggested that the maximized event-based volume with a 12-hour drain time be used.

Minimum and Maximum Tributary Catchment Areas. The minimum drainage area should permit sufficient base flow to prevent excessive retention times or severe drawdown of the permanent pool during dry seasons.

Unless regional experience is available for determining the minimum drainage area required in a particular location, it is recommended that a water balance calculation be performed using local runoff, evapotranspiration, exfiltration, and base flow data to ensure that the base flow is adequate to keep the pond full during the dry season.

The maximum tributary catchment area should be set to reduce the exposure of upstream channels to erosive stormwater flows, reduce effects on perennial streams and wetlands, and reduce public safety hazards associated with dam height. Again, regional experience will be useful in providing guidelines. For example, in the southeastern U.S., some stormwater master plans have restricted the maximum tributary catchments to 40 to 120 ha (100 to 300 ac) depending on the amount of imperviousness in the watershed, with highly impervious catchments restricted to the lower end of this range and vice versa. On the other hand, experience in semiarid areas has shown that even a small area of new land development can cause downstream erosion and that drainageway stabilization is needed between the new development and the pond for relatively small catchments.

Construction of Retention Ponds in Wetland Areas. One potential constraint on the use of retention ponds as regional BMPs is federal regulations that restrict the filling of wetland areas and the Section 404 permit program regulating any wetland or retention pond constructed for stormwater management. Although retention pond BMPs typically are designed to enhance pollutant removal by incorporating wetland areas along the perimeter, regulatory agencies may restrict their use if a significant amount of native wetlands will be submerged within the permanent pool. In addition, restorative maintenance of the created wetland areas, which includes removal of silt, may require a Section 404 permit. If work is performed without such a permit, the owner can be subject to federal and state enforcement action and fines. Thus, it is important to check with the local offices of the federal regulatory agencies, such as the U.S. Army Corps of Engineers and state regulators, about the need for such permits. A written response should always be obtained before proceeding with any restorative maintenance work.

Potential wetlands constraints must be addressed on a case-by-case basis during final design of each retention pond facility. If field inspections indicate that a significant wetlands area will be affected at a particular site, the following options can be pursued during final design:

- Investigate moving the embankment and permanent pool upstream of the major wetland area.
- If the above option is unfeasible, a wetland mitigation plan can be developed as a part of the retention pond design.
- If neither of the above options result in a design acceptable to regulatory agencies, consider using an extended detention basin instead. Eliminating the permanent pool can often reduce adverse effects on

native wetlands, but their direct oversight by regulatory agencies may not be avoided.

Basin Geometry. Relatively large length-to-width ratios can help reduce short circuiting, enhance sedimentation, and help prevent vertical stratification within the permanent pool. A minimum length-to-width ratio of 2:1 (3:1 preferred) is recommended for the permanent pool. The permanent pool should expand gradually from the basin inlet and contract gradually toward the outlet, maximizing the travel time from the inlet to the outlet. Baffles or islands within the pool can increase the flow path length and reduce short circuiting.

Soil Permeability. Highly permeable soils may not be acceptable for retention ponds because of excessive drawdown during dry periods. Where permeable soils are encountered, exfiltration rates can be minimized by scarifying and compacting a 0.3-m (12-in.) layer of the bottom soil of the pond, incorporating clay to the soil, or providing an artificial liner. Excavating the permanent pool into the groundwater table can also ensure its permanency, but seasonal fluctuations in the groundwater table need to be taken into account.

Forebay. To reduce the frequency of major cleanout activities within the pool area, a sediment forebay with a hardened bottom should be constructed near the inlet to trap coarse sediment particles. The forebay storage capacity should be approximately 10% of the permanent pool storage. Access for mechanized equipment should be provided to facilitate removal of sediment. The forebay can be separated from the remainder of the permanent pool by one of several means: a lateral sill with wetland vegetation, two ponds in series, differential pool depth, rock-filled gabions, a retaining wall, or a horizontal rock filter placed laterally across the permanent pool.

Inlet and Outlet Structures. The inlet design should dissipate flow energy and diffuse the inflow plume where it enters the forebay or permanent pool. Examples of inlet designs include drop manholes, energy dissipators at the bottom of paved rundown, a lateral bench with wetland vegetation, and the placement of large rock deflectors.

An outlet for a retention pond typically consists of a riser with a hood or trash rack to prevent clogging and an adequate antivortex device for basins serving large drainage areas. Some typical outlet structures are illustrated in Figure 5.17. Antiseep collars should be installed along outlet conduits passing through or under the dam embankment. If the pond is a part of a larger peak-shaving detention basin, the outlet should be designed for the desired flood control performance. An emergency spillway must be provided and designed using accepted engineering practices to protect the basin's embankment. Be certain that the pond embankment and spillway are designed in accordance with federal, state, and local dam safety criteria.

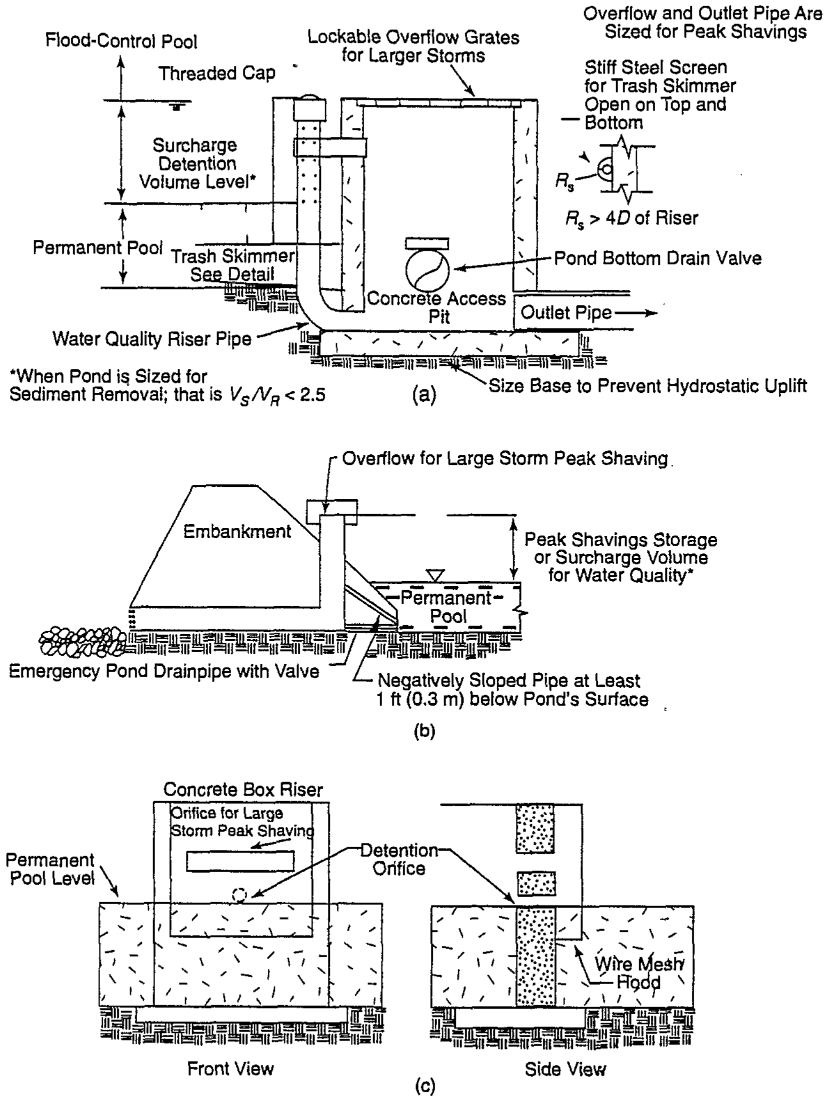

Figure 5.17 **Typical outlet structures: (a) outlet works with surcharge detention for water quality, (b) negatively sloped pipe outlet with riser, and (c) multiple orifice outlet (Schueler, 1987, and UDFCD, 1992).**

The channel that receives the discharge from the basin's outlet should be protected from erosive discharge velocities. Options include riprap lining of the channel or the provision of stilling basins, check dams, rock deflectors, or other devices to reduce outfall discharge velocities to nonerosive levels.

CONSTRUCTED WETLANDS

The use of constructed wetlands is popular for treating stormwater. Reported removal efficiencies vary. Strecker *et al.* (1992) summarized the performance of several wetlands in the U.S. for treatment of urban runoff; they found that suspended solids removals averaged 87%, with a range of 40 to 96%.

A significant deterrent to the comparison of removal efficiencies between wetlands is the lack of a standard set of design criteria. What is reported here is a general guidance based on information available in the literature.

DESIGN. General Considerations. Specific site conditions are important to the proper design of a wetland. Key site characteristics include soils, hydroperiod, and plant species and density. Depth to the confining layer or groundwater is important to ensure that the wetland does not dry up during extended periods of no rainfall. In addition, a constant source of surface water is recommended; stagnant water in the wetlands causes the underlying soil to become anaerobic, releasing ammonia, phosphorus, and heavy metals to the overlying water for washout during the next runoff event. Stagnant water also results in mosquito problems. Finally, the depth and duration of maximum submergence are important because an excess of either will kill the vegetation.

Hydraulic Design. The following hydraulic design criteria are recommended for wetlands:

- Maintain dry weather flow depths that vary through the wetland between 0.1 and 1.2 m (0.5 to 4 ft), depending on the types of vegetation planted, with the outlet structure designed so that the wetland can be periodically drawn down completely to dry the sediments (provides for natural oxidation of built-up organics);
- Size the wet weather storage volume using the methodology for extended detention basins but with a maximum surcharge depth above the dry weather flow depth of 0.6 m (2 ft) and a drawdown time of 24 hours; this will reduce stress on herbaceous wetland plants. The 0.6-m depth limitation will determine the surface area required for the wetland.
- Design inlet structures to achieve sheet flow across the wetland to the maximum extent possible.
- Design the outlet structure to control the water surface and protect it from plugging by floatables common in wetlands (see Inlet and Outlet Structures in this chapter).
- If open water is to be included in the wetland, it should be less than 50% of the total wetland area; the depth of the open water should follow the rules for the maximum permanent pool depth in retention ponds.

Configuration of the Wetland. The siting and configuration of the created wetland somewhat depend on adjacent land uses, the magnitude of contributing surface runoff, and the type of collection system (that is, shallow ditches or underground piping). Variations in topography and plant types will create more suitable habitat for wildlife. If the proposed site is large enough, some upland areas (peninsulas or islands) are preferable. Upland buffers increase the habitat value of a created wetland.

Figure 5.18 shows an idealized wetland basin designed to enhance stormwater quality. Urbonas and Stahre (1993) propose that the ideal shape is similar to an oval, with the outlet and inlet at opposite ends. If an oval shape is not possible, use any other elongated shape that separates the inlet and outlet as much as possible. The primary goals are to increase the contact time of the inflow with the wetland surfaces and ensure that the inflow does not short-circuit the facility. An elongated basin shape helps to achieve these goals. It is suggested that the length-to-width ratio of the wetland surface be no less than 3 (that is, $L/W > 3$); a 2:1 ratio is recommended by Livingston (1989).

The forebay shown in Figure 5.18 helps settle out the largest sediment particles before the flow passes over the areas covered with emergent vegetation. It also helps to spread the inflow uniformly over the entire wetland. The forebay should also have a baffle near the inlet as illustrated to break up the inflow jet and facilitate spreading of the inflow over the entire surface area of the wetland.

An overflow outlet, not dissimilar to a riser used in a retention pond, is placed within a deepened portion near the outlet end of the basin. This deepened basin helps keep the outflow zone free of emergent vegetation and makes the outlet less likely to clog. Wetlands serving small tributary watersheds will require small outlets to ensure that the drain time of the design capture volume is no fewer than 20 hours. However, designing small outlets that do not clog is difficult, if not impossible. For this case, a set of V-notch weirs or a sawtooth weir may be more appropriate for the outflow control device.

Vegetation. Suitable plants for created wetlands vary between different ecoregions. However, the wetland plants chosen for created wetlands should incorporate the following attributes:

- Tolerance to wide ranges of water elevations, salinity (salt content), temperature, and pH;
- A mixture of perennials and annuals;
- Moderate amounts of leaf production; and
- Proven removal efficiencies, for example, of *Scriptus* species.

Wetland plants are now commercially available in some municipalities from local nurseries who can provide additional information on tolerances and growth rates.

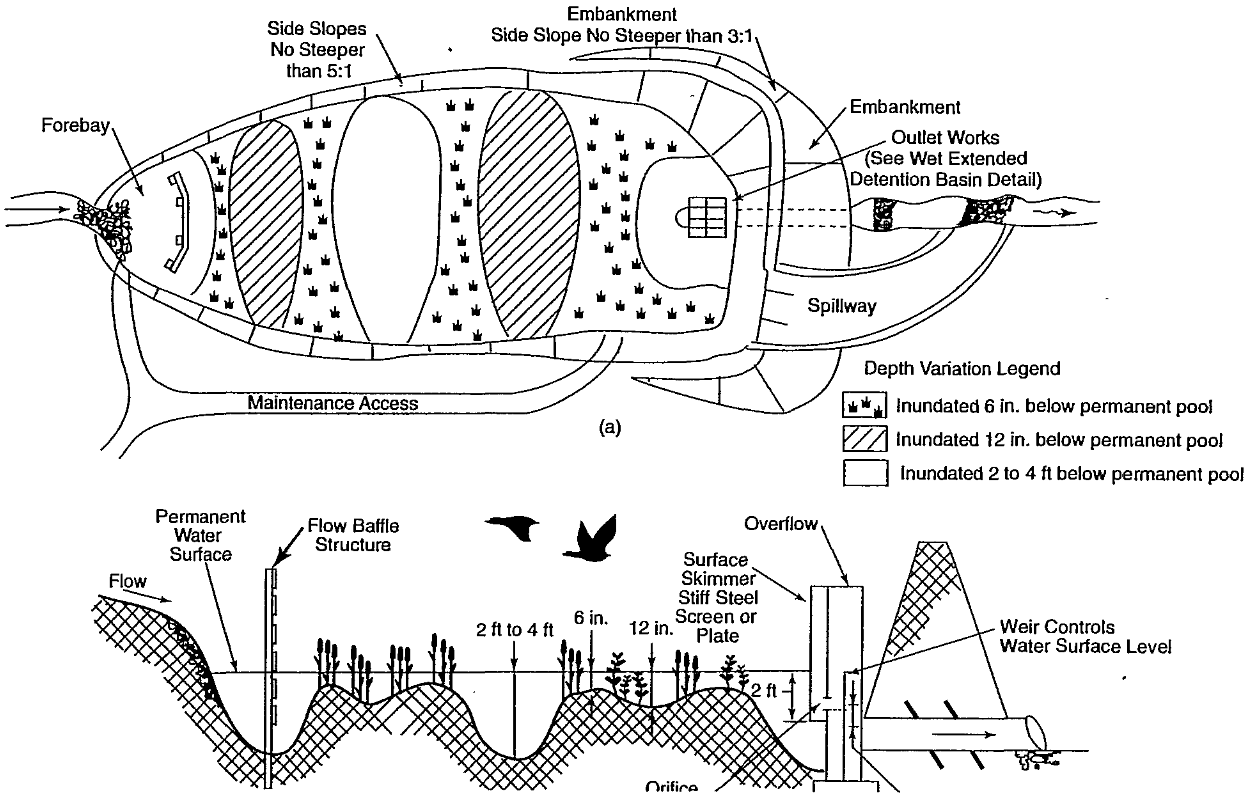

Figure 5.18 **Plan and profile of a wetland basin: (a) plan (not to scale) and (b) profile (not to scale) (ft × 0.304 8 = m; in. × 25.4 = mm).**

CONSTRUCTION. Construction management of the wetland is critical. Elevations and contouring of the constructed wetlands are the most important aspect of created wetlands—especially with respect to the groundwater. The confining layers of clay will vary from place to place within a specific area. If the clay layer is breached, clay should be replaced and the elevations of that location should be changed in the design.

Proper staging and sequencing will provide areas for dewatering during construction to reduce effects to adjacent waters. Rim ditches are particularly beneficial to avoid excessive pumping. When the created wetland is adjacent to an existing wetland, a temporary berm is needed until final grade has been achieved.

The use of organic soils is necessary to provide moisture-retaining abilities during drier periods and nutrients. If at all possible, soils (muck) from displaced wetlands should be stockpiled and used in the created wetland. Care should be taken to ensure wetland soils with nuisance species are not used. The displaced muck will provide root propagules, seed sources, micro- and mieofauna, and other invertebrates. Topsoil or peat can be substituted in the place of wetland muck. The muck/organic layer should be 0.1 to 0.3 m (6 to 12 in.) deep. Depths greater than 0.3 m (12 in.) tend to create difficulties in spreading the muck and planting.

If possible, it is best to control the hydration of the newly constructed wetland. The installation of plant material is most efficiently accomplished in saturated conditions, but standing water can cause poorly installed plants to float. Flash-board risers and adjustable gates can aid in controlling water levels during construction. However, if water control is not possible, wetland plants should be acclimated to inundation in the nursery before shipping to the site.

Keeping the soils saturated for 1 week after the muck/mulch has been spread will encourage seeds and propagules to sprout. If the wetland creation area is flooded with 0.15 m (6 in.) of water, by the second week this flooding will selectively remove upland species. The remaining water can be allowed to fill to design level after 3 weeks (Tesket and Hinckley, 1977).

MONITORING. Monitoring the created wetland will ensure proper coverage of the planted zones by desirable species. Monitoring should be done quarterly for the first year, semiannually for the second and third years, and (when necessary) annually for the fourth and fifth years.

Monitoring the wetland for the following information will help prevent future problems:

- Percent survivorship of planted species—subsamples can be used to provide quantitative results in larger wetlands,
- Percent cover of planted species and recruited desirable plants,
- Percent cover of nuisance species,
- Wildlife use, and
- Qualitative assessments of water quality.

Replanting as necessary to achieve the 85% survival rate at the end of each year is beneficial. It is critical to assess the created wetland for nuisance species. If the nuisance coverage is greater than 10%, maintenance through removal may be necessary.

MAINTENANCE. Maintenance includes three primary areas: replanting, nuisance species removal, and excavation of sediment sumps. Adjustments in plant type may be needed to accommodate differences in elevations. Typically, this is easier than regrading an established area. If water levels are lower than desired, adjustment of the control structure can increase survival.

Removal of nuisance species will increase the function and value of the constructed wetland. Harvesting wetland plants can be considered for nutrient removal but can resuspend trapped sediments. This resuspension, with habitat disturbance, is probably less beneficial than the actual nutrient removal.

MEDIA FILTRATION

Figure 5.19 shows a conceptual rendering of a media filtration facility widely used in the U.S. city of Austin, Texas. It consists of a settling basin followed by a filter. Field research indicates the sand filter has a suspended solids removal efficiency similar to that of retention ponds and extended detention.

The most typical filter is sand, but some use a peat and sand mixture because peat has the adsorptive ability to remove organics and dissolved contaminants. Clogging problems have been reported with the peat mixture (Tomasak *et al.*, 1987), but this may be because of the type of peat used (Galli, 1990). Limited research also indicates that compost made from leaves can be effective at removing dissolved phosphorus, metals, oil, and grease (Stewart, 1989), but field data show inconsistent performance.

Presettlement is essential to avoid rapid clogging of the filter. The device should not be on line during construction in the tributary watershed. Filters should be designed to have overflow or bypass for extreme events to protect against flooding because of backups if filter plugging occurs. It should be noted, however, that providing the bypass allows a clogged filter to appear to be operating effectively. The only way to ensure that the filter is not plugged is faithful periodic inspection providing a design that clearly indicates when the filter is no longer draining, such as excessive surface ponding or excessive bypasses by runoff.

THE AUSTIN, TEXAS, FILTER. The most extensive experience to date is with surface facilities of the type shown conceptually in Figure 5.19. This type of facility has been used on catchments of up to 20 ha (50 ac) in Austin, Texas, where it originated. Austin provides for two designs—one with full sedimentation and the other with partial sedimentation.

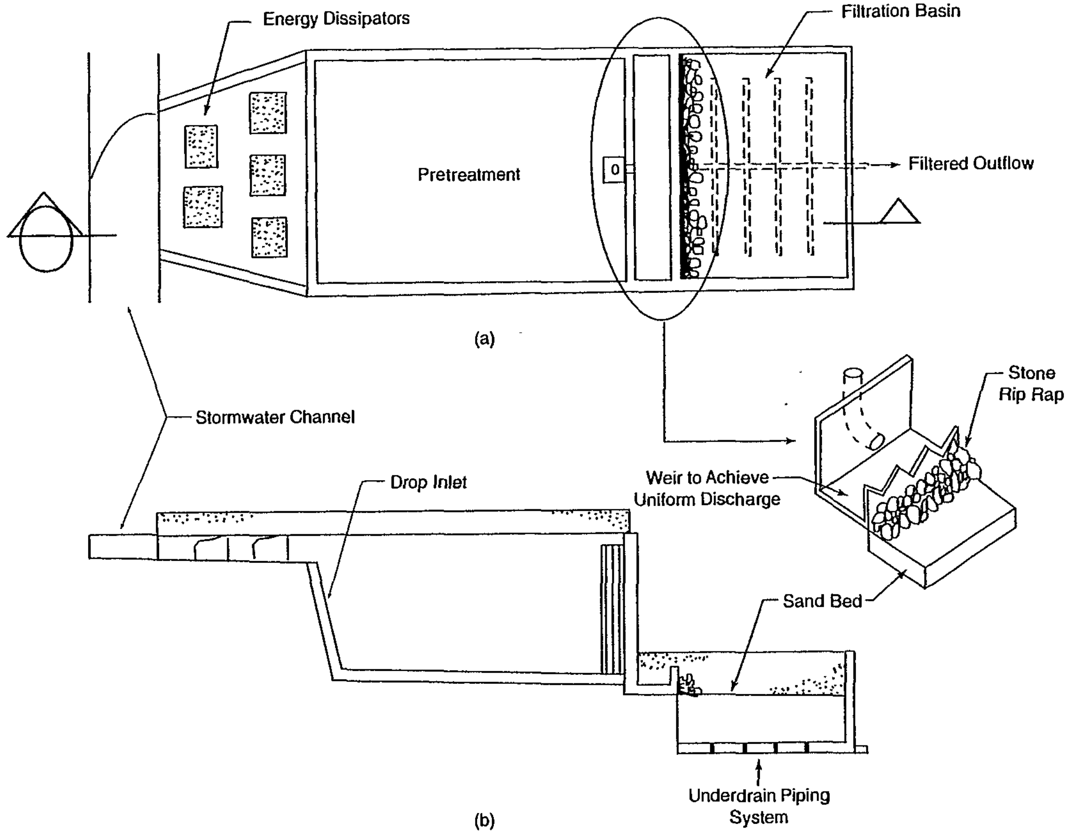

Figure 5.19 **Sand filter with a presettlement basin: (a) plan view and (b) elevation.**

The full sedimentation configuration includes a sedimentation basin designed to hold the entire water quality volume (that is, equivalent to the 40-hour drain time maximized volume) and to release this volume to the filter over a 40-hour drawdown period. This system should be used unless topographical constraints make this design unfeasible.

The partial sedimentation configuration requires less depth than the full sedimentation system and may be applicable where topographical constraints exist. In this system, a smaller sedimentation chamber is located upstream of the filtration basin and is designed to remove the heavier sediment and trash litter only. It requires more intensive maintenance than the full sedimentation system. The volume of the sediment chamber should be no less than 20% of the water quality volume used for the full sedimentation design. The design must ensure that the sediment chamber discharges the flow evenly to the filtration basin. Rock gabions composed of 300- to 450-mm (12- to 18-in.) diameter rocks can be used for this purpose. The outflow side of the sediment chamber should incorporate features to prevent gouging of the sand media (for example, concrete splash pad or riprap).

Determining the Surface Area of the Filter. This procedure is based on the design guidance provided in Austin, Texas. The design provides that a design water quality volume, namely the maximized volume, is processed through the filter without overtopping or bypassing the facility. The filter is sized as follows:

- Average hydraulic head on the filter is approximately 0.9 m (3 ft).
- For the full sedimentation design: 40-hour drawdown rate of the water quality volume and coefficient of permeability $K = 1.1$ m/d (3.5 ft/d).
- For the partial sedimentation design: 8-hour drawdown rate of the water quality volume and coefficient of permeability $K = 0.6$ m/d (2 ft/d).
- Clean concrete aggregate sand 0.02 to 0.04 in. in diameter (ASHTO C-33).

The above criteria result in the following equation:

$$A_F = \frac{A_T \cdot P_O}{12 \cdot K \cdot T_D} \tag{5.13}$$

Where

A_F = filter area, m^2 (sq ft);
A_T = area of the tributary catchment, m^2 (sq ft);
P_o = runoff volume equal to the maximized volume, mm (in.);
K = coefficient of permeability, m/d (ft/d); and
T_D = drawdown time of the maximized volume (40 hours for full sedimentation and 8 hours for partial sedimentation).

As an example, assume a 0.37-ha (40 000-sq ft) commercial catchment in the U.S. city of Dallas, Texas, with a runoff coefficient $C = 0.70$. Size a filter for the full sedimentation and the partial sedimentation conditions. Using Equation 5.2, the maximized runoff volume for this catchment is

P_O = 18.5 mm (0.73 in.) for the full sedimentation condition; and

P_O = 13.2 mm (0.55 in.) for the partial sedimentation condition.

Thus, for the full sedimentation condition, Equation 5.13 results in

$$A_F = \frac{(40\ 000)(0.73)}{12 \cdot (3.5) \cdot (40/24)} = 39 \text{ m}^2 \text{ (417 sq ft)}$$

and for the partial sedimentation condition, it becomes

$$A_F = \frac{(40\ 000)(0.55)}{12 \cdot (2.0) \cdot (8/24)} = 255 \text{ m}^2 \text{ (2 750 sq ft)}$$

Both filters will pass the maximized storm runoff volume or smaller without overtopping or bypassing any runoff, provided the filter is not excessively clogged. However, the full sedimentation design will have an extended detention basin upstream of the filter equal to 18.5 mm (0.73 watershed in.) of runoff, while the partial sedimentation design will have a basin with a volume equal to 20% of this volume. The design of choice will be governed by site constraints, maintenance considerations, and the owner's choices of which arrangement best fits the commercial site.

Configuring a Sand Filter. In addition to the coarse sediment and trash interception provided by the upstream detention storage, consider the following:

- Provide a trash rack at the outlet of the sedimentation basin,
- Provide access for maintenance equipment,
- Provide freeboard or a safe bypass when basin is full,
- Provide a sediment trap at the inlet to reduce resuspension,
- Use a flow spreader,
- Use one of two alternative sand bend designs (see Figure 5.20),
- Use a minimum sand bed thickness of 0.4 m (18 in.), and
- Provide underdrains under the sand.

LINEAR FILTERS—DELAWARE. An underground "linear" filter (see Figure 5.21) used in Delaware (U.S.) is suggested by Shaver (1991) for catchments of up to 2 ha (5 ac). This underground system uses a vault with a permanent pool of water as the pretreatment device. Shaver (1991) recommends that the volume of both the sedimentation and the filter chambers be approximately 38 m^3/ha (540 cu ft per contributing ac) and that the surface area of each chamber be 25 m^3/ha (360 sq ft per contributing ac). Configure the filter as follows:

- Depth of sand (0.4 m, or 18 in.).

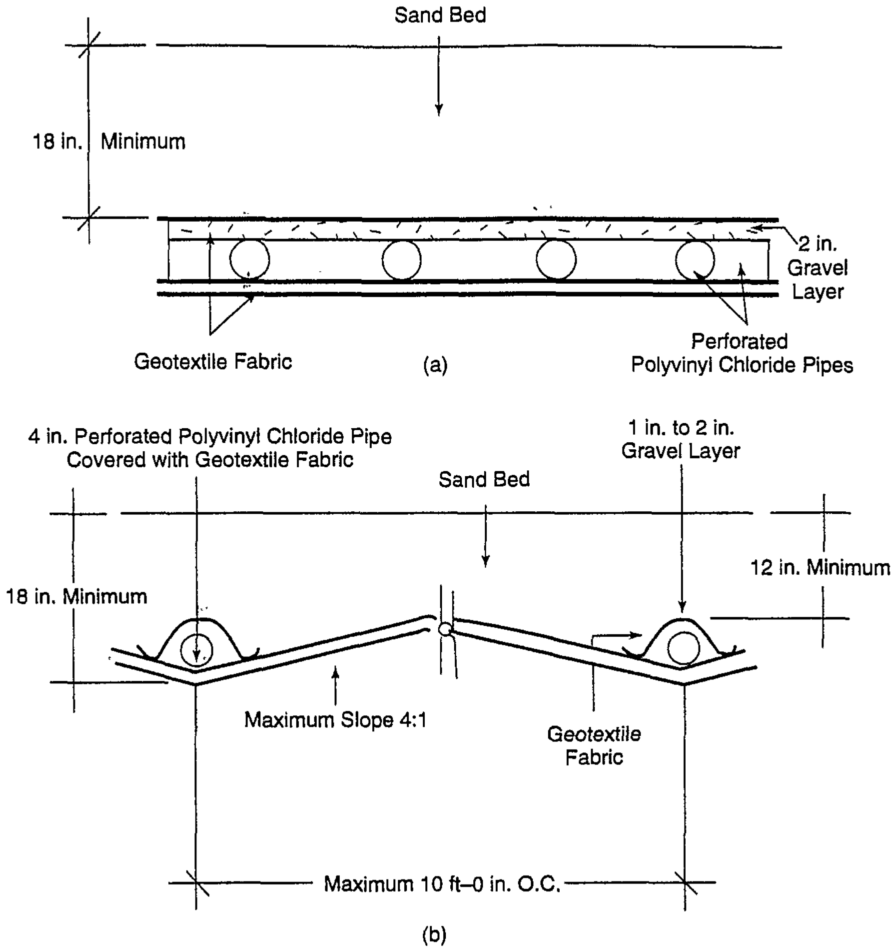

Figure 5.20 **Sand bed filtration configurations: (a) sand bed profile (with gravel layer) and (b) sand bed profile (trench design) (ft × 0.304 8 = m; in. × 25.40 = mm) (City of Austin, 1989).**

- Diameter of the outlet pipe should be 0.1 m (6 in.) or less (use multiple outlets if necessary).
- Position the filter relative to the pavement to evenly distribute the flow as it enters the sedimentation chamber. Pavement and inlet design and construction are, therefore, critical.

UNDERGROUND VAULT—WASHINGTON, D.C. A similar type of linear filter, illustrated in Figure 5.22, has been used in the Washington, D.C., area (U.S.). It is suggested that this particular design be viewed cautiously for the following reasons. First, the initial settling chamber is undersized for effective sedimentation, causing the filter to clog quickly. Second,

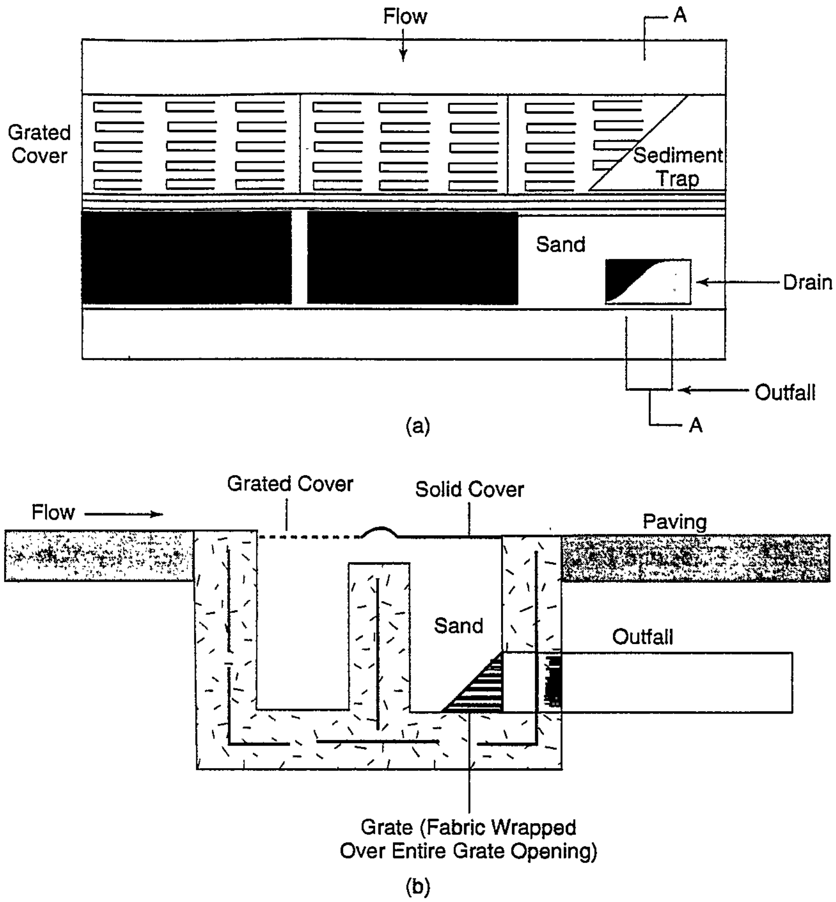

Figure 5.21 **Linear filter: (a) plan view and (b) section A-A (Shaver, 1995).**

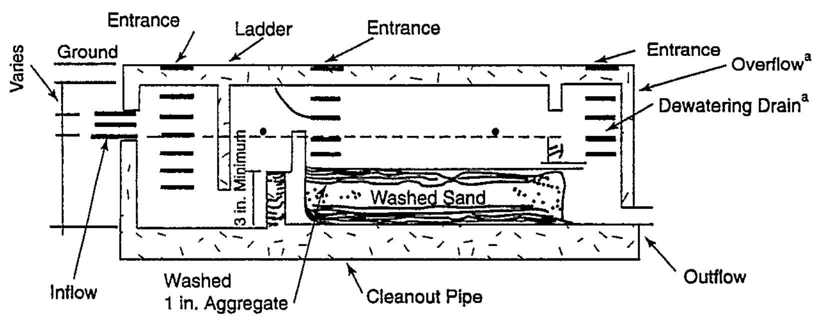

Figure 5.22 **Underground vault filter ([a]an ungated dewatering drain and overflow are not recommended) (in. × 25.40 = mm).**

R0017576

when the filter clogs, the flow will simply overtop the overflow weir and flow directly to the outlet, with no indication that the filter is plugged. If this filter type is to be used, it should be sized using the Delaware linear filter criteria, including the presettlement chamber. It is also strongly recommended that the overflow weir and dewatering drain in the filter chamber be blocked and that the entrance manhole covers over the sedimentation chamber and the outflow chamber be replaced with grates. Then, if the filter clogs, the water will back up in the vault, overflow out of the inlet grate over the sedimentation compartment, and back into the outfall chamber. This will be a clear visual indication that the filter is plugged.

MAINTENANCE. Inspect semiannually and after major storms. Sediment and all floatables should be removed: from the settling basin when 100 mm (4 in.) accumulates; from the filter when 2.5 mm (0.1 in.) or more accumulates; or when there is standing water over the filter 40 hours after the storm. Field experience in Austin, Texas (U.S.), indicates the filter surfaces must be cleaned about twice each year by raking off the dried sediment. If there are open space areas in the tributary catchment that are erosive, or if construction is occurring, more frequent cleaning will be necessary. Consult Shaver (1991) and Truong (1989) for additional design and maintenance criteria.

OIL AND WATER SEPARATORS

Oil and water separators are designed to remove petroleum compounds, grease, and grit. They will also remove other floatable debris. Two types of oil and water separators—conventional gravity separators and the coalescing plate interceptor (CPI)—are used at all bulk petroleum storage and refinery facilities. The lack of oil characteristics and the apparently low concentrations of oil in most stormwater result in considerable performance uncertainty.

APPLICATION. This treatment control is applicable when the concentrations of oil- and grease-related compounds are abnormally high and source control does not provide effective control. The typical business types of concern are gasoline stations and truck, car, and equipment maintenance and washing enterprises and other commercial and industrial facilities that generate high levels of oil products in runoff wastes. Public facilities for which separators may be considered include marine ports, airfields, fleet vehicle maintenance and washing facilities, and mass transit park-and-ride lots.

PERFORMANCE. Conventional separators are capable of removing oil droplets with diameters equal to or greater than 150 microns. A CPI separator should be used if smaller droplets must be removed. When the droplet size is of sufficient size, oil and grease concentrations can be reduced to 10 mg/L or less (Lettenmaier and Richey, 1985).

Separator sizing is based on the rise velocity of an oil droplet, using oil density and droplet size to calculate rise velocity or using direct measurement of rise velocities. With the exception of stormwater from oil refineries, there are no relevant design data describing the characteristics of petroleum products in urban stormwater. A portion of the petroleum products are attached to fine suspended solids and, therefore, are removed by settling not flotation. Consequently, the performance of oil–water separators for urban stormwater runoff is uncertain.

DESIGN. The basic configurations of the two types of separators are illustrated in Figure 5.23. With small installations, a conventional gravity separator has the general appearance of a septic tank but is longer with respect to its width. Larger facilities have the appearance of a municipal wastewater primary sedimentation tank. The CPI separator contains closely spaced plates that enhance the removal efficiency and consequently requires less space than a conventional separator. The angle of the plates to the horizontal ranges from 0 (horizontal) to 60 deg, although 45 to 60 deg is typical. The perpendicular distance between the plates typically ranges from 19 to 25 mm (0.75 to 1.0 in.). The stormwater will flow either across the plates or down through the plates, depending on the plate configuration.

SIZING. The sizing of a separator is based on the calculation of the rise velocity of the oil droplets using Equation 5.14 (modified from API, 1990):

$$V_P = \frac{5.76 \cdot (d_p - d_c) \cdot d^2}{n} \cdot 10^{-15} \tag{5.14}$$

Where

V_p = rise velocity, m/s (ft/sec);
d_p = density of the oil, kg/m^3 (lb/cu ft);
d_c = density of the water, kg/m^3 (lb/cu ft);
d = diameter of the droplet to be removed, m (ft); and
n = absolute viscosity of the water, kg/m^2 (lb/sq ft).

An appropriate water temperature value for selecting water density and viscosity is the expected temperature of the stormwater during the winter period. There are no data on the specific gravity of petroleum products in urban stormwater, but values between 0.85 and 0.95 typically are used. Also, distribution of droplet sizes must be known to select the appropriate droplet diameter for a stated efficiency goal. However, there is little information on the size distribution of oil droplets in urban stormwater. An oil droplet size and

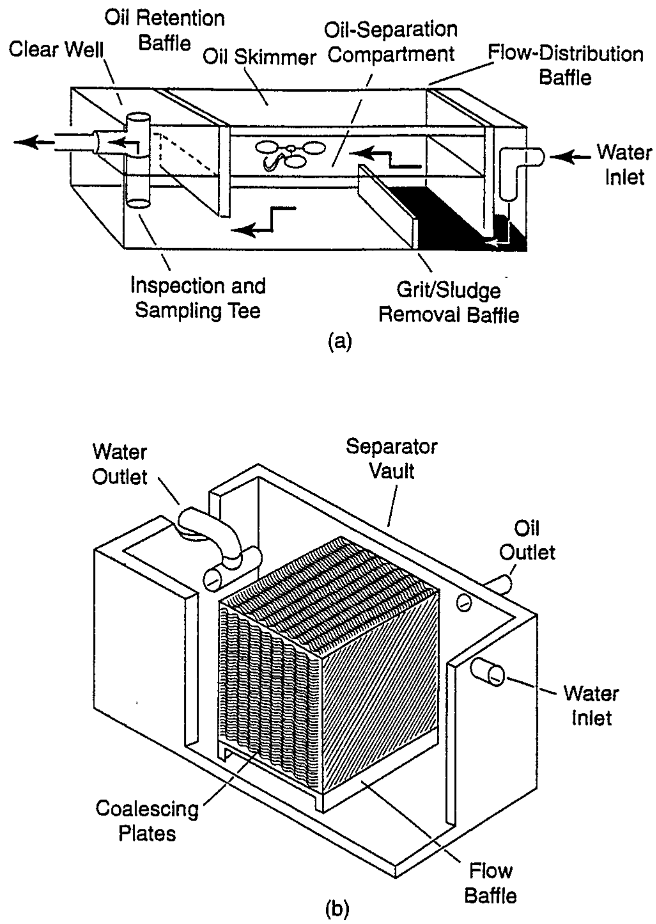

Figure 5.23 **(a) Conventional and (b) coalescing plate separators.**

volume distribution for stormwater from a petroleum products storage facility is depicted in Figure 5.24. Because a design influent concentration must be assumed, there will be considerable uncertainty because it will vary widely within and between storms.

If the effluent goal is 20 mg/L and the design influent concentration is 50 mg/L, a removal efficiency of 60% is required. Using Figure 5.24, this efficiency can be achieved by removing all droplets with diameters 90 microns or larger. Using a water temperature of 10°C (a water density of 0.999) and an oil density of 0.898, the rise velocity for a 90-micron droplet is 1.2 m/h (0.001 1 ft/sec).

It is typically believed that conventional separators are not effective at removing droplets smaller than 150 microns (API, 1990). Theoretically, a conventional separator can be sized to remove a smaller droplet, but the facility may be so large that the CPI separator may be more cost effective.

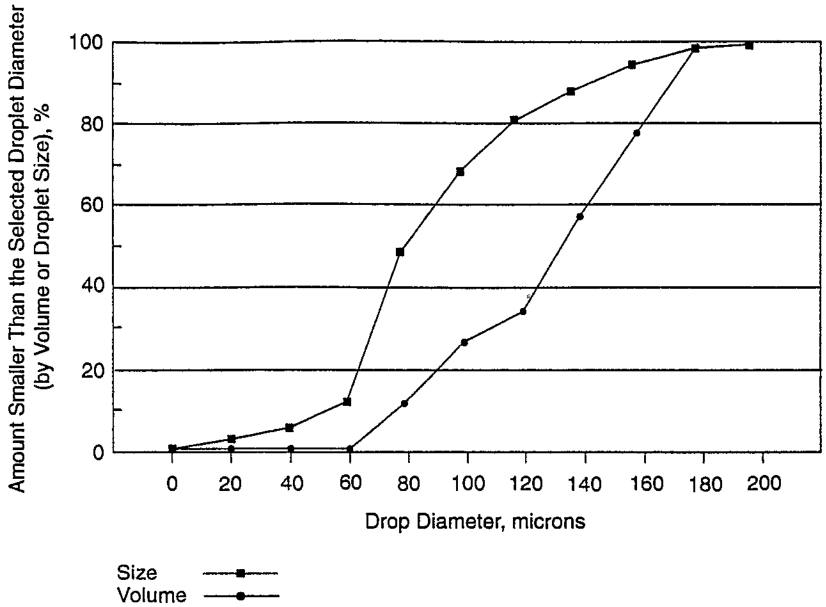

Figure 5.24 **Oil droplet size distribution in stormwater from petroleum products storage facilities.**

Sizing Conventional Separators. To size a conventional separator, first compute the depth:

$$D = \sqrt{\frac{Q}{2V}} \tag{5.15}$$

Where

D = depth, which should be between 0.9 and 2.4 m (3 and 8 ft);
Q = design flow rate, m^3/s (cfs); and
V = allowable horizontal velocity, no more than 15 times the design oil rise rate but not greater than 55 m/h (0.05 ft/sec).

If the computed depth exceeds 2.4 m (8 ft), design additional parallel units such that, at the design flow rate, the maximum recommended depth of 2.4 m (8 ft) is not exceeded. Minimum depth is 0.9 m (3 ft).

The next steps are

- Calculate length, $L = I \cdot D/V_p$;
- Select width, W = 2 to 3 times the depth, but not to exceed 6 m (20 ft);
- Baffle height-to-depth ratio of 0.85 for top baffles and 0.15 for bottom baffles;
- Locate the distribution baffle at 0.10L from the entrance;

R0017580

- Add 0.3 m (1 ft) for freeboard; and
- Install an inlet flow control and a bypass for flows in excess of the design flow.

Sizing Separators. Manufacturers can provide packaged separator units for flows up to several cubic metres (cubic feet) per second. For larger flows, the engineer must size the plate pack and design the vault. Given the variability of separator technology among manufacturers with respect to plate size, spacing, and inclination, it is recommended that the design engineer consult vendors for a plate package that will meet the engineer's criteria.

The engineer can size the facility using the following procedure. First, identify the expected plate angle (vertical above horizontal), H, in degrees, and calculate the total plate area required, A, in square metres (square feet):

$$A = \frac{Q}{V_P \cdot \cos(H)} \qquad (5.16)$$

where the terms are the same as defined under Equations 5.14 and 5.15.

Coalescing plate interceptor separators are not 100% hydraulically efficient, ranging from 0.35 to 0.95 depending on the plate design. If the engineer wishes to incorporate this factor, divide the result from Equation 5.16 by the selected efficiency.

- Select spacing, S, between the plates, typically 19 to 38 mm (0.75 to 1.5 in.).
- Identify reasonable plate width, W, and length, L.
- Number of plates $N = A/(W \cdot L)$.
- Calculate plate volume, P_v, m^3 (cu ft).

$$P_V = \left[\frac{N \cdot S}{12} + L \cdot \cos(H)\right] \cdot [W \cdot L \cdot \sin(H)] \qquad (5.17)$$

- Add 0.3 m (1 ft) beneath the plates for sediment storage.
- Add 0.1 to 0.3 m (6 to 12 in.) above the plates for water clearance so that the oil accumulates above the plates.
- Add 0.3 m (12 in.) for freeboard.
- Add a forebay for floatables and distribution of flow if more than one plate unit is needed.
- Add an afterbay for collection of the effluent from the plate pack area.
- For larger units include a device to remove and store oil from the water surface.

Horizontal plates require the least plate volume to achieve a particular removal efficiency.

Settleable solids will accumulate on the plates, complicating maintenance procedures. Experience shows that, even with slanted plates, some solids will stick to the plates because of the oil and grease. If debris is expected such as sticks, plastics, and paper, then select a larger plate separation distance. As an alternative, install a trash rack or screens with smaller openings than the plate spacing. The plates may be damaged by the weight when removed for cleaning.

MAINTENANCE. Check monthly during the wet season and clean several times a year. Always clean before the start of the wet season. Properly dispose of the oil.

Ocean Water
Regulatory & Monitoring Protocol

County of Los Angeles
Department of Health Services
Public Health Programs and Services
Environmental Health
Recreational Health Program
(Revised 5/5/99)

R0017597

PROGRAM DESCRIPTION

The Recreational Health Program is responsible for the ocean water contact sports area regulatory program. The program enforces laws and regulations regarding beach sanitation and water quality standards. Elements of the program include ocean water monitoring, posting of warning signs on beaches when State standards are not met and emergency response including beach closure when a sewage or chemical spill occurs.

REGULATORY PROGRAM

The California Health and Safety Code, Section 11580 and the California Code of Regulations, Title 17, Sections 7956-7962, authorize the local health officer to conduct ocean water bacteriological monitoring and take corrective action when standards are not met. The County of Los Angeles Department of Health Services (DHS) conducts a comprehensive regulatory program. A routine ocean water monitoring program is conducted through sample collection and bacterial analyses. Minimum standards prescribed by the State constitutes the basis for regulatory action.

Incident reports involving the discharge of sewage not meeting Waste Discharge Requirements established by the California Regional Water Quality Control Board are received and evaluated according to the policy outlined below. Reports of hazardous material discharges affecting the beach and surf zone waters are investigated by the appropriate agency. Information and reports received as a result of these investigations are received and evaluated.

In order to effectively discharge the duties of the health officer in regard to ocean water contact sports areas, a beach warning, beach closure and rain advisory policy have been developed and implemented.

BEACH WARNING, CLOSURE AND RAIN ADVISORY POLICY

BEACH WARNING: Regulatory action taken by the health officer posting " Beach Warning" signs in areas where a storm drain discharges to the ocean or where bacteria levels exceed State bacteriological single sample standards as set forth in the California Code of Regulations, Title 17. DHS will direct the Los Angeles County, Fire Department, Lifeguard Division, (LD) to post affected portions of the beach with "Beach Warning" signs. This information will be made available via a telephone hotline.

BEACH CLOSURE: Regulatory action taken by the health officer closing an affected area of beach. This action is taken when there is a known incident of sewage pollution or chemical contamination of ocean water. DHS will direct the Los Angeles County, Fire Department, Lifeguard Division, (LD) to close affected portions of the beach and post "Beach Closure" signs. The DHS Public Information Office will issue as soon as practicable a public advisory through the wire services explaining which beach areas are closed and why. In addition, this information will be made available via a telephone hotline.

HAZARDOUS MATERIALS DISCHARGE: Beaches impacted by the discharge of a verified hazardous material (visible material, strong odor, etc.).

ELEVATED BACTERIA LEVELS: Bacteria levels that exceed State bacteriological single sample standards as set forth in the California Code of Regulations, Title 17.

PUBLIC NOTIFICATION: The DHS Public Information Office will issue a public advisory as soon as practicable to the wire services whenever an advisory due to rain is issued or when a beach area is closed. In addition, this information will be made available via a telephone hotline.

BEACH RAINFALL ADVISORY: Action taken by the health officer when a significant rainstorm is predicted or as one occurs. The DHS Public Information Office will issue as soon as practicable a public advisory through the wire services explaining that storm drain flows may cause elevated bacterial counts for 72 hours and ocean water contact, especially in areas adjacent to storm drain flows, should be avoided. In addition, this information will be made available via a telephone hotline.

MONITORING PROGRAM

DHS routinely collects ocean water samples at 38 sampling locations from Ventura County, south to Redondo Beach Pier and on Catalina Island. The majority of sampling points are located at frequented beaches and in the vicinity of storm drains.

Samples are collected from ankle to knee-deep water, approximately 4 to 24 inches below the water surface in the surf zone.

Sample analyses are conducted by the Department of Health Service's laboratory for total coliform, fecal coliform and enterococcus bacteria. Bacterial analysis is made in accordance with procedures recommended by the latest edition of Standard Methods for Examination of Water and Wastewater.

Analyses are completed within 24-48 hours from the time samples are collected. Results are obtained from the laboratory via email. The laboratory will telephone results sooner if unusually high counts are detected.

Samples are collected every Monday. Samples from Catalina Island are collected every Tuesday between April 1st and October 31st. Holidays may require samples to be collected on alternate days due to laboratory scheduling requirements.

SUPPLEMENTAL MONITORING DATA FROM OTHER AGENCIES

The Los Angeles City, Bureau of Sanitation, Environmental Monitoring Division (EMD) laboratory provides the Recreational Health Program with daily bacteriological data for 20 shoreline stations with daily data for total coliform and fecal coliform. Tests for enterococcus bacteria are conducted five times a month. Data for Ballona Creek, selected storm drains and special sampling results are also included. Data is provided daily via email. Results are normally obtained within 24 - 48 hours except on weekends and holidays.

The Los Angeles County Sanitation District collects 8 shore samples from Malaga Cove to Outer Cabrillo Beach and conducts analyses for total coliform, fecal coliform and enterococcus bacteria. The Los Angeles County Sanitation District laboratory provides the Recreational Health Program with sampling results every Monday and Tuesday via fax.

DATA TABULATION

Samples results are reported, stored and analyzed using Microsoft Excel. Samples reported as "greater than" or "less than" are recorded as the number reported (e.g. >16,000 will be recorded as 16,000 and <10 as 10).

A summary report of samples collected by the Department of Health Services is prepared and distributed monthly using Microsoft Excel.

BACTERIOLOGICAL STANDARDS

Based on a single sample, the density of bacteria in water from each sampling station at a public beach or public water contact sports area shall not exceed:

10,000 total coliform bacteria per 100 ml or

400 fecal coliform bacteria per 100 ml or

104 enterococcus bacteria per 100 ml or

1,000 total coliform bacterial per 100 milliliters, if the ratio of fecal/total coliform bacteria exceeds 0.1.

SIGNS

There shall be three types of signs that are used to warn the public of hazardous conditions in ocean waters:

1. **BEACH CLOSURE SIGN** (aka "Yellow Sign") - This sign shall be posted when a beach

is closed due to a sewage spill or chemical contamination. The sign shall have the following verbiage in both English and Spanish:

Beach Closed - Sewage Contaminated Water - Contact May Cause Illness

The words "KEEP OUT" shall be in red letters and the remaining words in black letters on a yellow background. There shall be a graphic depiction of a swimmer in a red circle with a diagonal hash mark

2. **STORM DRAIN WARNING SIGN** (aka "White Sign") - This sign shall be posted at or in front of any flowing storm drain or creek discharging into the ocean. The sign shall have the following verbiage in both English and Spanish:

   WARNING - Storm Drain Water May Cause Illness

   The words "WARNING" shall be in red letters and the remaining words in black letters on a white background. There shall be a graphic depiction of a swimmer in a red circle with a diagonal hash mark and a yellow/black striping on the border.

3. **BEACH WARNING SIGN** (aka "Brown Sign") - This sign shall be posted at areas of beach where testing indicates that bacteria levels exceed State bacteriological single sample standards. The sign shall have the following verbiage in both English and Spanish:

   WARNING - Ocean Water Contact May Cause Illness - Bacteria Levels Exceed Health Standards

   The words "WARNING" shall be in red letters and the remaining words in black letters on a light brown background. There shall be a graphic depiction of a swimmer in a red circle with a diagonal hash mark and a red/black striping on the border.

PROCEDURES DURING SEWAGE SPILLS

A. All information and actions taken shall be recorded in the incidence log book maintained by the Recreational Health Program.
B. The following information should be obtained from the person reporting the spill:
   1. Location of spill.
   2. Whether sewage has entered or will enter ocean waters.
   3. Time the spill began and ended and the estimated number gallons involved.
   4. If flow is continuing, the estimated time of repair and present flow rate.
   5. Cause of the spill.
   6. Actions taken.
   7. Agencies involved in repairs and cleanup.
C. Affected areas of beach shall be closed as soon as possible regardless of bacteria levels.

D. Recreational Health Program staff assigned to driving beach emergency response vehicles may be reached by cellular telephone or pager. All affected Environmental Health programs should coordinate their activities.

E. When any beach or portion of beach is closed due to a sewage or chemical discharge, the notification list in Appendix I should be used.

F. GUIDELINES TO SAMPLING POINTS IN RELATION TO SIZE OF SEWAGE SPILL

Bacteriological water monitoring activities may be coordinated with other agencies, e.g., City of Los Angeles, Los Angeles County Department of Public Works, Los Angeles County Sanitation District.

Generally, in large spills, e.g. spills exceeding 500,000 gallons, enough time should be given for the spill to spread its maximum distance before assuming that negative bacteria results indicate safe levels.

The following is a suggested guideline for bacteriological sampling:

Less than 1,000 gallons	minimum of 3 samples within and at the limits of the closure zone
1,000 - 10,000 gallons	minimum of 5 samples within and at the limits of the closure zone
10,000 - 100,000 gallons	minimum of 7 samples within and at the limits of the closure zone
100,000 - 1 million gallons	minimum of 9 samples within and at the limits of the closure zone
1 - 2 million gallons	minimum of 11 samples within and at the limits of the closure zone
Over 2 million gallons	minimum of 13 samples within and at the limits of the closure zone

Circumstances and available data may dictate alternative courses of action.

PROCUDURES DURING ELEVATED BACTERIA LEVELS

A. All information and actions taken shall be recorded in the incidence log book maintained by the Recreational Health Program.

B. Elevated bacterial levels exist when any of the single sample standards are exceeded:

C. When a sampling station exhibits elevated bacterial levels, when practicable, a resample shall be taken between 24-48 hours after the initial sample. When resampling, a minimum of three samples shall be taken.

D. When there is an elevated bacterial level the following guidelines shall be followed:
   - All storm drains continually discharging or intermittently discharging during dry weather into the ocean shall be posted with a "Storm Drain Warning" sign at the point where the discharge meets the surf zone.
   - When a sampling station, in proximity to a storm drain, exceeds single State standards, "Beach Warning" signs shall be posted at 50 and 100 yards either side of the storm drain or where the point of discharge meets the surf zone. If not already posted, A "Storm Drain Warning" sign shall be posted directly in front of the storm drain or where the point of discharge meets the surf zone. Posting patterns and distances may vary depending on bacteria levels and local geographic conditions.
   - When a sampling station, not in proximity to a storm drain, exceeds single State standards, "Beach Warning" signs shall be posted at the sampling station and 50 yards either side of the sampling station. Posting patterns and distances may vary depending on bacteria levels and local geographic conditions.
   - Areas with a chronic history of elevated bacteria levels exceeding State standards, may be posted continuously with "Beach Warning" signs.

PROCEDURES DURING RAINFALL EVENTS

A. A rainfall event shall begin anytime there is greater than or equal to 0.1 inches of precipitation recorded by the National Weather Service at the Los Angeles Civic Center.

B. A rainfall event shall end 72 hours after cessation of all precipitation as recorded by the National Weather Service at the Los Angeles Civic Center.

C. A rainfall event may be declared if significant precipitation is recorded in other parts of Los Angeles County and not at the Los Angeles Civic Center.

E. When a rainfall event is declared the DHS Public Information Office will issue as soon as practicable a public advisory through the wire services explaining that storm drain flows may cause elevated bacterial counts for 72 hours and ocean water contact, especially in areas adjacent to storm drain flows, should be avoided. In addition, this information will be made available via a telephone hotline.

F. All flowing storm drains shall be posted during a rainfall event.

BEACH CLOSURE GUIDELINES IN THE EVENT OF A SEWAGE SPILL

Beaches affected by a known discharge of untreated or partially treated sewage not meeting the Waste Discharge Requirements established by the California Regional Water Quality Control Board.

Guidelines for closure are:

Less than 1,000 gallons = 100 yards - ¼ mile each side of discharge

1,000 to 10,000 gallons	=	¼ - ½ mile each side of discharge
10,000 to 100,000 gallons	=	¾ - 1 mile each side of discharge
100,000 to 1 million gallons	=	2 - 3 miles each side of discharge
1 to 2 million gallons	=	4 - 5 miles each side of discharge
More than 2 million gallons	=	minimum 5 miles each side of discharge

Samples will be collected at locations to be determined on the basis of reported volume of the spill, prevailing winds and currents, location of the discharge and the extent of the closure.

REOPENING BEACH AREAS

A. Beach areas that were closed due to a know release or spill of untreated or inadequately treated sewage shall be reopened when it has been determined that the source of the sewage release has been eliminated, the closure was for a minimum of 48 hours and all resampling results meet State standards.

B. Beach areas closed because of elevated bacteriological levels shall be reopened when all resampling results meet State standards

C. Beaches closed because of a hazardous materials discharge shall be reopened when the responsible County agency conducts an on-site inspection and the health officer determines that there is no significant risk to public health.

APPENDIX II

MONITORING LOCATIONS

Agency	No.	Monitoring Location
DHS	012	Leo Carrillo State Beach, 35000 Pacific Coast Hwy., Malibu. [in front of beach restrooms]
DHS	011	Nicholas Beach. [100 feet west of lifeguard tower]
DHS	010	Broad Beach, 31138 Broad Beach Rd., Malibu. [in front of public access stairs]
DHS	009	Trancas Beach, 30600 Pacific Coast Hwy., Malibu. [mouth of Trancas Creek]
DHS	008	Westward Beach, 6800 Westward Beach Rd., Malibu [in front of Monroe's restaurant]
DHS	007	Paradise Cove, 28128 Pacific Coast Hwy., Malibu [in front of the Sand Castle restaurant, 100 yds. west of the pier]
DHS	006	26610 Latigo Shore Drive., Malibu [in front of Latigo Bay Villa treatment plant]
DHS	005	Corral Beach, 26100 Pacific Coast Hwy., Malibu [at lifeguard station by bridge]
DHS	004	Malibu Point, Malibu Colony Dr., Malibu [50 yds. West of breech or at fence, east side]
DHS	003	Surfrider Beach, Malibu [50 yds. east of breech or in front of restrooms]
HYP	S1	Surfrider Beach, Malibu. [50 yds. east of breech]
DHS	002	Malibu Pier, Malibu [50 yards east of pier]
DHS	001	Big Rock Beach, 19900 Pacific Coast Hwy., Malibu [off point]
HYP	S2	Topanga Point, Malibu [in front of lifeguard station]
DHS	101	17200 Pacific Coast Hwy., Pacific Palisades. [1/4 mile east of Gladstone's restaurant and Sunset storm drain]
DHS	102	Bel Air Bay Club, 16801 Pacific Coast Hwy., Pacific Palisades. [at the chain link fence just east of the Bay Club]

HYP	S3	Puiga storm drain, Pacific Palisades. [50 yards east of storm drain]
DHS	103	Temescal storm drain, 15100 Pacific Coast Hwy., Pacific Palisades. [at the Will Rogers Beach lifeguard headquarters, 50 yards east of storm drain]]
HYP	S4	Santa Monica Canyon storm drain. Pacific Palisades.[50 yards east of storm drain]
DHS	104	San Vincente Blvd., extended, Santa Monica. [east side of Santa Monica Swim Club]
DHS	105	Montana Avenue extended, Santa Monica. [50 yards east of storm drain]
DHS	106	400 feet east of Wilshire Blvd., Santa Monica. [at tallest building]
HYP	S5	Santa Monica Pier, Santa Monica. [50 yards south of pier]
HYP	S6	Pico-Kenter storm drain, Santa Monica. [50 yards south of storm drain]
DHS	107	Strand Street extended, Santa Monica. [in front of restrooms]
DHS	108	Ashland storm drain, Santa Monica. [50 yards north of storm drain]
HYP	S7	Ashland storm drain, Santa Monica [50 yards south of storm drain]
DHS	109	Brooks Ave. extended, Los Angeles. [50 yards south of Brooks storm drain]
HYP	S8	Windward storm drain, Los Angeles. [50 yards north of storm drain]
DHS	110	Venice Pier, Venice. [50 yards south of pier]
DHS	111	Topsail Street extended, Venice.
DHS	112	Marina del Rey Beach, Marina del Rey. [extreme south end of swim area]
HYP	S9	Marina del Rey Beach. Marina del Rey. [at lifeguard tower]
DHS	113	Marina del Rey Beach, Marina del Rey. [extreme north end of swim area]
DHS	114	Jet ski launch. Basin H, Marina Del Rey.
HYP	S10	Ballona Creek, Playa del Rey. [50 yards south]
HYP	S11	Culver Blvd. extended, Playa del Rey. [north side of Culver storm drain]
DHS	115	World Way extended, Playa Del Rey. [.15 miles south of maintenance building, south of jetty]
HYP	S12	Imperial Highway storm drain, Playa Del Rey. [50 yards north of storm drain]

DHS	116	Opposite Hyperion plant, Playa Del Rey. [at the one mile outfall pipe (marked by sign on beach)]
DHS	117	Grand Avenue extended, El Segundo.
HYP	S13	40th Street extended, Manhattan Beach.
HYP	S14	Manhattan Beach Pier, Manhattan Beach. [50 yards south of pier]
DHS	118	26th Street extended, Hermosa Beach.
HYP	S15	Hermosa Beach Pier, Hermosa Beach. [50 yards south of pier]
DHS	119	Herondo Street extended, Redondo Beach. [50 yards north of Herondo storm drain]
HYP	S16	Redondo Pier, Redondo Beach. [50 yards south of pier]
DHS	120	Topaz Street extended, Redondo Beach. [north side of jetty]
HYP	S17	Avenue I extended, Redondo Beach. [50 yards south of storm drain]
HYP	S18	Arroyo Circle, extended, Malaga Cove, Palos Verdes Estates.
LACSD	MC	Malaga Cove, Palos Verdes Estates
LACSD	BC	Bluff Cove, Palos Verdes Estates
LACSD	S1	Long Point, Rancho Palos Verdes.
LACSD	S2	Abalone Cove, Rancho Palos Verdes.
LACSD	S3	Portuguese Bend, Rancho Palos Verdes.
LACSD	S5	White Point, San Pedro. [Western Avenue extended]
LACSD	S6	Wilder Addition Park, San Pedro.
LACSD	S7	Outer Cabrillo Beach, San Pedro.
TI	CB1	Inner Cabrillo Beach, San Pedro. [off of boat launch south side]
TI	CB2	Inner Cabrillo Beach, San Pedro. [in front of the lifeguard tower]
DHS	121	Avalon Beach [Adjacent to Storm Drain at South end of beach]
DHS	122	Avalon Beach [50 yds. South of Green Pleasure Pier]
DHS	123	Avalon Beach [Under the Green Pleasure Pier]
DHS	124	Avalon Beach [50 yds. North of Green Pleasure Pier]

DHS	125	Avalon Beach [Adjacent to Busy Bees Restaurant, South side]
DHS	126	Avalon Beach [Between Busy Bee Restaurant and Tuna Club]

Storm Water Management Fact Sheet
Storm Water Contamination Assessment

DESCRIPTION

A Storm Water Contamination Assessment (SWCA) reviews a facility and/or a site to find materials or practices that may contaminate storm water. This assessment helps target the most important pollutant sources for correction or prevention.

A SWCA program is closely related to other BMPs, such as materials inventory, non-storm water discharges, record keeping, and visual inspections.

APPLICABILITY

An SWCA program is applicable to any industrial facility which contains areas, activities, or materials which may contribute pollutants to storm water runoff from the total site. An assessment for storm water purposes may also be applicable in situations where a formal site assessment for hazardous waste purposes is being performed.

ADVANTAGES AND DISADVANTAGES

A comprehensive SWCA program can eliminate pollution sources that can impair receiving water quality. However, there are limitations associated with a contamination assessment program, including:

- Assessments need to be performed by qualified personnel.
- Assessments are useful only if there is corporate commitment to reduce any contamination sources discovered.
- Assessments need to be periodically updated.

KEY PROGRAM COMPONENTS

A SWCA program should include:

- Assessing potential pollutant sources and associated high risk activities such as loading and unloading operations, outdoor storage activities, outdoor manufacturing or processing activities, dust- or particulate-generating activities, and on-site waste disposal practices.
- Determining which of these sources pose the greatest risks of polluting storm water runoff from the site.
- Selecting other cost-effective BMPs to prevent or control pollution from the high-risk sources at the site.

IMPLEMENTATION

In addition to identifying problems within the storm sewer system, it is even more important to prevent problems from developing at all, and to provide an environment in which future problems can be avoided. Thus, an effective storm water assessment program should include follow-up activities including:

- Educating the public about the consequences of misusing storm sewers.
- Pretreating industrial storm water or disconnecting commercial and industrial storm water entries into the storm drainage system.
- Tackling the problem of widespread septic system failure.

- Disconnecting direct sanitary sewerage connections from the storm sewer system.

- Rehabilitating storm or sanitary sewers to abate infiltration by contaminated water.

- Developing zoning and other ordinances.

In some communities that are assumed to have separate sanitary and storm sewer systems, the storm sewer system may actually act as a combined sewer system. In these cases, the community may consider designating the storm sewer system a combined sewer and treating the discharge.

A SWCA program and the related correction program need to be periodically updated, based on their effectiveness and on the introduction of new raw materials or changes in processes at the site.

Because the results and performance of a SWCA program depend on the severity of the risks uncovered and the corrective actions taken, it is difficult to quantify the water quality benefits of a risk assessment program. Clearly, however, a program that identifies potential pollution sources and corrects them will improve water quality.

COSTS

Costs for the initial assessment may be high. However, by pinpointing high risk areas, a risk assessment may reduce overall costs associated with a complete BMP implementation program. The costs associated with a risk assessment program for storm water are small when compared with those of an overall hazardous waste site assessment.

Storm Water Management Fact Sheet
Coverings

DESCRIPTION

Covering is the partial or total enclosure of raw materials, byproducts, finished products, containers, equipment, process operations, and material storage areas that, when exposed to rain and/or runoff, could contaminate storm water. Tarpaulins, plastic sheeting, roofs, buildings, and other enclosures are examples of temporary or permanent coverings that are effective in preventing storm water contamination. The most prominent advantage of covering is that it is inexpensive in comparison to other BMPs.

APPLICABILITY

A review of numerous NPDES group applications indicates that covering is a commonly implemented BMP. As more facilities identify potential sources of storm water contamination, the use of coverings will increase significantly due to their effectiveness from a performance and cost perspective.

Covering is appropriate for loading/unloading areas, raw material, byproduct, and final product outdoor storage areas, fueling and vehicle maintenance areas, and other high risk areas.

ADVANTAGES AND DISADVANTAGES

Covering is a simple and effective storm water management BMP. Its advantages relative to other storm water management BMPs include its comparative ease of implementation, its potential low cost, and its widespread applicability.

Disadvantages associated with covering as a BMP include:

- Temporary covering methods, such as plastic sheeting, can become torn or ripped, exposing the contaminant to precipitation and/or storm water runoff.
- Costs may prohibit the building of complete enclosures.
- Health or safety problems may develop with enclosures built over certain materials or activities.
- Coverings require frequent inspection.
- A structure with only a roof may not keep out all precipitation.

The impact from a covered area depends on the degree of complexity in the covering design. Simple plastic sheeting can possibly create a storm water diversion, and allow for disposal of uncontaminated water to a storm sewer. An appropriate structure with a permanent roof may be less effective, if the material inside is not sufficiently protected from contact with runoff. An enclosed structure may need to have internal drainage. However, if the stored material is considered hazardous, it must not be connected to the storm sewer. Depending on the site's NPDES permit, connection to a sanitary sewer may also be unsuitable. The internal drains would then need to be connected to some suitable containment area for later pretreatment and disposal.

IMPLEMENTATION

When implementing a program to cover materials to reduce their exposure to runoff, one must first choose the proper covering. When deciding on a covering, it is necessary to evaluate the integrity and durability of the covering, as well as its compatibility with the material or activity being covered.

Covering alone may not protect exposed materials from storm water contact. Placing material on an elevated impermeable surface or building curbing around the outside of the materials may be required to prevent contact with storm water runoff from adjacent areas. If the program calls for a material to be enclosed, the designer should consider materials access, handling, and transfer during the design of the enclosure. Materials that pose environmental and/or safety dangers because they are radioactive, pathogenic, flammable, explosive, or reactive, require special ventilation and temperature design considerations.

In addition to properly designing an enclosure or cover, practicing proper materials management within an enclosure or underneath a covered area is essential. For example, floor drainage within an enclosure should be properly designed and connected to a sanitary sewer. The local publicly owned treatment works should be consulted to determine if there are any pretreatment requirements, restrictions, or compatibility problems prior to discharge of the storm water.

Based on data currently available, it is difficult to quantify the mitigation of runoff contamination when covering is used. However, significant runoff water quality benefits are expected by simply reducing the contact between potential contaminants and precipitation or storm water runoff. One source has estimated that 80 percent of the environmental damage from de-icing chemicals is caused by inadequate storage facilities.

Inspecting coverings must be part of an overall preventive maintenance program. Maintenance involves frequent inspection of the covering for rips, holes, and general wear.

COSTS

Covering costs vary in proportion to the degree of protection desired, and the required life span. The most inexpensive covering is plastic sheeting, but it is not suitable where a high degree of protection is desired for a long period. An enclosed building is the most expensive type of covering when materials for the structure, lighting, and ventilation are considered, but it offers the highest degree of protection for the longest period.

Storm Water Management Fact Sheet
Record Keeping

DESCRIPTION

Keeping records of spills, leaks, and other discharges can help a facility run more efficiently and cleanly. Records of past spills contain useful information for improving Best Management Practices (BMPs) to prevent future spills. Typical items that should be recorded include the results of routine inspections, and reported spills, leaks, or other discharges.

Records should include:

- The date, exact place, and time of material inventories, site inspections, sampling observations, etc.
- Names of inspector(s) and sampler(s).
- Analytical information, including the date(s) and time(s) analyses were performed or initiated, the analysts' names, analytical techniques or methods used, analytical results, and quality assurance/quality control results of such analyses.
- The date, time, exact location, and a complete characterization of significant observations, including spills or leaks.
- Notes indicating the reasons for any exceptions to standard record keeping procedures.
- All calibration and maintenance records of instruments used in storm water monitoring.
- All original strip chart recordings for continuous monitoring equipment.
- Records of any non storm water discharges.

Figure 1 shows a sample worksheet for tracking spills and leaks.

Record keeping is usually coordinated with internal reporting and other BMPs, and is often integrated into the development of a facility's Storm Water Pollution Prevention Plan (SWPPP) as part of the facility's NPDES storm water discharge permit.

APPLICABILITY

Records keeping is a basic business practice and is applicable to all facilities. If a separate record keeping system for tracking BMPs, monitoring results, etc., is not currently in place at a facility, existing record keeping structures can be easily adapted to incorporate this data. An ideal tool for implementation is the record keeping procedures laid out in an SWPPP.

ADVANTAGES AND DISADVANTAGES

Record keeping is a simple, easily implemented, and cost effective management tool. Complete, well-organized records can help ensure proper maintenance of facilities and equipment and can aid in determining the causes of spills and leaks; thus, record keeping can protect water quality by helping to prevent future leaks and spills.

Limitations of a record keeping system may including the following:

- Records must be updated regularly.

- Personnel completing and maintaining records must be trained to update records correctly.

- The records need to be readily accessible.

- Records containing any confidential information must be secured.

IMPLEMENTATION

The key to maintaining records is continual updating. Ensure that new information, such as analytical results, is added to existing inspection records or spill reports as it becomes available. In addition, update records if there are changes to the number and location of discharge points, principal products, or raw material storage procedures. Maintain records for least five years from the date of sample observation, measurement, or spill report. Some simple techniques used to accurately document and report results include:

- Field notebooks.

- Timed and dated photographs.

- Videotapes.

- Drawings and maps.

- Computer spreadsheets and database programs.

COSTS

Costs are those associated with staff hours used to develop and implement a record keeping system, costs for analyzing samples, and company overhead costs. Figure 2 is a sample worksheet that can be used to determine annual record keeping costs. Table 1 is an example of a completed record keeping costs sheet.

1.0 ACKNOWLEDGEMENTS

The Urban Drainage and Flood Control District (District) wishes to acknowledge all individuals and organizations that contributed to the development and publication of the second edition, dated September 1, 1999, of the *Urban Storm Drainage Criteria Manual, Volume – 3 Best Management Practices (Manual).* The list is too numerous to acknowledge everyone individually, for which we apologize. In addition to the organizations listed here, technical guidance and review were proved by members of the Stormwater Management Advisory Committee (SMAC) listed below. Many of the photographs in this edition were supplied by members of the SMAC. We wish to acknowledge the assistance rendered by the members of this group in the revision of the *Manual.*

The District specifically acknowledges the following organizations and individuals who contributed to the revision of this publication of the *Manual*:

Urban Drainage and Flood Control District

Ben R. Urbonas, P.E.	Editor-In Chief and co-author of *Manual*
L. Scott Tucker, P.E.	Overall review of *Manual*
John T. Doerfer	Co-author of Nonstructural and Construction chapters of *Manual*
Ken MacKenzie	Co-author of BMP AutoCAD™ Details and Design Spreadsheets

CH2M HILL

James T. Wulliman	Project Manager and co-author
Kyle Hamilton	Co-author
Joe Juergensen	Co-author
Patricia A. Nelson	Co-author
Mike Petrick	Graphics
Sandy Nordlander	Document Production

Others that Provided Review and Technical Input

Jim A. Worley	Cherry Creek Basin Authority
Richard E. Brandt	Town of Parker

2.0 PURPOSE OF *MANUAL*

Volume 3 of the *Urban Storm Drainage Criteria Manual* (*USDCM*) is designed to provide guidance for local jurisdictions, developers, contractors, and industrial and commercial operations in selecting, designing, maintaining, and carrying out best management practices (BMPs) to improve stormwater runoff quality. This volume of the *USDCM* covers a variety of topics related to stormwater quality BMPs and contains the following:

- An introduction to stormwater runoff quality management that includes an overview of water quality impacts and explains the selection and use of nonstructural and structural BMPs
- A discussion on stormwater runoff quality and hydrology, urban runoff, and pollutant loadings
- Technical criteria for a number of structural BMPs that are recommended for use in developing residential and commercial areas in the Denver metropolitan area and other areas with similar climate and meteorology
- Technical guidance for a number of structural BMPs that may be used at light industrial and certain commercial establishments
- A description of various nonstructural BMPs and how they may be used and implemented
- Guidance in the selection and use of erosion control practices and general management of stormwater runoff during construction
- A collection of typical details for structural BMPs

The Bibliography section for this volume includes references for all chapters. Additional materials on the topics presented in the *Manual* may be found in studying the published papers and documents listed there.

This volume is primarily targeted at developing and redeveloping residential and commercial areas. The 1999 edition of the *Manual* goes beyond its earlier edition (UDFCD, 1992) first published in 1992 by addressing BMPs for light industrial, or other types of land uses, some of which are being permitted directly by the State of Colorado or the U.S. Environmental Protection Agency. This list is not meant to be comprehensive–as information about BMPs is evaluated and refined, or new standards are promulgated by the State, additional BMPs may be added to the *Manual*. As a result, Volume 3 is expected to grow and change as the technology of stormwater BMPs matures and is refined in the future.

3.0 OVERVIEW OF *MANUAL*

Volume 3 is intended to meet the needs of a variety of users. Figure P-1 graphically illustrates the components of a Comprehensive Municipal Stormwater Quality Management Program, namely: stormwater quality programs, parties responsible for implementation of or participation in a particular program, and BMPs that can be used to satisfy the corresponding program requirements. Figure P-2 expands on Figure P-1 by detailing the BMPs that can be considered during the implementation of the various programs. These two figures give the user an overview of the contents of the *Manual.* Both the *Manual* and Figure P-1 move from general toward specific, starting with an overview chapter on Stormwater Quality Management (left portion of Figure P-1), moving through planning sections addressing New Development BMPs, Industrial and Commercial BMPs, and Construction BMPs, and then providing detailed design and implementation guidance in the Structural BMPs, Nonstructural BMPs, and Construction BMPs chapters (outlined in Figure P-2).

The *Manual* will be used by individuals associated with the development of residential property and the development or operation of industrial and commercial sites. Material included in the *Manual* will assist these individuals in determining the most applicable BMPs for each situation. The *Manual* will also benefit municipalities that address stormwater quality through land development and municipal operations. Table P-1 lists the chapters in the *Manual* relevant for various parties.

TABLE P-1
Relevant Chapters

User	Program	Volume 3 Sections
Developers/Owners	Construction, New Development, Industrial (for industrial sites)	Stormwater Quality Management, BMP Planning for New Development, Structural BMPs, Construction Site Program, Industrial and Commercial BMPs (for industrial sites)
Development Engineers	Construction, New Development	Stormwater Quality Management, BMP Planning for New Development, Structural BMPs, Construction BMPs
Contractors	Construction	Stormwater Quality Management, Construction BMPs
Municipal Staff	Public Education and Involvement, Illicit Discharges, Construction Sites, New Development, Industrial Sites	Stormwater Quality Management, BMP Planning for New Development, Structural BMPs, Industrial and Commercial BMPs, Nonstructural BMPs, Construction BMPs

1.0 STORMWATER RUNOFF QUALITY MANAGEMENT

Most of the publics concerns with stormwater are usually related to flooding, not water quality. People complain when their basements flood or roads become impassable and the public suffers when severe catastrophic floods cause widespread damage to property and loss of life. Very few people are aware of the water quality impacts that stormwater has on our rivers, streams, or lakes. Stormwater runoff quality can have significant impacts on the receiving waters that affect not only the aquatic ecosystem, but also the quality of life in a community by the nature of the streams that run through it or the lakes within its boundaries.

1.1 Environmental Impacts of Runoff

Many people are familiar with the environmental impacts from municipal and industrial wastewater discharges. Few are aware of the existence of a stormwater drainage sewer system much less the impact that it may create to the environment. Studies have shown that runoff from urban and industrial areas can contain significant quantities of the same general types of constituents that are found in wastewater and industrial discharges.

The impacts of stormwater on streams fit into four categories. These include stream hydrology, stream morphology, water quality and aquatic ecology. The extent of impact is related to the climate, land use, and the measures implemented to address the impacts.

Briefly, the impacts on streams are:

1. Stream Hydrology: Urban development affects the environment through changes in the size and frequency of storm runoff events, changes in base flows of the stream and changes in stream flow velocities during storms results in decrease in travel time for runoff. Peak discharges in a stream can increase from urbanization due to decrease in infiltration of rainfall into the ground, loss of buffering vegetation and resultant reduced evapotranspiration. This results in more surface runoff and larger loads of various constituents found in stormwater.

2. Stream Morphology: When the hydrology of the stream changes, it results in changes to the physical characteristic of the stream. Such changes include streambed degradation, stream widening, and streambank erosion. As the stream profile degrades and the stream tries to widen to accommodate higher flows, instream bank erosions increase along with increases in sediment loads. These changes in the stream bed also result in change to the habitat of aquatic life.

3. Stream Quality: Water quality is impacted through urbanization as a result of erosion during construction, changes in stream morphology, and washing off of accumulated deposits on the urban landscape. Water quality problems include turbid water, nutrient enrichment, bacterial

R0017641

contamination, organic matter loads, metals, salts, temperature increases and increased trash and debris.

Table SQ-1 lists the common constituents in stormwater runoff and their impacts.

TABLE SQ-1
Urban Runoff Pollutants

Constituents	Sources	Effects
Sediments— TSS, Turbidity, dissolved solids	Construction sites Urban/agricultural runoff Landfills, septic fields	Habitat changes, stream turbidity, recreation and aesthetic loss, contaminant transport, bank erosion
Nutrients— Nitrate, Nitrite, Ammonia, Organic Nitrogen, Phosphate, Total Phosphorus	Lawn/Agricultural runoff, Landfills, Septic fields, Atmospheric deposition, erosion	Algae blooms, Ammonia Toxicity, Nitrate Toxicity
Pathogens— Total and Fecal Coliforms, Fecal Streptococci Viruses, E.Coli, Enteroccus	Urban/Agricultural Runoff Septic Systems, illicit sanitary connections, domestic/wild animals	Ear/Intestinal infections, Shellfish bed closure, Recreation/aesthetic loss
Organic Enrichment— BOD, COD, TOC and DO	Urban/Agricultural Runoff, Landfills septic systems	Dissolved oxygen depletion, odors, fish kills
Toxic Pollutants— Metals, Organics	Urban/Agricultural Runoff, Pesticides/Herbicides, Underground storage tanks, Hazardous Waste Sites, landfills, illegal disposals, industrial discharges	Toxicity to humans and aquatic life, bioaccumulation in the foodchain
Salts— sodium chloride	Urban runoff snowmelt	Contamination of drinking water, harmful to salt intolerant plants

Source: Handbook: Urban Runoff Pollution Prevention and Control Planning, 1993.

Stormwater runoff into lakes can have some unique effects. These include:

1. Lakes respond more to the mass of a constituent and flow volume. The response time to storm events is measured in days or weeks unlike streams which show effects within hours or days.

2. A notable visible impact of stormwater on lakes consists of floating refuse and shore damage.

3. A significant water quality impact on lakes that is related to stormwater runoff is nutrient enrichment. This can result in the undesirable growth of algae and aquatic plants.

4. Lakes do not flush contaminants as quickly as streams, and act as sinks for nutrients, metals, and sediments. This means that lakes can take longer to recover if contaminated.

Table SQ-2 lists the potential sources of stormwater runoff and the types of pollutants expected from a variety of human activities.

1.2 NPDES Permit Regulations

In 1972, Congress passed what is currently referred to as the Clean Water Act (CWA). The Act established the National Pollutant Discharge Elimination System (NPDES) program. Until recently, efforts under the NPDES program have focused on non-stormwater discharges from industries and municipal wastewater treatment plants. In the last several years, the EPA has expanded the NPDES program to cover stormwater discharges.

1.2.1 Phase I Stormwater Regulations. As effective controls have been implemented on non-stormwater discharges, it has become more evident that diffuse sources can create impacts on water quality. In 1987, the CWA was revised to address stormwater discharges. The CWA defined municipal and industrial stormwater runoff discharges as "point source"and called for a two phase permitting strategy. Phase I affected:

- Any discharge of stormwater that was permitted under the NPDES program prior to February 4, 1987.
- Discharges associated with industrial activity.
- Any discharge from a large or medium municipal separate storm sewer system (MS4). A large system serves a population greater than 250,000. A medium system serves a population between 100,000 and 250,000.
- Those discharges that the permitting authority determines contributes to a violation of a water quality standard or is a significant contributor of pollutants to waters of the U.S.

Regulations which addressed permit application requirements for these affected facilities were published on November 16, 1990. These regulations have resulted in thousands of industries and a number of municipalities covered by stormwater permits. The municipalities in Colorado which have been impacted by the Phase I requirements include:

- Arapahoe County (including Arapahoe County Water and Wastewater Authority, East Cherry Creek Valley Water and Sanitation District and Inverness Water and Sanitation District as Co-Permittees)
- City of Aurora

General permits were issued to cover industries impacted by the regulation. They include heavy industries, light industries, mining, and recycling facilities. Existing permits were amended to include stormwater requirements. Industrial general permits require development of a stormwater management plan (SWMP). The plan must include:

1. A description of the activity.
2. Maps showing facility layout and drainage patterns.
3. Description of Potential Pollutant Sources/Material Inventory.
4. Stormwater Management Controls such as risk identification and assessment, prevention maintenance, good housekeeping, spill response procedures, and other appropriate structural and non-structural BMPs.
5. An inspection program.
6. Employee training program.

It is anticipated that the *Manual* will assist industries in fulfilling their regulatory requirements by providing lists of BMPs that can be implemented on site, and general procedures for evaluation of sites.

Unlike industries that have been covered by general permits, MS4 permits have been developed on a case-by-case basis. While each is somewhat unique, they all require that certain programs be in place. These programs are:

1. A Commercial/ Residential Management Program. This program includes the following areas:
   a. Maintenance of structural controls.
   b. A New Development Program that requires permanent water quality elements.
   c. Public street maintenance procedures to be in place to reduce water quality impacts from snow and ice handling practices, herbicide/pesticide uses, and other debris.
   d. Review of new flood control structures for inclusion of water quality elements and evaluation of existing facilities for retrofitting opportunities.

e. Program to address water quality concerns associated with the application of pesticides, herbicides and fertilizers by public and private applicators.

2. Illicit Discharge Management Program. This program generally includes the following areas:

   a. A program for the prevention of illicit discharges and illegal disposal. The program must include detection and removal of illicit discharges.

   b. Implementation of an ongoing field screening program. This involves sampling of dry weather flows from the MS4 outfalls.

   c. Investigation of illicit discharges.

   d. A program for responding to spills into the MS4.

   e. Educational activities to promote public reporting of illicit discharges and improper disposal as well as promote proper management and disposal of toxic materials.

   f. A program that controls sanitary sewer seepage into the MS4.

3. Industrial Facilities Program. The purpose of this program is to have the municipality control the industrial stormwater discharges into its system to assure that there is no impact on the MS4 from an industry.

4. Construction Sites Program. This program involves ensuring that adequate measures are taken to control runoff from construction sites that pose water quality concerns.

5. Municipal Facility Runoff Control Program. This program requires that measures comparable to those required for industrial activities be implemented at municipal facilities.

6. Wet Weather Monitoring Program. The purpose of this program is to monitor trends in water quality.

The MS4 has some latitude in how these programs are implemented. The *Manual* can be used to assist MS4s in development of these programs. Many of the elements of a commercial and residential Program can be found in the Structural and Nonstructural Best Management Sections. An outline of an illicit discharge program is included in the Nonstructural Chapter. The elements of the construction program can be found in the Construction Program chapter. The Industrial and Commercial Best Management Practice chapter can provide assistance to municipalities in the development of Municipal Facility Runoff Control Plans.

1.2.2 Phase II Stormwater Regulations. When the amendment to CWA was passed in 1987, the intent under the stormwater program was to require MS4s that were under 100,000 in population to apply for an NPDES permit no later than October 1992. This date was later changed to October 1, 1994. However, at the time the 1999 edition of this Volume 3 was published, regulations were not finalized that address permit application requirements and applicable permit conditions for these systems. On January 9, 1998, EPA published draft rules for the Phase II program. These draft regulations center on three major items. These are:

1. Reduction in the size of construction sites required to obtain an NPDES stormwater permit from 5 acres to one acre.
2. A expansion of the exemption from permitting for industrial facilities which have all sources covered.
3. Expansion of the MS4 permits to communities with populations under 100,000.

The proposed regulations extend the municipal stormwater program to small municipalities that are:

1. Within urbanized areas (except tribally owned systems serving less than 1,000 or others where requirements are waived by the State or EPA).
2. Designated via criteria not yet developed by the State or EPA.
3. Contributing significant loadings to a regulated MS4.

For Colorado, this means that approximately 50 additional communities could potentially fall under this program. The regulation proposes covering these Phase II communities under a general permit rather than individual permits. The proposed programs that will be required in the general permit include:

a. Public Education and Outreach on Stormwater Impacts–This would require the distribution of educational materials to the public or other equivalent outreach efforts.

b. Public Involvement/Participation–This element involves public notification and inclusion of the public in the development and implementation of the municipalities' stormwater management program.

c. Illicit Discharge Detection and Elimination–This involves some identification of pollutant sources, and the control and detection of illicit discharges.

d. Construction Site Program–This requires the development, implementation, and enforcement of a program for controlling runoff from construction sites that are equal to or greater than one acre.

e. Post-Construction Stormwater Management in New Development and Redevelopment–This would require the development and implementation of a program to address stormwater runoff from development and redevelopment sites equal to or greater than one acre.

f. Pollution Prevention/Good Housekeeping for Municipal Operations–As proposed, this involves the development and implementation of an operation and maintenance program to reduce the pollutant runoff from municipal sites such as parks and open spaces, fleet maintenance facilities, building oversight, and stormwater system maintenance facilities.

The Phase II regulation is scheduled to be finalized by October 1999. This date was agreed to as a result of a suit brought against EPA by the Natural Resources Defense Council (NRDC). As stated previously, the *Manual* will assist these municipalities with their program development.

1.2.3 Non-Stormwater Discharges. It is sometimes difficult to determine which discharges fall under the stormwater program and which require a traditional NPDES permit. It is clear that discharges from municipal wastewater treatment plants or industrial processes require an NPDES permit, but others are less obvious. A stormwater discharge is one which is a direct result of stormwater (rainfall or snow melt) and stops shortly after the event ends. Everything other than stormwater discharges require a permit if it enters state waters. The Colorado Water Quality Control Act defines "state waters" as any and all surface and subsurface waters which are contained in or flow through this state, but does not include waters in sewers systems, waters in treatment works or disposal systems, waters in potable water distribution systems, and all water withdrawn for use until use and treatment have been completed. However, State regulations do not allow a discharge into a ditch or man-made conveyance for the purpose of evading the requirement to obtain a permit, per CRS 25-8-501(1). Litigation has shown that the definition of state waters is interpreted very broadly.

Table SQ-3 lists common discharges that are not covered by industrial or MS4 stormwater permits. The table includes a description of the activity and suggestions of how to prevent the need for a permit. All these discharges could be permitted.

TABLE SQ-3
Non-Stormwater Discharges

Discharge	Description	Suggested Measures
Vehicle Washing (Non-residential)	• Spraying a vehicle to rinse off grime/dirt and allowing to flow into the MS4 or state waters. This is whether or not soaps or solvents are used. • Does not affect residents washing their vehicles.	• Do washing at third party facilities which are permitted • Ensure that waters are captured and not allowed offsite • With appropriate approval send to a sanitary sewer • Obtain a NPDES Permit
Rinsing of trucks carrying materials such as concrete trucks	• Involves the washing of concrete or other materials from the mixing or tank portions of a vehicle	• With appropriate approval, dispose into the sanitary sewer (not concrete trucks) • Ensure that all waters are captured and not allowed offsite • Obtain a NPDES Permit

TABLE SQ-3
Non-Stormwater Discharges

Discharge	Description	Suggested Measures
Swimming Pool/Spa Draining (Non-residential)	• Involves the emptying of the contents of a swimming pool or hot tub • Private residential discharges are not affected	• Use water for irrigation purposes • With appropriate approval, dispose into the sanitary sewer • Obtain a NPDES Permit
Hydrostatic Testing	• Involves the addition of water to a tank or pipeline to ensure water tightness and strength of joints	• Ensure that waters are captured and not allowed offsite • With appropriate approval, dispose into a sanitary sewer • Obtain a NPDES Permit

The NPDES stormwater regulations allow for certain non-stormwater discharges to be released under a municipal permit. Table SQ-4 lists these discharges.

TABLE SQ-4
Allowable Non-Stormwater Discharges

The following non-stormwater discharges or flows are not considered illicit or illegal unless they are identified by the municipality or the State as sources of pollutants.

- Landscape irrigation.
- Diverted stream flows.
- Rising ground waters.
- Uncontaminated ground water infiltration to separate storm sewers.
- Discharges from potable water sources.
- Foundation drains.
- Air conditioning condensation.
- Irrigation water.
- Natural springs.
- Water from crawl space pumps.
- Footing drains.
- Lawn watering.
- Individual residential car washing.
- Flows from riparian habitats and wetlands.
- Emergency fire fighting activities.
- Irrigation return flow.

R0017650

TABLE SQ-4
Allowable Non-Stormwater Discharges (continued)

Non-stormwater discharges allowed under the municipal stormwater permits, provided appropriate control measures are implemented to minimize impacts of these sources, include:

- Individual residential swimming pool and hot tub discharges.
- Individual residential street washing.
- Water-line flushing.
- Water line flushing (excludes flushing of disinfection water for new pipes).
- Municipally owned and dechlorinated swimming pool discharges.
- Street wash water.

Other sources of allowable dry weather flow include:

- Discharges of process wastewater as long as authorized under separate CDPS permits.

In order to address many small discharges, the Colorado Water Quality Control Division developed the minimal discharge general permit. This permit covers the following types of discharges:

- Facilities discharging wastewater from washing the exteriors of trucks, cars, airplanes, boats, driveways, parking lots, and roads.
- Facilities discharging wastewater from the washing of bleachers, elevated seating and grandstands, such as those found at outdoor sporting or entertainment events.
- Commercial facilities discharging wastewater from draining, cleaning, and filter backwash of swimming pools, spas, hot tubs, and similar structures including water slides and water theme amusement parks.
- Commercial facilities discharging wastewater from the washing of temporary stables, traveling petting zoos, or any other facility that discharges wash water associated with animal wastes.
- Facilities discharging wastewater from commercial mobile cleaning vehicles such as steam cleaning, carpet cleaning and pressure washing (including building washing).
- Facilities discharging groundwater from foundation, basement, or underground structure dewatering.
- Facilities discharging non-contact cooling or heating water.
- Facilities discharging hydrostatic test water from the testing of new or used pipes, tanks or other similar vessels.
- Facilities discharging water such as facilities that employ super chlorination (50 to 500 mg/L) of water for the disinfection of these facilities and wish to discharge effluent.
- Commercial facilities discharging wastewater from washing of root crops such as potatoes, sugar beets, onions, and other fruit/vegetable agricultural produce.

The general permit allows for quick coverage of these types of discharges. Compliance is required with state water quality standards and effluent guidelines. Monitoring and reporting of the quality of the discharge is also required.

1.3 Summary

The *Manual* has been structured to provide industries, municipalities, contractors and developers with information which can be used to control water quality impacts from stormwater and comply with applicable regulatory requirements.

2.0 STORMWATER QUALITY CHARACTERISTICS AND SOURCES

2.1 General

Urban runoff contains many types and forms of constituents-some occurring in higher concentrations than found in runoff before development and some that are not naturally present in surface runoff from undeveloped land. Runoff from undeveloped watersheds contains sediment particles, oxygen-demanding compounds, nutrients, metals, and other constituents. Once developed, constituent loads increase because surface runoff volumes increase and the sources of many of these pollutants also increase. Also, additional sources of constituents may exist in a catchment and find their way into runoff. They may include the following:

- Metals, lubricating compounds, solvents, and other constituents originating from vehicles, machinery, and industrial and commercial activities
- Pesticides, herbicides, and fertilizers
- Household solvents, paints, roofing materials, and other such materials
- Pet litter, garbage, and other debris
- Suspended solids washed off impermeable surfaces
- Increased soil erosion during construction activities

A phenomenon termed *first flush* has been discussed for a number of years resulting in mixed conclusions. The first flush represents the higher levels of initial concentrations of constituents that are washed off from a surface at the very beginning of a rainfall event. Some reports include a first flush because of atmospheric fallout that accumulates before a storm occurs. Other reports conclude that there is no first flush, or an insignificant first flush of pollutants in separate, namely, not combined sewer stormwater runoff. However, by designing facilities to capture in total and treat the majority of runoff events, whether a first flush exists or not becomes irrelevant. At the same time, if it does exist for larger runoff events, such designs will then also capture their "first flush"of runoff.

2.2 Typical Constituent Concentrations in Urban Runoff

Urban stormwater runoff data for the Denver metropolitan area was collected under an Environmental Protection Agency (EPA)-funded effort as part of their Nationwide Urban Runoff Program in 1980 and 1981. A similar stormwater monitoring program, funded by the District and the cities of Denver, Aurora, and Lakewood, was carried out in 1992 and 1993. The results from these two monitoring programs are summarized in a report by Doerfer and Urbonas, "Stormwater Quality Characterization in the Denver Metropolitan Area,"dated 1993 in terms of average event mean concentrations. Table SQ-5 summarizes these EMCs for 13 constituents from industrial, residential, commercial, and undeveloped land uses. It is important to recognize however that the data were highly variable and that these EMCs should not be expected from every storm runoff event.

TABLE SQ-5
Land-Use Average Event Mean Concentrations of Stormwater Runoff in the Denver Metropolitan Area

Constituent	Units	Industrial	Commercial	Residential	Undeveloped
Total Suspended Solids	(mg/L)	399	225	240	400
Total Dissolved Solids	(mg/L)	58	129	119	678
Biochemical Oxygen Demand	(mg/L)	29	33	17	4
Chemical Oxygen Demand	(mg/L)	232	173	95	72
Total Nitrogen	(mg/L)	2.7	3.3	3.4	3.4
Total Kjeldahl Nitrogen	(mg/L)	1.8	2.3	2.7	2.9
Nitrate plus Nitrite	(mg/L)	0.91	0.96	0.65	0.50
Total Phosphorus	(mg/L)	0.43	0.42	0.65	0.40
Dissolved Phosphorus	(mg/L)	0.20	0.15	0.22	0.10
Cadmium, Total Recoverable	(μg/L)	3	1	n/d	n/d

Lead, Total Recoverable	(μg/L)	130	59	53	100
Zinc, Total Recoverable	(μg/L)	520	240	180	100

n/d = below detection limit

R0017653

3.0 OVERVIEW OF BEST MANAGEMENT PRACTICES

3.1 Nonstructural and Structural BMPs

Urban stormwater runoff contains materials from various different land use types, such as residential, commercial and industrial sites. Urban stormwater runoff has been documented to contain a variety of constituents. When certain constituents are present in sufficient quantities, the potential exists for adverse effects on receiving waters.

Studies such as the Nationwide Urban Runoff Program (EPA, 1983) and the Denver Regional Urban Runoff Program (DRCOG, 1983) have documented concentrations of various constituents in urban stormwater. To reduce the concentrations and the loads of these constituents that reach the receiving waters, various BMPs have been suggested. These BMPs fall into the following two primary categories:

- Nonstructural-Including the subcategories of pollution prevention BMPs and source control BMPs
- Structural-Including facilities constructed to passively treat urban stormwater runoff before it enters the receiving waters. In fact, they are stormwater quality treatment devices.

The most cost-effective nonstructural BMPs are to prevent the disposal of constituents that may be potential pollutants on the urban landscape and to minimize the migration of constituents offsite from the point where they are being used, stored, or otherwise being exposed tostormwater. Measures that can prevent deposition of constituents are described in terms such as "Good Housekeeping,"Preventive Maintenance,"Spill Prevention"and others. A theme that runs through all of these is the need to educate the public on the impacts of its actions on the environment. Nonstructural source controls include administrative programs, preventing and controlling erosion during construction, street sweeping, modified street maintenance practices, employee-training and material handling practices. Nonstructural controls used to isolate pollutants from stormwater include covering potential pollutant areas such as service center gasoline pump islands. Source control BMPs are sometimes termed as "good housekeeping" measures because a clean site will produce lessstormwater contamination than will a dirty one. These and other nonstructural BMPs are further addressed in the nonstructural section of this volume.

Structural BMPs are facilities used to reduce runoff and/or remove constituents from runoff. Examples of structural BMPs include water quality detention (both dry basins and wet ponds), wetlands, porous pavement, and the use of vegetated zones. These BMPs may treat small volumes of stormwater on development sites or serve larger regional drainage areas.

3.2 Pollutant Removal Mechanisms

Although runoff may contain many individual pollutants, pollutants are grouped into two general categories in the *Manual*: particulate and soluble. Even though the exact boundary between the two does

R0017654

not need to be defined at this level of design, the boundary lies somewhere around the equivalent particle diameter of 0.4 micron (for example, very fine clays). In many cases, constituents (such as metals and oxygen demand compounds) become adsorbed or attached to particulate matter. Therefore, if the particulate matter is removed, so are the adsorbed or attached constituents.

One, or a combination of up to four basic pollutant removal or immobilization mechanisms, are used by the suggested BMPs to treat stormwater runoff for water quality enhancement. The following is a brief overview of each mechanism:

1. Sedimentation: Particulate matter is, in part, settled out of urban runoff. Smaller particles under 60 microns in size (fine silts and clays) (Stahre and Urbonas, 1990) can account for approximately 80 percent of the metals in stormwater attached or adsorbed along with other contaminants and can require long periods of time to settle out of suspension. Fortunately, extended detention allows smaller particles to agglomerate into larger ones (Randall et al, 1982), and for some of the dissolved and liquid state pollutants to adsorb to suspended particles, thus removing a larger proportion of them through sedimentation. Sedimentation is the primary pollutant removal mechanism for most structural BMPs.

2. Filtering: Particulates are removed, in part, from water by filtration. Filtration removes particles by attachment to small-diameter collectors such as sand.

3. Infiltration: Pollutant loads in surface runoff are removed or reduced as surface runoff infiltrates or percolates into the ground. Particulates are removed at the ground surface by filtration, while soluble constituents can be adsorbed into the soil, at least in part, as the runoff percolates into the ground. Site-specific soil characteristics, such as permeability, cation exchange potential, and depth to groundwater or bedrock limit the number of sites where this mechanism can be used effectively.

4. Biological Uptake: Plants and microbes require soluble and dissolved constituents such as nutrients and minerals for growth. These constituents are ingested or taken up from the water column and concentrated through bacterial action, phytoplankton growth, and other bio-chemical processes. In some instances, plants could be harvested to remove the constituents permanently. In addition, certain biological activities can reduce toxicity of some pollutants and/or possible adverse effects on higher aquatic species. Unfortunately, not much is understood yet about how biological uptake or activity interacts with stormwater during the relatively brief periods it is in contact with the biological media in most BMPs, with the possible exception of retention ponds between storm events (Hartigan, 1989).

5. Straining: Grasses strain out particulates when sheet flow is directed to flow slowly over vegetated areas.

3.3 Structural BMP Effectiveness

Table SQ-6 indicates ranges of removal efficiencies reported in literature for a number of structural BMPs. Although combinations of nonstructural/structural BMPs can improve the overall water quality of the runoff, the effectiveness of several BMPs in their ability to reduce influent pollutant concentrations as a group are not directly additive. Table SQ-6 also shows a most probable range of removal efficiencies for structural BMPs recommended in Volume 3.

3.4 Stormwater Quality Management Strategy

3.4.1 Municipalities. The selection of the most appropriate BMP categories within a municipality is determined by whether development is in place or has yet to occur. In areas with existing development, relying on nonstructural BMPs is most cost-effective because retrofitting structural controls into a developed area can be very expensive; that is, $5,000 to $50,000 per acre of tributary watershed. Structural controls are more appropriate for new development and significant redevelopment, particularly when they are integrated into the initial planning and design of municipal infrastructure and private development.

Structural BMPs are most cost-effective when included in the planning stages of development. It is recommended that the structural BMPs presented in the *Manual* be integrated into stormwater management planning by public entities and into the site planning process by land developers. Structural BMPs can also be used, in a cost-effective manner, whenever redevelopment or significant improvement occurs within fully developed areas.

An effective strategy for reducing stormwater pollution loads is to use multiple BMPs, including nonstructural measures, source controls, and structural BMPs. A single practice and/or facility cannot generally provide significant reductions in stormwater pollutant loads because these pollutants come from many sources within a municipality. Also, multiple BMPs can provide complementary water quality enhancement to achieve desired results. A multilevel BMP approach, schematically depicted in Figure SQ-1, deals with the many pollutant and runoff sources throughout a watershed and shows that whenever feasible, combining the most effective BMPs in a series can be an effective strategy to reduce pollutant loads being transported to the receiving waters by stormwater.

3.4.2 Industrial and Commercial. The selection of the most appropriate BMP controls for an industrial or commercial operation is determined by the activities that take place outside where they are exposed to stormwater. Similar to municipal BMPs, the determination as to whether to use structural or nonstructural BMPs is a function of whether the facility is under design or if it is existing.

R0017656

FIGURE SQ-1
Multi-level Stormwater Quality Management Strategy

R0017658

Structural controls, such as cover roofing, secondary containment, and detention facilities, can be readily integrated into the design of these facilities. It may be much more costly and less practical to put these controls into place after the facility is in operation.

An effective strategy for reducing stormwater pollution loads for industrial and commercial facilities is to focus on source controls using both structural and non-structural technologies. The multi-level stormwater strategy for municipalities is also of use for industrial and commercial sites.

3.5 Erosion Control During Construction

Control of construction activities is critical in stormwater quality management. During the relatively short period of time when land is converted from undeveloped to urban uses, a significant amount of sediment can erode from a construction site and be transported to adjacent properties and to receiving waters. If measures are not taken to reduce erosion and to capture sediment in runoff from construction sites, damage can occur to offsite areas and to aquatic habitats in the receiving water system.

Many methods are available to limit erosion and sediment losses from a construction site. One of the most effective is to prevent erosion from occurring. Oftentimes large areas are excavated or graded at one time in preparation for construction of site facilities and buildings. By limiting the amount of time that an area is disturbed through the use of phasing, soil erosion is reduced. Prevention, along with the application of erosion control practices to all areas disturbed during construction, can significantly reduce soil erosion. Finally, the proper installation and maintenance of sediment trapping devices at construction sites can ensure that soil erosion and sediment transport offsite is controlled to the maximum extent practicable.

There are many structural and nonstructural options available in the design of an erosion and sediment control plan. It is recommended, however, that the erosion and sediment control plan be developed consistent with the post-development stormwater management goals of the site. Opportunities often exist for converting temporary sediment control structures into permanent structural stormwater BMPs at the end of the construction phase. These options should be explored by the designer of an erosion control plan, final site BMPs, and their eventual owners.

Regardless of the specific details used in an erosion control plan, the goal is to implement erosion and sediment control as a standard practice at all construction sites, and to incorporate it as an integral part of any stormwater quality management strategy. To facilitate sound erosion and sediment control practices during construction, technical criteria were developed, along with a model ordinance for their implementation by local municipalities. These criteria and the model ordinance are contained in the *Construction Best Management Practices* chapter of Volume 3 of the *Manual.*

4.0 STORMWATER QUALITY HYDROLOGY

4.1 Overview

Urbanization affects stormwater runoff by increasing the following:

- The volumes and rates of surface runoff
- The concentrations and the types of pollutants found in stormwater
- The loads of pollutants carried and their transfer rates to receiving waters

Urbanization leads to a decrease in pervious land areas, an increase in impervious areas, and enhanced efficiency of surface runoff. The influx of commercial, residential, and industrial products into an urban area often brings new pollutants that result in concentrations of these pollutants in stormwater greater than before urbanization has occurred. Additional impervious areas can make pollutants more easy to wash off the surface and quicken their conveyance through the watershed. The cumulative effect is that urbanization results in much larger loads (with the possible exception of nutrients found in runoff coming from irrigated agricultural land), and in the delivery of certain pollutants, such as petroleum-based products not normally found in nonurban and nonindustrial runoff.

The rate of runoff and the extent of pollutant loads depend on the hydrologic conditions that lead to stormwater runoff. Some investigators hypothesize that pollutant loads being delivered by the urban stormwater system are affected by the period between storms (storm separation). They suggest that this period provides time for pollutants in the atmosphere and from other sources to build up on impervious areas. However, the Denver Regional Urban Runoff Program (DURP) studies (Mustard et al., 1985) conducted by the USGS did not support this hypothesis beyond a 2- to 5-day dry buildup period. This is not to say that the above-mentioned hypothesis is not true for other regions of United States.

4.2 Denver Area Precipitation Statistics

Studies of the precipitation for 36 years from the Denver Stapleton Rain Gage have revealed several pertinent hydrologic patterns. Analyses show that the average storm based on 6-hour separation period has an 11-hour duration and that the average time interval between storms (storm separation) is 11.5 days. However, the great majority of storms are less than 11 hours in duration. The limited number of storms with long rainfall periods within the data base tend to increase this average. Table SQ-7 summarizes the relationship between total storm depth and the annual number of storms. As the table shows, about 46 of a total of 75 storm events that occur on an annual average basis, or 61 percent, have less than 0.1 inches of precipitation. These storms produce practically no runoff. The table also shows that about 22 of the 30 remaining runoff-producing events, or 75 percent, total between 0.1 inches and 0.5 inches of depth. If runoff can be controlled from most of the storms that range 0.1 inches to 0.5 inches in precipitation, the overall treatment of stormwater runoff in the Denver region should be very effective.

R0017660

TABLE SQ-7
Number of Rainfall Events in the Denver Area

4.0 to 5.0	0.028
>5.0	0
Total	**75.318**

4.3 Diminishing Returns with Increasing Size of Design Storms

The above analysis and other studies indicate that small-sized, frequently occurring storm events account for the predominate number of events that result in stormwater runoff from urban catchments. Consequently, these frequent storms also account for a significant portion of the annual pollutant loads. Capture and treatment of the stormwater from these small and frequently occurring storms is the recommended design approach for water quality enhancement, as opposed to flood control facility designs that focus on less frequent, larger events. Incorporating both sets of criteria into a single stormwater management facility is not only possible, but is encouraged.

The analysis of precipitation data collected from 1948 through 1984 (36 years) at the Denver Stapleton Rain Gage revealed a relationship between the percent imperviousness of a watershed and the capture volume needed to significantly reduce stormwater pollutants (Urbonas, Guo, and Tucker, 1990). Subsequent studies (Guo and Urbonas, 1996 and Urbonas, Roesner, and Guo, 1996) of precipitation resulted in a recommendation by the Water Environment Federation (1998) that stormwater quality treatment facilities (i.e., structural BMPs) be based on the capture and treatment of runoff resulting ranging in size from "mean" to "maximized" storms. These two extremes represent 70 to 90 percentile storms. As a result of these studies, water quality facilities for the front range of Colorado are recommended to capture and treat the 80th percentile runoff event. Capturing and properly treating this volume was estimated to remove between 80 and 90 percent of the annual TSS load, while doubling the capture volume was estimated to increase the removal rate by only 1 to 2 percent.

R0017661

While bigger may appear to be better in the case of stormwater quality, larger water quality detention basins can provide less holding time for the predominant number of smaller storms. Larger basins can result in less net reduction of pollutants than is obtained when using the recommended 80th percentile capture volume that can be obtained from Figure SQ-2. Storms larger than the 80th percentile events still receive some treatment when their capacity is exceeded by larger storms, but at a somewhat lower efficiency. Thus, the law of diminishing returns for cost-effective pollutant removal takes effect, not only because of the large number of small storms found in the total population of storms, but because the first flush of runoff for larger storm is also captured and that pollutant removal continues to occur for in-line capture basins when the runoff exceeds their design capacity.

4.4 Determining the Water Quality Capture Volume

4.4.1 Use of Directly Connected Impervious Area. The procedures described in the *Rainfall* and in the *Runoff* chapters of Volume 1 of the *USDCM* are intended for the design of drainages and flood facilities that prevent damage to property and help protect human life. These procedures show that the depth of rainfall produced from a design storm varies somewhat throughout the Denver region and that runoff is a function of total imperviousness. Water quality enhancement focuses more on the smaller events that deliver frequent flow pulses and pollutant loads to the receiving waters. The runoff volume for smaller events is especially sensitive to the impervious area that is hydraulically connected to the stormwater runoff system.

The impervious portion of a watershed determines the runoff volume that needs to be used for the design of water quality facilities, and the percentage of impervious surface therefore becomes important in the design of structural BMPs. The methodology for calculating basin imperviousness is presented in the *Runoff* chapter of Volume 1 of the *USDCM.* This procedure needs to be modified, however, when using the practice of *minimizing directly connected impervious areas*in combination with *extended detention basins, retention ponds, wetlands,* and other practices depended on a design water quality capture volume. Whenever applicable, the needed modifications are described in the appropriate chapters of this volume of the *USDCM.*

4.4.2 Water Quality Capture Volume (WQCV). All structural BMPs recommended in this volume of *USDCM* are based on the 80th percentile event. Specific guidance for finding the needed WQCV is provided in each BMP types'design section. This WQCV varies with the type of BMP used and is based on the time it takes to fully drain the brim-full WQCV. Figure SQ -2 summarizes the WQCV requirements as a function of the tributary catchments total imperviousness as a ratio of the total area of the catchment for 6-, 12-, 24-, and 40-hour drain times of the WQCV.

Figure SQ-2 is appropriate for use in Colorado's high plains near the foothills. For other portions of Colorado or of United States, the WQCV obtained from this figure can be adjusted using the following relationships:

$$WQCV_O = d_6 \frac{WQCV}{0.43}$$

in which,

$WQCV_O$	=	Water quality capture volume outside the Denver region
d_6	=	Depth of average runoff producing storm from Figure SQ-3 (watershed inches)

Once the WQCV in watershed inches is found from Figure SQ-2, then determine the required storage volume in acre-feet as follows:

$$Required\ storage = \left[\frac{WQCV}{12}\right](Area)$$

in which,

Required storage	=	Required storage volume in acre-feet
Area	=	The tributary catchment's area upstream in acres

The independent variable in Figure SQ-2 is the total imperviousness ratio (i.e., $i=I_{wq}/100$) of the tributary watershed (catchment). The chapter on *Runoff* in Volume 1 of the *USDCD* contains guidance for how to find the total imperviousness of a watershed and its use is recommended with one exception. Figure 2-1 in *Runoff* chapter of Volume 1 relate housing density to the impervious area percentage is no longer valid. Instead use Figures SQ-4, SQ-5 and SQ-6 to estimate the imperviousness of single family residential areas. Note that these figures require the knowledge of the average housing densities, types of housing, and their average square footage to find the imperviousness of these areas.

1.0 BMP PLANNING FOR NEW DEVELOPMENT AND SIGNIFICANT REDEVELOPMENT

1.1 Overview

This chapter contains guidance for the selection and siting of structural best management practices (BMPs) for new development. The guidance is provided within the context of a four-step process that may be followed for new site developments and significant redevelopments.

Detailed descriptions, sizing and design criteria, and design procedures for these BMPs are provided in the chapter titled *Structural Best Management Practices.*

The selection of BMPs for a development site is intended to be made collaboratively as a result of coordination between the developer and the local jurisdiction. It is recommended that discussions regarding proposed BMPs occur early in each project between the developer's planner and engineer and municipal staff.

1.2 Four-Step Process

The following four-step process is recommended for selecting structural BMPs in newly developing and redeveloping urban areas:

- Step 1. Employ Runoff Reduction Practices. To reduce runoff peaks and volumes from urbanizing areas, employ a practice generally termed "minimizing directly connected impervious areas"(MDCIA). The principal behind MDCIA is twofold -- to reduce impervious areas and to route runoff from impervious surfaces over grassy areas to slow down runoff and promote infiltration. The benefits are less runoff, less stormwater pollution, and less cost for drainage infrastructure. There are several approaches to reduce the effective imperviousness of a development site:

  - Reduced Pavement Area. The use of smaller roadway cross sections is encouraged. Sometimes, creative site layout can reduce the extent of paved areas, thereby saving on initial capital cost of pavement and then saving on pavement maintenance, repair, and replacement over time.

  - Porous Pavement. The use of modular block porous pavement or reinforced turf in low-traffic zones such as parking areas and low use service drives such as fire lanes can significantly reduce site imperviousness. This practice can reduce the extent and size of the downstream storm sewers and detention.

  - Grass Buffers. Draining impervious areas over grass buffers slows down runoff and encourages infiltration, in effect reducing the impact of the impervious area.

R0017670

- Grass Swales. The use of grass swales instead of storm sewers, like grass buffers, slows down runoff and promotes infiltration, also reducing effective imperviousness. It also can reduce the size and cost of downstream storm sewers and detention.

Implementing these approaches on a new development site is discussed further in Subsection 1.3. This subsection provides a procedure for estimating a reduced imperviousness based on the use of grass buffers and swales. The latter three of the approaches for reducing imperviousness are structural BMPs and are described in detail in the following sections of the *Structural Best Management Practices* chapter:

Section	Structural BMP
1.0	Grass Buffer
2.0	Grass Swale
3.0	Modular Block Porous Pavement (or Stabilized-Grass Porous Pavement)

- Step 2. Provide Water Quality Capture Volume (WQCV). A fundamental requirement for any site addressing stormwater quality is to provide WQCV. One or more of six types of water quality basins, each draining slowly to provide for long-term settling of sediment particles, may be selected. Subsection 1.4 provides information on selecting and configuring one or more of these WQCV facilities at a site. These six BMPs are described in detail in the following sections of the *Structural Best Management Practices* chapter:

Section	Structural BMP
4.0	Porous Pavement Detention
5.0	Porous Landscape Detention
6.0	Extended Detention Basin
7.0	Sand Filter Extended Detention Basin
8.0	Constructed Wetland Basin
9.0	Retention Pond

- Step 3. Stabilize Drainageways. Drainageway, natural and manmade, erosion can be a major source of sediment and associated constituents, such as phosphorus. Natural drainageways are often subject to bed and bank erosion when urbanizing areas increase the frequency, rate, and volume of runoff. It is important that drainageways adjacent to or traversing development sites be stabilized. One of three basic methods of stabilization may be selected.

  - Constructed Grass, Riprap, or Concrete-Lined Channel This method of channel stabilization has been in practice for some time; it is described in Volume 2 of the *Urban Storm Drainage Criteria Manual* (*USDCM*). The water quality benefit associated with these channels is the

R0017671

reduction of severe bed and bank erosion that can occur in the absence of a stabilized channel. On the other hand, the hard-lined low flow channels that are often used do not offer much in the way of water quality enhancement or wetland habitat. The Urban Drainage and Flood Control District does not recommend the use of riprap or concrete lined flood conveyance channels, but does recommend the use of rock lined low-flow channels.

- Stabilized Natural Channel. This method of channel stabilization is also addressed in Volume 2 of the *USDCM*. However, in practice, many natural drainageways in and adjacent to new developments in the Denver area are frequently left in an undisturbed condition. While this may be positive in terms of retaining desirable riparian vegetation and habitat, urban development may cause the channel to become destabilized. When degradation occurs in these drainageways, significant erosion, loss of riparian and aquatic habitat, and elevated levels of sediment and associated pollutants can result. Therefore, it is recommended that some level of stream stabilization always be considered. Small grade control structures sized for a 5-year or larger runoff event are often an effective means of establishing a mild slope for the baseflow channel and arresting stream degradation. Severe bends or cut banks may also need to be stabilized. Such efforts to stabilize a natural waterway also preserves and promotes natural riparian vegetation which can provide paybacks in terms of enhanced aesthetics, habitat, and water quality.

One additional method of drainageway stabilization gives special attention to stormwater quality and is described in the following section of the *Structural Best Management Practices* chapter:

Section	Structural BMP
10.0	Constructed Wetland Channel.

- Step 4. Consider Need for Industrial and Commercial BMPs. If a new development or significant redevelopment activity is planned for an industrial or commercial site, the need for specialized BMPs must be considered. Several approaches are described in the following sections of the *Structural Best Management Practices* chapter:

Section	Structural BMP
11.0	Covering of Storage/Handling Areas
12.0	Spill Containment and Control

Guidance for planning of industrial and commercial BMPs is provided in the chapter titled *Industrial and Commercial Best Management Practices*. In addition, nonstructural practices applicable to industrial and commercial activities are described in the chapter on *Nonstructural Best Management Practices*.

1.3 Other BMPs

The structural BMPs identified above were selected after a comprehensive screening of known structural BMPs with representatives of a number of cities and counties in the Denver metropolitan area, Colorado Department of Transportation, Colorado Water Quality Control Division, industry, homebuilders, and a municipality located outside the Denver metropolitan area. Final selection by this group was based on the review of documentation on potential effectiveness in a semiarid climate, local applicability, maintenance considerations, and cost.

Several other BMPs were considered but were not included in Volume 3 at this time. These include manufactured devices such as water quality vaults and inlets, infiltration trenches, oil/grease separators, fabric inserts for inlets, and stream buffer setbacks. Some of these BMPs show promise but need further independent research to determine their pollutant removal effectiveness in a semiarid climate and to develop cost-effective design criteria to insure that they are properly designed, constructed, and maintained. As additional BMPs are field tested, and as supporting information becomes available, they may be added to the *Manual*.

1.4 Implementing Step 1. Employ Runoff Reduction Techniques

1.4.1 Benefits of Reducing Imperviousness. Reducing imperviousness offers the following benefits:

- Increased infiltration and decreased rate and volume of site runoff
- Decreased WQCV and, in turn decreased size of required WQCV facilities
- Decreased 2-year and 5-year peak runoff rates and volumes for downstream conveyance and detention facilities
- Reduced need for irrigation
- Less curb and gutter
- Smaller storm sewer systems
- Decreased pavement
- Decreased runoff rates and volumes further downstream in watershed, especially if MDCIA is used on a widespread basis

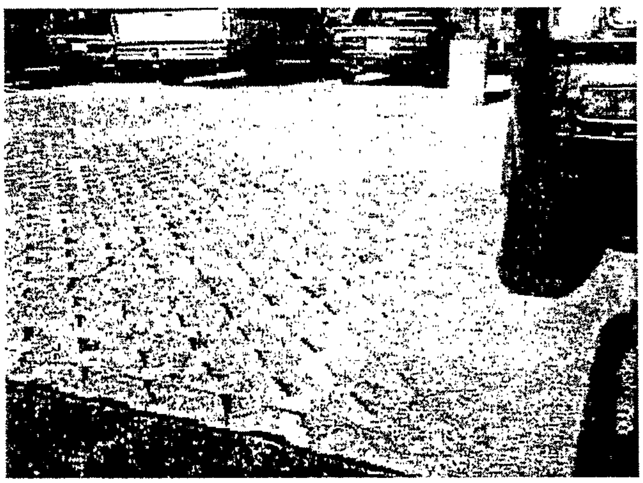
1.4.2 BMPs for Minimizing Effective Imperviousness. Described next are structural BMPs that minimize effective imperviousness.

Grass Buffer (GB)

Uniformly graded and densely vegetated area of turf grass. This BMP requires sheet flow to promote filtration, infiltration, and settling to reduce runoff pollutants.

Grass Swale (GS)

Densely vegetated drainageway with low-pitched side slopes that collects and slowly conveys runoff. Design of longitudinal slope and cross-section size forces the flow to be slow and shallow, thereby facilitating sedimentation while limiting erosion.



Modular Block Porous Pavement (MBP)

Modular block porous pavement consists of open void concrete slab units underlain with gravel. The surface voids are filled with sand. This BMP is intended to be used in low traffic areas to accommodate vehicles while facilitating stormwater infiltration near its source. A variation of this BMP is termed stabilized-grass porous pavement, consisting of plastic rings affixed to filter fabric underlain with gravel. The surface voids are filled with sand and grass sod/or seed.

R0017674

1.4.3 Applying MDCIA to a Site. Minimizing directly connected impervious area requires a basic change in land development design philosophy. This change seeks to reduce paved areas and directs stormwater runoff to landscaped areas, grass buffer strips, and grass-lined swales to slow down the rate of runoff, reduce runoff volumes, attenuate peak flows, and encourage filtering and infiltration of stormwater. Traditional land development practices do not focus on water quality enhancement. Instead, they promote runoff from rooftops, parking lots, driveways, and roads to quickly flow to a curb and gutter and to a formalized stormwater conveyance system. This practice concentrates runoff quickly, which results in a fast responding system and relatively large peak runoff rates during small storms.

Minimizing DCIAs can be made an integral part of landscape and drainage planning for any development. Roof collection systems can direct flow to landscaped areas, infiltration areas, grassed buffer strips, and to grass swales. Instead of using solid curbing, eliminate curbing or use slotted curbing along with stabilized grass shoulders and swales. Residential driveway runoff can be redirected from flowing directly into the street. Large parking lots can reduce DCIAs by using modular block or stabilized grass porous pavement in less used portions of the lot to encourage local infiltration or storage.

Site slopes should be capable of directing stormwater runoff by gravity in a sheet flow away from buildings, roads, and parking lots toward grass-covered or porous pavement covered areas. The runoff then needs to flow as a sheet over these porous surfaces before it reaches swales, storage, stormwater collection, and stormwater conveyance systems. As a result, in areas of high permeability soils (Hydrologic Soil Class A and B soils), the ground can provide for infiltration of large portions of surface runoff. Where less permeable soils are present, significant runoff losses can also be achieved, while the use of sand trenches with underdrains under grass swales can be used to prevent the nuisance of standing water.

Steep sites with average terrain slopes exceeding 4 percent may not lend themselves well to implementing some aspects of this BMP. Some of the difficulties can be dealt with by using terracing and retaining walls. Nevertheless, most sites with general terrain slopes flatter than 4 percent should be suitable for this BMP; the flatter the better.

Minimizing DCIAs can be implemented in varying degrees. Two general levels associated with minimizing DCIAs have been identified for the purpose of the *Manual* and are described below:

- Level 1. The primary intent is to direct the runoff generated by impervious surfaces to flow over grass-covered areas, and to provide sufficient travel time so as to encourage the removal of suspended solids before runoff leaves the site, enters a curb and gutter, or enters another stormwater collection system. Thus, at Level 1, *all* impervious surfaces are made to drain over grass buffer strips before reaching a stormwater conveyance system.

R0017675

- Level 2. As an adjunct to Level 1, this level replaces street curb and gutter systems with low-velocity grass-lined swales and pervious street shoulders. Conveyance systems and storm sewer inlets will still be needed to collect runoff at downstream intersections and crossings where stormwater flow rates exceed the capacity of the swales. Small culverts will be needed at street crossings and at individual driveways until inlets are provided to convey the flow to a storm sewer.

1.4.4 Calculating Effective Imperviousness. The first step in estimating the magnitude of runoff from a site is to first estimate the site's imperviousness. The total imperviousness of a site is the weighted average of individual areas of like imperviousness. For instance, according to Table 3-1 of Volume 1 of the USDCM, paved streets (and parking lots) have an imperviousness of 100-percent, drives and walks have an imperviousness of 96-percent, roofs have an imperviousness of 90-percent, and lawn areas have an imperviousness of 0-percent. The total imperviousness of a site can be determined taking an area-weighted average of the imperviousness of the street, walk, roof, and lawn areas.

Structural BMPs for minimizing imperviousness impact this calculation in two ways. First, the use of modular block porous pavement reduces the imperviousness associated with parking areas and drives built using modular block pavement from 100- and 96-percent, respectively, to 35-percent (assuming the use of underdrains). Second, the use of grass buffers and grass swales provides a reduction in imperviousness according to Figure ND-1. This figure represents the reduction in imperviousness associated with Level 1 and Level 2 MDCIA as discussed above. Grass buffers and/or grass swales are to be configured according to the design procedure documented in the *Structural Best Management Practices* chapter.

1.4.5 Application Examples. The following figures provide a number of illustrations of how the principle of MDCIA can be applied to development sites. Figure ND-2 shows an example of MDCIA for a residential and commercial site. Figure ND-3 shows an example for a multi-family residential site. Figure ND-4 shows typical application examples of modular block porous pavement.

The Total Percent of Watershed Imperviousness for the traditional residential layout in Figure ND-2 is approximately 47%. Using porous pavement and a grass swale, as shown at the bottom of the figure, reduces the Total Percent of Watershed Imperviousness to 34%. This shows that the inclusion of BMPs can significantly reduce total imperviousness. Additional BMP benefits are achieved when the user determines the Impervious Percent to Use with WQCV in Figure ND-1 because the MDCIA layout allows the use of the Level 2 MDCIA curve. The resulting Impervious Percent to Use with WQCV values for the traditional residential layout and the residential MDCIA layout are 47% and 20%, respectively.

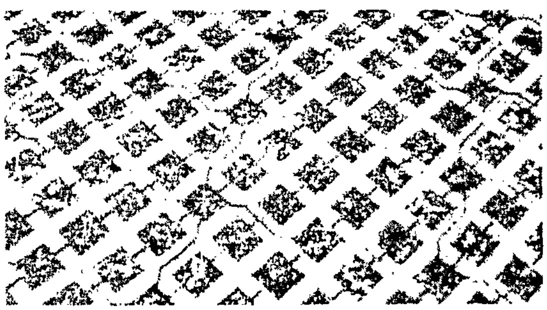
1.5 Implementing Step 2. Provide Water Quality Capture Volume (WQCV)

1.5.1 Benefits of WQCV Facilities. These BMPs are designed to capture and provide treatment for a specific volume of stormwater runoff (about half of the runoff from a 2-year storm). This volume is equivalent to the runoff from an 80th percentile storm, meaning that 80 percent of the most frequently occurring storms are fully captured and treated and larger events are partially treated. Detention periods range from 6- to 40-hours, depending on the type of facility. The primary pollutant removal mechanism consists of physical settling of suspended sediments and associated adsorbed pollutants. Secondary pollutant removal mechanisms include filtering, biological uptake, and adsorption.

The WQCV treatment facilities described herein have been selected for the USDCM because they have demonstrated proven results in the Denver area, are relatively cost-effective and are necessary at any site addressing stormwater quality. Runoff from 100-percent of the impervious surfaces of a site must flow through a properly designed installation of one or more of the six WQCV BMPs that are listed herein. Alternate designs may be considered, but they must have equivalent functional requirements of these six BMPs as to WQCV and drain times.

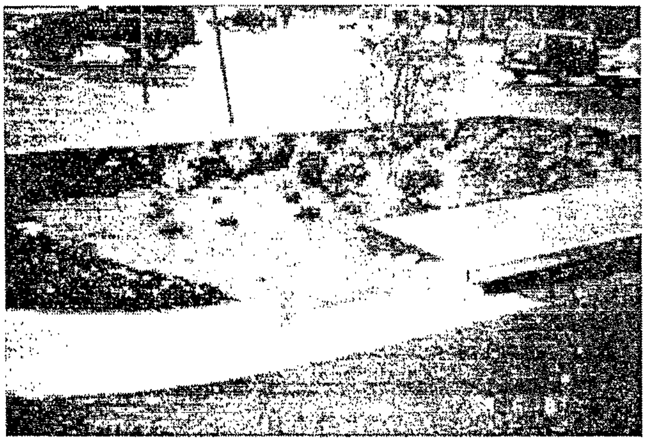
1.5.2 Types of WQCV Facilities. A brief description of the six types of WQCV facilities follows.



Porous Pavement Detention (PPD)

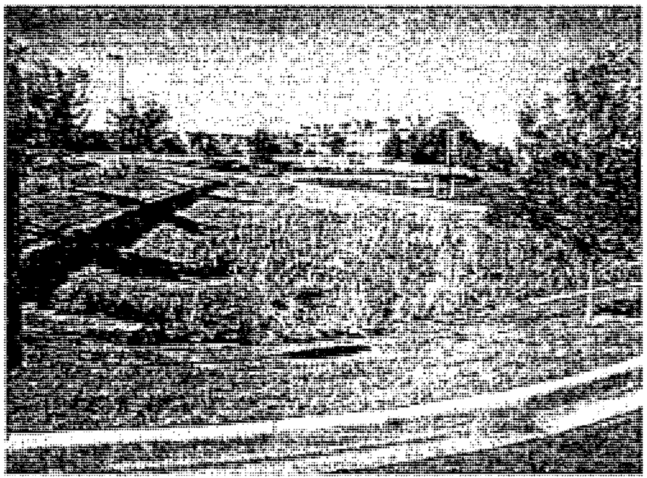
Porous pavement detention consists of modular block porous pavement that is installed flat and is provided with a 2-inch deep detention zone above its surface to temporarily store the WQCV from the tributary drainage area including its own surface. Runoff infiltrates into the void spaces of the gravel base course through the sand filter and slowly exits through an underdrain.

R0017681



Porous Landscape Detention (PLD)

Porous landscape detention consists of a low lying vegetated area underlain by a sand bed with an underdrain. A shallow surcharge zone exists above the porous landscape detention for temporary storage of the WQCV. This BMP allows small amounts of WQCV to be provided on parking lots or adjacent to buildings without requiring the setaside of significant developable land areas.



Extended Detention Basin (EDB)

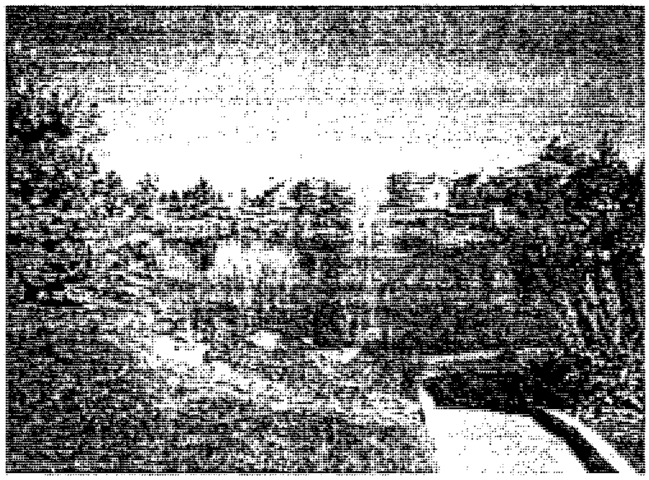
An extended detention basin is appropriate for larger sites and is designed to totally empty out sometime after stormwater runoff ends. The extended basin uses a much smaller outlet than a flood control detention basin which extends the emptying time for the more frequently occurring runoff events to facilitate pollutant removal.

Sand Filter Extended Detention Basin (SFB)

A sand filter extended detention basin consists of a sand bed and underdrain system. Above the vegetated sand bed is an extended detention basin sized to capture the WQCV. A sand filter extended detention basin provides pollutant removal through settling and filtering and is generally suited to offline, onsite configurations where there is no base flow and the sediment load is relatively low.

Constructed Wetland Basin (CWB)

A constructed wetland basin is appropriate for large catchments and is a shallow retention pond which requires a perennial supply of water to permit the growth of rushes, willows, cattails, and reeds. It treats runoff by slowing it down to allow time for settling and biological uptake.



Retention Pond (RP)

A retention pond is appropriate for larger catchments. It has a permanent pool of water that is replaced with stormwater, in part or in total, during storm runoff events. In addition, a temporary extended detention volume is provided above this permanent pool to capture storm runoff and enhance sedimentation. It requires a perennial supply of water to maintain the pool.

1.5.3 Application Examples for Porous Pavement and Porous Landscape Detention. Porous pavement and porous landscape detention provide an opportunity to incorporate WQCV into a new land development site or a redevelopment site while minimizing the impact on developable area. Just as the principle of MDCIA requires a change in drainage philosophy, so does the application of porous pavement and porous landscape detention. These BMPs need to be applied on a relatively small scale and are ideally suited to small sites or individual small sub-catchment areas of large sites.

The following figures provide a number of illustrations of how porous pavement and porous landscape detention can be applied in a development site. Figure ND-5 shows an example for a residential site. Figure ND-6 and ND-6A show an example for a multi-family residential site, and Figure ND-7 shows an example for a commercial site parking lot.

R0017687

1.5.4 Guidance for Selecting and Locating WQCV Facilities. Figure ND-8 depicts a decision tree for selecting one of the six WQCV BMPs based on drainage catchment area and whether water is available to satisfy evapotranspiration requirements. Porous pavement and porous landscape detention is generally suited for small drainage areas (i.e. much less than 1.0 acres); however, larger subwatersheds can be subdivided into individual drainage sub-catchment areas meeting the criteria shown in Figure ND-8 for these BMPs.

Laying out WQCV facilities within a development site and watershed requires thought and planning. Often, this decision-making occurs during a master planning process undertaken by local jurisdictions and the District. Outfall system plans and other reports may depict a recommended approach for implementing WQCV on a watershed basis. Such reports may call for a few large regional WQCV facilities, smaller sub-regional facilities, or alternatively an onsite approach. It is always a good idea to find out if a master planning study has been completed that addresses water quality and to attempt to follow the plan's recommendations.

The following guidance is for areas where a master plan addressing water quality has not been completed. One of the questions involved in laying out WQCV facilities on a site is whether to locate a BMP onstream or offstream. Onstream refers to locating a BMP on a drainageway that traverses a site such that all of the runoff from the upstream watershed flows through the facility. A single onstream BMP can treat both site runoff and runoff generated in any upstream offsite catchment areas that are part of that watershed. Locating BMPs offstream requires that all onsite catchment areas flow though a BMP prior to entering the drainageway. Offstream BMPs do not provide treatment of runoff from any upstream drainage catchment areas.

Onstream WQCV facilities are only recommended if the offsite drainage catchment area tributary to the drainageway has less impervious area than the onsite drainage catchment's impervious area tributary to the same drainageway. **Nevertheless, onstream WQCV facilities must be designed to serve the entire upstream watershed, including any catchment areas upstream of the development, based on future development conditions.** This is true even if upstream developments have installed their own WQCV facilities.

Figure ND-9 provides an illustration of selection and location options for WQCV facilities based on the principles discussed above. Table ND-1 indicates the BMP options for the four watershed areas shown in Figure ND-9.

R0017688

					Suitable WQCV BMP
o					Porous Pavement Detention (PPD) with Underdrain
	o				Porous Pavement Detention (PPD) with Infiltration
o					Porous Landscape Detention (PLD) with Underdrain
	o				Porous Landscape Detention (PLD) with Infiltration
		o	o	o	Extended Detention Basin (EDB)
		o			Sand Filter Extended Detention Basin (SFB)
				o	Construction Wetland Basin (CWB)
				o	Retention Pond (RP)

Note: Large drainage areas may be subdivided into areas < 20 acres for use of SFD or PLD or <1 acre for use of PPD.

		Retention Pond	1	70
4	Offstream	Porous Pavement Detention	6	1
		Porous Landscape Detention	1	6
		Extended Detention Basin	1	6
		Sand Filter Extended Detention Basin	1	6

1.5.5 Incorporating WQCV into Stormwater Quantity Detention Basins. Wherever possible, it is recommended that WQCV facilities be incorporated into stormwater quantity detention facilities. This is relatively straightforward for an extended detention basin, constructed wetland basin, and a retention pond. When combined, the 2-, 5-, 10-, and/or 100-year detention levels are provided above the WQCV and the outlet structure is designed to control two or three different releases. Figure 2 in the section on *Water Quality Structure Details* shows of examples of combined quality/quantity outlet structure. Stormwater quantity detention could be provided above the WQCV for porous pavement and landscape detention provided the drain times for the larger events are kept short.

Local jurisdictions in the Denver area use different approaches for sizing a combined water quality and quantity detention facility. This varies from requiring no more than the 100-year detention volume even though the WQCV is incorporated within it, to requiring the 100-year detention volume plus the full WQCV. The *Manual* does not stipulate or recommend which policy should be used. When a local policy is lacking and is being set, the *Manual* suggests the following approach:

- Water Quality. The full WQCV is to be provided according to the design procedures documented in the Structural BMP Section.
- Minor Storm. The full WQCV plus the full minor storm quantity detention volume is to be provided.

R0017691

- <u>100-Year Storm</u>. One-half the WQCV plus the full 100-year detention volume is to be provided.

However, local governments may have criteria different than that described above, and such criteria takes precedence over the approach suggested herein. For instance, some jurisdictions require that the full WQCV be added to the full 100-year detention volume and some require no more than the 100-year detention volume even if WQCV is incorporated within the facility

At this time the *Manual* recommends that water quality detention not be incorporated into underground detention facilities, such as installations of buried large-diameter pipe sections, stone trenches, underground "infiltrating" devices, etc.

<u>1.5.6 Separate Presedimentation Facilities.</u> The design criteria shown in the Structural BMP section shows presedimentation forebays at the upstream end of the extended detention basin, constructed wetland basin, and retention pond. The purpose of the forebay is to settling out coarse sediment and skim off floatables prior to the main body of the facility. An option to this approach is to install a separate facility upstream from the main WQCV facility. If this option is selected, the recommended size is at least 20 percent of the WQCV and the recommended drain time is 1 hour for the presedimentation forebay volume only. Using this approach, the size of the main WQCV facility may be reduced by 10 percent, any requirement for sediment storage in the main facility may be reduced by one-half, and the forebay within the main facility may be eliminated.

It is extremely important that high sediment loading be controlled for porous pavement detention, porous landscape detention, and sand filter extended detention basins. These facilities are best suited to being brought on line at the end of the construction phase where disturbed ground has been established with pavement or vegetation.

STRUCTURAL BEST MANAGEMENT PRACTICES

This chapter provides a description and design information for the following structural BMPs:

1. Grass Buffer (GB)
2. Grass Swale (GS)
3. Modular Block Porous Pavement (MBP)
4. Porous Pavement Detention (PPD)
5. Porous Landscape Detention (PLD)
6. Extended Detention Basin (EDB)
7. Sand Filter Extended Detention Basin (SFB)
8. Constructed Wetlands Basin (CWB)
9. Retention Pond (RP)
10. Constructed Wetlands Channel (CWC)
11. Covering of Storage/Handling Areas
12. Spill Containment and Control

Detailed design procedures criteria are described. Forms that designers can use to document the design procedure are included at the end of Volume 3. Typical design details are shown in the section titled Typical Details.

1.0 GRASS BUFFER (GB)

1.1 Description

Grass buffer (GB) strips are an integral part of the MDCIA land development concept. They are uniformly graded and densely vegetated areas of turf grass. They require sheet flow to promote filtration, infiltration and settling to reduce runoff pollutants. GBs differ from grass swales as they are designed to accommodate overland sheet flow rather than concentrated or channelized flow. They can be used to remove larger sediment from runoff off impervious areas.

Whenever concentrated runoff occurs, it should be evenly distributed across the width of the buffer via a flow spreader. This may be a porous pavement strip or another type of structure to achieve uniform sheet-flow conditions. GBs can also be combined with riparian zones in treating sheet flows and in stabilizing channel banks adjacent to major drainageways and receiving waters. GBs can be interspersed with shrubs and trees to improve their aesthetics and to provide shading. Irrigation in the semi-arid climate of Colorado is required to maintain a healthy and dense grass on the GB to withstand the erosive forces of runoff from impervious areas.

1.2 General Application

A GB can be used in residential and commercial areas. They are typically located adjacent to impervious areas. When used, they should be incorporated into site drainage, street drainage, and master drainage planning. Because their effectiveness depends on having an evenly distributed sheet flow over their surface, the size of the contributing area, and the associated volume of runoff have to be limited. Flow can be directly accepted from an impervious area such as from a parking lot and building roofs, provided the flow is distributed uniformly over the strip. GBs provide only marginal pollutant removal and require

R0017697

that follow-up structural BMPs be provided. They do, however, help to reduce some of the runoff volume from small storms.

1.3 Advantages/Disadvantages

1.3.1 General. The grass and other vegetation provide aesthetically pleasing green space, which can be incorporated into a development landscaping plan. In addition, their use adds little cost to a development that has to provide open space, and their maintenance should be no different than routine maintenance of the site's landscaping. Eventually, the grass strip next to the spreader or the pavement will have accumulated sufficient sediment to block runoff. At that point in time, a portion of the GB strip will need to be removed and replaced.

Grass and trees within these buffer strips can provide wildlife habitat and help reduce runoff through infiltration. If infiltration occurs, it can reduce the size of downstream drainage facilities. Gravel underdrains can be used where soils are not best suited for infiltration and to help keep the GB's surface dry.

1.3.2 Physical Site Suitability. The site, after final grading, should have a uniform slope and be capable of maintaining an even sheet flow throughout without concentrating runoff into shallow swales or rivulets. The allowable tributary area depends on the width, length, and the soils that lay under the GB. Hydrologic Soil Groups A and B provide the best infiltration capacity, while Soil Groups C and D provide best site stability. The swelling potential of underlying soils should also be taken into account in how the soils may affect adjacent structures and pavement when water is delivered to the grassed areas. Because of the semi-arid nature of Colorado's high plains, an irrigated grass cover is required to be effective.

1.3.3 Pollutant Removal. Pollutant removal depends on many factors such as soil permeability, site slope, the flow path length along the buffer, the characteristics of drainage area, runoff volumes and velocities, and the type of vegetation. The general pollutant removal of both particulate and soluble pollutants is projected to be low to moderate. GBs rely primarily upon the settling and interception of solids, and to only a minor degree, on biological uptake and runoff infiltration. See Table SQ-6 for estimated range of pollutant removals.

1.4 Design Considerations

Design of GBs are based primarily on maintaining sheet-flow conditions across a uniformly graded, irrigated, dense grass cover strip. When a GB is used over unstable slopes, soils, or vegetation, formation of rills and gullies that disrupt sheet flow will occur. The resultant short-circuiting will invalidate the intended water quality benefits. GBs should be protected from excessive pedestrian or vehicular traffic that can damage the grass cover and affect even sheet-flow distribution. A mixture of grass and trees may offer benefits for slope stability and improved aesthetics.

1.5 Design Procedure and Criteria

The following steps outline the GB design procedure and criteria. Figure GB-1 is a schematic of the facility and its components.

1. Design Discharge — Determine the 2-year peak flow rate of the area draining to the GB. Also, determine the flow control type; sheet or concentrated.

2. Minimum Length — Calculate the minimum length (normal to flow) of the GB. The upstream flow needs to be uniformly distributed over this length. General guidance suggests that the hydraulic load should not exceed 0.05 cfs/linear foot of buffer in the Colorado high plains region during a 2-year storm to maintain a sheet flow of less than 1 inch throughout dense grass that is at least 2 inches high. The minimum design length (normal to flow) is therefore calculated as:

$$L_G = \frac{Q_{2-year}}{0.05}$$

In which:

L_g = Minimum design length (feet)

Q_{2-year} = Peak discharge supplied to the GBs by a 2-year event (cfs)

Longer lengths may be used.

3. Minimum Width — The minimum width (W_G) (the distance along the sheet flow direction) of the BG shall be determined by the following criteria for onsite and concentrated flow control conditions:

A. Sheet Flow Control (use the larger value)

$$W_G = 0.2L_I \text{ or } 8 \text{ feet}$$

In which:

L_I = The length of flow path of the sheet flow over the upstream impervious surface (feet)

B. Concentrated Flow Control (use the larger value)

$$W_G = 0.15(A_t/L_t) \text{ or } 8 \text{ feet}$$

In which:

A_t = The tributary area (square feet)

L_t = The length of the tributary (normal to flow) upstream of the GB (feet)

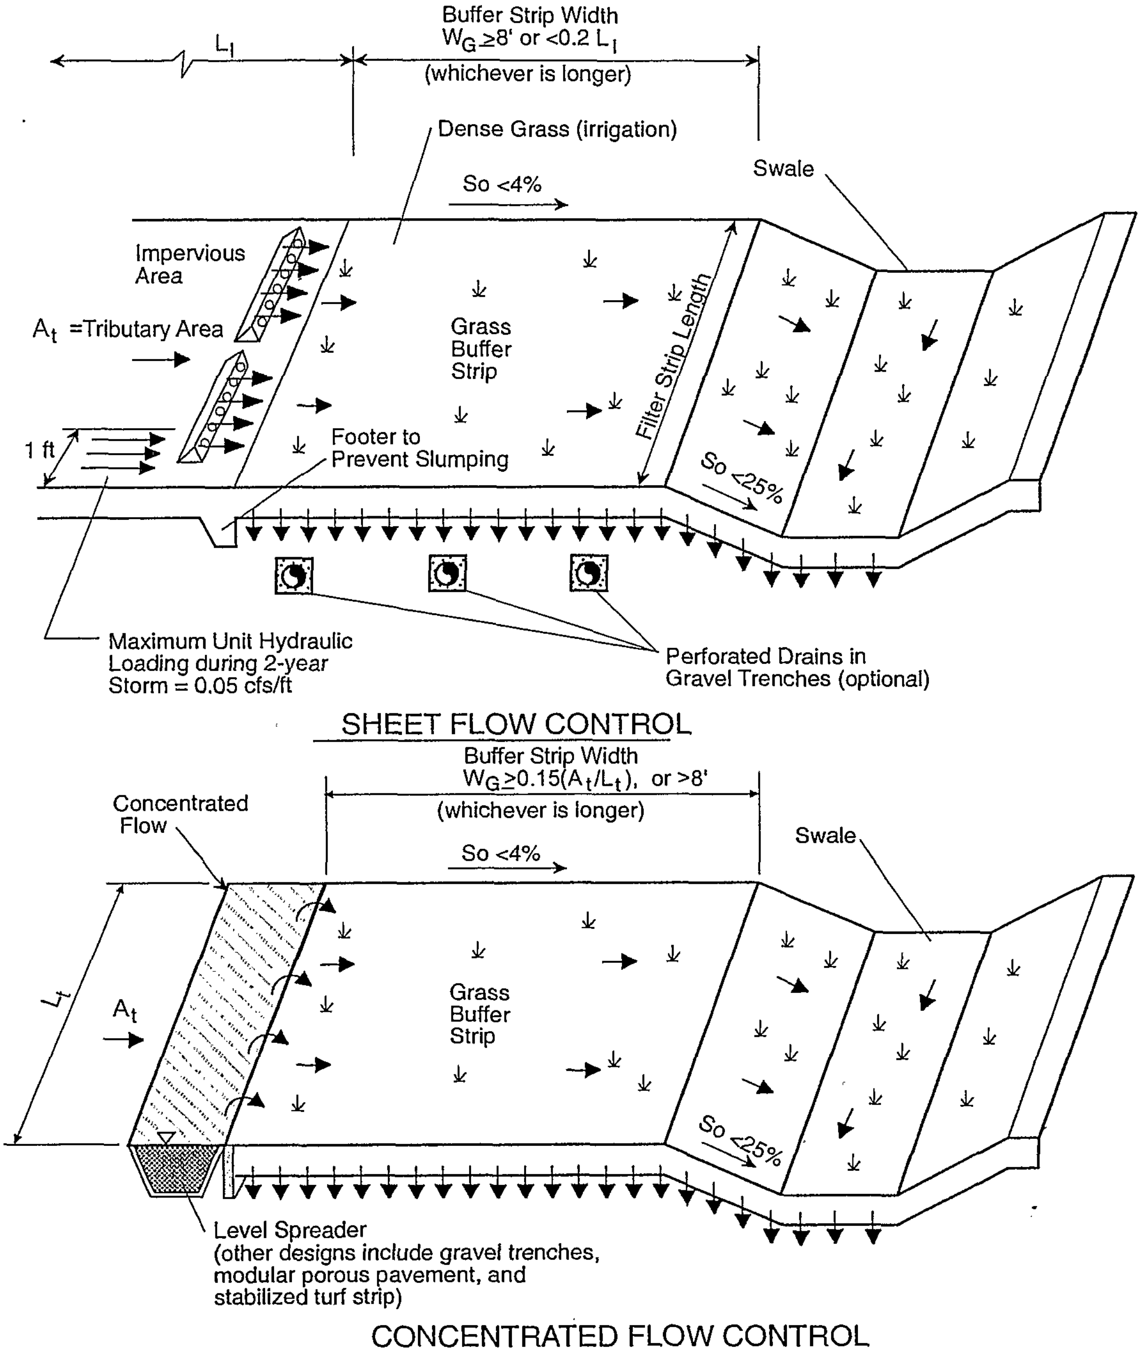
The longer the buffer area is relative to the impervious area draining to it, the smaller the effective imperviousness, per Figure ND-1.

R0017699

		A generally rectangular shape strip is preferred and should be free of gullies or rills that concentrate the overland flow.
4.	Maximum Slope	Design slopes shall not exceed 4 percent.
5.	Flow Distribution	Incorporate a device on the upstream end of the buffer to evenly distribute flows along the design length. Slotted curbing, modular block porous pavement (MBP), or other spreader devices can be used to apply flows. Concentrated flow supplied to the GB must use a level spreader (or a similar concept) to evenly distribute flow onto the buffer.
6.	Vegetation	Vegetate the GB with irrigated dense turf in semi-arid areas of Colorado to promote sedimentation and entrapment and to protect against erosion.
7.	Outflow Collection	Provide a means for outflow collection. Most of the runoff during significant events will not be infiltrated and will require a collection and conveyance system. A GS can be used for this purpose and can provide another MDCIA type of a BMP. The buffer can also drain to a storm sewer or to a street gutter.

1.6 Design Example

Design forms that provide a means of documenting the design procedure are included in the Design Forms section. A completed form follows as a design example.



Note: Not to Scale

2.0 GRASS SWALE (GS) – SEDIMENTATION FACILITY

2.1 Description

A grass swale (GS) sedimentation facility is an integral part of the MDCIA development concept. They are densely vegetated drainageways with low-pitched sideslopes that collect and slowly convey runoff. Design of their longitudinal slope and cross-section size forces the flow to be slow and shallow, thereby facilitating sedimentation while limiting erosion. Berms or check dams should be installed perpendicular to the flow as needed to slow it down and to encourage settling and infiltration.

2.2 General Application

A GS can be located to collect overland flows from areas such as parking lots, buildings, residential yards, roadways and grass buffer strips (GBs). They can be made a part of the plans to minimize a directly connected impervious area by using them as an alternative to a curb-and-gutter system. A GS is set below adjacent ground level, and runoff enters the swales over grassy banks. The potential exists for wetland vegetation to become established if the swale experiences standing water or if there is a base flow. If that condition is possible, consider the use of underdrains. A site with a base flow should be managed as either a swale with an unlined trickle channel, or as a wetland bottom channel, the latter providing an additional BMP to stormwater runoff.

2.3 Advantages/Disadvantages

2.3.1 General. A GS, which can be more aesthetically pleasing than concrete or rock-lined drainage systems, is generally less expensive to construct. Although limited by the infiltration capacity of local soils, this BMP can also provide some reduction in runoff volumes from small storms. Dense grasses can reduce flow velocities and protect against erosion during larger storm events. Swales in residential and commercial settings can also be used to limit the extent of directly connected impervious areas.

The disadvantages of using GSs without underdrains include the possibility of soggy and wet areas in front yards, the potential for mosquito breeding areas, and the potential need for more right-of-way than is needed for a storm sewer.

2.3.2 Physical Site Suitability. A GS is practical only at sites with general ground slopes of less than 4 percent and are definitely not practical for sites steeper than 6 percent. The longitudinal slopes of a GS should be kept to less than 1.0 percent, which often necessitates the use of grade control checks or drop structures. Where the general terrain slope exceeds 4 percent, a GS is often practical only on the upslope side of the adjacent street.

When soils with high permeability (for example, Class A or B) are available, the swale will infiltrate a portion of the runoff into the ground, but such soils are not required for effective application of this BMP. When Class C and D soils are present, the use of a sand/gravel underdrain is recommended.

2.3.3 Pollutant Removal. Removal rates reported in literature vary and fall into the low to medium range. Under good soil conditions and low flow velocities, moderate removal of suspended solids and associated other constituents can be expected. If soil conditions permit, infiltration can remove low to moderate loads of soluble pollutants when flow velocities are very low. As a result, small frequently occurring storms can benefit the most. See Table SQ-6 in the *Stormwater Quality Management* chapter for estimated ranges in pollutant removal rates by this BMP.

2.4 Design Considerations and Criteria

Figure GS-1 shows trapezoidal and triangular swale configurations. A GS is sized to maintain a low velocity during small storms and to collect and convey larger runoff events, all for the projected fully developed land use conditions. If the design flows are not based on fully developed land conditions, the swales will be undersized and will not provide the intended pollutant removal, flow attenuation, or flow conveyance capacity.

A healthy turf grass cover must be developed to foster dense vegetation. Permanent irrigation in some cases may be necessary. Judicious use of GSs can replace both the curb-and-gutter systems and greatly reduce the storm sewer systems in the upper portions of each watershed when designed to convey the "initial storm" (for example, a 2- or a 5-year storm) at slow velocities. However, if one or both sides of the GS are also to be used as a GB, the design of the GB has to follow the requirements of *Section 1. Grass Buffers.*

2.5 Design Procedure and Criteria

The following steps outline the GS design procedure and criteria.

1.	Design Discharge	Determine the 2-year flow rate in the proposed GS using hydrologic procedures described in Volume 1 of the *USDCM*.
2.	Swale Geometry	Select geometry for the GS. The cross section should be either trapezoidal or triangular with side slopes flatter than 4:1 (Horizontal/ Vertical), preferably 5:1 or flatter. The wider the wetted area of the swale, the slower the flow.
3.	Longitudinal Slope	Maintain a longitudinal slope for the GS between 0.2 and 1.0 percent. If the longitudinal slope requirements can not be satisfied with available terrain, grade control checks or small drop structures must be incorporated to maintain the required longitudinal slope. If the slope of the swale exceeds 0.5 percent in semi-arid areas of Colorado, the swale must be vegetated with irrigated turf grass.
4.	Flow Velocity and Depth	Calculate the velocity and depth of flow through the swale. Based on Mannings equation and a Mannings roughness coefficient of n=0.05, find the channel velocity and depth using the 2-year flow rate determined in Step 1. Maximum flow velocity of the channel shall not exceed 1.5 feet per second and the maximum flow depth shall not exceed 2 feet at the 2-year peak flow rate. If these conditions are not attained, repeat steps 2 through 4 each time altering the depth and bottom width or longitudinal slopes until these criteria are satisfied.
5.	Vegetation	Vegetate the GS with dense turf grass to promote sedimentation, filtration, and nutrient uptake, and to limit erosion through maintenance of low flow velocities.
6.	Street and Driveway Crossings	If applicable, small culverts at each street crossing and/or driveway crossing may be used to provide onsite stormwater capture volume in a similar fashion to an EDB (if adequate volume is available).
7.	Drainage and Flood Control	Check the water surface during larger storms such as the 5-year through the 100-year floods to ensure that drainage from these larger events is being handled without flooding critical areas or residential, commercial, and industrial structures.

2.6 Design Example

Design forms that provide a means of documenting the design procedure are included in the Design Forms section. A completed form follows as a design example.

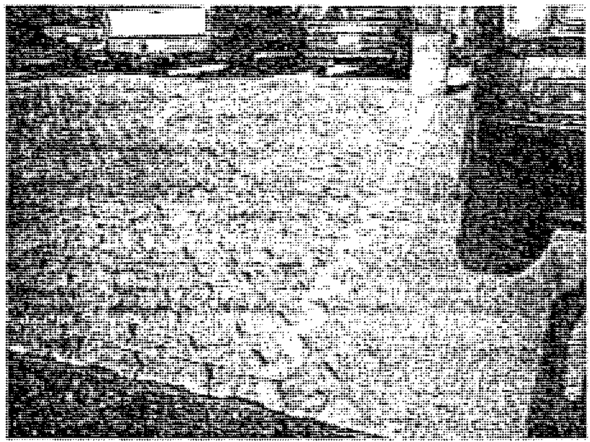
3.0 MODULAR BLOCK POROUS PAVEMENT (MBP)



3.1 Description

Modular block porous pavement (MBP) consists of open void concrete block units laid on a gravel subgrade. The surface voids are filled with sand or sandy loam turf. An alternate approach is to use stabilized-grass porous pavement, consists of grass turf semiforced with plastic rings and filter fabric underlain by gravel. This BMP is intended to be used in low vehicle movement areas to accommodate vehicles while facilitating stormwater infiltration from rain falling directly on the porous pavement. The MBP may be sloped or flat, and functions to decrease the effective imperviousness of a site. An alternate application of MBP provided for a surcharge zone to capture the WQCV and provide water quality detention. This application is described in Section 4.0 entitled *Porous Pavement Detention* of this chapter. MBP has been in use since the mid-1970s. Although field data that quantify its long-term performance are somewhat limited, the data collected locally and the episodical record from other parts of United States indicate it is reliable and has experienced few problems regardless of the local climatic conditions.

A stabilized (reinforced) sandy loam turf surface (e.g., Invisible Structures, Inc., or equal) may be substituted for the modular concrete block surface if the details below the surface are kept the same as shown in this section of the *Manual.*

3.2 General Application

MBP is best used in low vehicle movement zones such as residential driveways and is often used as a parking pad surface. Although MBP is most commonly used as parking pads in a parking lot, the following are other potential applications:

- Low vehicle movement airport zones such as parking aprons and maintenance roads

- Crossover/emergency stopping/parking lanes on divided highways
- Residential street parking lanes
- Residential driveways
- Maintenance roads and trails
- Emergency vehicle and fire access lanes in apartment/multi-family/office complex situations

Vehicle movement (i.e., not parking) lanes that lead up to the porous pavement parking pads need to be solid asphalt or concrete pavement.

Grass can be used in the block voids; however, it requires irrigation and lawn care in Coloradoś semi-arid climate.

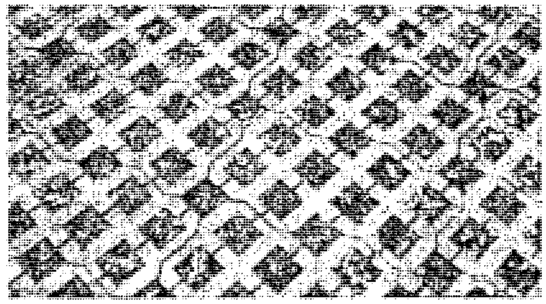
3.3 Advantages/Disadvantages

3.3.1 General. Aside from the potential for high particulate pollutant removal and the removal of other constituents similar to what a sand filter would provide, MBP can reduce flooding potential by infiltrating or slowing down runoff. Modular block patterns, colors, and materials can serve functional and aesthetic purposes.

The primary disadvantages for use of MBP are cost and the lack of significant volume of performance data in semi-arid areas that are subject to severe freeze-thaw cycles; however, the limited testing by the Urban Drainage and Flood Control District as well as observation of several sites since 1990 and the episodic descriptions from public works professional from other parts of the country and Canada indicate this type of pavement, when properly installed, functions well in freeze-thaw cycles. Other disadvantages could be associated with uneven driving surfaces and potential traps for the high heels of women's shoes. Also, the cost of restorative maintenance can be somewhat high when the system seals with sediment and no longer functions as permeable pavement.

3.3.2 Physical Site Suitability. This BMP may be installed without free draining subsoils when provided with underdrains. An underdrain ensures drainage of the gravel subgrade whenever the subsoils are not free draining. In those cases an impermeable liner should be provided to drain the water in the gravel pack and to mitigate concerns about expansive soils. This BMP should be located far enough from foundations in expansive soils so as to limit damage potential to structures. In addition, when a commercial or an industrial site may be handling chemicals and petroleum products that may spill onto the ground, an impermeable liner with an underdrain is required to prevent groundwater and soil contamination.

3.3.3 Pollutant Removal. See Table SQ-6 for estimated ranges in pollutant removals. Specific field data on pollutant removal rates are somewhat limited. Removal rates are projected to be high for both suspended sediment and associated constituents, such as metals, oil, and grease. Runoff filtration through the sand and gravel of the modular block voids and entrapment in the gravel media are the primary removal mechanisms of pollutants along with the filtration, adsorption, and ion exchange that occur as stormwater travels through the underlying soils before the stormwater reaches groundwater. Removal rates for dissolved constituents are expected to be low to moderate, depending on the filtering media used and on the specific constituent.



3.4 Design Considerations

MBP has been tested as a stormwater BMP in the Denver area and the design guidance presented here is based, in part, on those tests. The above photo depicts one type of local available block. Other block patterns are acceptable provided they have at least 40 percent of its surface area as voids. Figures MBP-1 and MBP-2 show a cross-sections of modular block installation and its subgrades. Upon installation, every effort should be made to assure even flow distribution over the entire porous surface. Figure MBP-3 depicts typical applications of modular block porous pavement.

For the purpose of sizing downstream drainage systems and followup BMPs, assume that the permeable pavement areas are only 35 percent impervious.

3.5 Design Procedure and Criteria

The following steps outline the MBP design procedure and criteria.

1.	Select Block	Select appropriate modular blocks that have no less than 40 percent of the surface area open. The manufacturers installation requirements shall be followed with the exception that *Rock Media Pore Volume Inlay Material* and *Base Course* dimensions and requirements in this section shall be adhered with.
2.	Select Porous Pavement Infill	The MBP openings should be filled with ASTM C-33 graded sand (fine concrete aggregate).
3.	Base Coarses	Provide AASHTO No. 8 (CDOT Section 703) coarse aggregate with all fractured surfaces as called for in Figure MBP-1. Assume 30 percent is open pore space.
4.	Design Area Ratio	Calculate the design area ratio which is the contributing impervious area divided by porous pavement area. This ratio cannot exceed 3.0.
5.	Perimeter Wall (optional)	Provide a concrete perimeter wall to confine the edges of the MBP block area. The wall should be minimum 6-inch wide and 6 inches deeper than all the porous media and modular block depth combined (see Figure MBP-2).
6.	Contained Cells	Provide 20 mil or thicker liner placed vertically or concrete walls to separate individual cells of the porous base course so as to cut-off horizontal flow of water (see Figure MBP-2). Space these cut-offs according to the following equation:

R0017710

$$L_{MAX} = \frac{0.8}{S_O}$$

in which

L_{MAX} = Maximum distance between cut off membrane normal to the flow (feet)

S_O = Slope of the base course (ft/ft).

7.	Subbase	If expansive soils are a concern or the tributary catchment has chemical or petroleum products handled or stored, install an impermeable membrane and place the base coarse on top of the membrane. Otherwise install a non-woven geotextile membrane to encourage infiltration.
8.	Subdrain Outlet	When needed due to site and soil conditions, design the subdrain with a permanent restrictor outlet to drain the available pore space volume in the base course in 12 hours. Subdrains are required when the pavement is located on low permeability soils such as clayey silt, sandy clays, clays, etc.

3.6 Design Example

Design forms that provide a means of documenting the design procedure are included in the Design Forms section. A completed form follows as a design example.

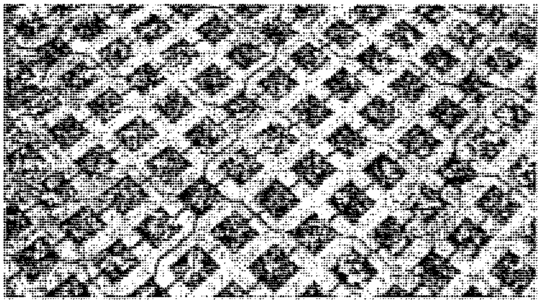
R0017716

4.0 POROUS PAVEMENT DETENTION (PPD)



4.1 Description

Porous pavement detention (PPD) consists of an installation of MBP that is flat (i.e., S_o=0.00% in all directions) and is provided with a 2-inch deep surcharge zone to temporarily store the WQCV draining from an adjacent drainage area. Runoff will infiltrate into the void spaces of the gravel base course through the sand filter media and sandy loam turf. The latter is not used for the PPD facility to insure more rapid drainage of the parking surface and easy maintenance when the media needs to be replaced to maintain rapid drainage of the ponding areas. The ponded and filtered water slowly exits through an underdrain. The application of MBP without the flat slope (i.e., S_o=0.00%) and surcharge zone, described in Section 3, functions to reduce imperviousness of pavement areas (from 100 percent to 35 percent). However, with the detention features, this BMP has the potential to satisfy the WQCV requirement for a site.

4.2 General Application

PPD may be used in the same types of low vehicle movement zones identified in Subsection 3.0 for MBP with the driveways leading up to them being solid pavement.

4.3 Advantages/Disadvantages

PPD has generally the same advantages and disadvantages as MBP. Its additional advantage is to provide a means to provide WQCV for a site that has little available open area for detention.

4.4 Design Considerations

Figure PPD-1 shows a cross-section of modular block installation and its subgrade for PPD.

4.5 Design Procedure and Criteria

The following steps outline the PPD design procedure and criteria.

1. Basin Storage Volume — Provide a storage volume equal to the WQCV based on a 6-hour drain time.

R0017717

A. Find the required storage volume (watershed inches of runoff):

Determine the Required WQCV (watershed inches of runoff) using Figure PPD-2, based on 12-hour drain time. Assume imperviousness of 100 percent for the PPD area.

B. Calculate the Design Volume in cubic-feet as follows:

$$Design\ Volume = \left(\frac{WQCV}{12}\right) * Area$$

In which:

Area = The watershed area tributary to the extended detention pond (square feet)

2. Surface Area — Calculate minimum required surface area as follows:

$$\text{Minimum surface area } (FT^2) = \frac{\text{Design Volume } (ft^3)}{0.17 \text{ feet}}$$

3. Select Block — Select appropriate modular blocks that have no less than 40 percent of the surface area open. The manufacturer's installation requirements shall be followed with the exception that *Rock Media Pore Volume Inlay Material* and *Base Course* dimension and requirements of this section shall be adhered with.

4. Select Porous Pavement Infill — The MBP openings should be filled with ASTM C-33 graded sand (fine concrete aggregate) and not sandy loam turf.

5. Base Coarses — Provide base courses as shown in Figure PPD-1.

6. Perimeter Wall — Provide a concrete perimeter wall to confine the edges of the PPD area. The wall should be minimum 6-inch wide and at least 6 inches deeper than all the porous media and modular block depth combined.

7. Subbase — If expansive soils are a concern or the tributary catchment has chemical or petroleum products handled or stored, install an impermeable membrane below the base coarse. Otherwise install a non-woven geotextile membrane to encourage infiltration.

8. Overflow — Provide an overflow, possibly with an inlet to a storm sewer, set at 2 inches (-0, + ½-inch) above the level of the porous pavement surface. Make sure the 2-inch ponding depth is contained and does not flow out of the area at ends or sides until the 2-inch ponding depth is reached.

4.6 Design Example

Design forms that provide a means of documenting the design procedure are included in the Design Forms section. A completed form follows as a design example.

For an example of where PPD would be applied see Sections A-A and B-B of Figure MBP-3.

R0017721

5.0 POROUS LANDSCAPE DETENTION (PLD) – SEDIMENTATION FACILITY

Photo: Courtesy Prince Georges County

5.1 Description

Porous landscape detention (PLD) consists of a low lying vegetated area underlain by a sand bed with an underdrain pipe. A shallow surcharge zone exists above the PLD for temporary storage of the WQCV. During a storm, accumulated runoff ponds in the vegetated zone and gradually infiltrates into the underlying sand bed, filling the void spaces of the sand. The underdrain gradually dewaters the sand bed and discharges the runoff to a nearby channel, swale, or storm sewer. Like PPD, this BMP allows WQCV to be provided on a site that has little open area available for stormwater detention.

5.2 General Application

5.2.1 Locating. A PLD can be located in just about any of the open areas of a site. It is ideally suited for small installations such as:

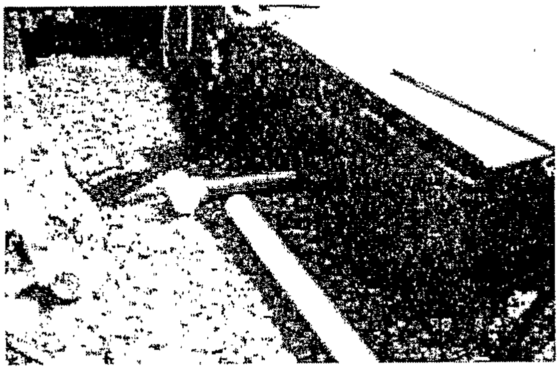
- Parking lot islands
- Street medians
- Roadside swale features
- Site entrance or buffer features

This BMP may also be implemented at a larger scale, serving as an infiltration basin for an entire site if desired provided the water quality capture volume and average depth requirements contained in this section are met.

Vegetation may consist of irrigated bluegrass or natural grasses with shrub and tree plantings if desired.

5.2.2 Example Application. The following photos illustrate an installation of PLD in Prince Georges County, Maryland.

Parking lot island before installation of PLD

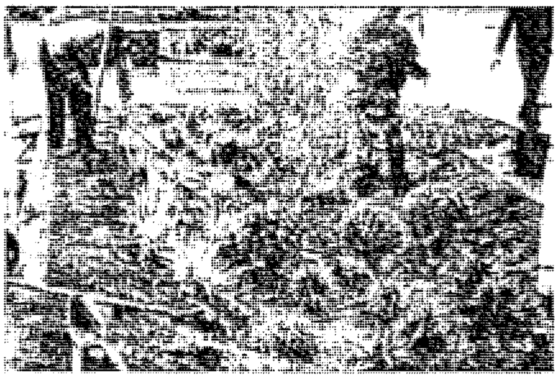


Excavation and installation of underdrain.

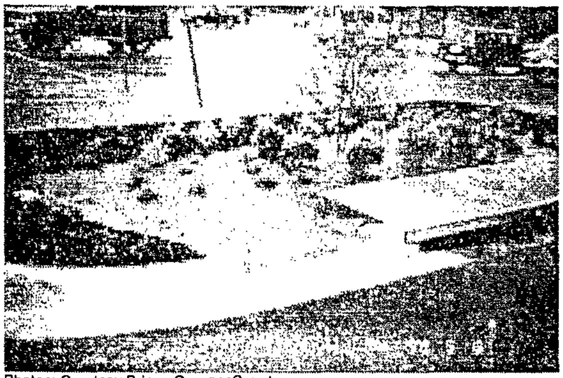
Sandy material used as planting medium

Photos: Courtesy Prince Georges County

R0017723



Installation of plant materials

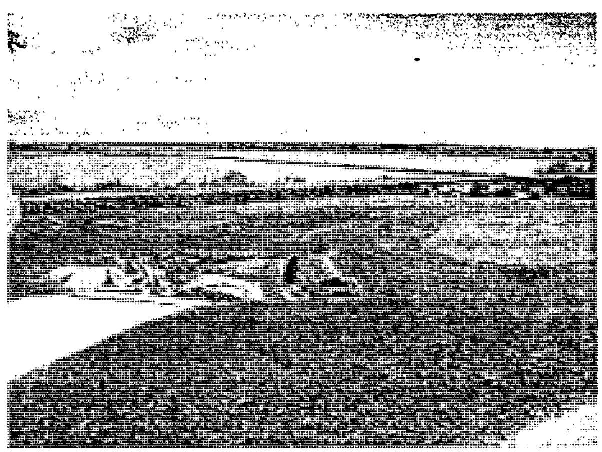


Completed PLD facility during storm event

Photos: Courtesy Prince GeorgesCounty

5.3 Advantages/Disadvantages

5.3.1 General. A primary advantage of PLD is making it possible to provide WQCV on a site while reducing the impact on developable land. It works well with irrigated bluegrass, whereas experience has shown that conditions in the bottom of extended detention basins (EDBs) become too wet for bluegrass. A PLD provides a natural moisture source for vegetation, enabling "green areas" to exist with reduced irrigation. The adjacent photograph shows an example of a relatively large PLD facility featuring a bluegrass bottom with a putting green.



The primary disadvantage of PLD is a potential for clogging if a moderate to high level of silts and clays is allowed to flow into the facility. Also, this BMP needs to be avoided close to building foundations or other areas where expansive soils are present, although an underdrain and impermeable liner can ameliorate some of this concern.

5.3.2 Physical Site Suitability. If an underdrain system is incorporated into this BMP, PLD is suited for about any site regardless of in-situ soil type. If sandy soils are present, the facility can be installed without an underdrain (infiltration option); sandy subsoils is not a requirement. This BMP has a relatively flat surface area, and may be more difficult to incorporate it into steeply sloping terrain.

5.3.3 Pollutant Removal. Although not tested to date in the Denver area, the amount of pollutant removed by this BMP should be significant and should equal or exceed the removal rates provided by sand filters. In addition to settling, PLD provides for filtering, adsorption, and biological uptake of constituents in stormwater. See Table SQ-6 for estimated ranges in pollutant removals.

5.4 Design Considerations

Figure PLD-1 shows a cross-section for a PLD. When implemented using multiple small installations on a site, it is increasingly important to accurately account for each upstream drainage area tributary to each PLD site to make sure that each facility is properly sized, and that all portions of the development site are directed to a PLD.

5.5 Design Procedure

The following steps outline the PLD design procedure and criteria.

1. Basin Storage Volume — Provide a storage volume based on a 12-hour drain time.

   A. Find the required storage volume (watershed inches of runoff):

   Using the tributary areas imperviousness, determine the Required WQCV (watershed inches of runoff) using Figure PLD-2, based on the PLD 12-hour drain time.

   B. Calculate the Design Volume in cubic feet as follows:

$$Design\ Volume = \left(\frac{WQCV}{12}\right) * Area$$

   In which:

   $Area$ = The watershed area tributary to the extended detention pond (square feet)

2. Surface Area — Calculate the minimum required surface area as follows:

$$Surface\ Area = \frac{Design\ Volume\ in\ ft^3}{d_{av}}$$

   in which,

   d_{av} = average depth of the PLD basin.

3. Base Coarses — Provide base coarses as shown in Figure PLD-1.

4. Subbase — If expansive soils are a concern, install an impermeable membrane and place the base coarse on top of the membrane. If soils are not expansive, use geotextile fabric to line the entire basin bottom and walls.

R0017725

5.	Average Depth	Maintain the average WQCV depth between 6" and 12". Average depth is defined as water volume divided by the water surface area.
6.	Sand-Peat Mix Filter Layer	Provide a minimum of a 12-inch thick layer above the base course consisting of a thoroughly mixed ASTMC-3 Sand and Peat for filtration and adsorption of constituents.
7.	Irrigated Vegetative Layer	Provide a sandy loam turf layer above the sand-peat mix layer. This layer shall be no less than 6-inches thick, but a thicker layer is recommended to promote healthier vegetation.

5.6 Design Example

Design forms that provide a means of documenting the design procedure are included in the Design Forms section. A completed form follows as a design example.

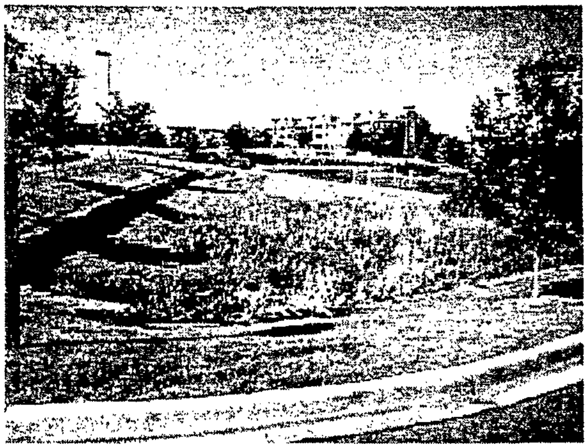
R0017729

6.0 EXTENDED DETENTION BASIN (EDB)— SEDIMENTATION FACILITY



6.1 Description

An extended detention basin (EDB) is a sedimentation basin designed to totally drain dry sometime after stormwater runoff ends. It is an adaptation of a detention basin used for flood control. The primary difference is in the outlet design. The EDB uses a much smaller outlet that extends the emptying time of the more frequently occurring runoff events to facilitate pollutant removal. The EDB's drain time for the brim-full water quality capture volume (i.e., time to fully evacuate the design capture volume) of 40 hours is recommended to remove a significant portion of fine particulate pollutants found in urban stormwater runoff. Soluble pollutant removal can be somewhat enhanced by providing a small wetland marsh or ponding area in the basin's bottom to promote biological uptake. The basins are considered to be "dry" because they are designed not to have a significant permanent pool of water remaining between storm runoff events. However, EDB may develop wetland vegetation and sometimes shallow pools in the bottom portions of the facilities.

6.2 General Application

An EDB can be used to enhance stormwater runoff quality and reduce peak stormwater runoff rates. If these basins are constructed early in the development cycle, they can also be used to trap sediment from construction activities within the tributary drainage area. The accumulated sediment, however, will need to be removed after upstream land disturbances cease and before the basin is placed into final long-term use. Also, an EDB can sometimes be retrofitted into existing flood control detention basins.

EDBs can be used to improve the quality of urban runoff from roads, parking lots, residential neighborhoods, commercial areas, and industrial sites and are generally used for regional or follow-up treatment. They can also be used as an onsite BMP and work well in conjunction with other BMPs, such as upstream onsite source controls and downstream infiltration/filtration basins or wetland channels. If

R0017730

desired, a flood routing detention volume can be provided above the water quality capture volume (WQCV) of the basin.

6.3 Advantages/Disadvantages

6.3.1 General. An EDB can be designed to provide other benefits such as recreation and open space opportunities in addition to reducing peak runoff rates and improving water quality. They are effective in removing particulate matter and the associate heavy metals and other pollutants. As with other BMPs, safety issues need to be addressed through proper design.

6.3.2 Physical Site Suitability. Normally, the land required for an EDB is approximately 0.5 to 2.0 percent of the total tributary development area. In high groundwater areas, consider the use of retention ponds (RP) instead in order to avoid many of the problems that can occur when the EDB's bottom is located below the seasonal high water table. Soil maps should be consulted, and soil borings may be needed to establish design geotechnical parameters.

6.3.3 Pollutant Removal. The pollutant removal range of an EDB was presented in Table SQ-6 in the *Stormwater Quality Management* chapter of this volume. Removal of suspended solids and metals can be moderate to high, and removal of nutrients is low to moderate. The removal of nutrients can be improved when a small shallow pool or wetland is included as part of the basin's bottom or the basin is followed by BMPs more efficient at removing soluble pollutants, such as a filtration system, constructed wetlands or wetland channels.

The major factor controlling the degree of pollutant removal is the emptying time provided by the outlet. The rate and degree of removal will also depend on influent particle sizes. Metals, oil and grease, and some nutrients have a close affinity for suspended sediment and will be removed partially through sedimentation.

6.3.4 Aesthetics and Multiple Uses. Since an EDB is designed to drain very slowly, its bottom and lower portions will be inundated frequently for extended periods of time. Grasses in this frequently inundated zone will tend to die off, with only the species that can survive the specific environment at each site eventually prevailing. In addition, the bottom will be the depository of all the sediment that settles out in the basin. As a result, the bottom can be muddy and may have an undesirable appearance to some. To reduce this problem and to improve the basin's availability for other uses (such as open space habitat passive recreation), it is suggested that the designer provide a lower-stage basin as suggested in the Two Stage Design procedure. As an alternative, a retention pond (RP) could be used, in which the settling occurs primarily within the permanent pool.

6.4 Design Considerations

Whenever desirable and feasible, incorporate the EDB within a larger flood control basin. Also, whenever possible try to provide within the basin for other urban uses such as passive recreation, and wildlife habitat. If multiple uses are being contemplated, consider the multiple-stage detention basin to limit inundation of passive recreational areas to one or two occurrences a year. Generally, the area within the WQCV is not well suited for active recreation facilities such as ballparks, playing fields, and picnic areas. These are best located above the WQCV pool level.

Figure EDB-1 shows a representative layout of an EDB. Although flood control storage can be accomplished by providing a storage volume above the water quality storage, how best to accomplish this is not included in this discussion. Whether or not flood storage is provided, all embankments should be protected from catastrophic failure when runoff exceeds the design event. The State Engineer's regulatory requirements for larger dam embankments and storage volumes must be followed whenever regulatory height and/or volume thresholds are exceeded. Below those thresholds, the engineer should design the embankment-spillway-outlet system so that catastrophic failure will not occur.

Perforated outlet and trash rack configurations are illustrated in the typical details section. Figure EDP-3 equates the WQCV that needs to be emptied over 40 hours, to the total required area of perforations per row for the standard configurations shown in that section. The chart is based on the rows being equally spaced vertically at 4-inch centers. This total area of perforations per row is then used to determine the number of uniformly sized holes per row (see detail in the typical details section). One or more perforated columns on a perforated orifice plate integrated into the front of the outlet can be used. Other types of outlets may also be used, provided they control the release of the WQCV in a manner consistent with the drain time requirements and are approved in advance by the District.

Although the soil types beneath the pond seldom prevent the use of this BMP, they should be considered during design. Any potential exfiltration capacity should be considered a short-term characteristic and ignored in the design of the WQCV because exfiltration will decrease over time as the soils clog with fine sediment and as the groundwater beneath the basin develops a mound that surfaces into the basin.

High groundwater should not preclude the use of an EDB. Groundwater, however, should to be considered during design and construction, and the outlet design must account for any upstream base flows that enter the basin or that may result from groundwater surfacing within the basin itself.

Stable, all weather access to critical elements of the pond, such as the inlet, outlet, spillway, and sediment collection areas must be provided for maintenance purposes.

6.5 Design Procedure and Criteria

The following steps outline the design procedure and criteria for an EDB.

1. Basin Storage Volume — Provide a storage volume equal to 120 percent of the WQCV based on a 40-hour drain time, above the lowest outlet (i.e., perforation) in the basin. The additional 20 percent of storage volume provides for sediment accumulation and the resultant loss in storage volume.

   A. Determine the WQCV tributary catchment's percent imperviousness. Account for the effects of DCIA, if any, on Effective Imperviousness. Using Figure ND-1, determine the reduction in impervious area to use with WQCV calculations.

   B. Find the required storage volume (watershed inches of runoff):

   Determine the Required WQCV (watershed inches of runoff) using Figure EDB-2, based on the EDB's 40 -hour drain time.

   Calculate the Design Volume in acre-feet as follows:

$$Design\ Volume = \left(\frac{WQCV}{12}\right) * Area * 1.2$$

   In which:

   Area = The watershed area tributary to the extended detention pond

   1.2 factor = Multiplier of 1.2 to account for the additional 20% of required storage for sediment accumulation

2. Outlet Works — The Outlet Works are to be designed to release the WQCV (i.e., not the 'Design Volume') over a 40-hour period, with no more than 50 percent of the WQCV being released in 12 hours. Refer to the *Water Quality Structure Details* section for schematics pertaining to structure geometry; grates, trash racks, and screens; outlet type: orifice plate or perforated riser pipe; cutoff collar size and location; and all other necessary components.

   For a perforated outlet, use Figure EDB-3 to calculate the required area per row based on WQCV and the depth of perforations at the outlet. See the *Water Quality Structure Details* section to determine the appropriate perforation geometry and number of rows (The lowest perforations should be set at the water surface elevation of the outlet micropool). The total outlet area can then be calculated by multiplying the the area per row by the number of rows.

3.	Trash Rack	Provide a trash rack of sufficient size to prevent clogging of the primary water quality outlet. Size the rack so as not to interfere with the hydraulic capacity of the outlet. Using the total outlet area and the selected perforation diameter (or height), Figures 6, 6a or 7 in the *Water Quality Structure Details* section will help to detemrine the minimum open area required for the trash rack. If a perforated vertical plate or riser is used as suggested in the *Manual*, use one-half of the total outlet area to calculate the trash rack's size. This accounts for the variable inundation of the outlet orifices. Figures 6 and 6a were developed as suggested standardized outlet designs for smaller sites.
4.	Basin Shape	Shape the pond whenever possible with a gradual expansion from the inlet and a gradual contraction toward the outlet, thereby minimizing short circuiting. The basin length to width ratio between the inlet and the outlet should be between 2:1 to 3:1, with the larger being preferred. It may be necessary to modify the inlet and outlet points through the use of pipes, swales or channels to accomplish this.
5.	Two-Stage Design	A two-stage design with a pool that fills often with frequently occurring runoff minimizes standing water and sediment deposition in the remainder of the basin. The two stages are as follows: A. Top Stage: The top stage should be 2 or more feet deep with its bottom sloped at 2 percent toward the low flow channel. B. Bottom Stage: The active storage basin of the bottom stage should be 1.5 to 3 feet deeper than the top stage and store 5 to 15 percent of the WQCV. Provide a micro-pool below the bottom active storage volume of the lower stage at the outlet point. The pool should be ½ the depth of the upper WQCV depth or 2.5 feet, whichever is the larger.
6.	Low-Flow Channel	Conveys low flows from the forebay to the bottom stage. Erosion protection should be provided where the low-flow channel enters bottom stage. Lining the low flow channel with concrete is recommended. Otherwise line its sides with VL Type riprap and bottom with concrete. Make it at least 9 inches deep; at a minimum provide capacity equal to twice the release capacity at the upstream forebay outlet.
7.	Basin Side Slopes	Basin side slopes should be stable and gentle to facilitate maintenance and access. Side slopes should be no steeper than 4:1, the flatter, the better and safer.
8.	Dam Embankment	The embankment should be designed not to fail during a 100-year <u>and larger storms</u>. Embankment slopes should be no steeper than 3:1, preferably 4:1 or flatter, and planted with turf forming grasses. Poorly compacted native soils should be excavated and replaced. Embankment soils should be compacted to at least 95 percent of their maximum density according to ASTM D 698-70 (Modified Proctor). Spillway structures and overflows should be designed in accordance with local drainage criteria and should consider UDFCD drop-structure design guidelines.
9.	Vegetation	Bottom vegetation provides erosion control and sediment entrapment. Pond bottom, berms, and side sloping areas may be planted with native grasses or with irrigated turf, depending on the local setting.

10.	Access	All weather stable access to the bottom, forebay, and outlet works area shall be provided for maintenance vehicles. Maximum grades should be 10 percent, and a solid driving surface of gravel, rock, concrete, or gravel-stabilized turf should be provided.
11.	Inlet	Dissipate flow energy at pond's inflow point(s) to limit erosion and promote particle sedimentation. Inlets should be designed in accordance with UDFCD drop structure criteria or as another type of an energy dissipating structure.
12.	Forebay Design	Provide the opportunity for larger particles to settle out in the inlet in an area that has a solid surface bottom to facilitate mechanical sediment removal. A rock berm should be constructed between the forebay and the main EDB. The forebay volume of the permanent pool should be 5 to 10 percent of the design water quality capture volume. A pipe throughout the berm to convey water the EDB should be offset from the inflow streamline to prevent short circuiting and should be sized to drain the forebay volume in 5 minutes.
13.	Flood Storage	Combining the water quality facility with a flood control facility is recommended. The 10-year, 100-year, or other floods may be detained above the WQCV. See Section 1.5.5 of the *BMP Planning For New Development and Significant Redevelopment*chapter of this volume for further guidance.
14.	Multiple Uses	Whenever desirable and feasible, incorporate the EDB within a larger flood control basin. Also, whenever possible try to provide for other urban uses such as active or passive recreation, and wildlife habitat. If multiple uses are being contemplated, use the multiple-stage detention basin to limit inundation of passive recreational areas to one or two occurrences a year. Generally, the area within the WQCV is not well suited for active recreation facilities such as ballparks, playing fields, and picnic areas. These are best located above the EDB level.

7.0 SAND FILTER EXTENDED DETENTION BASIN (SFB)

7.1 Description

A sand filter extended detention basin (SFB) is a stormwater filter that consists of a runoff storage zone underlain by a sand bed with an underdrain system. During a storm, accumulated runoff ponds in the surcharge zone and gradually infiltrates into the underlying sand bed, filling the void spaces of the sand. The underdrain gradually dewaters the sand bed and discharges the runoff to a nearby channel,swale, or storm sewer.

7.2 General Application

A SFB is generally suited to offline, onsite configurations where there is no baseflow and the sediment load is relatively low.

7.3 Advantages/Disadvantages

7.3.1 General. Primary advantages of SFBs include effective water quality enhancement through settling and filtering. The primary disadvantage is a potential for clogging if a moderate to high level of silts and clays are allowed to flow into the facility. For this reason, it should **not** be put into operation while construction activities are taking place in the tributary catchment. Also, this BMP should not be located close to building foundations or other areas where expansive soils are a concern, although an underdrain and impermeable liner can ameliorate some of this concern.

7.3.2 Physical Site Suitability. Since an underdrain system is incorporated into this BMP, SFB is suited for about any site; presence of sandy subsoils is not a requirement. This BMP has a relatively flat surface area, so it may be more challenging to incorporate it into steeply sloping terrain.

R0017742

7.3.3 Pollutant Removal. Although not fully tested to date in the Denver area, the tests on filter vaults in the Denver area and other parts of United States show that the amount of pollutant removed by this BMP should be significant and should at least equal the removal rates by sand filters tested elsewhere. See Table SQ-6 for estimated ranges in pollutant removals.

7.3.4 Maintenance Needs. Before selecting this BMP, be sure that the maintenance specified in the "Maintenance" chapter of the *Manual* will be provided by either a local government or by the owner. This BMP's performance is critical on having regular maintenance provided.

7.4 Design Procedure and Criteria

The following steps outline the design procedure and criteria for an SFB.

1. Basin Storage Volume — Provide a storage volume equal to 100 percent of the WQCV based on a 40-hour drain time, above the sand bed of the basin.

   A. Determine the WQCV tributary catchment's percent imperviousness. Account for the effects of DCIA, if any, on Effective Imperviousness. Using Figure ND-1, determine the reduction in impervious area to use with WQCV calculations.

   B. Find the required storage volume (watershed inches of runoff):

   Determine the Required WQCV (watershed inches of runoff) using Figure SFB-2, based on the SFB's 40-hour drain time.

   C. Calculate the Design Volume in acre-feet as follows:

   $$Design\ Volume = \left(\frac{WQCV}{12}\right) * Area$$

   In which:

   $Area$ = The watershed area tributary to the extended detention pond (acres)

2. Basin Depth — Maximum Design Volume depth shall be 3 feet.

3. Filter's Surface Area — Calculate the **minimum** sand filter area (A_s) at the basin's bottom with the following equation:

   $$A_s = Design\ Volume / 3 \quad *43{,}560 \text{ (square feet)}$$

4. Outlet Works — An 18 inch layer of sand (ASTM C-33) over a 9 inch gravel layer (AASHTO No. 8; CDOT Section 703, #8) shall line the entire SFB for purposes of draining the WQCV.

   If expansive soils are a concern or if the tributary catchment has chemical or petroleum products handled or stored, install an impermeable membrane below the gravel layer.

   In addition, an overflow shall be provided to convey flows in excess of the WQCV out of the basin.

R0017743

8.0 CONSTRUCTED WETLANDS BASIN (CWB)— SEDIMENTATION FACILITY

8.1 Description

A constructed wetlands basin (CWB) is a shallow retention pond (RP) which requires a perennial base flow to permit the growth of rushes, willows, cattails, and reeds to slow down runoff and allow time for sedimentation, filtering, and biological uptake. It is a sedimentation basin and a form of a treatment plant.

A CWB differ from "natural" wetlands as they are totally human artifacts that are built to enhance stormwater quality. Sometimes small wetlands that exist along ephemeral drainageways on Colorado's high plains could be enlarged and incorporated into the constructed wetland system. Such action, however, requires the approval of federal and state regulators.

Current (1999) regulations intended to protect natural wetlands recognize a separate classification of wetlands constructed for a water quality treatment. Such wetlands generally are not allowed on receiving waters and cannot be used to mitigate the loss of natural wetlands but are allowed to be disturbed by maintenance activities. Therefore, the legal and regulatory status of maintaining a wetland constructed for the primary purpose of water quality treatment, such as the CWB, is separate from the disturbance of a natural wetland. Nevertheless, the U.S. Army Corps of Engineers has established maximum areas that can be maintained under a nationwide permit. Thus, any activity that disturbs a constructed wetland should be first cleared through the U.S. Army Corps of Engineers to ensure it is covered by some form of an individual, general, or nationwide 404 permit.

8.2 General Application

A CWB can be used as a followup structural BMP in a watershed, or as a stand-alone onsite facility if the owner provides sufficient water to sustain the wetland. Flood control storage can be provided above the CWB's water quality capture volume (WQCV) pool to act as a multiuse facility.

R0017748

CWB requires a net influx of water to maintain its vegetation and microorganisms. A complete water budget analysis is necessary to ensure the adequacy of the base flow.

8.3 Advantages/Disadvantages

8.3.1 General. A CWB offers several potential advantages, such as natural aesthetic qualities, wildlife habitat, erosion control, and pollutant removal. It can also provide an effective followup treatment to onsite and source control BMPs that rely upon settling of larger sediment particles. In other words, it offers yet another effective structural BMP for larger tributary catchments.

The primary drawback of the CWB is the need for a continuous base flow to ensure viable wetland growth. In addition, silt and scum can accumulate and unless properly designed and built, can be flushed out during larger storms. In addition, in order to maintain a healthy wetland growth, the surcharge depth for WQCV above the permanent water surface cannot exceed 2 feet.

Along with routine good housekeeping maintenance, occasional "mucking out" will be required when sediment accumulations become too large and affect performance. Periodic sediment removal is also needed for proper distribution of growth zones and of water movement within the wetland.

8.3.2 Physical Site Suitability. A perennial base flow is needed to sustain a wetland, and should be determined using a water budget analysis. Loamy soils are needed in a wetland bottom to permit plants to take root. Exfiltration through a wetland bottom cannot be relied upon because the bottom is either covered by soils of low permeability or because the groundwater is higher than the wetland's bottom. Also, wetland basins require a near-zero longitudinal slope, which can be provided using embankments.

8.3.3 Pollutant Removal. See Table SQ-6 for estimated ranges in pollutant removals. Reported removal efficiencies of constructed wetlands vary significantly. Primary variables influencing removal efficiencies include design, influent concentrations, hydrology, soils, climate, and maintenance. With periodic sediment removal and routine maintenance, removal efficiencies for sediments, organic matter, and metals can be moderate to high; for phosphorous, low to high; and for nitrogen, zero to moderate. Pollutants are removed primarily through sedimentation and entrapment, with some of the removal occurring through biological uptake by vegetation and microorganisms. Without a continuous dry-weather base flow, salts and algae can concentrate in the water column and can be released into the receiving water in higher levels at the beginning of a storm event as they are washed out.

Researchers still do not agree whether routine aquatic plant harvesting affects pollutant removals significantly. Until research demonstrates and quantifies these effects, periodic harvesting for the general upkeep of wetland, and not routine harvesting of aquatic plants, is recommended.

R0017749

8.4 Design Considerations

Figure CWB-1 illustrates an idealized CWB. An analysis of the water budget is needed to show the net inflow of water is sufficient to meet all the projected losses (such as evaporation, evapotranspiration, and seepage for each season of operation). Insufficient inflow can cause the wetland to become saline or to die off.

8.5 Design Procedure and Criteria

The following steps outline the design procedure for a CWB.

1. **Basin Surcharge Storage Volume** — Provide a surcharge storage volume equal to the WQCV based on a 24-hour drain time, above the lowest outlet (i.e., perforation) in the basin.

   A. Determine the WQCV using the tributary catchments percent imperviousness. Account for the effects of DCIA, if any, on Effective Imperviousness. Using Figure ND-1, determine the reduction in impervious area to use with WQCV calculations.

   B. Find the Required Storage Surcharge Volume (watershed inches of runoff) above the permanent pool level.

   Determine the Required Storage (watershed inches of runoff) using Figure CWB-2, based on the constructed wetland basin 24-hour drain time.

   Calculate the Surcharge Volume in acre-feet as follows:

$$Design\ Surcharge\ Volume = \left(\frac{WQCV}{12}\right) * Area$$

   In which:

   $Area$ = The tributary drainage area tributary to the CWB (Acres).

2. **Wetland Pond Depth and Volume** — The volume of the permanent wetland pool shall be no less than 75% of the WQCV found in Step 1.

   Proper distribution of wetland habitat is needed to establish a diverse ecology. Distribute pond area in accordance with the following:

TABLE 1

Components	Percent of Permanent Pool Surface Area	Water Design Depth
Forebay, outlet and free water surface areas	30% to 50%	2 to 4 feet deep
Wetland zones with emergent vegetation	50% to 70%	6 to 12 inches deep*

*One-third to one-half of this zone should be 6 inches deep.

3. **Depth of Surcharge WQCV** — The surcharge depth of the WQCV above he permanent pool's water surface shall not exceed 2.0 feet.

4. Outlet Works

Provide outlet works that limit WQCV depth to 2 feet or less. Use a water quality outlet that is capable of releasing the WQCV in no less than a 24-hour period. Refer to the *Water Quality Structure Details* section for schematics pertaining to structure geometry; grates, trash racks, and screens; outlet type: orifice plate or perforated riser pipe; cutoff collar size and location; and all other necessary components.

For a perforated outlet, use Figure CWB-3 to calculate the required area per row based on WQCV and the depth of perforations at the outlet. See the *Water Quality Structure Details* section to determine the appropriate perforation geometry and number of rows (The lowest perforations should be set at the water surface elevation of the outlet pool). The total outlet area can then be calculated by multiplying the the area per row by the number of rows.

5. Trash Rack

Provide a trash rack of sufficient size to prevent clogging of the primary water quality outlet. Size the rack so as not to interfere with the hydraulic capacity of the outlet. Using the total outlet area and the selected perforation diameter (or height), Figures 6, 6a or 7 in the *Water Qaulity Structure Details* section will help to detemrine the minimum open area required for the trash rack. If a perforated vertical plate or riser is used as suggested in the *Manual*, use one-half of the total outlet area to calculate the trash racks size. This accounts for the variable inundation of the outlet orifices. Figures 6 and 6a were developed as suggested standardized outlet designs for smaller sites.

6. Basin Use

Determine if flood storage or other uses will be provided for above the wetland surcharge storage or in an upstream facility. Design for combined uses when they are to be provided for.

7. Basin Shape

Shape the pond with a gradual expansion from the inlet and a gradual contraction to the outlet, thereby limiting short circuiting. The basin length to width ratio between the inlet and outlet should be 2:1 to 4:1 with 3:1 recommended. It may be necessary to modify the inlet and outlet point through the use of pipes, swales, or channels, to accomplish this.

8. Basin Side Slopes

Basin side slopes are to be stable and gentle to facilitate maintenance and access needs. Side slopes should be no steeper than 4:1, preferably 5:1 or flatter.

9. Base Flow

A net influx of water must be available throughout the year that exceeds all of the losses. The following equation and parameters can be used to estimate the net quantity of base flow available at a site:

$$Q_{net} = Q_{Inflow} - Q_{Evap} - Q_{Seepage} - Q_{E.T.}$$

Where:

Q_{Net} = Net quantity of base flow (acre-ft/year)

Q_{Inflow} = Estimated base flow (acre-ft/year) (Estimate by seasonal measurements and/or comparison to similar watersheds)

Q_{Evap} = Loss attributed to evaporation less the precipitation (acre-ft/year) (Computed for average water surface)

R0017751

	$Q_{Seepage}$	= Loss (or gain) attributed to seepage to groundwater (acre-ft/year)
	$Q_{E.T.}$	= Loss attributed to plant evapotranspiration (computed for average plant area above water surface, not including the water surface)

10.	Inlet/Outlet Protection	Provide a means to dissipate flow energy entering the basin to limit sediment resuspension. Inlets should correspond to UDFCD drop-structure criteria. Outlets should be placed in an offbay that is at least 3 feet deep. The outlet should be protected from clogging by a skimmer shield that starts at the bottom of the permanent pool and extends above the maximum capture volume depth. Provide for a trash rack also.
11.	Forebay Design	Provide the opportunity for larger particles to settle out in an area that has a solid driving surface bottom for vehicles to facilitate sediment removal. The forebay volume of the permanent pool should be 5 to 10 percent of the design water quality capture volume.
12.	Vegetation	Cattails, sedges, reeds, and wetland grasses should be planted in the wetland bottom. Berms and side-sloping areas should be planted with native or irrigated turf-forming grasses. Initial establishment of the wetlands requires control of the water depth. After planting wetland species, the permanent pool should be kept at 3 to 4 inches to allow growth and to help establish the plants, after which the pool should be raised to its final operating level.
13.	Maintenance Access	Provide vehicle access to the forebay and outlet area for maintenance and removal of bottom sediments. Maximum grades should not exceed 10 percent, and a stabilized, all-weather driving surface needs to be provided.

8.6 Design Example

Design forms that provide a means of documenting the design procedure are included in the Design Forms section. A completed form follows as a design example.

9.0 RETENTION POND (RP)— SEDIMENTATION FACILITY

9.1 Description

A Retention Pond (RP) is a sedimentation facility and a form of a treatment plant that has a permanent pool of water that is replaced with stormwater, in part or in total, during storm runoff events. In addition, a temporary detention volume is provided above this permanent pool to capture storm runoff and enhance sedimentation. RPs are similar to EDBs because they are designed to capture in total, as a surcharge to the pond, runoff from frequently occurring storms. However, RPs differ from extended detention basins (EDBs) because the influent water mixes with the permanent pool water as it rises above the permanent pool level. The surcharge captured volume above the permanent pool is then released over 12 hours.

RPs require a dry-weather base flow to maintain the permanent pool. They can be very effective in removing pollutants, and, under the proper conditions, can satisfy multiple objectives.

9.2 General Application

A RP can be used to improve the quality of urban runoff from roads, parking lots, residential neighborhoods, commercial areas, and industrial sites and is generally used as regional or follow-up treatment because of the base-flow requirements. It can be used as an onsite BMP if the owner provides sufficient water to keep the pond full between storms. A RP works well in conjunction with other BMPs, such as upstream onsite source controls and downstream filter basins or wetland channels.

R0017759

9.3 Advantages/Disadvantages

9.3.1 General. A RP can be cost-effective for larger tributary watersheds. It provides the following:

- Achieves moderate to high removal rates of many urban pollutants
- Creates wildlife habitat opportunities
- Provides recreation, aesthetics, and open space opportunities
- Be a part of a larger flood control basin

Their primary disadvantages include safety concerns, more difficult maintenance sediment removal than for EDBs, floating litter, scum and algal blooms, possible nuisance odors and possible mosquito problems. Aquatic plant growth can be a factor in clogging outlet works. The permanent pool can attract water fowl, which can add to the nutrient load entering and leaving the pond.

9.3.2 Physical Site Suitability. Although site suitability concerns are similar to those stated for an EDB, a RP has one primary difference— it requires sufficient continuous base flow to maintain the pool. A complete water budget under the projected urbanized watershed conditions should be performed to assure that the base flow will exceed evaporation, evapotranspiration, and seepage losses.

9.3.3 Pollutant Removal. See Table SQ-6 for pollutant removal ranges. A RP achieves moderate to high removal rates for particulate matter through sedimentation during and shortly after the runoff event. During a storm event, a portion or all of the permanent pool water is displaced and the pool becomes a mixture of the former pool water and new runoff. The period between storms allows biological uptake of soluble nutrients and metals from the water column in the permanent pool while also providing time for quiescent settling of fine sediment particles that remain in the pool after a storm. Some of the sediment can resuspend and soluble compounds can remobilize if a large storm event causes intense mixing or when unfavorable chemical conditions exist in the pool (such as low dissolved oxygen [DO] or pH). Also, algal growth and other biological activity can produce suspended solids and increased concentrations of certain forms of phosphates and nitrogen compounds in dry-weather base flow discharges from the pond.

Without a sufficient continuous base flow, a wet pond can concentrate levels of salts and algae between storm events through evaporation. Besides contributing to nuisance problems, the water quality of the pool is very important. A storm event will displace any concentrated pond water, and in some instances, can result in discharges of water with pollutant concentrations exceeding the inflow, exactly the opposite of the intent for providing this BMP.

9.3.4 Aesthetics and Multiple Uses. A RP offers improved aesthetics and multiple-uses beyond those typically found at an EDB. The bulk of the capture volume occurs as a surcharge above the permanent pool, with some of it occurring above the dry-weather bank areas. As a result, most of the sediment deposits are left behind within the permanent pool zone, where they are not seen by the public. Also, the permanent pool offers some aquatic habitat and is a habitat for water fowl. However, water fowl can be a nuisance because of the fecal matter they deposit on the banks and in the pool.

9.4 Design Considerations

The required total basin design volume of a RP facility includes the volume needed for a permanent pool (≥water quality capture volume) plus a water quality capture volume as a surcharge above the permanent pool. If desired, a flood routing detention volume can be provided above the water quality capture volume.

Whenever desirable and feasible, incorporate the RP within a larger flood control basin. Also, whenever possible try to provide for other urban uses such as active or passive recreation, and wildlife habitat. Try to locate recreational areas to limit the frequency of inundation to one or two occurrences a year. Generally, the area within the water quality capture volume is not well suited for active recreation facilities such as ballparks, playing fields, and picnic areas. These should be located above this pool level.

Land requirements are typically 0.5 to 2 percent of the tributary watershed's area. High exfiltration rates can initially make it difficult to maintain a permanent pool in a new RP, but the bottom can eventually seal with fine sediment and become relatively impermeable over time. It is best, however, to seal the bottom and the sides of a permanent pool if the pool is located on permeable soils and to leave the areas above the permanent pool unsealed to promote exfiltration of the stormwater detained in the surcharge water quality capture volume.

There are two primary differences in design between a RP and an EDB:

- The RP requires a base flow to maintain and to flush a permanent pool.
- A RP is designed to empty the surcharge water quality capture volume over a 12-hour period, instead of the longer 40 hours needed for an EDB. The reason for this is that the sediment removal process is more efficient when the outflow occurs above the bottom of the basin. Sediments become trapped below the outlet and sedimentation continues in the pool after the captured surcharge volume is emptied.

Figure RP-1 shows a representative layout for a RP. Although flood storage has not been addressed in these recommendations for the same reasons mentioned under EDBs, it can be easily provided for above the surcharge water quality capture volume. Embankment design and safety design considerations for a RP are identical to those discussed for an EDB, except more attention should be given to cutoff collars on the outlet pipe to safeguard against piping along the outlet.

The amount of construction activity within a basin, the erosion control measures implemented, and the size of the basin will influence the frequency of sediment removal from the pond. It is estimated that accumulated sediment will need to be removed at 5- to 20-year intervals if there are no construction activities within the tributary catchment.

9.5 Design Procedure and Criteria

The following steps outline the design procedure and criteria for a RP.

1. Basin Surcharge Storage Volume

Provide a storage volume equal to the WQCV based on a 12-hour drain time, above the lowest outlet (i.e., perforation) in the basin.

A. Determine the WQCV using the tributary catchment's percent imperviousness. Account for the effects of DCIA, if any, on Effective Imperviousness. Using Figure ND-1, determine the reduction in impervious area to use with WQCV calculations.

B. Find the required storage surcharge volume (watershed inches of runoff).

Determine the required water quality capture volume in watershed inches of runoff using Figure RP-2, based on the RP, 12-hour drain time. The water quality capture volume is the surcharge volume above the permanent pool.

Calculate the design surcharge volume in acre-feet as follows:

$$Design\ Surcharge\ Volume = \left(\frac{WQCV_i}{12} \right) * Area$$

In which:

$WQCQ_i$ = Water quality capture volume from Figure RP-2 in watershed inches

$Area$ = The tributary drainage area tributary to the RP (acres).

2. Permanent Pool

The permanent pool provides stormwater quality enhancement between storm runoff events through biochemical processes and continuing sedimentation.

A. Volume of the permanent pool:

$$Permanent\ Pool = 1.0\ to\ 1.5\ (WQCV)$$

B. Depth Zones: The permanent pool shall have two depth zones:

1. A littoral zone 6 to 12 inches deep that is between 25 to 40 percent of the permanent pool surface area for aquatic plant growth along the perimeter of the permanent pool, and
2. A deeper zone of 4 to 8 feet average depth in the remaining pond area to promote sedimentation and nutrient uptake by phytoplankton. Maximum depth in the pond shall not exceed 12 feet.

R0017762

3. Base Flow

A net influx of water must be available through a perennial base flow and must exceed the losses. The following equation and parameters can be used to estimate the net quantity of baseflow available at a site:

$$Q_{Net} = Q_{Inflow} - Q_{Evap} - Q_{Seepage} - Q_{E.T.}$$

In which:

Q_{net} = Net quantity of base flow (acre-ft/year)

Q_{inflow} = Estimated base flow (acre-ft/year) (Estimate by seasonal measurements and/or comparison to similar watersheds)

Q_{evap} = Loss because of evaporation less the precipitation (acre-ft/year) (Computed for average water surface)

$Q_{Seepage}$ = Loss (or gain) because of seepage to groundwater (ac-ft/year)

$Q_{E.T.}$ = Loss because of plant evapotranspiration (additional loss through plant area above water surface not including the water surface)

4. Outlet Works

The Outlet Works are to be designed to release the WQCV (above the permanent pool elevation) over a 12-hour period. Refer to the *Water Quality Structure Details* section for schematics pertaining to structure geometry; grates, trash racks, and screens; outlet type: orifice plate or perforated riser pipe; cutoff collar size and location; and all other necessary components.

For a perforated outlet, use Figure RP-3 to calculate the required area per row based on WQCV and the depth of perforations at the outlet. See the *Water Quality Structure Details* section to determine the appropriate perforation geometry and number of rows (The lowest perforations should be set at the water surface elevation of the permanent pool). The total outlet area can then be calculated by multiplying the the area per row by the number of rows.

5. Trash Rack

Provide a trash rack of sufficient size to prevent clogging of the primary water quality outlet. Size the rack so as not to interfere with the hydraulic capacity of the outlet. Using the total outlet area and the selected perforation diameter (or height), Figures 6, 6a or 7 in the *Water Quality Structure Details* section will help to detemrine the minimum open area required for the trash rack. If a perforated vertical plate or riser is used as suggested in the *Manual*, use one-half of the total outlet area to calculate the trash rack's size. This accounts for the variable inundation of the outlet orifices. Figures 6 and 6a were developed as suggested standardized outlet designs for smaller sites.Basin Slope Shape the pond with a gradual expansion from the inlet and a gradual contraction toward the outlet, thereby limiting short circuiting. The basin length to width ratio between the inlet and outlet should be between 2:1 and 3:1, with the larger being preferred. It may be necessary to modify the inlet and outlet pointed through the use of pipes, swales, or channels to accomplish this.

6.	Basin Side Slopes	Side slopes should be stable and sufficiently gentle to limit rill erosion and to facilitate maintenance. Side slopes above the permanent pool should be no steeper than 4:1, preferably 5:1 or flatter. The littoral zone should be very flat (that is, 40:1 or flatter) with the depth ranging from 6 inches near the shore and extending to no more than 12 inches at the furthest point from the shore. The side slope below the littoral zone shall be 3:1 or flatter.
7.	Dam Embankment	The embankment should be designed not to fail during a 100-year or larger storm. Embankment slopes should be no steeper than 3:1, preferably 4:1 or flatter, covered with turf-forming grasses to limit erosion. Poorly compacted native soils should be removed and replaced. Embankment soils should be compacted to 95 percent of their maximum density according to ASTM D 698-70 (modified proctor).
8.	Vegetation	Vegetation provides erosion control and enhances site stability. Berms and side-sloping areas should be planted with native turf-forming grasses or irrigated turf, depending on the local setting and proposed uses for the pond area. The shallow littoral bench should have a 4- to 6-ing organic topsoil layer and be vegetated with aquatic species.
9.	Maintenance Access	Access to the basin bottom, forebay, and outlet area must be provided to maintenance vehicles. Maximum grades should be 10 percent, and a solid driving surface of gravel, rock, concrete, or gravel stabilized turf should be provided.
10.	Inlet	Dissipate flow energy at the inlet to limit erosion and to diffuse the inflow plume where it enters the pond. Inlets should be designed in accordance with *USDCM* drop-structure and energy-dissipating structure criteria in Volume 2.
11.	Forebay Design	To provide an opportunity for larger particles to settle out, install an area that has a solid driving surface bottom to facilitate sediment removal. A berm consisting of rock and topsoil mixture should be part of the littoral bench to create the forebay and have a minimum top width of 8 feet and side slopes no steeper than 4:1. The forebay volume of the permanent pool should be 5 to 10 percent of the design water quality capture volume.
12.	Underdrains	Provide underdrain trenches near the edge of the pond. The trenches should be no less than 12 inches wide filled with ASTM C-33 sand to within 2 feet of the ponds permanent pool water surface, and with an underdrain pipe connected through a valve to the outlet. These underdrains will permit the drying out of the pond when it has to be "mucked out" to restore volume lost due to sediment deposition.

9.6 Design Example

Design forms that provide a means of documenting the design procedure are included in the Design Forms section. A completed form follows as a design example.

10.0 CONSTRUCTED WETLANDS CHANNEL (CWC)— SEDIMENTATION FACILITY

10.1 Description

Constructed wetland-bottomed channels takes advantage of dense natural vegetation (rushes, willows, cattails, and reeds) to slow down runoff and allow time for settling out sediment and biological uptake. It is another form of a sedimentation facility and a treatment plant.

Constructed wetlands differ from "natural" wetlands as they are artificial and are built to enhance stormwater quality. Sometimes small wetlands that exist along ephemeral drainageways on Colorado's high plains may be enlarged and incorporated into the constructed wetland system. Such action, however, requires the approval of federal and state regulators.

Regulations intended to protect natural wetlands recognize a separate classification of wetlands constructed for a water quality treatment. Such wetlands generally are not allowed to be used to mitigate the loss of natural wetlands but are allowed to be disturbed by maintenance activities. Therefore, the legal and regulatory status of maintaining a wetland constructed for the primary purpose of water quality enhancement is separate from the disturbance of a natural wetland. Nevertheless, any activity that disturbs a constructed wetland should be first cleared through the U.S. Army Corps of Engineers to ensure it is covered by some form of an individual, general, or nationwide 404 permit.

10.2 General Application

Wetland bottom channels can be used in the following two ways:

- A wetland can be established in a totally man-made channel and can act as a conveyance system and water quality enhancement facility. This design can be used along wide and gently sloping channels.

R0017771

- A wetland bottom channel can be located downstream of a stormwater detention facility (water quality and/or flood control) where a large portion of the sediment load can be removed. The wetland channel then receives stormwater and base flows as they drain from the detention facility, provides water quality enhancement, and at the same time conveys it downstream. This application of a wetland channel is recommended upstream of receiving waters and within lesser (i.e., ephemeral) receiving waters, thereby delivering better quality water to the more significant receiving water system.

A CWC requires a net influx of water to maintain their vegetation and microorganisms. A complete water budget analysis is necessary to ensure the adequacy of the base flow.

10.3 Advantages/Disadvantages

10.3.1 General. Constructed wetlands offer several potential advantages, such as natural aesthetic qualities, wildlife habitat, erosion control, and pollutant removal. Constructed wetlands provide an effective follow-up treatment to onsite and source control BMPs that rely upon settling of larger sediment particles. In other words, they offer yet another effective BMP for larger tributary basins.

The primary drawback to wetlands is the need for a continuous base flow to ensure their presence. In addition, salts and scum can accumulate and unless properly designed and built, can be flushed out during larger storms.

Other disadvantages include the need for regular maintenance to provide nutrient removal. Regular harvesting and removal of aquatic plants, cattails, and willows is required if the removal of nutrients in significant amounts has to be assured. Even with that, recent data puts into question the net effectiveness of wetlands in removing nitrogen compounds and some form of phosphates. Periodic sediment removal is also necessary to maintain the proper distribution of growth zones and of water movement within the wetland.

10.3.2 Physical Site Suitability. A perennial base flow is needed to sustain a wetland, and should be determined using a water budget analysis. Loamy soils are needed in wetland bottom to permit plants to take root. Infiltration through a wetland bottom cannot be relied upon because the bottom is either covered by soils of low permeability or because the groundwater is higher than the wetland's bottom. Wetland bottom channels also require a near-zero longitudinal slope; drop structures are used to create and maintain a flat grade.

10.3.3 Pollutant Removal. Removal efficiencies of constructed wetlands vary significantly. Primary variables influencing removal efficiencies include design, influent concentrations, hydrology, soils, climate, and maintenance. With periodic sediment removal and plant harvesting, expected removal efficiencies for sediments, organic matter, and metals can be moderate to high; for phosphorous, low to moderate; and for nitrogen, zero to low. Pollutants are removed primarily through sedimentation and

R0017772

entrapment, with some of the removal occurring through biological uptake by vegetation and microorganisms. Without a continuous dry-weather base flow, salts and algae can concentrate in the water column and can be released into the receiving water in higher levels at the beginning of a storm event as they are washed out.

Harvesting aquatic plants and periodic removal of sediment also removes nutrients and pollutants associated with the sediment. Researchers still do not agree that routine aquatic plant harvesting affects pollutant removals. Until research documents these effects, periodic harvesting for the general upkeep of wetland, and not routine harvesting of aquatic plants, is recommended.

10.4 Design Considerations

Wetlands can be set into a drainageway to form a wetland bottom channel (see Figure CWC-1). The criteria for a wetland bottom channel presented in the following section differs somewhat from the criteria presented in Volume 2 of the *USDCM* under the *Major Drainage* chapter. This is because of the water quality focus of this BMP. An analysis of the water budget is needed so that the inflow of water throughout the year is sufficient to meet all the projected losses (such as evaporation, evapotranspiration, and seepage). An insufficient base flow could cause the wetland bottom channel to dry out and die.

10.5 Design Procedure and Criteria

The following steps outline the Constructed Wetlands Channel design procedure. Refer to Figure CWC-1 for its design components.

1. Design Discharge — Determine the 2-year peak flow rate in the wetland channel *without* reducing it for any upstream ponding or flood routing effects.

2. Channel Geometry — Define the newly-built channel's geometry to pass the design 2 -year flow rate at 2.0 feet per second with a channel depth between 2.0 to 4.0 feet. The channel cross-section should be trapezoidal with side slopes of 4:1 (Horizontal/Vertical) or flatter. Bottom width shall be no less than 8.0 feet.

3. Longitudinal Slope — Set the longitudinal slope using Mannings equation and a Mannings roughness coefficient of n=0.03, for the 2-year flow rate. If the desired longitudinal slope can not be satisfied with existing terrain, grade control checks or small drop structures must be incorporated to provide desired slope.

4. Final Channel Capacity — Calculate the final (or mature) channel capacity during a 2-year flood using a Mannings roughness coefficient of n=0.08 and the same geometry and slope used when initially designing the channel with n=0.03. The channel shall also provide enough capacity to contain the flow during a 100-year flood while maintaining one foot of free-board. Adjustment of the channel capacity may be done by increasing the bottom width of the channel. Minimum bottom width shall be 8 feet.

5. Drop Structures	Drop structures should be designed to satisfy the drop structure criteria of the *Major Drainage* chapter in Volume 2 of the *USDCM.*
6. Vegetation	Vegetate the channel bottom and side slopes to provide solid entrapment and biological nutrient uptake. Cover the channel bottom with loamy soils upon which cattails, sedges, and reeds should be established. Side slopes should be planted with native or irrigated turf grasses.
7. Maintenance Access	Provide access for maintenance along the channel length. Maximum grades for maintenance vehicles should be 10 percent and provide a solid driving surface.

10.6 Design Example

Design forms that provide a means of documenting the design procedure are included in the Design Forms section. A completed form follows as a design example.

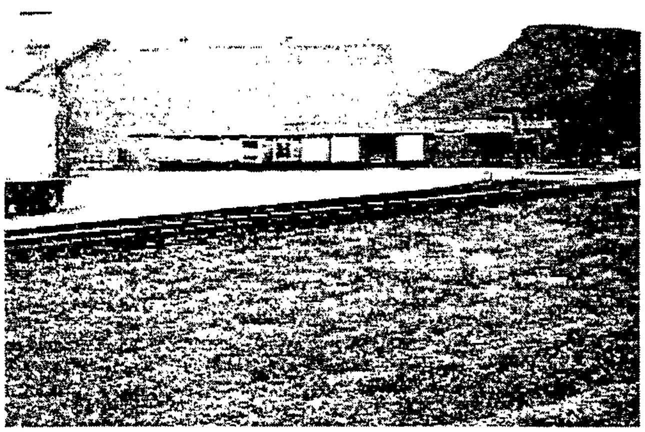
R0017776

11.0 COVERING OF STORAGE/HANDLING AREAS



11.1 Description

Covering of areas for storage and for handling facilities associated with potential industrial or commercial pollutants, such as salt piles, oil products, pesticides, fertilizers, etc. will reduce the likelihood of storm water contamination and will prevent loss of material from wind or rainfall erosion. Coverings can be permanent or temporary and consist of tarpaulins, plastic sheeting, roofing, enclosed structures, or any other device that prevent rain and wind from spreading possible contamination.

11.2 General Application

Covering is appropriate for areas where solids (gravel, salt, compost, building materials, etc.) or liquids (oil, gas, tar, etc.) are stored, prepared, or transferred.

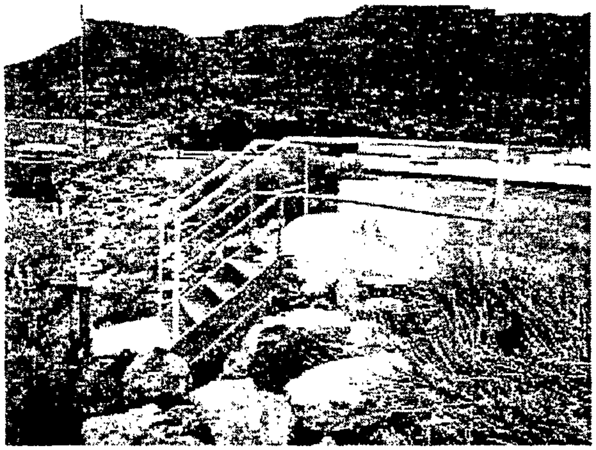
11.3 Advantages/Disadvantages

11.3.1 General. Coverings can be inexpensive and easy to install. When an enclosed structure is built, ventilation, lighting, and other issues must be accounted for. Less expensive coverings (tarpaulins, plastic sheeting, etc.) may require frequent inspection and maintenance.

11.3.2 Physical Site Suitability. The size of the area to be covered will determine the most efficient and cost effective type of covering. If the area is too large to be entirely covered, at a minimum the critical areas should be covered.

11.3.3 Pollutant Removal. Spill containment berming can be installed around the covered area to contain spills until proper removal and disposal can occur.

12.0 SPILL CONTAINMENT AND CONTROL



12.1 Description

Spill containment within industrial and some commercial sites consists of berming and gates that allow for the control of spilled material. Berming consists of temporary or permanent curbs or dikes that surround a potential spill site preventing spilled material from entering surface waters or storm sewer systems. The berm may be made concrete, earthen material, metal, synthetic liners, or any material that will safely contain the spill. A potential spill site is one that allows the storage or transfer of potential spill material. Spill material is that which is not allowed into surface waters or storm sewer systems according to local, state, or federal regulations. Spill control devices include valves, slide gates, or any other device which can contain material when required and then release the spilled material in a controlled fashion.

12.2 General Application

Two methods of berming can be used: 1) containment berming that contains an entire spill and 2) curbing that routes spill material to a collection basin. Containment berming should be of sufficient size to safely contain a spill from the largest storage tank, rail car, tank truck, or other containment device located inside the possible spill area. A small collection basin should be provided for removal of storm water and leaked material.

Curbing is used to route spill material to a large collection basin. The curb should be of sufficient size to safely route a spill from the largest storage tank, rail car, tank truck, or other containment device located inside the possible spill area. A containment device must be provided to safely store the spilled material until removal is possible.

If the capacity of the containment berming or the collection basin are exceeded, a spill control device must be used. The spill control device ideally would convey flow into a portable containment device for removal of the material. However, if material is escaping the berming area through the spill control

R0017778

device, two available means of controlling a spill are to use sorbents (adsorption and absorption through chemical processes) or gelling agents (physically or chemically gel the spill material; solidification eventually occurs).

12.3 Advantages/Disadvantages

12.3.1 General. The spill containment berm is an effective means to prevent spill material from entering surface waters or storm sewer systems. In some cases, the spill material may be collected and recycled. The cost of installation and maintenance will be a function of the type of berm used.

12.3.2 Physical Site Suitability. The spill area must have an impermeable floor (asphalt or concrete) so that contamination of groundwater does not occur. If the existing conditions are insufficient to prevent seepage, an impermeable floor or liner must be installed.

12.3.3 Pollutant Removal. In the event of a spill, a method of removal must be provided, such as application of sorbent materials and the use of a pump or vacuum truck. Any material removed from the spill site must be disposed of according to local, state, and federal standards. Recycling of the spill material may be possible if contact or uptake of foreign material is minimal. Water that collects within the berming due to rainfall or snowmelt must be treated to meet standards before release from the spill area.

Typical Outlet Structure Notes:

1. The details shown are intended to show design concepts. Preparation of final design plans, addressing details of structural adequacy, excavation, foundation preparation, concrete work, reinforcing steel,backfill, metalwork, and appurtenances, including preparation of technical specifications, are the responsibility of the design engineer.

2. Alternate designs to the typical outlet structures shown may be considered; however, alternate designs must address the hydraulic and trash handling functional elements of the structures shown in the *Manual*.

3. Wingwalls shown are intended to enable the structure to be backfilled to be flush with the side slopes of the basin, which is the recommended geometry. Other geometries may be considered if their designs related to public safety, aesthetics, maintainability, and function are equal to or better than the designs shown in the *Manual*.

4. Permanent Water Surface shown refers to micro–pool for Extended Detention Basin or permanent pool for Constructed Wetland Basin or Retention Pond.

5. An orifice plate is shown as the outflow control; however, an upturned pipe, with orifices may also be used. See Figure 4 for orifice design information.

6. A Vertical Trash Rack option is generally shown; however, an Adverse–Slope Trash Rack may also be used. Continuous–Slope Trash Racks for use with WQCV outlets are not recommended. See figure 6 for trash rack design information.

7. References are made to 2– or 10–year detention above the WQCV; however, detention above the WQCV may be sized for any storm event, according to local criteria.

8. The underdrain, including a shutoff valve, from the perimeter of the pond is required for a Wetland Basin and a Retention Pond. An underdrain, without a shutoff valve, is optional for the micro–pool and may be used to help dry the micro–pool during dry–weather periods.

9. When outlet designs differ from those shown herein:

   a) Provide needed orifices that are distributed over the vertical height of the WQCV, with the lowest orifice located at 2'–6" or more above the bottom of the micro–pool.

   b) Provide full hydraulic calculations demonstrating that the outlet will provide no less than the minimum required drain time of the Water Quality Capture Volume for the BMP type being designed.

   c) All outlet openings (i.e., orifices) shall be protected by a trash rack sized to provide a minimum net opening area called for by Figure 7, and all trash rack opening dimensions shall be smaller than the smallest dimension of the outlet orifices.

   d) Trash racks shall be manufactured from stainless steel or aluminum alloy structurally designed to not fail under a full hydrostatic load on the upstream side.

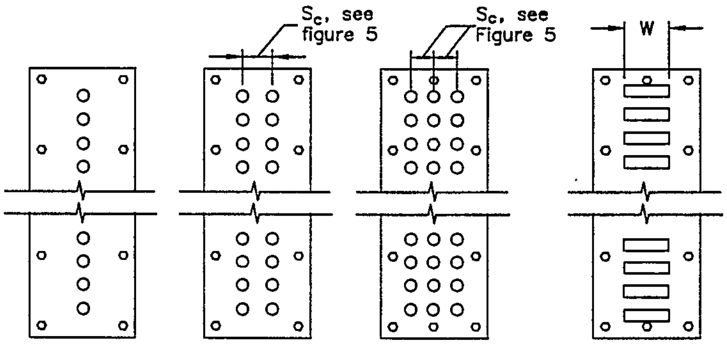
Rectangular Openings: $W_{Conc.}$ = (Width of Rectangular Perforation W) + 12"

Rectangular Openings: $W_{Opening}$ (see Figure 6–b) Obtained From Table 6b–1



Example Perforation Patterns

Note: The goal in designing the outlet is to minimize the number of columns of perforations that will drain the WQCV in the desired time. Do not, however, increase the diameter of circular perforations or the height of the rectangular perforations beyond 2 inches. Use the allowed perforation shapes and configurations shown above along with Figure 5 to determine the pattern that provides an area per row closest to that required without exceeding it.

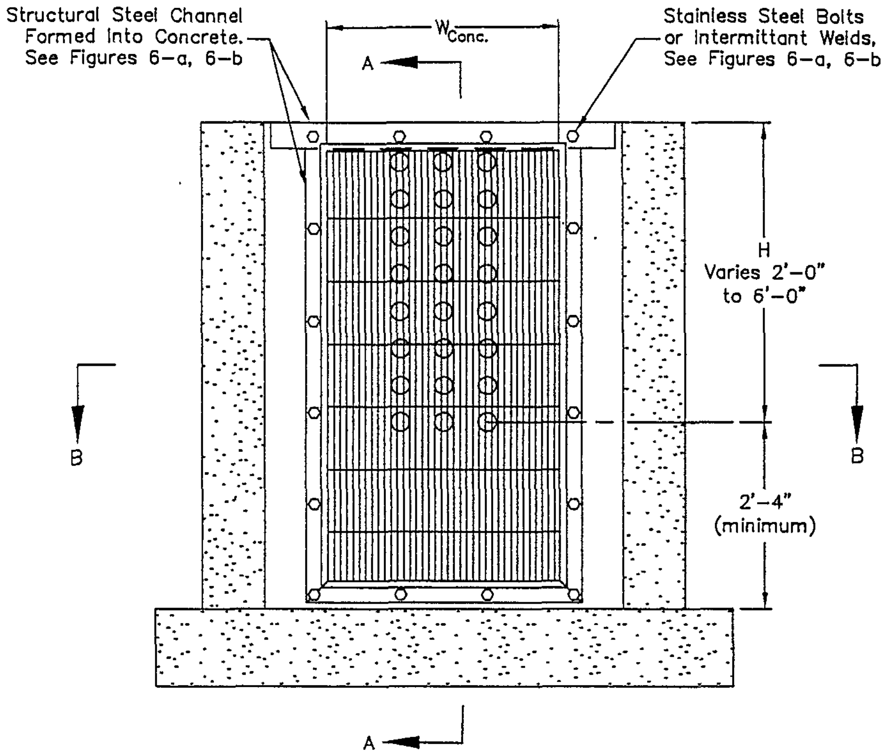
Note: Vertical WQCV Trash Racks are shown in Figures 6, 6–a, and 6–b for suggested standardized outlet design. Adverse–Slope Trash Rack design may be used for non–standardized designs, but must meet minimum design criteria.



Elevation

WQCV Trash Racks:

1. Well–screen trash racks shall be stainless steel and shall be attached by intermittant welds along the edge of the mounting frame.
2. Bar grate trash racks shall be aluminum and shall be bolted using stainless steel hardware.
3. Trash Rack widths are for specified trash rack material. Finer well–screen or mesh size than specified is acceptable, however, trash rack dimensions need to be adjusted for materials having a different open area/gross area ratio (R value)
4. Structural design of trash rack shall be based on full hydrostatic head with zero head downstream of the rack.

Overflow Trash Racks:

1. All trash racks shall be mounted using stainless steel hardware and provided with hinged and lockable or boltable access panels.
2. Trash racks shall be stainless steel, aluminum, or steel. Steel trash racks shall be hot dip galvanized and may be hot powder painted after galvanizing.
3. Trash Racks shall be designed such that the diagonal dimension of each opening is smaller than the diameter of the outlet pipe.
4. Structural design of trash rack shall be based on full hydrostatic head with zero head downstream of the rack.

[1] US Filter, St. Paul, Minnesota, USA

DESIGN EXAMPLE:

Given: A WQCV outlet with three columns of 5/8 inch (0.625 in) diameter openings. Water Depth H above the lowest opening of 3.5 feet.

Find: The dimensions for a well screen trash rack within the mounting frame.

Solution: From Table 6a-1 with an outlet opening diameter of 0.75 inches (i.e., rounded up from 5/8 inch actual diameter of the opening) and the Water Depth H = 4 feet (i.e., rounded up from 3.5 feet). The minimum width for each column of openings is 6 inches. Thus, the total width is $W_{conc.} = 3 \cdot 6 = 18$ inches. The total height, after adding the 2 feet below the lowest row of openings, and subtracting 2 inches for the flange of the top support channel, is 64 inches. Thus,

Trash rack dimensions within the mounting frame = 18 inches wide x 64 inches high

From Table 6a-2 select the ordering specifications for an 18", or less, wide opening trash rack using US Filter (or equal) stainless steel well-screen with #93 VEE wire, 0.139" openings between wires, TE .074" x .50" support rods on 1.0" on-center spacing, total rack thickness of 0.655" and ¾" x 1.0" welded carbon steel frame.

Table 6b-2: Standardized WQCV Outlet Design Using 2" Height Rectangular Openings.
Klemp™ KRP Series <u>Aluminum</u> Bar Grate[1] (or equal) Trash Rack Design Specifications.

Water Depth Above Lowest Opening, H	Minimum Bearing Bar Size, Bearing Bars Aligned Vertically
2.0 ft.	1" x 3/16"
3.0 ft.	1-1/4" x 3/16"
4.0 ft.	1-3/4" x 3/16"
5.0 ft.	2" x 3/16"
6.0 ft.	2-1/4" x 3/16"

[1] Klemp Corporation, Orem, Utah, USA

DESIGN EXAMPLE:

Given: A WQCV outlet with 2" height by 6.5" width openings.
Water Depth H above the lowest opening of 4.5 feet.

Find: The dimensions for an aluminum bar grate trash rack.

Solution: Using Table 6b-1 for openings having a width of 6.5 inches and Water Depth H = 5 feet (i.e., round up from 4.5 feet). The minimum width is 7'-6". The net height, after accounting for the 2 feet below the lowest opening, is 6'-6". An additional 6" must be added to the width and an additional 4" to the height to allow for mounting hardware. Thus, Trash rack dimensions = 8'-0" wide by 6'-10" high

Note also from Table 6b-1, that for orifice plate rectangular openings wider than 4", cross rod spacing of 4" is allowed.

From Table 6b-2, select the ordering specifications for H = 5.0 feet or less, a 8.0' wide by 6'-10" high trash rack using Klemp Corporation aluminum bar grate (or equal) with 2" by 3/16" bearing bars spaced 1-3/16" on-center, cross rods spaced 4" on-center. **Bearing bars are to be aligned vertically.**

1.0 GRASS BUFFER (GB)

Grass buffers require general maintenance of the turf grass cover and repair of any rill or gully development. Table GB-1 presents a summary of specific maintenance requirements and a suggested frequency of action.

TABLE GB-1
Irrigated Grass Buffer Strip Maintenance Considerations

Required Action	Maintenance Objective	Frequency of Action
Lawn mowing	Maintain a dense grass cover at a recommended length of 2 to 4 inches. Collect and dispose of cuttings offsite or use a mulching mower.	Routine – As needed or recommended by inspection.
Lawn care	Use the minimum amount of biodegradable, nontoxic fertilizers and herbicides needed to maintain dense grass cover, free of weeds. Reseed and patch damaged areas.	Routine – As needed.
Irrigation	Adjust the timing sequence and water cover to maintain the required minimum soil moisture for dense grass growth. Do not overwater.	As needed.
Litter removal	Remove litter and debris to prevent gully development, enhance aesthetics, and prevent floatables from being washed offsite.	Routine – As needed by inspection
Inspections	Inspect irrigation, turf grass density, flow distribution, gully development, and traces of pedestrian or vehicular traffic and request repairs as needed.	Annually and after each major storm (that is, larger than 0.75 inches in precipitation).

R0017796

TABLE GB-1
Irrigated Grass Buffer Strip Maintenance Considerations

Required Action	Maintenance Objective	Frequency of Action
Turf replacement	To lower the turf below the surface of the adjacent pavement, use a level flow spreader, so that sheet flow is not blocked and will not cause water to back up onto the upstream pavement.	As needed when water padding becomes too high or too frequent a problem. The need for turf replacement will be higher if the pavement is sanded in winter to improve tire traction on ice. Otherwise, expect replacement once every 5 to 15 years.

2.0 GRASS SWALES (GS)

Table GS-1 summarizes maintenance needs and related issues and shows the recommended frequency of various maintenance activities.

Healthy grass can generally be maintained without using fertilizers because runoff from lawns and other areas contains the needed nutrients. Occasionally inspecting the grass over the first few years will help to determine if any problems are developing and to plan for long-term restorative maintenance needs.

TABLE GS-1
Grass-Lined Swale Maintenance Considerations

Required Action	Maintenance Objective	Frequency of Action
Lawn mowing and Lawn care	Maintain irrigated grass at 2 to 4 inches tall and nonirrigated native grass at 6 to 8 inches tall. Collect cuttings and dispose of them offsite or use a mulching mower.	Routine – As needed.
Debris and Litter removal	Keep the area clean for aesthetic reasons, which also reduces floatables being flushed downstream.	Routine – As needed by inspection, but no less than two times per year.
Sediment removal	Remove accumulated sediment near culverts and in channels to maintain flow capacity. Replace the grass areas damaged in the process.	Routine – As needed by inspection. Estimate the need to remove sediment from 3 to 10 percent of total length per year, as determined by annual inspection.
Grass reseeding and mulching	Maintain a healthy dense grass in channel and side slope.	Nonroutine – As needed by annual inspection.
Inspections	Check the grass for uniformity of cover, sediment accumulation in the swale, and near culverts.	Routine – Annual inspection is suggested.

R0017798

3.0 MODULAR BLOCK POROUS PAVEMENT (MBP)

TABLE MBP-1
Modular Block Porous Pavement Maintenance Considerations

Requires Action	Maintenance Objective	Frequency of Action
Debris and litter removal	Accumulated material should be removed as a source control measure.	Nonroutine – As needed.
Sod maintenance	If sandy loam turf is used, provide lawn care, the irrigation system, and inlay depth maintenance as needed.	Routine – As dictated by inspection.
Inspection	Inspect representative areas of surface filter sand or sandy turf for accumulation of sediment or poor infiltration.	Routine and during a storm event to ensure that water is not bypassing these surfaces by not infiltrating.
Replacement of Surface Filter Layer	Remove, dispose, and replace surface filter media by pulling out turf plugs and by vacuuming out sand media from within the annular spaces of the blocks. Replace with fresh ASTM C-33 sand and, if appropriate, sandy loam turf plugs.	Nonroutine – when it becomes evident that runoff does not rapidly infiltrate into the surface. May be as often as every year or as little as every 5 to 10 years.

4.0 POROUS PAVEMENT DETENTION (PPD)

TABLE PPD-1
Porous Pavement Detention Maintenance Considerations

Requires Action	Maintenance Objective	Frequency of Action
Debris and litter removal	Accumulated material should be removed as a source control measure.	Nonroutine – As needed.
Inspection	Inspect representative areas of surface filter sand accumulation of fine sediment.	Routine and during a storm event to ensure that water is not bypassing these surfaces or taking too long to drain out.
Replacement of Surface Filter Layer	Using a power vacuum remove all sand media within the annular spaces of the concrete blocks. Replace with fresh ASTM C-33 sand, vibrate into place and remove excess.	Nonroutine – when it becomes evident that runoff does not rapidly infiltrate into the surface, namely, the ponded water does not drain within one hour. May be as often as once a year or as little as once every 5 to 10 years.

R0017800

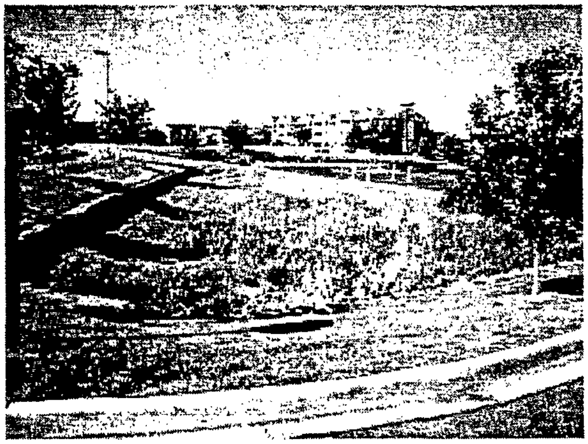
5.0 POROUS LANDSCAPE DETENTION (PLD)

TABLE PLD-1
Porous Landscape Detention Maintenance Considerations

Required Action	Maintenance Objectives	Frequency
Lawn mowing and vegetative care	Occasional mowing of grasses and weed removal to limit unwanted vegetation. Maintain irrigated turf grass as 2 to 4 inches tall and nonirrigated native turf grasses at 4 to 6 inches.	Routine – Depending on aesthetic requirements.
Debris and litter removal	Remove debris and litter from detention area to minimize clogging of the sand media.	Routine – depending on aesthetic requirements
Landscaping removal and replacement	The sandy loam turf and landscaping layer will clog with time. This layer will need to be removed and replaced, along with all turf and other vegetation growing on the surface, to rehabilitate infiltration rates.	Every 5 to 10 years, depending on infiltration rates needed to drain the WQCV in 12-hours or less. May need to do it more frequently if exfiltration rates are too low to achieve this goal.
Inspections	Inspect detention area to determine if the sand media is allowing acceptable infiltration.	Routine – bi-annual inspection of hydraulic performance

R0017801

6.0 EXTENDED DETENTION BASINS (EDB)



Extended detention basins have low to moderate maintenance requirements. Routine and nonroutine maintenance is necessary to assure performance, enhance aesthetics, and protect structural integrity. The dry basins can result in nuisance complaints if not properly designed or maintained. Bio-degradable pesticides may be required to limit insect problems. Frequent debris removal and grass-mowing can reduce aesthetic complaints. If a shallow wetland or marshy area is included, mosquito breeding and nuisance odors could occur if the water becomes stagnant. Access to critical elements of the pond (inlet, outlet, spillway, and sediment collection areas) must be provided. The basic elements of the maintenance requirements are presented in Table EDB-1.

TABLE EDB-1
Extended Detention Basin Maintenance Considerations

Required Action	Maintenance Objective	Frequency of Action
Lawn mowing and lawn care	Occasional mowing to limit unwanted vegetation. Maintain irrigated turf grass as 2 to 4 inches tall and nonirrigated native turf grasses at 4 to 6 inches.	Routine – Depending on aesthetic requirements.
Debris and litter removal	Remove debris and litter from the entire pond to minimize outlet clogging and improve aesthetics.	Routine – Including just before annual storm seasons (that is, April and May) and following significant rainfall events.
Erosion and sediment control	Repair and revegetate eroded areas in the basin and channels.	Nonroutine – Periodic and repair as necessary based on inspection.
Structural	Repair pond inlets, outlets, forebays, low flow channel liners, and energy dissipators whenever damage is discovered.	Nonroutine – Repair as needed based on regular inspections.

R0017802

TABLE EDB-1
Extended Detention Basin Maintenance Considerations

Required Action	Maintenance Objective	Frequency of Action
Inspections	Inspect basins to insure that the basin continues to function as initially intended. Examine the outlet for clogging, erosion, slumping, excessive sedimentation levels, overgrowth, embankment and spillway integrity, and damage to any structural element.	Routine – Annual inspection of hydraulic and structural facilities. Also check for obvious problems during routine maintenance visits, especially for plugging of outlets.
Nuisance control	Address odor, insects, and overgrowth issues associated with stagnant or standing water in the bottom zone.	Nonroutine – Handle as necessary per inspection or local complaints.
Sediment removal	Remove accumulated sediment from the forebay, micro-pool, and the bottom of the basin.	Nonroutine – Performed when sediment accumulation occupies 20 percent of the WQCV. This may vary considerably, but expect to do this every 10 to 20 years, as necessary per inspection if no construction activities take place in the tributary watershed. More often if they do. The forebay and the micro-pool will require more frequent cleanout than other areas of the basin, say every 1 or 2 years.

7.0 SAND FILTER EXTENDED DETENTION BASIN (SFB)

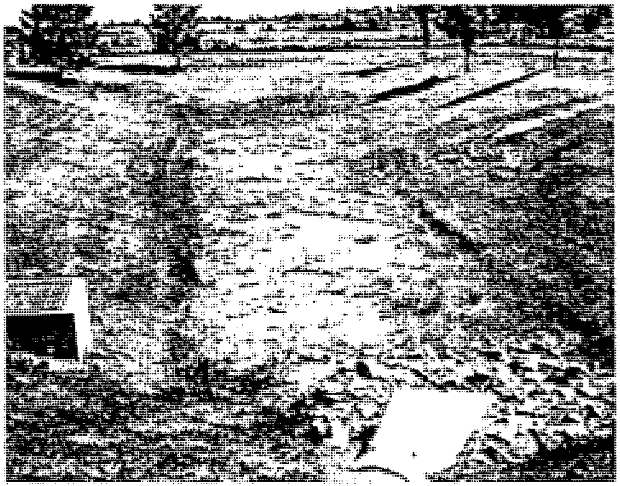


TABLE SFB-1
Sand Filter Detention Basin Maintenance Considerations

Required Action	Maintenance Objectives	Frequency
Debris and litter removal	Remove debris and litter from detention area to minimize clogging of the sand media.	Routine – depending on aesthetic requirements
Landscaping removal and replacement	If the sand filter is covered with rock mulch, bluegrass, or other landscaping covers, the cover must be removed to allow access to the sand media. Replace landscaping cover after maintenance of sand media is complete.	Every 2 to 5 years
Scarify Filter Surface	Scarify top 3 to 5 inches by raking the filter's surface.	Once per year or when needed to promote drainage.
Sand filter removal	Remove the top 3 inches of sand from the sand filter. After a third removal, backfill with 9 inches of new sand to return the sand depth to 18 inches. Minimum sand depth is 12 inches.	If no construction activities take place in the tributary watershed, every 2 to 5 years depending on observed drain times, namely when it takes more than 24 hours to empty 3-foot deep pool. Otherwise more often. Expect to clean out forebay every 1 to 5 years.
Inspections	Inspect detention area to determine if the sand media is allowing acceptable infiltration.	Routine – bi-annual inspection of hydraulic performance, one after a significant rainfall.

R0017804

8.0 CONSTRUCTED WETLANDS BASIN (CWB)

To achieve and maintain a healthy wetland for water quality enhancement, the proper depth and the spatial distribution of growth zones must be maintained. Table CWB-2 summarizes suggested activities and their frequencies to maintain an operational wetland.

TABLE CWB-1
Constructed Wetlands Maintenance Considerations

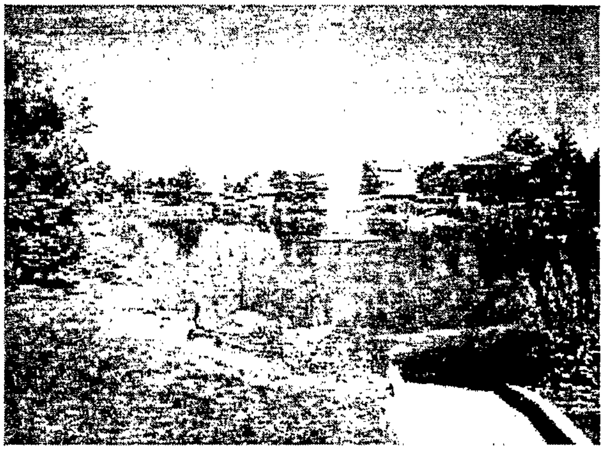
Required Action	Maintenance Objective	Frequency of Action
Lawn mowing and lawn care	Mow occasionally to limit unwanted vegetation. Maintain irrigated turf grass at 2 to 4 inches tall and nonirrigated native turf grasses at 4 to 6 inches.	Routine – Depending on aesthetic requirements.
Debris and litter removal	Remove debris and litter from entire pond to minimize outlet clogging and aesthetics. Include removal of floatable material from the pond's surface.	Routine – Including just before annual storm seasons (that is, in April and May) and following significant rainfall events.
Sediment removal	Remove accumulated sediment and muck along with much of the wetland growth. Re-establish growth zone depths and spatial distribution. Revegetate with original wetland species.	Nonroutine – Every 10 to 20 years as needed by inspection if no construction activities take place in the tributary watershed. More often if they do. Expect to clean out forebay every 1 to 5 years.
Aquatic plant harvesting	Cut and remove plants growing in wetland (such as cattails and reeds) to remove nutrients permanently with manual work or specialized machinery.	Nonroutine until further evidence indicates such action would provide significant nutrient removal. In the meantime, perform this task once every 5 years or less frequently as needed to clean the wetland zone out.

TABLE CWB-1
Constructed Wetlands Maintenance Considerations

Required Action	Maintenance Objective	Frequency of Action
Inspections	Observe inlet and outlet works for operability. Verify the structural integrity of all structural elements, slopes, and embankments.	Routine – At least once a year, preferably once during one rainfall event resulting in runoff.

R0017806

9.0 RETENTION POND (RP)



The amount of construction activity within a basin, the erosion control measures implemented, and the size of the basin will influence the frequency of sediment removal from the pond. With aggressive erosion control is practiced in the tributary watershed, it is estimated that accumulated sediment will need to be removed at 5- to 20-year intervals. Table RP-1 summarizes the required maintenance activities and their frequency for retention ponds.

TABLE RP-1
Retention Pond Basin Maintenance Considerations

Required Action	Maintenance Objective	Frequency of Action
Lawn mowing and lawn care	Mow occasionally to limit unwanted vegetation. Maintain irrigated turf grass 2 to 4 inches tall and non-irrigated native turf grasses at 4 to 6 inches.	Routine – Depending on aesthetic requirements.
Debris and litter removal	Remove debris and litter from the entire pond to minimize outlet clogging and aesthetics. Include the removal of floatable material from the pond's surface.	Routine – Including just before annual storm seasons (that is, April and May) and following significant rainfall events.
Erosion and sediment control	Regrade and revegetate eroded and slumped areas above the pond and along channels. Repair damaged inlet and outlet energy dissipators.	Nonroutine – Periodic and repair as necessary based on inspection.
Inspections	Inspect the retention pond for functioning as initially intended. Pay attention to outlet clogging. Also note erosion, slumping, sedimentation levels, overgrowth, embankment and spillway integrity, and damage to structural elements of the facility.	Routine – Annual inspection of hydraulic and structural facilities. Biannual performance and maintenance inspections.
Nuisance control	Address odor issues, insects, and overgrowth with appropriate measures.	Nonroutine – As necessary per inspection or local complaints.

R0017807

TABLE RP-1
Retention Pond Basin Maintenance Considerations

Required Action	Maintenance Objective	Frequency of Action
Structural repairs	Repair such items as inlet/outlet works and energy dissipator liners. Stabilize banks and berms. Repair damage caused by larger storm events.	Nonroutine – As necessary per inspection.
Sediment removal	Empty the pond, divert the base flow, and dry out bottom sediments in fall and winter months to allow access with backhoe. Remove accumulated sediment along with aquatic growth overlaying them. Re-establish original design grades and volumes and replant aquatic vegetation.	Nonroutine – As indicated per inspections and sediment accumulation. Expect to do this every 10 to 20 years if no construction activities take place in the tributary watershed. More often if they do. Expect to clean out the forebay every 1 to 5 years.
Aquatic Growth Harvesting	Remove aquatic plants such as cattails or reeds, which also permanently removes nutrients. Use an aquatic harvester and dispose of the material offsite.	Nonroutine – Perform every 5 to 15 years or as needed to control their accumulation.

10.0 CONSTRUCTED WETLANDS CHANNEL (CWC)

To achieve and maintain a healthy wetland for water quality enhancement, the proper depth and the spatial distribution of growth zones must be maintained. Table CWC-1 summarizes suggested activities and their frequencies to maintain an operational wetland.

TABLE CWC-1
Constructed Wetlands Maintenance Considerations

Required Action	Maintenance Objective	Frequency of Action
Lawn mowing and lawn care	Mow occasionally to limit unwanted vegetation. Maintain irrigated turf grass at 2 to 4 inches tall and nonirrigated native turf grasses at 4 to 6 inches.	Routine – Depending on aesthetic requirements.
Debris and litter removal	Remove debris and litter from the channel.	Routine – Including just before annual storm seasons (that is, in April and May) and following significant rainfall events.
Sediment removal	Remove accumulated sediment and muck along with wetland vegetation growing on top of it. Re-establish growth zone depths and revegetate with original wetland species.	Nonroutine – Every 10 to 20 years as needed by inspection if no construction activities take place in the tributary watershed. More often if they do.
Aquatic plant harvesting	Cut and remove plants growing in wetland (such as cattails and reeds) to remove nutrients permanently with manual work or specialized machinery.	Nonroutine until further evidence indicates such action would provide significant nutrient removal. In the meantime, perform this task once every 5 years or less frequently as needed to clean the wetland zone out.
Inspections	Observe inlet and outlet works for operability. Verify the structural integrity of all structural elements, slopes, and embankments.	Routine – At least once a year, preferably once during one rainfall event resulting in runoff.

1.0 INTRODUCTION

1.1 Overview

This chapter contains guidance for incorporation of BMPs for controlling stormwater discharges at industrial and commercial facilities. The guidance addresses:

- Planning Considerations for establishment of BMPs for new and existing facilities.
- An evaluation of the possible pollutant sources that are found at industrial and commercial sites.
- Recommendations on structural and nonstructural controls for stormwater discharges from these facilities.

1.2 Applicability

The BMPs described in this section are applicable to many different circumstances that occur at industrial and commercial locations. While this section is directed toward application to smaller industries and any size commercial facility, many of the practices are applicable to any size of facility. It is anticipated that the majority of industries that may develop BMPs will be manufacturers of different products.

Commercial sites which may find this information of value are those that store materials outside, use or store large quantities of hazardous or toxic chemicals as part of their business or perform activities that could result in discharges into the storm sewer such as vehicle maintenance and painting.

The requirement to develop and implement best management plans is usually a result of the regulatory requirement that industries obtain NPDES stormwater permits. In some cases, specific local governments may require implementation of BMPs to address water quality. Some local governments may wish to receive copies of stormwater management plans developed by industries. It is recommended that local governments be contacted for additional requirements.

2.0 PLANNING CONSIDERATIONS

There are many different measures that can be taken to minimize the impact on water quality from commercial and industrial facilities. These measures are called best management practices (BMPs). They are usually divided into structural practices, which involve the construction of a system to remove contaminants to nonstructural. The latter includes those measures which are aimed at controlling the "human factor". They are procedural in nature.

Incorporation of structural BMPs is most easily done prior to construction of the facility when site layout is still under design. Many practices, such as providing coverage and containment around potential pollutant sources can be incorporated during the design of buildings or layout of the site. At the planning stage, it is possible to incorporate the different elements that can address both stormwater and other regulatory concerns with out the need for later plant modifications.

For existing facilities, it is necessary for the owner/operator to evaluate the current activities that take place on site. Based on this evaluation, it may be necessary to retrofit existing structures as part of the incorporation of best management practices. Other concerns regarding existing facilities include that there may be significant limitations in trying to find room for structural BMPs that require large amounts of land (for example, detention basins). Structural BMPs that do not require significant amounts of land such as infiltration basins are more likely to be incorporated into existing facilities. Nonstructural BMPs have no problems being implemented into existing facilities and developed areas.

The first step in planning for the inclusion of best management practices at new or existing sites is to evaluate what activities take place at the site and the possible pollutant sources may be at the site. Once the sources are identified, best management practices that address them can be determined. The assessment and evaluation process is:

1.) Assess the activities on the site that could be potential sources of storm water pollution from the facility because of the material that is used in the process or because of the byproducts/products of the process. Activities to assess include the storage of materials or equipment, waste disposal practices, formation of products from raw materials, coating of materials, generation of power, etc.

2.) Based on the assessment of activities, conduct a material inventory to determine what materials are kept on the site that could cause a problem if they were discharged from the site. It is important also to evaluate the quantities of these materials. Some materials may be of concern only if stored or used in significant quantities.

3.) For existing facilities, evaluate past spills and leaks to determine if there are any materials or activities that create chronic stormwater runoff pollution problems. Inadequate clean up of spills can result in contamination.

4.) Evaluate the data gathered and determine where potential pollutant sources or potentially polluting activities (i.e., fueling) are located. This could be done by the creation of a map. Based on the results, a determination on what structural or nonstructural measures are required can be made. Potential sources can be addressed singularly or in combination.

5.) For existing sites, once the sources have been determined, a review of the site and current practices should occur to determine if present practices/measures are adequate to protect water quality.

6.) Evaluate existing conditions at the site. A determination should be made of storm water drainage patterns.

7.) Determine the BMPs that are best for your site. It is important that each source be addressed by a BMP or a group of BMPs. Where possible, a single BMP can be used to address multiple sources. Factors which should be evaluated in choosing BMPs are:

- Pollutants Controlled: BMPs which address sediment may not control oils.
- Effectiveness of BMPs: Each control measure should provide a sufficient pollutant control to warrant its inclusion.
- Reliability/Sustainability: Measures should be effective over an extended time and be able to be properly implemented over time.
- Implementation Cost: Control measures with low planning, design, and land acquisition, construction, and equipment costs should be chosen.
- Maintenance Costs: Control measures with low operation, maintenance, repair, support service, and replacement costs should be preferred.
- Public Acceptability: BMPs should be assessed on the expected response from the public.
- Agency Acceptability: BMPs should be evaluated on the expected response of agencies which will oversee the measures taken and their relationship to regulatory requirements.
- Risk Liability: Control measures should be evaluated in terms of the risks or liabilities which occur during implementation.

8.) Once the BMPs are implemented it will be necessary to ensure that structural BMPs are properly operated and maintained and that employees are carrying out nonstructural type BMPs. This may involve making checks on BMPs, designation of responsible individuals for BMPs and education of employees in your pollution prevention efforts.

9.) It is important following implementation of BMPs that they be re-evaluated. Changes in the business may result in the ability to discontinue certain BMPs and implementation others.

3.0 POLLUTANT SOURCES

To develop a useful evaluation of the potential risk of stormwater pollutant sources it is necessary to review the use of the site, pollutant sources, the topography of the site, the locations of activities and material storage and to understand where spills are likely to occur.

3.1 Topography

As discussed above, a review of the site drainage patterns should be made to determine where runoff from potential sources of pollutants drains. This is important for several reasons. Drainage patterns are useful in determining where structural controls can be established, where different run-on sources commingle, and it may also show where it is possible to grade a site to prevent run-on from offsite drainage areas that have a high potential for polluting stormwater.

3.2 Activities That Pose a Potential Stormwater Impact

The following activities have the potential to cause an impact on stormwater runoff quality from an industrial or commercial sites:

3.2.1 Fueling Areas. When stormwater mixes with fuel spilled or leaked onto the ground, it becomes polluted by petroleum based materials that are harmful to humans, fish, and wildlife. Fuel overflows during storage tank filling can be a major source of contamination. This could occur at large industrial sites or at small commercial sites such as gas stations, convenience stores, strip malls or garages. Sources of contaminates typically are:

- Spills and leaks during fueling or oil delivery,
- Spills caused by "topping off" fuel tanks,
- Allowing rainfall to run onto the fuel area,
- Hosing or washing down of the fuel area, or
- Mobile fueling operations.

3.2.2. Vehicle and Equipment Maintenance and Storage. Vehicle and equipment maintenance operations use materials and create wastes that can be harmful to humans and the environment if not property handled. Stormwater runoff from these areas can become polluted with a variety of contaminates including solvents and degreasing products, waste automotive fluids, oils and greases, acids and caustic wastes. Sources of contaminates typically are:

- Parts cleaning,
- Shop cleanup,
- Spilled fuel, oil, or other materials such as battery acid,

- Replacement of fluids, such as oil, oil filters, hydraulic fluids, transmission fluid and radiator fluids,
- Dripping fluids from vehicles and equipment, and
- Disposal of greasy rags, oil filters, air filters, batteries, battery fluids, spent coolant, degreasers, oils, etc.

3.2.3 Painting. Many painting operations use materials or create wastes that are harmful to humans and the environment. Paint solvents used to remove or thin paint and dusts from sanding and grinding operations contain toxic metals like cadmium and mercury. These can pollute stormwater and create significant water quality impacts. Sources of contamination typically are:

- Painting and chemical paint removal,
- Sanding or paint stripping
- Spills of paint or paint thinner,
- Sand blasting residue, or
- Equipment painting.

3.2.4 Washing. Washing vehicles and equipment outdoors or in areas where wash water flows onto the ground can pollute stormwater. Vehicle wash water is considered process water not stormwater. Operators must have a NPDES/CDPS permit to discharge vehicle wash water. Wash waters can contain high concentrations of oil and grease, solvents, phosphates, and high-suspended solids loads. Sources of washing contamination typically include:

- Outside equipment or vehicle cleaning (washing, degreasing, or steam cleaning),
- Wash water discharge to the ground or directly to storm drain,
- Mobile fleet washing, or
- Pressure washing of buildings.

Other types of washing include spraying down concrete and asphalt surfaces such as those outside of commercial sites where sales of products may have occurred, areas where dirt and mud have accumulated, loading dock areas, or parking and sidewalk areas that have accumulated wastes. These activities must have an NPDES or ICDPS permit. In some cases, these types of discharges are incorporated into the municipality stormwater permit. These areas also need to be taken into consideration with the possibility of potentially polluting stormwater.

3.2.5 Loading and Unloading. Loading and unloading operations usually take place outside on docks, truck, terminals or outside storage or staging areas at both industrial and commercial sites. Materials spilled, leaked or lost during loading and unloading may collect in the soil or other surfaces and be

R0017816

carried away by runoff, or when the area is cleaned. Rainfall may wash pollutants off machinery used to unload and load materials. Typically sources of contamination include:

- Pumping of liquids or gases to or from a truck or rail car into a storage facility,
- Pneumatic transfer of dry chemicals to or from the vehicles,
- Transfer by mechanical conveyor systems, or
- Transfer of bags, boxes, drums, or other containers by forklift, trucks, or other material handling equipment.

3.2.6 Above Ground Tanks— Liquid Storage Accidental releases of chemicals from above ground liquid storage tanks can contaminate storm water with many different pollutants. Materials spilled, leaked, or lost from storage tanks may accumulate in soils or on other surfaces and be carried away by runoff. Typical causes of contamination from accidental releases include:

- External corrosion and structural failure,
- Installation problems,
- Spills and overfills due to operator error,
- Failure of piping systems including pipes, pumps, flanges, couplings, hoses, and valves, or
- Leaks or spills during pumping of liquids or gases from trucks or rail cars to a storage facility or vice versa.

3.2.7 Outside Manufacturing. Outside manufacturing activities can also contaminate stormwater runoff. Activities such as parts assembly, rock grinding or crushing, metals painting or coating, grinding or sanding, degreasing, parts cleaning or operations that use hazardous materials are of concern. Metal and wood shavings, excess lubricants, and other residuals resulting from outside manufacturing that are left on the ground can also be washed into the drainage system. Typical contaminate sources include:

- Processes or equipment that generate dust, vapors or other emissions,
- Outside storage of hazardous materials and raw materials,
- Dripping or leaking fluids from equipment or processes,
- Liquid wastes discharged directly onto the ground or into the storm sewer, or
- Concrete manufacturing (pipes, inlets, etc.).

3.2.8 Waste Management. Areas where industrial or chemical waste is stored, treated or disposed of can cause stormwater pollution. Wastes spilled, leached, or lost from management areas or outside manufacturing activities may build-up in soils or on other surfaces and be carried away by rainfall runoff. There is also the potential for liquid wastes from lagoons or surface impoundments to overflow to surface waters or soak the soil where they can be picked up by runoff. Possible stormwater contaminants include toxic compounds, oil and grease, oxygen-demanding organics, paints and solvents, heavy metals and high levels of suspended solids.

In addition to the management of wastes from industrial facilities, the management of solid wastes at commercial sites is also of concern. Improper disposal of liquid wastes in a solid waste dumpster can result in the liquids draining out of the container and into the stormwater system. Lack of coverage of waste receptacles can result in rainwater seeping through the material and collecting contaminants or the material being blow around the site and into the stormwater collection system.

Typical contaminate sources include:

- Landfills,
- Waste Piles,
- Wastewater and solid waste treatment and disposal,
- Land application sites,
- Dumpsters, or
- Unlabeled 55-gallon drums.

3.2.9 Outside Storage of Materials. Raw materials, by-products, finished products, containers, and materials storage areas exposed to rain and/or runoff can pollute storm water. Stormwater can become contaminated by a wide range of contaminates (e.g. metals, oils and grease, sediment) when solid materials wash off or dissolve into water, or by spills or leaks. Typical contaminate sources include:

- Fuels,
- Raw materials,
- By-products,
- Intermediates,
- Final products,
- Process residuals, or
- Wind-blown debris.

3.2.10 Salt Storage. Salt left exposed to rain or snow may migrate to the stormsewer or contaminate soils. Salt spilled or blown onto the ground during loading or unloading will dissolve in stormwater runoff. Stormwater contaminated with salt in high concentrations can be harmful to vegetation and aquatic life. Salty stormwater runoff soaking into the ground may contaminate ground water, thus making the groundwater unsuitable as a drinking water supply. Typical contaminate sources include:

- Salt stored outside in piles or bags that are exposed to rain or snow,

- Salt loading and unloading areas located outside or in areas where spilled salt can contaminate stormwater, or
- Salt/sand storage piles used for deicing operations.

3.2.11 Parking. Areas where customers park can also be a source of contamination. Typical sources of contamination can include:

- Improper disposal of trash
- Leaky vehicles can result in oils and other contaminants being deposited in the parking lot and then washed to the stream during a storm event.

3.2.12 Bare Soil. Bare soil areas occur at industrial and commercial sites where no pavement has been laid or adjacent to areas where pavement has been laid. They occur most often in areas that are under development. Bare soil areas can be caused by individuals that repeatedly park on these areas, use the areas as exits or a different route to another area, or even from repeated pedestrian walking. The sediment in the area that will be contaminated by the activities that occur on the area, therefore, the following can be practiced to remedy the problems. Typical sources of contamination include:

- Sediment from stormwater runoff, or
- Improper disposal of trash.

3.2.13 Landscaping Practices. Chemicals used to maintain landscaping areas can have a significant impact on the water quality of stormwater runoff. Herbicides, pesticides, and fertilizers can be washed into create impacts if they are not applied correctly. Contaminant sources include:

- Improper storage of chemicals,
- Improper storage cleaning equipment used to apply these chemicals, or
- Improper application.

R0017819

4.0 ASSESSMENT AND SELECTION OF BEST MANAGEMENT PRACTICES

Once information has been gathered on the sources of potential pollutants, it is necessary to determine the suitable BMPs to be used. To do this, it is necessary to first screen the BMPs, then rank them.

4.1 Screening Best Management Practices

Once the potential sources have been identified, one of the next steps is to determine what BMPs would be appropriate for the types of pollutants. A list of the various structural and non-structural BMPs that are effective for addressing the pollutants should be developed. As part of this process, obviously inappropriate practices are eliminated. Criteria to be used includes primary pollutants removed, drainage area served, soil conditions, land requirements, and institutional structure. It is important to understand BMP effectiveness.

4.1.1 Non-Structural BMPs. Since the number of possible BMPs is large, initial screening will reduce the number of prior to final screening. Practices can be divided into subpractices. For example, a solid waste practice could be divided into management of leaves, litter, and yard waste.

To screen BMPs, one could develop a matrix. For example, one axis would list the BMPs while the other, the criteria. The BMP would be rated on a range of 1 to 5 for each criteria. Criteria which may be appropriate for non-structural BMPs include:

- Pollutant Removal: Different source control practices are designed to address different pollutants. BMPs which address the pollutants of primary concern should receive the highest ranking.
- Existing Business Structure: Some practices implemented require a specific structure to work effectively. For example, delaying on inspections may not be practical if there are insufficient resources or knowledge to perform the inspection.
- Acceptance: Employees need to understand and accept the requirements to modify their behavior. Practices which meet with resistance will not be implemented and should be eliminated.
- Authority: Employees implementing the practices need the authority to require that certain actions occur, and to take appropriate follow-up when problems occur. Practices which require levels of authority to be implemented which do not exist should be eliminate.
- Technical Feasibility: BMPs which require large expenditures or extensive efforts might not be suitable for small industries which lack resources.
- Pollutants Controlled: BMPs which address sediment may not control oils.

R0017820

- Effectiveness of BMPs: Each control measure should provide a sufficient pollutant control to warrant its inclusion.
- Reliability/Sustainability: Measures should be effective over an extended time and be able to be properly implemented over time.
- Implementation Cost: Control measures with low planning, design, and land acquisition, construction, and equipment costs should be chosen.
- Maintenance Costs: Control measures with low operation, maintenance, repair, support service, and replacement costs should be preferred.
- Public Acceptability: BMP should be assessed on the expected response from the public.
- Agency Acceptability: BMPs should be evaluated on the expected response of agencies which will oversee the measures taken and their relationship to regulatory requirements.
- Risk Liability: Control measures should be evaluated in terms of the risks or liabilities which occur during implementation.

Based on the results of this screening, a list of potential BMPs would be determined.

An additional review would be done of those BMPs which were found to be the most desirable. An option for selection of the BMPs is to divide them into source controls, hydraulic controls, and treatment options. The development of alternatives which mix the various BMPs would be the next step. These alternatives could be ranked based on cost and implementability. The best alternative would then be implemented.

5.0 STRUCTURAL CONTROLS

Table IC-1 provides a listing of structural controls that could be applied to the various sources to address stormwater runoff from industrial and commercial sites. A detailed description of the control can be found in the chapter on Structural BMPs.

TABLE IC-1
Suggested Structural Controls

Control	Sources	Applicability
Grass Buffer	Parking Areas	Applicable to Industrial and Commercial Operations
Grass Swale	Parking Areas	Applicable to Industrial and Commercial Operations
Modular Block Parsons Pavement	Parking Areas	Applicable to Industrial and Commercial Operations
Pavement Micro-Detention	Parking Areas	Applicable to Industrial and Commercial Operations
Landscape Micro-Detention	Parking Areas	Applicable to Industrial and Commercial Operations
Extended Detention Basin	Parking Areas	Applicable to Industrial and Commercial Operations
Constructed Wetlands	Parking Areas	Applicable to Industrial and Commercial Operations
Retention Pond	All Sources	Associated with Industrial or commercial operations with storage of large quantities of toxic pollutants.
Constructed Wetlands Channel	Parking Areas	Applicable to Industrial and Commercial operations
Spill Containment and Control (Containment Diking, Curbing, Installation of spill and overflow protection)	Liquid Storage, Washing, Manufacture, Outside Storage, Waste Management, Fueling Areas, Loading and Unloading	Applicability to all Industrial and Commercial operations
Covering of Storage/Handling Facilities	Fueling Areas, Loading and Unloading, Liquid Storage, Material Storage, Outside Manufacturing, Waste Management	Applicability to all Industrial and Commercial operations

R0017822

6.0 NONSTRUCTURAL CONTROLS

Table IC-2 provides a listing of nonstructural controls that could be applied to potential pollutant sources to address stormwater runoff from industrial and commercial sites. A detailed description of the control can be found in the Chapter on Nonstructural BMPs.

TABLE IC-2
Summary of Nonstructural BMPs

BMP	Source	Applicability
Household Wastes and Toxics	Litter	Most likely associated with Commercial operations such as fast food restaurants.
	Used Oil and Automotive Fluids	Associated with Commercial operations that perform vehicle maintenance such as gasoline stations, quick lube shops, etc.
	Toxic Wastes	Associated with Commercial and Industrial facilities. Toxic wastes are used everywhere.
Pesticides, Herbicides, and Fertilizer	Application to Landscaping	Associated with Commercial and Industrial facilities which must maintain open areas. Pesticides may also be used at sites to control insects such as office buildings and restaurants.
Illicit Discharge Controls	Accidental Spill Response	Associated with Commercial or Industrial sites which transport, store, or dispose of toxic substances.
	Illicit Connections	Associated most closely with old industrial sites where the plumbing system is not well known.
Good Housekeeping Mitigation	Operation and Maintenance	Associated with Commercial and Industrial sites which store materials or equipment outside.
	Material Storage Practices	Associated with Industries which keep a large amount of materials onsite.
Preventative Maintenance	Vehicles and Equipment	Associated with medium to large Industrial facilities. Also associated with commercial operations which perform vehicle maintenance such as fleet operations.
	Building and Grounds	Associated with large Commercial or Industrial facilities.
Spill Prevention and Response, Minimization of Exposure	Spill Prevention Measures, Identification of Spill Areas, Spill Response Procedures	Associated with Commercial operations which are automotive related, and industries.
Painting Operations	Painting, Sand Blasting, and Cleanup	Associated with Commercial operations which perform painting or stripping of painted objects, specifically operations which finish metal such as auto painting.

R0017823

TABLE IC-2
Summary of Nonstructural BMPs

BMP	Source	Applicability
Above Ground Storage Tanks	Tanks	Associated with Industrial facilities or large commercial operations with above ground tanks for the storage of oils or other liquids used in bulk.
BMP Loading and Unloading	Docks	Associated with Industrial sites and large or medium Commercial operations which receive materials in bulk. Examples include stores which receive landscaping chemicals, paints, solvents.
	Tanker Trucks to Tanks	Associated with Industries and medium or large commercial operations and gasoline stations of any size.
Fuel Operations	Fuel Dispensing Area, General Facility	Associated with Industrial and Commercial operations which have fueling operations such s transportation fleets or gasoline stations.
Outside Material Storage	Outside Materials	Associated with Industrial or Commercial operations which store materials outside.
Vehicle and Equipment Washing	Vehicle and Equipment Washing	Applies to Industrial and Commercial operations which wash vehicles or equipment outside.
Dead-end Sumps	Liquid storage, Loading and unloading	Associated with Industrial operations.
Oil/Water Separators	Fueling, Maintenance, Washing	Associated with Industrial operations and commercial operations which deal with large quantities of oils.
Impervious Liners	Liquid Storage, Salt Storage	
Drip Pans	Maintenance areas, Fueling areas, Loading and Unloading (liquids)	Applicable to Commercial operations such as vehicle maintenance operations

1.0 INTRODUCTION TO NONSTRUCTURAL BMPs

1.1 Overview

This section contains guidance on the evaluation, selection and use of nonstructural Best Management Practices (BMPs). Each BMP is described and discussed as to its general application in an urban area. The following is a list of major areas of nonstructural BMPs that are considered to be appropriate and effective in stormwater quality improvement and are described in following sections of this chapter.

- Disposal of Household Waste and Toxics.
- Use of Pesticides, Herbicides and Fertilizer.
- Illicit Discharge Controls.
- Spill Prevention and Response.
- Preventative Maintenance.
- Painting Operations.
- Outside Material Storage.
- Stormwater Prevention Education.
- Mitigation.
- Vehicle Washing.
- Above Ground Storage Tanks.
- Good Housekeeping.
- Loading and Unloading.
- Fueling.
- Exposure Minimization.
- Outside Manufacturing.

Nonstructural BMPs are intended to prevent or reduce the contamination of stormwater runoff. They are applicable to a variety of different sources or activities. By reducing pollutant generation, adverse water quality impacts are reduced from potential pollutant sources. Preventing and controlling the sources of these pollutants requires a change in behavior. Some municipalities or industrial facilities will have already implemented many of the nonstructural practices as a means to address other concerns such as to control product loss, minimize waste production, accident and fire prevention, worker health and safety, site security, or to comply with other environmental regulations rather than for stormwater quality purposes.

1.2 Advantages of Nonstructural BMPs

Pollution of stormwater originates from many sources in urban areas. Structural controls reduce the amounts of pollutants that migrate off the urban landscape by reducing runoff and by providing facilities

R0017827

to remove pollutants from stormwater. Nonstructural BMPs prevent or limit the entry of pollutants into stormwater at their source. Prevention is desirable and can be cost effective because it minimizes pollution in the first place and thereby reduces the amounts that need to be removed by subsequent treatment. In urbanized portions of the municipality or existing facilities, it may be one of the few affordable methods for stormwater quality enhancement.

The advantages of nonstructural BMPs, among others, are:

- The quality of stormwater runoff is improved.
- The volume of sediment, debris, oils, chemicals and other pollutants deposited in receiving waterbodies is reduced.
- Frequency of needed maintenance of structural controls is reduced.
- Additional benefits to air quality, ground water quality, and solid waste control are realized.
- The public awareness of water-quality problems and involvement in solutions is heightened.
- Increased public awareness of stormwater quality issues.
- Most require only a modification of existing practices, are simple to understand, and make good sense.
- Implementation can occur rapidly.
- Does not require major capital construction financing.

1.3 Disadvantages of Nonstructural BMPs

Because nonstructural BMPs are tied closely to peoples'activities and behavior, their effectiveness depends on the peoples' attitude, their willingness to accept information, and their willingness to put BMPs into practice. Low participation will result in little or no benefit. A high percentage of participation has the potential for noticeable improvements in water quality.

Disadvantages to the use of nonstructural BMPs include:

- Public information is expensive to develop and distribute, and must be updated and redistributed on an ongoing basis.
- Effectiveness of good housekeeping measures is determined primarily by voluntary participation and consistency of activities.

- Initial public/private funding partnerships are needed to ensure participation and to encourage development of information and infrastructure improvements such as recycling centers and household toxics, and hazardous waste collection programs.
- Requires a dedicated workforce and funding to maintain viable programs and to continue citizen participation.
- Effects on stormwater quality from nonstructural BMPs are virtually impossible to quantify and to measure accurately without long-term data. On the other hand, the amounts of materials collected and recycled are quantifiable and could serve as an indirect measure of overall success.

2.0 USE OF NONSTRUCTURAL BMPS

2.1 Objectives in the Use of Nonstructural BMPs

Nonstructural BMPs are used to complement structural BMPs or as the only available control method in existing developed areas where retrofit construction of structural BMPs is not cost effective. Implementation of only nonstructural efforts, however, may or may not achieve measurable water quality benefits.

As part of the development of the *Manual*, a number of nonstructural BMPs were identified for potential use by municipalities and industrial /commercial areas. A group of local government representatives recommended the following as the nonstructural BMPs for inclusion in the *Manual* after evaluating these for effectiveness, feasibility of implementation, cost, and maintenance. Additional nonstructural measures will be examined in the future, and if they prove to be promising in reducing the amount of pollutants being delivered by stormwater to the receiving water system, they will be included in the future editions of the *Manual*.

This list includes nonstructural BMPs which are applied to various different types of sites. Nonstructural BMPs are implemented by various entities. Because they rely on actions and not structures, nonstructural BMPs must be implemented constantly and repetitively over time.

Other nonstructural BMPs were considered for inclusion in the *Manual*, but were deemed at this time to be inappropriate to use, for local governments to require their use by others, or were judged to be not effective enough in controlling sources of pollution. There are two main objectives of using nonstructural BMPs. These are:

(1) Reduce or eliminate the pollutants that impact water quality at their source, thus reducing the need for structural control requirements. For example, nonstructural BMPs implemented at an industrial site may result in elimination or reduction of the introduction of oils and greases into the stormwater. This could result in the better efficiency of a infiltration basin or the elimination of the need for additional treatment for oils.

(2) Address water quality concerns that are not cost effectively handled by structural controls. An example is an effective system for determining illicit discharges or connections into a stormwater system. It would not be practical for all stormwater to be collected and treated to address water quality impacts from such discharges. It is more effective to develop and implement a program for finding these sources and addressing them.

2.2 Nonstructural BMP Effectiveness

To be effective, nonstructural BMPs need to prevent or reduce the sources of stormwater pollution. They fall into the general categories of prevention and source controls. Preventing and controlling the source of pollutants that come in contact with stormwater requires a change in the behavior of the urban population and in the waste disposal practices they employ.

The objectives for promoting the use of nonstructural BMPs are as follows:

- Improve the quality of receiving waters.
- Increase consistency with stormwater quality objectives.
- Increase consistency with structural BMPs.
- Improve cost effectiveness.
- Widespread applicability in all urban areas.
- Widespread public acceptance.

The effectiveness of nonstructural BMPs is difficult, if not impossible, to quantitatively assess. For example, to determine the effectiveness of a public education program on chemical usage, it would be necessary to have data on the residential and commercial chemical usage in the area, the amounts of chemicals which enter the storm sewer system that is attributable to improper usage and/or disposal, and the amount washed off by stormwater before and after the implementation of the program.

The recommendations for the use of nonstructural practices included in the *Manual* are based more on an intuitive presumption that some level of improvement will be realized if the practices are implemented. Preventing or reducing the amount of pollutants at the source is usually more cost effective than structural controls that remove pollutants after they have entered stormwater.

It can also be argued that aggressive use of nonstructural measures will reduce concentrations and loads of various pollutants in stormwater being conveyed to downstream structural BMPs or to the receiving waters. This is especially the case in existing urban areas where structural controls cannot be easily built, or are extremely expensive to retrofit into the fully-developed urban landscape.

2.3 Pollutant Removal Mechanisms

Nonstructural BMPs can, to some degree, prevent the deposition of pollutants on the urban landscape or remove pollutants at their source. The source of pollutants for assimilation into stormwater is the land surface itself, especially the impervious surfaces in the urban area. Thus, it is expected that when nonstructural measures are effectively implemented, they will reduce the amount of pollutants being deposited on land surfaces for eventual contact with stormwater and transported to the receiving water system.

2.4 Nonstructural BMP Selection and Use Guidelines

Most nonstructural BMPs are applicable for use in residential, commercial, and industrial areas. This can be said for newly developing areas, recently developed areas, and old neighborhoods as well.

For newly developing and redeveloping areas, nonstructural BMPs include municipal programs to ensure that new urban development and redevelopment incorporates appropriate temporary erosion and sediment control during construction and also permanent structural BMPs as a part of the development. Such municipal programs include institutional mechanisms that require the proponents of a new development to prepare and submit stormwater quality control management plans in accordance with the municipality's stormwater BMP design criteria and standards, including the erosion control and stormwater management during construction. These programs need adequate staff and fiscal resources to review and approve development plans and to ensure that the approved stormwater quality provisions of these plans are properly implemented.

The remaining nonstructural BMPs described in the *Manual*, are targeted at developed areas and industrial/commercial sites. Most rely primarily on public education, and procedural changes and possible enforcement programs. In selecting the appropriate nonstructural pollutant reduction programs to adopt, each manager facility needs to evaluate its current land-use condition and the potential for removal of pollutants offered by each of these practices. The specifics for selection and use of each nonstructural BMP effort are described for each management practice.

Nonstructural BMPs fall into several categories which include:

- Waste Minimization - Source Control
- Good Housekeeping
- Preventative Maintenance
- Minimization of Exposure
- Spill Minimization and Prevention
- Public Education
- Mitigation

Within these categories, some BMPs are more appropriate for industrial/commercial sites while others apply to construction sites. In some cases the BMP may be applicable to residents and thus are best addressed by local or state government.

In determining which nonstructural BMPs should be implemented, it is recommended that as part of the overall planning process an evaluation be made of the potential sources of pollutants and the best means of addressing them. For example, if the concern is bacteria loadings, then a program on pet litter may be appropriate. If the problem is oil and grease in the runoff from a gasoline station or autoshop, then nonstructural controls dealing with spill prevention may be appropriate. Thus, once the source or activities are determined the list of BMPs should be consulted to determine the most applicable practices.

3.0 DISPOSAL OF HOUSEHOLD WASTE AND TOXICS

3.1 Primary Users

These best management practices apply to municipalities, civic groups, commercial businesses, and industry.

3.2 Description

Improperly disposed waste materials are a source of stormwater pollution. These wastes can include household chemicals, pet waste, yard waste, litter, automotive maintenance waste and others. This is especially true when wastes are placed on impervious surfaces or directly into the storm drainage system, such as streets, alleys, parking lots and sidewalks, and pervious structures such as ditches, drainageways, gulches, etc.

The development of education programs and dissemination of information that promotes proper disposal of household (solid) waste, litter, pet waste, yard waste, used oil, and toxic waste is a nonstructural Best Management Practice (BMP). The passage of laws, rules, or ordinances prohibiting improper disposal of these materials, and their enforcement, is another step in this management practice. An on-going education program, along with facilities for such disposal, has been judged to be most effective at this time.

3.3 Application

Waste materials deposited on the urban landscape, especially the impervious surfaces, can be washed off by stormwater runoff and delivered to the receiving water system. Thus, all measures that help to minimize the presence of these materials on the urban landscape can improve water quality. Proper disposal of household waste and toxics can reduce the deposition of solids, organics, nutrients, oxygen-demanding substances, solvents, caustics, paints, automotive fluids, toxic substances and fecal matter on the land and reduce their presence in stormwater reaching the receiving waters.

3.3.1 Public Education. Public education can be used to explain to the general public how improper disposal of wastes can degrade stormwater quality, and how proper disposal can help to protect the quality of receiving waters. Public education is also a means to show how water quality personally affects each of us (e.g., higher treatment costs, health, etc.) Several categories of waste materials were identified where public education can be effective in reducing the amounts of pollutants entering municipal stormwater runoff. Each of these are discussed below.

3.3.1.1 Household Waste. Household waste includes materials discarded on the land surface or into the stormwater system from residential and commercial areas. Wastes from commercial businesses are generated by stores, restaurants, hotels, offices, and other non-manufacturing activities. Commercial waste is considered to be similar to residential waste and is addressed collectively under this definition. Toxic wastes from residential and commercial areas are considered a subcategory of household waste.

Refuse is solid waste that is contained, whereas litter is uncontained. Refuse is controlled through existing programs of solid waste collection and disposal. The goal of household waste disposal is to contain all refuse, reduce litter, and encourage proper waste disposal through public education.

Examples are:

<u>3.3.1.2 Litter</u>. Most litter is biodegradable and can create an oxygen demand in water as it decomposes. Examples of litter are paper products, used diapers, etc. Research by Keep America Beautiful, Inc. (1990) has shown that people litter where litter has already accumulated. Also according to Keep America Beautiful, Inc. (1987), pedestrians and motorists account for less than 25% of litter, the other sources being household waste, commercial and industrial waste, haulage vehicles, loading docks, and construction sites. Reduction of litter through proper disposal can reduce its accumulation on the urban landscape and its eventual entry into the stormwater system.

<u>3.3.1.3 Pet Waste</u>. Pet waste deposited on impervious surfaces can be transported by the stormwater drainage system to receiving waters. Fecal matter potentially contains pathogenic viruses and bacteria, and also creates an oxygen demand in water.

The majority of improperly disposed pet waste occurs in public areas, such as streets and parks. Pet waste ordinances are common in municipalities, however, these are difficult to enforce especially with limited municipal resources. Public education can help bring this problem to the public's attention, and can thereby reduce deposition of pet waste on urban surfaces.

<u>3.3.1.4 Yard Waste</u>. Yard waste is also a category of household waste. Examples of yard waste include leaves and grass clippings. It is distinguished from other categories of household waste in that it can be disposed of by composting. Composting is the aerobic decomposition of plant and other organic materials.

Yard waste accounts for 18% of the municipal waste stream on a weight basis (Keep America Beautiful, 1987). Fallen tree leaves, grass clippings and garden debris can become water pollutants when they are disposed of in alleys, driveways, parking lots, streets, street gutters, irrigation ditches, and drainage channels. Public education efforts on the benefits of composting and on proper disposal of yard waste can help to reduce the volume of yard waste entering the stormwater system and receiving waters.

<u>3.3.1.5 Used Oil and Automotive Fluids</u>. Used oil and automotive fluids including antifreeze, brake fluid, transmission fluid, grease, other lubricants, and petroleum-based cleaning solvents are wastes generated during automobile maintenance by residential households and commercial businesses. These can enter the storm drainage system if poured directly into storm inlets or from residual on concrete or asphalt exposed to precipitation.

Improper disposal of used oil and automotive fluids cause receiving waters to become contaminated with hydrocarbons and residual metals that can be toxic to stream organisms. Used oil and other petroleum products can be recycled. A number of different recycling centers presently exist in the metropolitan area. Public education on the location of these centers, the benefits of recycling, prevention of fluid leaks, and the importance of proper disposal for improving stormwater quality, can reduce the amounts of oil and used automotive fluids reaching receiving waters.

3.3.1.6 Toxic Wastes. Toxic wastes are generated by residential households and commercial businesses. These primarily consist of certain types of used and unused consumer products. Included among these are paint, solvents, putties, cleaners, waxes, polishes, oil products, aerosols, acids, caustics, pesticides, herbicides, and certain medicines or cosmetics. These products and their containers should always be disposed of properly. Some of these unused toxic materials can also be recycled.

Improper disposal of toxic substances cause stormwater to become contaminated by these wastes. This occurs when toxic substances are dumped into street gutters or storm inlets. This also happens when stormwater comes in contact with toxic substances or where they have been improperly disposed on land surfaces.

There is no need for improper disposal of toxic substances since, according to legislation passed by the U.S Congress (1976), small amounts of toxic materials can legally be disposed of in landfills. Educational efforts to heighten public awareness of the environmental damage due to improper disposal, and to encourage proper disposal and recycling can reduce the amountsof these pollutants entering stormwater, provided the public as a whole actively participates.

3.3.1.7 Cost Considerations. Collection and disposal of household wastes can be expensive. Where hazardous/toxic wastes are involved there is a need for operators to be adequately trained, analysis to be done of unknown materials, safe transport and containers, and extensive recordkeeping.

There are also regulatory requirements on how wastes can be disposed. Disposal or hazardous wastes must follow the requirements outlined in the Resource Conservation and Recovery Act and associated regulations.

3.4 Implementation

The implementation of a public education and information program can include one or more of the following general approaches:

- Development, publication and distribution of brochures
- Utility bill inserts, flyers and handbills
- Newspaper articles and/or advertisements
- Development and distribution of educational videos

- Public workshops, including field demonstrations
- Developing school curricula, and
- Developing and installing posters and signs

The following are specific examples that may be considered for use:

- Signs, including graphics, on dumpsters and other locations encouraging proper waste disposal
- Brochures and utility bill inserts on separation of wastes and recycling
- Advertising the locations of existing toxic disposal sites and waste recycling centers
- Advertising the locations of existing automobile fluids and used oil disposal sites
- Establishing and maintaining household toxics disposal sites
- Annual or curbside collection of household toxics
- Signs in parks and along streets on pet waste control and ordinances
- Pet waste disposal bags in public parks
- Voluntary neighborhood clean-up efforts
- Waste containers in problem litter areas
- Requiring waste-haulage truck covers
- Seasonal collection programs for tree branches and leaves
- On-going collection program, or disposal sites, for grass clippings and other yard waste
- Distribution programs to recycle compost as mulch
- Advertisements or notices of private locations accepting yard waste for composting
- Information on backyard or neighborhood composting and proper disposal of yard waste

All of these examples are not likely to be used by a municipality at any given time. Local conditions, public attitudes, and fiscal constraints will determine what combination is most appropriate and effective for use in each municipality.

3.5 Advantages and Disadvantages

It is unknown at present the extent of runoff contamination due to improper disposal of various household waste materials. The amount of water quality improvement that can result from public education on proper disposal methods and opportunities for recycling have yet to be quantified. Intuitively, there should be some benefit if the amount of these wastes is reduced.

3.5.1 Advantages. Major advantages of public education on proper disposal of household waste and toxics can include:

- Reduction in the quantities of solids, metals, floatable materials, oxygen-consuming materials, nutrients, fecal matter, oil and toxic substances transported by stormwater to receiving waters
- Improved aesthetics of parks and public areas.

R0017837

- Appropriate disposal of more wastes at landfills.
- Reduced littering on the urban landscape.
- Increased recycling and resource recovery.
- Heightened awareness and public understanding of how each person can pollute receiving waters and how each person can help to prevent their pollution.

3.5.2 Disadvantages. Some disadvantages associated with the use of this BMP include:

- Its success and effectiveness depends on voluntary efforts.
- Places an increased demand on recycling facilities and products.
- Extremely difficult to quantify pollutant load reduction.
- Requires an on-going effort to continuously provide public education through distribution of educational materials and a means to respond to questions the public may have relative to disposal.
- May require ordinances and enforcement actions in some cases to address the more difficult and persistent activities generating pollutants.

4.0 USE OF PESTICIDES, HERBICIDES AND FERTILIZER

4.1 Primary Users

This BMP applies to commercial applicators and municipalities and industries who apply their own pesticides, herbicides and fertilizers.

4.2 Description

Pesticides, herbicides, and fertilizers are used to maintain landscaping in residential, commercial and industrial areas. These substances are usually toxic and can contaminate surface runoff if not properly used. This nonstructural BMP consists of the development and dissemination of information to the public that encourages proper use and application of pesticides, herbicides, and fertilizers.

4.3 Application

Pesticides, herbicides, and fertilizers are chemicals used in landscape maintenance. Pesticides are used for insect control, herbicides are used for weed control, and fertilizers are used to promote growth of grasses, flowers, trees, shrubs, and other vegetation. While pesticides and herbicides are toxic to aquatic life at low concentrations, fertilizers are usually only toxic at high concentrations. Fertilizers, however, are more commonly a problem because of their nutrient-enrichment effect on receiving waterbodies. An oversupply of phosphorus and nitrogen will promote alga growth that can lead to a depletion of dissolved oxygen needed for fish and other aquatic organisms. These chemicals are applied on urban landscape areas and, when improperly applied or used, can be transported to receiving waters in surface runoff.

The rate and timing of application of pesticides, herbicides, and fertilizer are important to minimize transport by surface runoff, as well as to optimize their intended purpose in landscape maintenance. Overapplication and overspraying of pesticides, herbicides, and fertilizers onto impervious areas, such as streets and sidewalks, need to be avoided as well as excessive or too frequent use of these chemicals. Use of these chemicals in accordance with manufacturer's recommendations can prevent most of the surface water contamination being attributed to their use.

Public education can be an effective method of ensuring proper use of these chemicals. Raising the general level of understanding of how individual action in the use of these chemicals can contaminate surface runoff and the receiving waterbodies can make each person aware of the problem. Whether this awareness will translate into an improved use of these products will then depend on individual attitudes. Thus, dissemination of information to the public on the impacts of improper use and how to use landscape maintenance chemicals is the basis for this nonstructural BMP.

4.4 Implementation

The development of an ongoing educational program is the basis of this nonstructural BMP. The audience to be targeted is residential homeowners and small businesses.

As a first step, technical information on pesticides, herbicides and fertilizers and their proper use must be developed. The following sources can be consulted:

- Existing state regulations on pesticide application, certification, and weed control,
- Federal legislation, regulations and technical reports,
- Chemical manufacturer's technical manuals, product labels and use directions, storage and proper disposal guidelines, and material safety data sheets,
- Sprayer manufacturer's calibration guides,
- Sorbent manufacturer's spill management guides,
- University and County Agricultural Extension Service horticultural guides,
- Rocky Mountain Poison Center safety guidelines, and
- Other studies and available information.

One method being used by some is Integrated Pest Management (IPM). This is best applicable to commercial, agricultural and other large scale users of pesticides. IPM is a decision-making process for pest management whose goal is an intelligent, environmentally sound control of pests. It uses biological, chemical, and genetic information to determine the best type of control, the timing and extent of chemical applications and whether non-chemical means can attain an acceptable level of pest control.

IPM is a preventive measure aimed at knowing the exact pest(s) being targeted for control, the locations and times when pests will pose problems, the level of pest-induced damage that can be tolerated without taking action, the most vulnerable life stage, and control actions that are least damaging to the environment. The major components of IPM are as follows: monitoring and inventory of pest populations, determination of pest-induced injury and action levels, identification of priority pest problems, selection and timing of least toxic management tools, site-specific treatment with minimized chemical use, and evaluation and adjustment of pesticide applications. Monitoring of pest populations is a key to successful IPM implementation. Pest problems are universally easier to control if the problem can be discovered early. With IPM pesticides are used only as a last resort; maximization of natural controls, including biological controls and removal of pests by hand, is a guiding rule.

Methods available for public education on the use of pesticides, herbicides and fertilizers are very similar to those described in Section 4.4 of this chapter and the reader is referred to that section for details.

Methods available for public education on the use of pesticides, herbicides and fertilizers are very similar to those described in Section 4.4 of this chapter and the reader is referred to that section for details.

4.5 Advantages and Disadvantages

Although it is possible to quantify the amounts of pesticides, herbicides, and fertilizers used by residential, commercial, and industrial areas within a geographic location, it is not known what part of that quantity is improperly used. There should be some amount of overall benefit, however, if educational efforts result in a general increase in the number of people properly using and applying these chemicals in urban areas.

4.5.1 Advantages. Major advantages of the use of this BMP include:

- Can reduce the source of pesticides, herbicides and fertilizers eventually entering receiving waters.
- Can help reduce the level of phosphorus and nitrogen in receiving waters, thereby positively affecting the problem of nuisance growth of algae, and eutrophication of small lakes and tributary streams.
- Encourage the use of less toxic or substitute methods of pest and weed control that, if followed, further reduce the supply of pesticides and herbicides for contact with surface runoff.
- Heighten the awareness and public understanding of how individual actions can add to or reduce stormwater pollution.

4.5.2 Disadvantages. Some disadvantages associated with the use of this BMP include:

- Difficult to reach and influence all commercial and residential users of these chemicals.
- Difficult to present technical information in simplified form to all users.
- Extremely difficult to quantify extent of how implementation of this BMP translates into water quality effects in receiving waters.
- Requires on-going educational activities and the distribution of information.

R0017841

5.0 ILLICIT DISCHARGE CONTROLS

5.1 Primary Users

This BMP applies primarily to municipalities. It could also be applicable to large commercial enterprises or industry, such as office parks, which have multiple activities occurring at its site.

5.2 Description

Activities that reduce the entry of pollutants into the municipal storm sewer system from physical connections to the storm drain system of sanitary sewers and floor drains, or from illicit discharges, accomplished through regulation, inspection, testing, and education can enhance the quality of receiving waters. These include controls on illegal dumping of toxic substances and petroleum products, responses to contain accidental spills, measures to locate and disconnect illicit connections of sanitary sewers to storm sewers, and measures to prevent additional illicit sanitary sewer connections in the future. To their credit, many municipalities already have programs in place to address all of these concerns. Measures that limit these types of illicit discharges to the storm drainage system are considered nonstructural best management practices (BMPs).

5.2.1 Illegal Dumping. Illegal dumping occurs whenever toxic substances or other pollutants are dumped into or disposed of directly into storm inlets, other storm drainage facilities, or onto the urban landscape. Prohibitions against such activity have been enacted by many municipalities, however, enforcement is difficult because of the often clandestine nature of illegal dumping and the large areas over which such activities can take place.

Nonstructural BMPs that can be considered for implementation by local municipalities are based on efforts to increase surveillance of illegal dumping. These include developing educational materials for the public about these illegal practices and the hazards they create to the public health and the environment, encouraging increased public reporting, possibly establishing a "hotline" telephone number for citizens to call to report dumping incidents, or making illegal dumping a part of the 911 reporting network. Strong enforcement action against violations, accompanied by publicity, could discourage such activities by others.

5.2.2 Accidental Spill Response. The storage, transport and disposal of hazardous and toxic substances is a regulated activity under state and federal laws. Response procedures for management of accidental spills of pollutants are practiced presently by many municipalities. As a result, many local police, fire, or other departments are equipped to respond to such spills. Nevertheless, most spills have the potential to contaminate receiving waters via transport by the storm sewer system.

Additional measures that might be considered by local governments include mapping of storm sewer systems and detention ponds to identify the locations of stormwater inlets for drainage system. Such maps can then be used by the emergency response crews to help identify which inlets, areas, or sewers to protect or block off in the event of a spill. Once a spill occurs, it should be monitored to determine when the area of the spill has been adequately cleaned up. All of these measures, as well as on-going practices, need periodic updating and refresher training to be current. Training, updating of procedures, field exercises and proper equipment are all part of a spill response program.

5.2.3 Illicit Connections. Illicit connections of sanitary sewers to the stormwater runoff system in new developments can be prevented by an aggressive and competent inspection program by municipal or utility personnel. Illicit connections can exist, however, in older developments. Some municipalities have taken steps in the past to identify these and have disconnected those that were found. A well-organized program to find illicit sanitary connections also requires accurate mapping of the sanitary and storm sewer systems and a thorough understanding of these systems. Program elements may include:

- Ensure that existing building and plumbing codes prohibit physical connections of nonstormwater discharges to the storm drain system.
- Require visual inspection of new developments or redevelopments during the construction phase.
- Develop documentation and recordkeeping protocols to track inspections and catalog the storm drain system.
- Use techniques such as zinc chloride smoke testing, fluorometric dye testing, and television camera inspection to verify physical connections.

To isolate likely sources, personnel first need to look for visual signs of illicit connections at storm sewer outfalls, relying on sight and smell. If the initial screening indicates a possible illicit connection, random dry-weather sampling and testing for indicator constituents can help to further identify if there may be illicit connections in the system. These then need to be investigated further with a well-planned "seek and destroy" effort that is designed to address the specific nature of the storm drainage and wastewater systems. Occasional random dry-weather screening can also be conducted, especially in areas where the greatest potential exists for illicit connections, however, these are of limited usefulness for detecting illicit discharges. These tests may identify illicit connections that discharge occasionally and in a random manner, a typical scenario for individual wastewater discharges. Excavation of sewer lines at the point of connection, and reconnection of the sanitary sewer line to the appropriate system is the final step to correct the problem.

5.3 Implementation

Public awareness is the key to implementation of this BMP. Awareness that discharges enter the stormwater system, that separate systems exist for stormwater and sanitary wastewater, and that illicit discharges to the stormwater system are not treated may be sufficient to limit these discharges in the future.

The following actions, if not already in place, can be considered for use by local jurisdictions:

- Enactment of ordinances prohibiting illegal dumping and illicit connections.
- Developing a public education program advising the residents of potential problems that can result from illegal dumping, illicit connections and accidental spills. Educate the public about an existing or new anti-dumping ordinance.
- Install a "hotline" telephone number, or make 911 a part of this program to handle calls from citizens reporting illegal dumping or accidental spills.
- Review and update training procedures, equipment and material inventories, and administrative procedures for spill containment and management.
- Conduct random field screening of stormwater outfalls to find illicit wastewater connections to storm drainage systems. Illicit connections that are discovered should be plugged or tapped into the sanitary sewer or other acceptable or legal disposal systems. This may include obtaining an NPDES permit.
- Train field inspectors and develop field inspection procedures that prevent new illicit connections of sanitary sewer lines to storm sewers.
- Have a program in place to review and approve any proposed connection into a storm sewer.

5.4 Advantages and Disadvantages

The question of whether actions to reduce illegal dumping, contamination from accidental spills and illicit discharges have advantages or disadvantages is immaterial. This is evidenced by the fact that many municipalities have one or more programs currently in place. Pollutants entering the storm sewer systems by illegal dumping, spills, and illicit connections can contribute to public health problems that deserve on-going attention. Thus, mitigation efforts can provide benefits to water quality in the receiving system while protecting public health and welfare. However, there are costs associated with these activities. Possible limitations for this BMP include the fact that proper connections can be altered after initial connection, the cost of equipment for monitoring and inspection can be expensive, and improper physical connections to the storm drain system can occur in many different ways such as overflow of cross connection and floor drains from businesses such as autoshops and restaurants.

6.0 GOOD HOUSEKEEPING

6.1 Primary Users

These BMPs involve three key audiences: municipal employees, the general public, and small businesses.

6.2 Descriptions

Good housekeeping requires keeping potential areas where pollutants exist clean and orderly.

6.3 Application

Good housekeeping practices are designed to maintain a clean and orderly work environment. The most effective first steps towards preventing pollution in stormwater from work sites simply involves using good common sense to improve the facility's basic housekeeping methods. Poor housekeeping practices result in more waste being generated than necessary and an increased potential for stormwater contamination.

A clean and orderly work site reduces the possibility of accidental spills caused by mishandling of chemicals and equipment and should reduce safety hazards to personnel. A well-maintained material and chemical storage area will reduce the possibility of stormwater mixing with pollutants.

Some simple procedures a facility can use to promote good housekeeping are: improved operation and maintenance of machinery and processes, material storage practices, material inventory controls, routine and regular clean-up schedules, maintaining well organized work areas, signage, and educational programs for employees and the general public about all of these practices.

6.4 Implementation

These BMPs are applicable to the following areas: operation and maintenance, material storage, material inventory, and training and participation.

6.4.1 Operation and Maintenance. To ensure that equipment and work related processes are working well the following practices can be implemented:

- Maintain dry and clean floors and ground surfaces by using brooms, shovels, vacuum cleaners or cleaning machines rather than wet clean-up methods.
- Regularly pickup and dispose of garbage and waste material.
- Make sure all equipment and related processes are working properly and preventative maintenance is kept up with on both.

- Routinely inspect equipment and processes for leaks or conditions that could lead to discharges of chemicals or contact of stormwater with raw materials, intermediate materials, waste materials, or products used on site.
- Ensure all spill clean up procedures are understood by employees. Training of employees on proper clean up procedures should be implemented.
- Designate separate areas of the site for auto parking, vehicle refueling and routine maintenance.
- Clean up leaks, drips and other spills immediately.
- Cover and maintain dumpsters and waste receptacles.

6.4.2 Material Storage Practices. Improperly storing of material on site can lead to the release of materials and chemicals that can cause stormwater runoff pollution. Proper storage techniques include the following:

- Provide adequate aisle space to facilitate material transfer and ease of access for inspection.
- Store containers, drums, and bags away from direct traffic routes to prevent accidental spills.
- Stack containers according to manufacturer's instructions to avoid damaging the containers from improper weight distribution.
- Store containers on pallets or similar devices to prevent corrosion of containers that results from containers coming in contact with moisture on the ground.
- Store toxic or hazardous liquids within curbed areas or secondary containers.
- Assign responsibility of hazardous material inventory to a limited number of people that are trained to handle such materials.

6.4.3 Material Inventory Practices. An up-to-date inventory kept on all materials (both hazardous and non-hazardous) present on site will help keep material costs down caused by overstocking, track how materials are stored and handled onsite, and identify which materials and activities pose the most risk to the environment. The following description provides the basic steps in completing a material inventory:

- Identify all chemical substances present at work site. Perform a walk through of the site, review purchase orders, list all chemical substances used and obtain Material Safety Data Sheets (MSDS) for all chemicals.

- Label all containers. Labels should provide name and type of substance, stock number, expiration date, health hazards, handling suggestions, and first aid information. This information can also be found on a MSDS.
- Clearly mark on the hazardous materials inventory which chemicals require special handling, storage, use and disposal considerations.

Institute a shelf-life program to improve material tracking and inventory that can reduce the amount of materials that are overstocked and ensure disposal of out-dated materials. Careful tracking of materials ordered can result in more efficient materials use. Decisions on the amounts of hazardous materials that are stored on site should include an evaluation of any emergency control systems that are in place. All storage areas should be designed to contain any spills.

6.4.4 Training and Participation. Frequent and proper training in good housekeeping techniques reduces the possibility of chemicals or equipment that will be mishandled. Reducing waste generation is another important pollution prevention technique. The following are ways to get people involved in good housekeeping practices:

- Provide information sessions on good housekeeping practices in training programs.
- Discuss good housekeeping at meetings.
- Publicize pollution prevention concepts through posters or signs.
- Post bulletin boards with updated good housekeeping procedures, tips and reminders.

6.5 Advantages and Disadvantages

An advantage of Good Housekeeping BMPs is that they are inexpensive to implement. The primary cost is staff time. Benefits of a clean and orderly site can go beyond stormwater quality improvement. This could include a more accurate inventory of materials on site or reduction in worker injuries, for example, slips on wet surfaces.

A disadvantage of this BMP is that, like many nonstructural BMPs, employee awareness and education is key. Continued awareness training is necessary to ensure that positive behaviors are maintained.

7.0 PREVENTATIVE MAINTENANCE

7.1 Primary Users

This BMP is applicable to industrial and commercial sites.

7.2 Description

Preventative maintenance involves the regular inspection and testing of plant equipment and operational systems. These inspections should uncover conditions such as cracks or slow leaks which could cause breakdowns or failures that result in discharges of chemicals to surface waters either by direct overland flow or through storm drainage systems. The purpose of the preventative maintenance program should be to prevent breakdowns and failures by adjustment, repair, or replacement of equipment before a major breakdown or failure can occur.

Preventative maintenance has been practiced predominantly where excessive down time is extremely costly. As a stormwater best management practice (BMP), preventative maintenance should be used selectively to eliminate or minimize the spill of contaminants to receiving waters. For many facilities, this would simply be an extension of the current plant preventative maintenance program to include items to prevent stormwater runoff contamination.

For sites that have storm drainage facilities, proper maintenance is necessary to ensure that the drainage facilities serve their intended function. Without adequate maintenance, sediment and other debris can quickly clog facilities and render them useless. Typically, a preventative maintenance program should include inspections of conveyance channels, storm sewers, inlets, catch basins, stormwater detention areas, and other water quality treatment systems.

Most plans already have preventative maintenance programs that provide some degree of environmental protection. This program could be expanded to include stormwater considerations, especially the upkeep and maintenance of storage tanks, valves, pumps, pipes, and other process-water or chemical feed devices.

7.3 Application

Preventative maintenance procedures and activities are applicable to almost every facility. Preventative maintenance should be part of a general good housekeeping program designed to maintain a clean and orderly work environment. Often the most effective first step towards preventing stormwater pollution from sites simply involves good common sense to improve the facility preventative maintenance and general good housekeeping methods.

7.4 Implementation

Elements of good preventative maintenance program should include:

- Identification of equipment or systems which may malfunction and cause spills, leaks, or other situations that could lead to contamination of stormwater runoff. Typical equipment to inspect include pipes, pumps, storage tanks and bins, pressure vessels, pressure release valves, process and material handling equipment, and stormwater management devices.
- Once equipment and areas to be inspected have been identified at the facility, establish schedules and procedures for routine inspections.
- Periodic testing of plant equipment for structural soundness is a key element in a preventative maintenance program.
- Promptly repair or replace defective equipment found during inspection and testing.
- Keep spare parts for equipment that needs frequent repair.
- Replace parts that are severely worn prior to failure.
- It is important to include a record keeping system for scheduling tests and documenting inspections in the preventative maintenance program.
- Record test results and follow-up with corrective action taken. Make sure records are complete and detailed. These records should be kept with other visual inspection records.

The key to properly tracking a preventative maintenance program is through the continual updating of maintenance records. Records should be updated immediately after preventative maintenance, or when any repair has been performed on any item in the plant. An annual review of these records should be conducted to evaluate the overall effectiveness of the preventative maintenance program. Refinements to the preventative maintenance procedures and tasking should be implemented as necessary.

Maintenance activities associated with vehicle and equipment include the following:

- Maintain clean equipment, no excessive amounts of oil and grease buildup.
- Use drip pans or absorbents where repairs are performed outside and in potential problem areas.
- Use appropriate facilities to perform repairs involving exchange of fluids and lubricants and lot painting.
- Drain and crush oil filters before recycling or disposal.
- Clean any catch basins that receive runoff from a maintenance area.

- Do not hose down work areas or use concrete cleaning products; use mops or dry sweeping compound. Store mechanical parts and equipment under cover.
- Drain all fluids and remove batteries from salvage vehicles and equipment.
- Recycle or dispose of the following in the correct manner: greases, oils, antifreeze, brake fluid, all cleaning solutions, hydraulic fluid, batteries, transmission fluid, worn parts, filters and rags.
- Use recycled products and substitute materials with less hazardous properties where feasible.
- Provide employee awareness training.
- Store solvents, greases, oils, hydraulic fluids, paints, thinners and hazardous materials indoors.
- Store used oil for recycling in self-contained labeled tanks.
- Keep spill response information and spill cleanup materials on the site and readily available.
- Located used oil tanks and drums away from the nearest inlet to the storm drainage system, flowing streams and preferably indoors if possible.

Maintenance activities associated with building and grounds include:

- Chemical applicators should be required to adhere to all regulations regarding handling, storage and application of herbicides, insecticides, fungicides and rodenticides.
- All chemicals should be handled and stored in compliance with their Material Safety Data Sheets (MSDS).
- All chemicals should have their associated MSDS information sheets logged on the inevntory maintained by the site administrator responsible for stormwater management.
- All materials should be stored as described in the Outdoor Materials Storage BMPs.
- Where possible, leave native vegetation undisturbed, and plant native vegetation in disturbed soil areas, to reduce irrigation, fertilizer and pesticide needs.
- Sweeping of paved surfaces.
- Cleaning of stormwater drainage systems should occur at appropriate intervals.
- Proper disposal of wash water, sweepings and sediments should occur.

7.5 Advantages and Disadvantages

There are several advantages associated with preventative maintenance. These include:

- Reduction in the amount of down time due to unanticipated equipment breakage.
- Planned equipment down time.

Disadvantages associated.with preventative maintenance include:

- Additional costs.
- Availability of trained preventative maintenance staff.

8.0 SPILL PREVENTION AND RESPONSE

8.1 Primary Users

Owners and operators of commercial and industrial facilities that store, process or refine liquid products.

8.2 Description

This BMP includes measures to be taken to ensure that spills do not result in water quality impacts.

Spills and leaks together are one of the largest sources of stormwater pollutants, and in most cases are avoidable.

8.3 Application

The primary objective of the following BMPs is the prevention and reduction of discharges of pollutants to stormwater as a result of spilled products and materials.

8.4 Implementation

8.4.1 Spill Prevention Measures. For industrial facilities and automotive related industries the following preventative strategies are:

- Identify all equipment that may be exposed to stormwater, pollutants that may be generated, and possible sources of leaks or discharges.
- Perform regular maintenance of each piece of equipment to check for: proper operation, leaks, malfunctions, and evidence of leaks or discharge (stains). Develop a procedure for spill reporting, clean up, and repair.
- Drain or replace motor oil or other automotive fluids in an area away from streams or storm or sanitary sewer inlets. Collect spent fluids and recycle or dispose of properly.
- In fueling areas, clean up spills with dry clean up methods (absorbents), and use damp cloths on gas pumps and damp mops on floors instead of a hose.

An important part of spill prevention is employee training. Make sure employees are trained in spill prevention practices and adhere to them.

The best way to prevent pollutants from entering the storm drains is to prevent stormwater from contacting equipment or surfaces that may have oil, grease, or other pollutants. Some good activities to help prevent negative impacts on stormwater quality include:

- Dispose of stormwater that has collected in containment areas properly (may need permit if contaminated).

- Adopt effective housekeeping practices.
- Ensure adequate security.

8.4.2 Identification of Spill Areas. It is important to identify potential spill areas and their drainage points to determine preventative measures and spill response actions. Areas and activities that are most vulnerable to spills include transportation facilities where vehicle spills could be a problem:

- Loading and Unloading areas
- Storage Areas
- Process Activities
- Dust or Particulate Generating Processes
- Waste Disposal Activities

In addition to these areas, evaluate spill potential in other areas (access roads, parking lots, power generating facilities, etc.). It is also important to estimate the possible spill volume and drainage paths.

8.4.3 Material Handling Procedures. For industrial facilities recommended outdoor materials handling procedures include:

- Keep bulk solid materials (including raw materials, sand, gravel, topsoil, compost, concrete, packing materials, metal products) covered and protected from stormwater.
- When possible, store materials on a paved surface.
- Hazardous materials must be stored according to federal, state, and local HazMat requirements.
- Leaks and spills from liquid containers must be contained so it is not exposed to stormwater. This includes placement on an impermeable surface, within a curb wall, and/or under a cover.
- Try to recycle, reuse or reclaim process materials to reduce the volume brought into the facility. Adopt a materials flow/plant layout (i.e. do not store bags that are easily punctured in high traffic areas). Add a waste-capture circuit (e.g., collection pans for lubricating fluids).
- Adopt procedures that reduce the chance of spills or leaks during filling or transfer of materials.
- Substitute less or non-toxic materials for toxic materials.

8.4.4 Spill Response Procedures and Equipment. For industrial facilities and automotive-related industries the recommended immediate response actions are:

- Wipe up small spills with a shop rag, store shop rags in covered rag container, and dispose of properly (or take to professional cleaning service and inform them of the materials on the rag).
- Contain medium-sized spills with absorbents (kitty litter, sawdust, etc.) and use inflatable berms or absorbent "snakes" as temporary booms for the spill. Store and dispose of absorbents properly. Wet/dry vacuums may also be used, but not for volatile fluids.
- For large spills, first contain the spill and plug storm drain inlets where the liquid may migrate off-site, then clean up the spill.

8.4.5 Spill Plan Development. A spill prevention and control plan may need to be developed and implemented for certain products that are stored, processed and refined. A Spill Prevention Plan identifies areas where spills can occur onsite, specifies materials handling procedures, storage requirements, and identifies spill cleanup procedures. The purpose of this plan is to establish standard operating procedures, and the necessary employee training to minimize the likelihood of accidental releases of pollutants that can contaminate stormwater runoff. Spill prevention is prudent from both an economic as well as environmental standpoint because spills increase operating costs and lower productivity.

Stormwater contamination assessment, flow diversion, record keeping, internal reporting, employee training, and preventative maintenance are associated BMPs that should be incorporated into a comprehensive Spill Prevention Plan.

A Spill Prevention Plan is applicable to facilities that transport, transfer, and store hazardous materials, petroleum products, and fertilizers that can contaminate stormwater runoff. An important factor of an effective spill prevention plan is quick notification of the appropriate emergency response teams. In some plants, each area or process may have a separate team leader and team experts.

Emergency spill cleanup plans should include the following information:

- A description of the facility including the nature of the facility activity, and general types and quantities of chemicals stored at the facility.
- A site plan showing the location of storage areas of chemicals, the location of storm drains, site drainage patterns, fire-fighting equipment and water source locations, and the location and description of any devices used to contain spills such as positive control valves.
- Notification procedures to be implemented in the event of a spill such as phone numbers of key personnel and appropriate regulatory agencies.

- Instructions regarding cleanup procedures.
- Designated personnel with overall spill response cleanup responsibility.

A summary of the plan should be written and posted at appropriate points in the building (i.e., lunch rooms, cafeteria, and areas with a high spill potential), identifying the spill cleanup coordinators, location of cleanup kits, and phone numbers of regulatory agencies to be contacted in the event of a spill.

Cleanup of spills should begin immediately. No emulsifier or dispersant should be used.

In fueling areas, absorbent should be packaged in small bags for easy use and small drums should be available for storage of absorbent and/or used absorbent. Absorbent materials shall not be washed down the floor drain or into the storm sewer.

Emergency spill containment and cleanup kits should be located at the facility site. The contents of the kit should be appropriate to the type and quantities of chemicals or goods stored at the facility.

The following procedures should be followed when implementing an emergency spill cleanup plan:

- Key personnel should receive formal training in plan execution with additional training to the people who are likely to be the first on the site. All employees should have a basic knowledge of spill control procedures.
- A plan summary should be posted at appropriate site locations. The summary should include the identification of the spill cleanup coordinators, location of cleanup equipment, and phone numbers of site personnel and regulatory agencies to be contacted in the event of a spill.
- Perform the following notifications in the event of a spill:
  - Fire Department
  - Colorado Department of Public Health and Environment
  - State Office of Emergency Services
  - National Response Center (only if spill exceeds the reportable quantity)
  - Designated Stormwater Coordinator
- Containment and cleanup of any spills should begin immediately.
- Absorbents should be readily used in fueling areas.
- An inventory of cleanup materials should be maintained onsite and strategically deployed based on the type and quantities of chemicals present.

8.5 Advantages and Disadvantages

Table NS-1 lists the advantages and disadvantages of different BMPs for spills.

Limitations

Spill prevention planning can be limited by the following:

- Lack of employee motivation to implement plan.
- Lack of commitment from senior management.
- Key individuals identified in the Spill Prevention Plan may not be properly trained in the areas of spill prevention, response, and cleanup.

TABLE NS-1
Advantages and Disadvantages of BMPs for Spill Prevention and Response BMPs

Best Management Practice	Advantages	Disadvantages
Drip pans – pans used to contain small volumes of leaks	Inexpensive; simple installation and operation; possible reuse/recycle of material; empty/ discarded containers can be used as drip pans	Small volumes; inspected and cleaned frequently; must be secured during poor weather conditions, personnel must be trained in proper disposal methods
Covering –enclosure of outdoor materials, equipment, containers, or processes	Simple and effective; usually inexpensive	Frequent inspection, possible health/ safety problems if built over certain activities, large structures can be expensive
Vehicle positioning – locating trucks or rail cars to prevent spills during transfer of materials	Inexpensive, easy, effective	May require redesign of loading and unloading areas, requires signage to designated areas
Loading/Unloading by Air Pressure or Vacuum – for transfer of dry chemicals or solids	Quick and simple; economical if materials can be recovered; minimize exposure of pollutants to stormwater	Costly to install and maintain; may be inappropriate for denser materials, site-specific design; dust collectors may need permit under Clean Air Act
Sweeping – with brooms to remove small quantities of dry chemicals/ solids exposed to precipitation	Inexpensive, no special training; recycling opportunities	Labor-intensive; limited to small releases of dry materials, requires disposal to solid waste container
Shoveling – for removal of large quantities of dry materials, wet solids and sludge	Inexpensive; recycling opportunities, remediate larger releases; wet and dry releases	Labor-intensive; not appropriate for large spills, requires backfill of excavated areas to maintain grade
Excavation – by plow or backhoe for large releases of dry material and contaminated areas	Cost effective for cleaning up dry materials release; common and simple	Less precise, less recycling and reuse opportunities, may require imported material for backfill

R0017857

TABLE NS-1
Advantages and Disadvantages of BMPs for Spill Prevention and Response BMPs (continued)

Best Management Practice	Advantages	Disadvantages
Dust Control (Industrial) – water spraying, negative pressure systems, collector systems, filter systems, street sweeping	May reduce respiratory problems in employees around the site; may cause less loss of material and save money; efficient collection of larger dust particles	More expensive than manual systems; difficult to maintain by plant personnel; labor and equipment intensive; street sweepers may not be effective for all pollutants
Signs and Labels	Inexpensive and easily used	Must be updated/maintained so they are legible, subject to vandalism and loss
Security – to prevent accidental or intentional release of materials	Preventative safeguard; easier detection of vandals, thieves, spills, leaks, releases; prevents spills with better lighting, no unauthorized access to facility	May not be feasible for smaller facilities; may be costly; may increase energy costs due to increased lighting; dispersed locations require individuals enclosures, requires maintenance
Area Control Measures – good housekeeping measures, brushing off clothing before leaving area, etc.	Easy to implement; results in cleaner facility and improved work environment	May be seen as tedious by employees and may not be followed
Preservation of Natural Vegetation	Can handle more stormwater runoff than newly seeded areas; effective immediately; increases filter capacity; enhances aesthetics; provides areas for infiltration; wildlife can remain undisturbed; provides noise buffers; less maintenance than new vegetation	Planning required to preserve and maintain existing vegetation; may not be cost effective with high land costs; may constrict area available for construction activities, may require signage or fencing, subject to disturbance
Temporary seeding – short-term vegetative cover on disturbed areas	Inexpensive and easy to do; establishes plant cover quickly in good conditions; stabilizes soils well; aesthetic; sedimentation controls for other site areas; helps reduce maintenance costs of other controls	Requires soil preparation, may require mulching or reseeding of failed areas, seasonally limited, may require signage or fencing, subject to disturbance

1.0 INTRODUCTION

This section of the *Manual* provides a set of criteria and technical guidance for erosion and sediment control at construction sites. In addition, it describes best management practices (BMPs) for drainageway protection, utility construction, and non-sediment material storage. Also, provided are suggested plan submittal requirements, planning considerations, general exemptions, and variances that cities and counties may wish to follow. The practices contained in this document should be viewed as suggested minimum requirements. A model erosion control ordinance is included in Appendix A. An example erosion and sediment control plan is included in Appendix B. A glossary of terms is also provided in Appendix C.

1.1 General

These criteria were developed to help mitigate the increased soil erosion and subsequent deposition of sediment off-site during the period of construction from start of earth disturbance until final landscaping and stormwater quality measures are effectively in place.

An *Erosion and Sediment Control Plan* must be developed and submitted to the local jurisdiction to obtain a construction or site grading permit. Site planning and drainage planning should, whenever possible, occur concurrently with site grading and erosion control planning. When site grading precedes final development, an erosion and sediment control plan for site grading must be submitted. This plan may have to be modified at the time a final site development plan is prepared. This modified plan must be submitted for review and approval prior to final development.

Implementation and maintenance of erosion control measures are ultimately the responsibility of the property owner. Because site conditions will affect the suitability and effectiveness of erosion control measures, a plan specific to each site is required. In addition, should the approved plan not function as intended, and it is determined by the city or county that additional measures are needed, the owner will have to provide additional measures needed to reduce soil erosion and sediment discharged from the construction site.

Nothing in these criteria limit the right of individual cities and counties to impose additional or more stringent standards.

1.2 Performance Objectives

The objectives for erosion control during construction include the following:

1. Conduct all land disturbing activities in a manner that effectively reduces accelerated soil erosion and reduces sediment movement and deposition off-site.
2. Schedule construction activities to minimize the total amount of soil exposed at any given time to reduce the period of accelerated soil erosion.
3. Establish temporary or permanent cover on areas that have been disturbed as soon as possible after final grading is completed.
4. Design and construct all temporary or permanent facilities for the conveyance of water around, through, or from the disturbed area to limit the flow of water to non-erosive velocities.
5. Remove sediment caused by accelerated soil erosion from surface runoff water before it leaves the site.
6. Stabilize the areas of land disturbance with permanent vegetative cover or stormwater quality control measures.

1.3 Erosion and Sediment Control Plan

An *Erosion and Sediment Control Plan* consisting of a written narrative report and a site plan map must be submitted to the appropriate local government for review and approval. Figures C-1 and C-1A provide standard symbols that can be used on such plans. An example plan is given in Appendix B.

1.3.1 Narrative Report. The narrative report must contain, or refer to, the drainage report and should contain the following:

1. Name, address, and telephone number of the applicant. The name, address, and telephone number of the professional engineer preparing the *Erosion and Sediment Control Plan* should also be included if different from the applicant.
2. Project description - A brief description of the nature and purpose of the land disturbing activity, the total area of the site, the area of disturbance involved, and project location including township, range, section, and quarter-section, or the latitude and longitude, of the approximate center of the project.
3. Existing site conditions - A description of the existing topography, vegetation, and drainage; and a description of any wetlands on the site.

R0017865

4. Adjacent areas - A description of neighboring areas such as streams, lakes, residential areas, roads, etc., which might be affected by the land disturbance.

5. Soils - A brief description of the soils on the site including information on soil type and names, mapping unit, erodibility, permeability, hydrologic soil group, depth, texture, and soil structure. (This information may be obtained from the soil report for the site, or, if available, from soils reports from adjacent sites if acceptable to the local jurisdiction).

6. Areas and Volumes - An estimate of the quantity (in cubic yards) of excavation and fill involved, and the surface area (in acres) of the proposed disturbance.

7. Erosion and sediment control measures - A description of the methods described in this chapter of the *Manual* which will be used to control erosion and sediment on the site.

8. Timing schedule indicating the anticipated starting and completion time periods of the site grading and/or construction sequence, including the installation and removal time periods of erosion and sediment control measures, and the time of exposure of each area prior to the completion of temporary erosion and sediment control measures.

9. Permanent stabilization - A brief description, including specifications, of how the site will be stabilized after construction is completed.

10. Stormwater management considerations - Explain how stormwater runoff from and through the site will be handled during construction. Provide a brief description of the post-construction stormwater quality control measures to be included as a part of the site development.

11. Maintenance - A schedule of regular inspections during construction and repair of erosion and sediment control structures should be described. A description of routine sediment basin maintenance should also be included.

12. The estimated total cost (installation and maintenance) of the required temporary soil erosion and sediment control measures to assist the city or county determine surety or bonding requirements for the proposed plan.

13. Calculations - Any calculations made for the design of such items as sediment basins, diversions, waterways; and calculations for runoff and stormwater detention basin design (if applicable).

14. Other information or data as may be reasonably required by the local jurisdiction.

15. A surety, bond, letter-of-credit, escrow account or other financial arrangement acceptable to the local jurisdiction submitted in an amount sufficient to install and maintain for a period of one year the temporary and permanent erosion and sediment control measures described in the plan.

16. The following note - "This *Erosion and Sediment Control Plan* has been placed in the (insert name of local jurisdiction) file for this project. The plan appears to fulfill the Urban Drainage and Flood Control District's technical criteria and the criteria for erosion control and requirements of (insert name of local jurisdiction). I understand that additional erosion control measures may be needed if unforeseen erosion problems occur or if the submitted plan does not function as intended. The requirements of this plan shall run with the land and be the obligation of the land owner until such time as the plan is properly completed, modified or voided.".

17. Signature page for owner/developer acknowledging the review and acceptance of responsibility, and a statement by the Professional Engineer acknowledging responsibility for the preparation of the *Erosion and Sediment Control Plan*.

1.3.2 Site Plan. The site plan must show:

1. A general location map at a scale of 1-inch to 1000-feet to 1-inch to 8000-feet indicating the general vicinity of the site location.

2. The property lines for the site on which the work will be performed.

3. The *Erosion and Sediment Control Plan* at a scale of 1-inch to 20-feet up to 1-inch to 200-feet. The plan may be placed on the site drainage plan if it can be clearly presented. The plan must include:

    a. Existing topography at one- or two-foot contour intervals. The map should extend a minimum of 100-feet beyond the property line.

    b. Proposed topography at one- or two-foot contour intervals. The map should show elevations, dimensions, location, extent, and the slope of all proposed grading, including building site and driveway grades, if known.

    c. Location of any existing structures or hydrologic features on the site.

    d. Location of all structures or natural features on the land adjacent to the site and within a minimum of 100 feet of the site boundary line. The map must show the location of the street gutter, storm sewer, channel, or other waters receiving storm runoff from the site.

    e. Location of all proposed structures and development on the site, if known.

    f. Limits of clearing and grading - Areas which are to be cleared and graded.

    g. Location of soil stockpiles - Areas designated for topsoil and subsoil storage.

    h. Location of storage areas - Areas designated for equipment, fuel, lubricants, chemical and waste storage.

i. Location of temporary roads designated for use during the construction period.

j. Plans of all drainage features, paved areas, retaining walls, cribbing, planting, temporary or permanent soil erosion control measures, or other features to be constructed in connection with, or as a part of, the proposed work together with a map showing the drainage area of land tributary to the site and estimated 2-year runoff of the area served by all drains. All erosion control measures should be depicted using the standard map symbols given in Figures C-1 and C-1A.

k. Detail drawings - Design drawings of sediment controls, temporary diversions, and any practices used that are not referenced in these criteria.

l. Other information or data as may be reasonably required by the local jurisdiction.

m. The following note: "This *Erosion and Sediment Control Plan* has been placed in the (insert name of local jurisdiction) file for this project and appears to fulfill applicable erosion control criteria. I understand that additional erosion control measures may be required of the owner and his or her agents due to unforeseen erosion problems or if the submitted plan does not function as intended. The requirements of this plan shall run with the land and be the obligation of the land owner until such time as the plan is properly completed, modified or voided".

n. Signature block for owner (or agent) acknowledging the review and acceptance of responsibility, and a signed and stamped statement by the Professional Engineer acknowledging responsibility for the preparation of the *Erosion and Sediment Control Plan*.

1.3.3 Approval of Erosion and Sediment Control Plan. An *Erosion and Sediment Control Plan* must be approved prior to issuance of an Overlot Grading or Site Disturbance Permit by the city or county. The final *Erosion and Sediment Control Plan* must be consistent with a Drainage Report considered acceptable to the approving jurisdiction. Approval of the *Erosion and Sediment Control Plan* does not imply acceptance or approval of Drainage Plans, Utility Plans, Street or Road Plans, Design of Retaining Walls, or any other aspect of site development.

1.3.4 Exemptions and Variances. A provision for exemptions and variances may be provided by a city or county. These are generally processed according to the applicable subdivision regulations and reviewed on a case-by-case basis.

R0017868

1. Exemptions from the erosion control planning process will be considered for any of the following; however, exempting the owner from preparing an erosion control plan and applying for a grading permit does not exempt the owner from controlling erosion of soil at each construction site through the use of the techniques described in the *Manual*:

   a. Agricultural use of land.

   b. Grading or an excavation below finished grade for basements, footings, retaining walls, or other structures on plots zoned R1 - R3 of less than five (5) acres in size unless required otherwise.

   c. A sidewalk or driveway authorized by a valid permit.

   d. Land-disturbing activities involving less than five (5) acres of disturbed area. Individual lots involving less than five (5) acres of disturbed area in a larger subdivision project shall not be considered separate development projects, but rather as a part of the subdivision development as a whole. It will be the responsibility of the homeowner or homebuilder to conform to all requirements of the locally-approved *Erosion and Sediment Control Plan* for the subdivision. As part of any Building Permit for which a specific erosion control plan is not required, the following statement must be included: "We have reviewed the *Erosion and Sediment Control Plan* for (subdivision name) and agree to conform to all requirements contained therein and all erosion control requirements of the (insert name of local jurisdiction). We further agree to construct and maintain all erosion and sediment control measures required on the individual lot(s) subject to this Building Permit and/or in accordance with the provisions of the Erosion Control section of the *Manual* of the Urban Drainage and Flood Control District."

   e. Underground utility construction including the installation, maintenance, and repair of all utilities under hard-surfaced roads, streets, or sidewalks provided such land-disturbing activity is confined to the area which is hard-surfaced and provided that runoff and erosion from soil stockpiles are confined and will not enter the drainage system.

   f. Gravel, sand, dirt or topsoil removal as authorized pursuant to approval of the Colorado Mined Land Reclamation Board, provided said approval includes an erosion and sediment control plan that meets the minimums specified.

   g. Projects having a period of exposure (from time of land disturbance until permanent erosion control measures are installed) of less than 14 days.

   h. Where the owner certifies in writing to local jurisdiction and the local jurisdiction agrees in writing that the planned work and the final structures or topographical changes will not result in or contribute to soil erosion or sedimentation and will not interfere with any existing drainage course in such a manner as to cause damage to any adjacent property or result in the deposition of debris or sediment on any public way, will not present any hazard to any persons or property, and will have no detrimental influence upon the public welfare or upon the total development of the watershed.

2. Variances - Cities and counties may consider waiving or modifying any of the criteria which are deemed inappropriate or too restrictive for site conditions by granting a variance. Variances may be granted at the time of plan submission or request for plan revision. Variances must be requested in accordance with the subdivision regulations and must define:

   a. The criteria from which the applicant seeks a variance.

   b. The justification for not complying with the criteria.

   c. Alternate criteria or standard measures to be used in lieu of these criteria. The criteria and practices specified within this section of the *Manual* relate to the application of specific erosion and sediment control practices. Other practices or modifications to specified practices may be used if approved by the local jurisdiction prior to installation. Such practices must be thoroughly described and detailed to the satisfaction of the local city or county reviewing and approving the erosion control plan.

To expedite the review and decisions on variance requests, it is suggested that a variance request be included with, or submitted prior to, the initial *Erosion and Sediment Control Plan* submittal.

2.0 EROSION CONTROL PLANNING

2.1 Erosion and Sedimentation

2.1.1 Erosion. Soil erosion is the process by which the land surface is worn away by the action of wind, water, ice, and gravity. This section of the *Manual* addresses erosion caused by wind and water. Erosion is a natural process and has occurred since the earth was formed. The shape of the land as we know it was created, in large part, by erosional processes. The natural rate of erosion is increased greatly by many urban activities--especially construction activities. Any activity that disturbs the natural soil and vegetation has the potential to increase erosion because bare, loose soil is easily moved by wind or water.

Wind erosion is caused when winds of sufficient velocity create movement of soil particles. The potential for wind erosion is dependent upon soil cover, soil particle size, wind velocity, duration of wind, and unsheltered distance. Within the Denver metropolitan area winds often exceed 60 miles per hour (mph), and occasionally exceed 100 mph. Wind erosion can begin at a wind velocity as low as 10 mph, and can even result from turbulence created by passing vehicles.

Water erosion has five primary mechanisms: raindrop erosion, sheet erosion, rill erosion, gully erosion, and channel erosion. Raindrops detach soil particles and splash them into the air. These detached particles are then vulnerable to stormwater runoff or snowmelt. Shallow surface flows rarely move as a uniform sheet for more than several feet before concentrating in surface irregularities, known as rills. As the flow changes from a shallow sheet to a deeper rill flow, the velocity and turbulence of the flow increase. The energy of the concentrated flow is able to detach and transport soil particles. This action begins to cut into the soil mantle and form tiny to large channels. Rills are small, but well-defined channels which are only a few inches deep. Gullies occur as the flows in rills come together into larger and larger channels. The major difference between rill and gully erosion is size. Rills caused by erosion can be smoothed out by standard surface treatments such as harrowing. Gully erosion on the other hand cannot be repaired with standard farming equipment and requires heavy equipment to regrade and stabilize the gullies.

2.1.2 Sedimentation. During a rainstorm, runoff normally builds up rapidly to a peak and then diminishes. Because the amount of sediment a watercourse can carry is dependent upon the velocity and volume of runoff, sediment is deposited as runoff decreases. The deposited sediments may be resuspended when future runoff events occur. In this way, sediments are moved progressively downstream in the waterway system.

Windblown silt and sand particles are deposited whenever the force of the wind lessens. Much of the wind-eroded material is deposited behind fences, in landscaped areas or downwind of buildings or other obstructions to the wind. (Dust will form "drifts" just like snow.) Materials transported by bouncing or creeping along the surface are often trapped in surface irregularities near the point of initial movement.

2.1.3 Factors Influencing Erosion. Factors affecting the erosion potential of any site include soil type, geology, vegetative cover, topography, climate, and land use. Physical properties of soils such as particle size, cohesiveness, and density affect its erodibility. Loose silt and sand-sized particles are more susceptible to erosion than "sticky" clay soils. Rocky soils are also less susceptible to wind erosion, but are often found on steep slopes that are subject to water erosion. Most of the soil types found locally are calcareous in nature and are susceptible to either wind or water erosion, or both.

When surface cover and soil structure are disturbed, the soil's erodibility potential increases. Construction activities disrupt the soil structure and it's vegetative cover. Examples are excavation and grading for construction of homes, roads, utilities, commercial and industrial areas. In some parts of the Denver metropolitan area, overgrazing by livestock also contributes to increased erosion.

Vegetation plays an extremely important role in controlling erosion. Roots bind particles together and the leaves or blades of grass reduce raindrop impact forces on the soil. Grass, forest floor litter and other ground cover traps rain which allows infiltration and reduces runoff velocity. Vegetation reduces wind velocity at the ground surface, and provides a rougher surface which will trap particles moving along the ground. Once vegetation is removed, erosion can proceed unchecked.

2.1.4 Principles of Erosion and Sediment Control. The objective of erosion control is to limit the amount and rate of erosion occurring on disturbed areas. The objective of sediment control is to capture the soil that has been eroded before it leaves the construction site. Despite the use of both erosion control and sediment control measures, it is recognized that some amount of sediment will remain in runoff leaving the construction site.

An erosion and sediment control plan is comprised of three major elements:

1. The erosion control measures that will be used to limit erosion of soil from disturbed areas at a construction site;
2. The sediment control measures that will be used to limit transport of sediment to off-site properties and downstream receiving waters; and,
3. The drainageway protection measures that will be used to protect streams and other drainageways located on the construction site from erosion and sediment damages.

Erosion controls are surface treatments that stabilize soil exposed by excavation or grading. Erosion control measures, or Best Management Practices (BMPs) are variously referred to as source controls, vegetative controls or non-structural controls.

Sediment controls capture soil that has been eroded. Soil particles suspended in runoff can be filtered through a porous media or deposited by slowing the flow and allowing the natural process of sedimentation to occur. Sediment controls (or BMPs) are facilities built to perform this function, and are also referred to as structural controls.

Drainageway control measures (or BMPs) protect channels or storm sewers during site construction. This can be accomplished by limiting equipment travel across a stream, constructing a temporary channel crossing, or diverting a stream into a temporary channel while work is done on the permanent channel. Where storm sewers are used, sediment can be filtered prior to entry of runoff into the storm drainage system.

Non-sediment impacts to water quality can be managed by controls (or BMPs) on equipment, material storage, or use of chemicals at construction sites. These additional practices are included for discussion in the *Manual* because they occur commonly at construction sites.

2.2 Summary of Criteria

The list below is a summary of erosion and sediment control activities as described in the *Manual*:

- Erosion Control. Permanent or temporary soil surface stabilization must be applied to disturbed areas and soil stockpiles as soon as possible but no later than 14 days after final grade is reached on any portion of the site. Soil surface stabilization should also be applied within 14 days to disturbed areas that may not be at final grade but will remain dormant (undisturbed) for longer than an additional 30 days. (Section 3.0).
- Surface Roughening. Surface roughening should be performed after final grading to create depressions two to four inches deep and four to six inches apart. (Section 3.1).
- Mulching. All disturbed areas must be properly mulched, or seeded and mulched, within 14 days after final grade is reached on any portion of the site not otherwise permanently stabilized. (Section 3.2).
- Revegetation. A viable vegetative cover should be established within one year on all disturbed areas and soil stockpiles not otherwise permanently stabilized. Vegetation is not considered established until a ground cover is achieved which, in the opinion of the city or county of jurisdiction, is sufficiently mature to control soil erosion and can survive severe weather conditions. (Section 3.3).
- Temporary Revegetation. Temporary revegetation is required on all disturbed areas having a period of exposure prior to final stabilization of one year to two years. All temporary seeding shall be properly mulched. (Section 3.3.2).
- Permanent Revegetation. Permanent revegetation is required on all disturbed areas having a period of exposure greater than two years, or for an indeterminate length of time. A perennial grass mix should be planted and mulched. (Section 3.3.3).
- Roads and Soil Stockpiles. Road cuts, road fills, and parking lot areas should be covered as early as possible with the appropriate aggregate base course where this is specified as part of

the pavement. This practice is not needed when final construction of roads will take place within 30 days of reaching final subgrade level.

All non-paved portions of roads should be seeded and mulched as soon as possible after final grading has occurred, but in no case later than 14 days after grading has been completed.

Soil stockpiles expected to be in place longer than 60 days should be seeded with a temporary grass cover and mulched within 14 days after completion of stockpile construction.

If stockpiles are located within 100 feet of a drainageway, additional sediment controls, such as a diversion dike or silt fence, should be provided. (Section 3.4).

- Sediment Control. Properties and roadways adjacent to a construction site should be protected from eroded sediment being transported to them. (Section 4.0).
- Vehicle Tracking. Whenever construction vehicles enter onto paved roads, provisions must be made to prevent the transport of sediment (mud and dirt) by vehicles tracking onto the paved surface. Whenever sediment is transported onto a public road, regardless of the size of the site, the roads shall be cleaned at the end of each day. (Section 4.1).
- Slope Diversion Dikes. Temporary diversion dikes shall be provided as required by the provisions of Section 4.2. Diversion dikes located above disturbed areas may be discharged to a permanent or temporary channel. Diversion dikes located midslope on a disturbed area must discharge to temporary slope drain. Diversion dikes located at the base of a disturbed area must discharge to a sediment trap or basin. (Sections 4.2.1 and 4.3).
- Roads and Roadside Swales. For road areas that are not paved within 30 days of final grading, and have not received early application of roadbase, rough-cut street controls should be provided. (Section 4.2.2).
- Sediment Entrapment Facilities. Sediment entrapment facilities include straw bale barriers, silt fences, and sediment basins. The criteria for selection and use of sediment entrapment facilities are given in Table C-2 and design criteria are described in Section 4.3.

  All runoff leaving a disturbed area shall pass through at least one sediment entrapment facility before it exits the site. (Section 4.3).
- Working Within or Crossing a Waterway. Construction vehicles shall be kept out of waterways to the maximum extent practicable. Where an actively-flowing watercourse must be crossed regularly by construction vehicles, a temporary stream crossing or channel diversion must be provided. (Sections 5.1 and 5.2).

- Outlet Protection. The outlets of temporary slope drains, culverts, sediment traps, and sediment basins must be protected from erosion and scour. (Section 5.3).
- Inlet Protection. All storm sewer inlets made operable during construction must have sediment entrapment facilities installed to prevent sediment-laden runoff from entering the inlet. (Section 5.4).
- Chemicals, Oils and Material Storage. Areas used for storage of chemicals, petroleum-based products and waste materials, including solid and liquid waste, shall be designed to prevent discharge of these materials in the runoff from a construction site. (Section 6).
- Underground Utility Construction. Construction of underground utility lines that are not exempted is subject to the provisions of Section 7. (Section 1.3.4 for exemptions and Section 7).
- Disposition of Temporary Measures. All temporary erosion and sediment control measures shall be removed within 30 days after final stabilization is achieved, or after the temporary measures are no longer needed, whichever occurs earliest, or as authorized by the city or county of local jurisdiction. (Section 8).
- Maintenance. All temporary and permanent erosion and sediment control practices shall be maintained and repaired by the owner during the construction phase as needed to assure continued performance of their intended function. All facilities must be inspected and replaced if necessary, following each precipitation or snowmelt event that results in runoff. (Section 9).

2.3 Planning Process

Erosion control planning should occur early in the site development process. The planning process can be divided into five separate steps:

1. Gather information on topography, soils, drainage, vegetation and other predominant site features.
2. Analyze the information in order to anticipate erosion and sedimentation problems.
3. Devise a plan which schedules construction activities and minimizes the amount of erosion created by development.
4. Develop an *Erosion and Sediment Control Plan* which specifies effective erosion and sediment control measures.
5. Follow the *Erosion and Sediment Control Plan* and revise it when necessary.

2.3.1 Site Assessment. Topography is the primary factor to be considered in developing an *Erosion and Sediment Control Plan*. Soils, vegetation, and hydrologic features must also be considered.

Final grading will determine slope gradient and slope length of the disturbed area. Small areas, or subbasins, will be created that have relatively uniform characteristics of slope and slope length. After grading is completed, areas that remain exposed to precipitation and runoff will require erosion control, and the overall size of subbasin areas will determine what sediment controls are appropriate for each area.

Soil conditions should be assessed as to their potential for erosion and suitability for revegetation. A detailed analysis of soil-erosion potential is not necessary because all soils will be subject to erosion and can be generalized as equivalent for the design of control measures recommended in the *Manual*.

Most vegetation will be removed from a construction site during clearing and grading operations. An assessment of existing vegetation on the site is of limited use when post-development landscaping and irrigation are planned, but can be useful in selecting grasses when non-irrigated revegetation is planned. Analysis of soil is useful to determine fertilizer requirements for vegetation establishment.

Analysis of waterbodies and other hydrologic features of a site is important in the design of sediment controls. The drainage basins upslope and within the site should be assessed. The configuration of hillslope areas and drainageways, in the context of planned roads and buildings, will determine what erosion and sediment controls will be needed. The location of permanent drainage channels and other elements of the drainage system should be defined as a part of the plan.

2.3.2 Selection of Controls. The following guidelines are recommended in developing the erosion and sediment control plan:

1. Determine the limits of clearing and grading. If the entire site will not undergo excavation and grading, the boundaries of cut-and-fill operations should be defined. Buffer strips of natural vegetation may be utilized as a control measure.

2. Define the layout of buildings and roads. This will have been decided previously as a part of the general development plan. If building layout is not final, the road areas stabilized with pavement and the drainage features related to roads should be defined as they relate to the plan.

3. Determine permanent drainage features. The location of permanent channels, storm sewers, roadside swales, and stormwater quality controls such as ponds, wetlands, grassed-lined swales, buffer strips, and areas of porous pavement, if known, should be defined.

4. Determine extent of temporary channel diversions. If permanent channel improvements are a part of the plan, the route, sizing, and lining needed for temporary channel diversions should be determined. Location and type of temporary channel crossings can be assessed.

5. Determine the boundaries of watersheds. The size of drainage basins will determine the types of sediment controls to be used. Areas located off the site that contribute overland flow runoff must be assessed. Measures to limit the size of upland overland flow areas, such as diversion dikes, may be initially considered at this stage.

6. Select sediment controls. Areas greater than one acre will require that sediment basins be installed. Division of large drainage basins into subareas each served by a sediment basin can also be considered.

   Areas smaller than one acre can utilize other sediment controls. Limitations on the size of areas served by individual controls are defined in these criteria. (Section 4.3).

7. Determine staging of construction. The schedule of construction will determine what areas must be disturbed at various stages throughout the development plan. The opportunity for staging cut-and-fill operations to minimize the period of exposure of soils can be assessed. The sequence for installing sediment controls and erosion controls can also be determined at this time.

8. Identify locations of topsoil stockpiles. Areas for storing topsoil should be determined.

9. Identify location of temporary construction roads, vehicle tracking controls, and material storage areas. These three elements can be determined in the context of previously defined aspects of the plan.

10. Select Erosion Controls. All areas of exposed soil will require a control measure be defined dependent on the duration of exposure. These can be selected based on the schedule of construction.

An example erosion and sediment control plan for a small commercial development has been included as Appendix B. Figure C-2 shows an oblique view of an example highway construction project and the sediment controls used. Figure C-3 illustrates how these measures are described on a site plan map.

2.4 Consistency with Other Plans

2.4.1 Drainage Plans. The *Erosion and Sediment Control Plan* should be prepared consistent with the final drainage plan for a development. All of the hydrologic features of the drainage plan must be incorporated into the site at the time of development. Permanent drainage features will be built during the construction phase. Temporary sediment controls can be located and designed to take advantage of the final drainage design features. All temporary controls should be staged and removed at the appropriate time relative to the construction of permanent drainage features.

R0017877

2.4.2 Stormwater Quality Plans. New developments will incorporate elements of stormwater quality control into their design. The erosion and sediment control plan must be prepared consistent with these structural and nonstructural controls. Many of the temporary controls used for sediment control can be modified into permanent structural controls. Where possible, permanent stormwater quality controls can be constructed at the initial stages of construction, or modified at the end of construction.

Where local regulations have not been developed, stormwater quality plans should be developed consistent with the guidelines in the *Stormwater Quality Management* and *BMP Planning for New Development and Redevelopment* chapters of Volume 3 of the *Manual.*

2.4.3 Air Quality Plans. All of the erosion and sediment control measures specified in this section will perform as well to control wind erosion. The surface stabilization measures identified for control of precipitation-induced erosion act also to prevent soils from becoming windborne. Although these guidelines were developed to control erosion by rainfall and snowmelt, they are consistent with design principles for wind erosion and will be effective for this purpose.

The Air Pollution Control Division, Colorado Department of Public Health and Environment, has passed air quality regulations consistent with federal legislation. Regulation No. 3 requires submittal of an Air Pollutant Emission Notice (APEN) for sources of fugitive dust from construction sites, as well as other sources. Regulation No. 1 defines particulate emission control regulations for haul roads and roadways. Additional controls, such as road watering, may be necessary to fully comply with these regulations at a construction site. In certain counties in Colorado, the local health department administers these regulations. This agency, or CDH, should be contacted about APENs and other air quality requirements.

FIGURE C-3
Site Plan Map for Example Construction Site

3.0 EROSION CONTROL

The planning for the installation of permanent or temporary soil erosion controls needs to begin in advance of all major soil disturbance activities on the construction site. After construction begins, soil surface stabilization shall be applied within 14 days to all disturbed areas that may not be at final grade but will remain dormant (undisturbed) for periods longer than an additional 30 calendar days.

Soil surface stabilization protects soil from the erosive forces of raindrop impact, flowing water, and wind. Erosion control practices include surface roughening, mulching, establishment of vegetative cover, soil treatments, and the early application of gravel base on areas to be paved. Stabilization measures to be used should be appropriate for the time of year, site conditions and estimated duration of use. The maximum time limits of land exposure for selection of erosion controls are summarized in Table C-1.

TABLE C-1
Maximum Time Limits of Land Exposure
for Selection of Erosion Controls

Erosion Control Method	Maximum Allowable Period of Exposure (Months)
Surface Roughening	1
Mulching	12
Temporary Revegetation	12-24
Permanent Revegetation	24 or more
Soil Stockpile Revegetation	2
Early Application of Road Base	1

3.1 Surface Roughening

Surface roughening provides temporary stabilization of disturbed areas from wind and water erosion. It is particularly useful where temporary revegetation cannot be immediately established due to seasonal planting limitations.

The soil surface is considered roughened if depressions are created two to four inches deep and are spaced approximately four to six inches apart. If slopes are sufficiently rough after final grading, no further treatment is required. The surface of exposed soil can be roughened by a number of techniques and equipment. A chisel or ripping implement can be used in most soil conditions. Roughening cannot be performed in very sandy or rocky soil.

Surface roughening, also referred to as scarification, should be performed after final grading. Fill slopes can be constructed with a roughened surface. Cut slopes that have been smooth graded can be roughened as a subsequent operation. Roughening of ridges and depressions should follow along the contours of the slope. On slopes steeper than 2:1, the tracks left by a dozer working perpendicular to the contour can leave acceptable horizontal depressions. A diagram illustrating surface roughening is shown on Figure C-4.

Care should be taken not to drive vehicles or equipment over areas that have been scarified. Tire tracks will smooth the roughened surface and encourage runoff to collect into channels. As surface roughening is only a temporary control, additional treatments may be necessary to maintain the soil surface in a roughened condition.

3.2 Mulching

All disturbed areas must be mulched, or seeded and mulched, within 14 days after final grade is reached on any portion of the site not otherwise permanently stabilized. Areas that will remain in an interim condition for more than one year should also be seeded (See Section 3.3.2). An example of mulching is shown on Figure C-5.

To protect newly seeded areas and to provide temporary cover on other disturbed areas which will not require temporary revegetation, or which cannot be seeded due to seeding date limitations, a mulch should be applied consisting of:

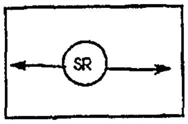
1. Clean, weed- and seed-free, long-stemmed grass hay (preferred) or cereal grain straw. Hay is preferred as it is less susceptible to removal by wind. Mulch should be applied evenly at a rate of two tons per acre. At least 50 percent of the mulch, by weight, should be ten inches or more in length.

   Mulch must be anchored. This can be accomplished mechanically by crimping or with the aid of tackifiers or nets. Anchoring with a crimping implement is preferred, and is the recommended method for all areas equal to or flatter than 3:1. Mechanical crimpers must be capable of tucking the long mulch fibers into the soil four inches deep without cutting them. An agricultural disk, while not an ideal substitute, <u>may</u> work if the disk blades are dull or blunted and set vertically. However, the frame may have to be weighted to afford proper soil penetration.

   On small areas sheltered from the wind and from heavy runoff, spraying a tackifier on the mulch is satisfactory for holding it in place. For steep slopes and other special situations, blankets, anchored with staples, may be required instead of mulch.

2. Hydraulic mulching shall be limited to those situations where it is too difficult to apply and anchor a mulch of long-stemmed grass hay or cereal straw; namely, slopes steeper than 3:1 or where access is limited. Wood cellulose fibers must be mixed with water and a tackifying agent and applied at a rate of 2,000 pounds per acre with a hydraulic mulcher.

R0017882



SR

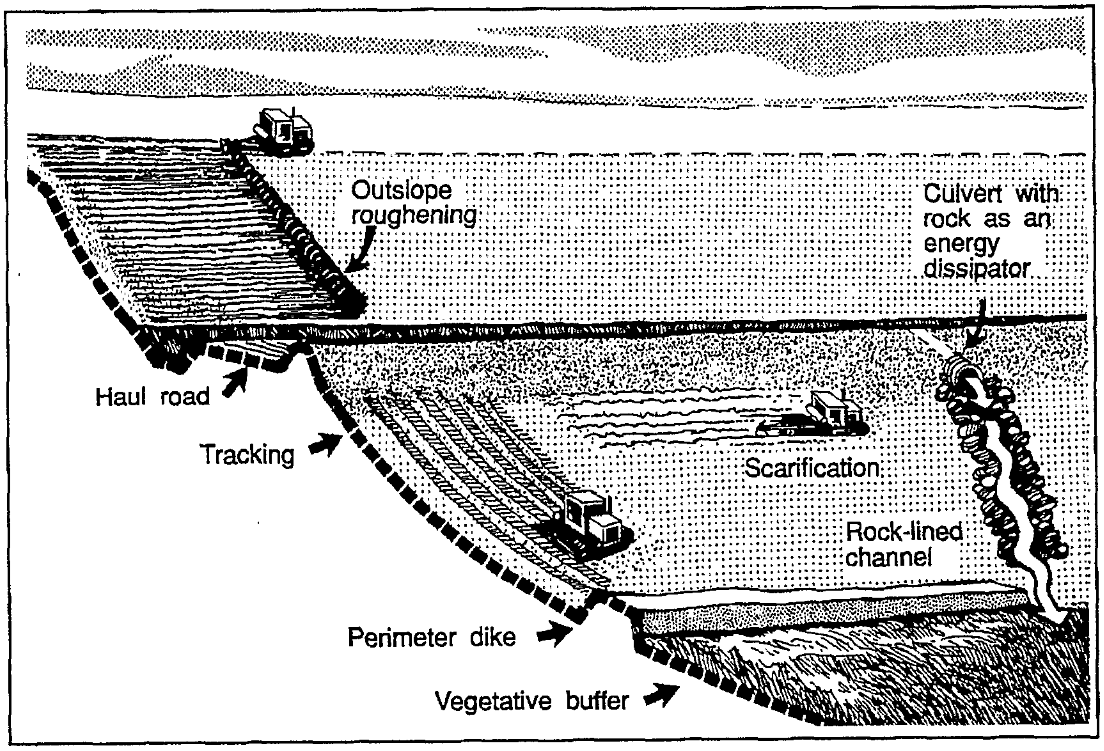
SURFACE ROUGHENING

Definition

Provide a rough soil surface with horizontal depressions created by operating a tillage or other suitable implement on the contour, or by leaving slopes in a roughened condition by no fine-grading them.

Purposes

1. To aid in seed bed preparation and establishment of vegetative cover.
2. To reduce runoff velocity and increase infiltration.
3. To reduce runoff and wind erosion and provide for sediment trapping.



From: Environmental Protection Agency, 1976

FIGURE C-4
Surface Roughening

R0017883

MU

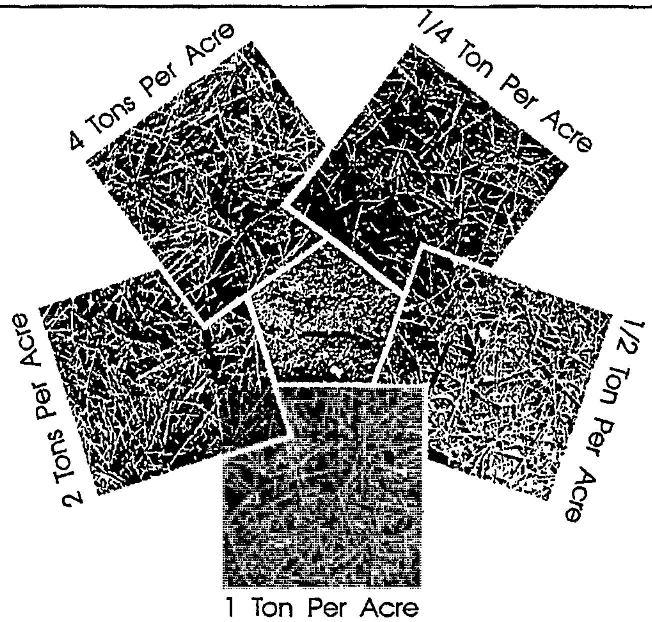
MULCHING

<u>Definition</u>

Application of plant residues or other suitable materials to the soil surface.

<u>Purposes</u>

1. To prevent erosion by protecting the soil surface from raindrop impact and reducing the velocity of overland flow.
2. To foster the growth of vegetation by increasing available moisture and providing insulation against extreme heat and cold.



From: Environmental Protection Agency, 1976

FIGURE C-5
Mulching

R0017884

3. Mats, blankets, and nets are available to help stabilize steep slopes and drainage channels. Depending on the product, these may be used alone or in conjunction with grass or straw mulch. Normally, use of these products will be restricted to relatively small areas. Mats made of jute, coconut fiber, or various geosynthetic fibers can be used instead of mulch. Blankets are straw mulch that have been woven and oftentime include a synthetic layer or net. Plastic netting can be used to anchor mulch. Two diagrams showing installation and orientation of these materials are provided as Figures C-6 and C-7.

4. Some synthetic tackifiers or binders may be used to anchor mulch to limit sediment movement and or, if approved by review agency, directly applied to the soil to provide soil stabilization. Caution should be used to prevent the introduction of any potentially harmful material into the environment. Manufacturer's recommendations should be followed at all times.

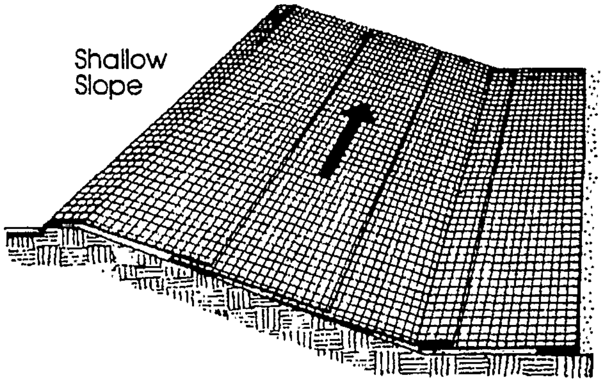
5. Rock can also be used as a mulch. It provides protection of exposed soils to wind and water erosion and allows infiltration of precipitation. Rock of aggregate base-coarse size can be spread on disturbed areas for temporary or permanent stabilization. Rock must be removed from those areas planned for vegetation establishment.

3.3 Revegetation

A viable vegetative cover should be established within one year on all disturbed areas and soil stockpiles not otherwise permanently stabilized. Vegetation is not considered established until a ground cover is achieved which, in the opinion of the city or county of jurisdiction, is sufficiently mature to control soil erosion and can survive severe weather conditions.

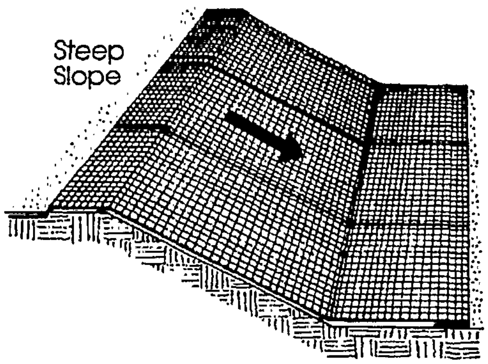
3.3.1 Seedbed Preparation. Areas to be revegetated should have soil conditions capable of supporting vegetation. Overlot grading will oftentimes bring to the surface subsoils that have low nutrient value, little organic matter content, few soil microorganisms, rooting restrictions, and conditions less conducive to infiltration of precipitation. Under certain conditions, soil amendments and treatments may be necessary to provide an adequate growth medium to sustain vegetation.

R0017885



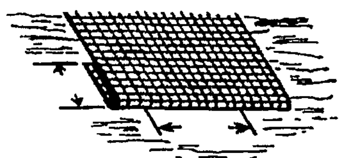
On shallow slopes, strips of netting may be applied across the slope.

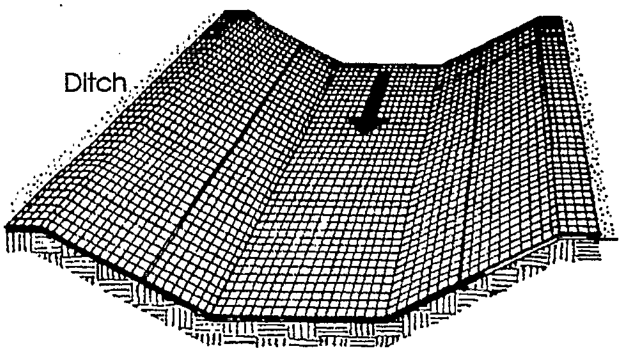
Where there is a berm at the top of the slope, bring the netting over the berm and anchor it behind the berm.



On steep slopes, apply strips of netting parallel to the direction of flow and anchor securely.

Bring netting down to a level area before terminating the installation. Turn the end under 6" and staple at 12" intervals.



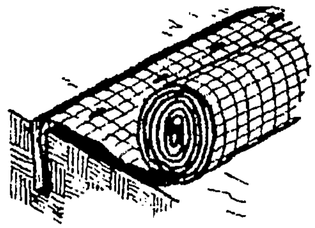


In ditches, apply netting parallel to the direction of flow. Use check slots every 15 feet. Do not join strips in the center of the ditch.

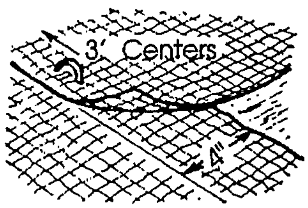
From: Virginia Soil and Water Conservation Commission, 1985

FIGURE C-6
Orientation of Blankets, Netting and Matting

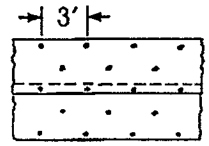
R0017886

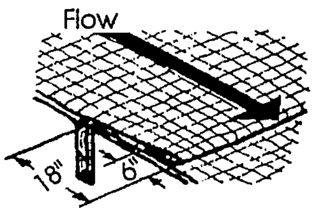


Anchor Slot: Bury the up-channel end of the net in a 6" deep trench. Tamp the soil firmly. Staple at 12" intervals across the net.

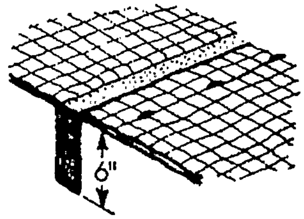


Overlap: Overlap edges of the strips at least 4". Staple every 3 feet down the center of the strip.

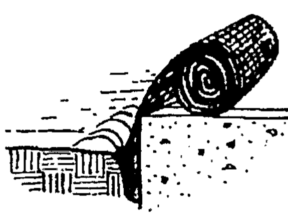




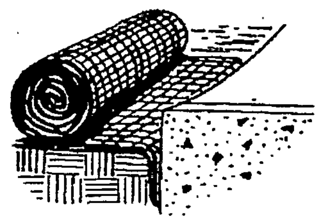
Joining Strips: Insert the new roll of net in a trench, as with the Anchor Slot. Overlap the up-channel end of the previous roll 18" and turn the end under 6". Staple the end of the previous roll just below the anchor slot and at the end at 12" intervals.



Check Slots: On erodible soils or steep slopes, check slots should be made every 15 feet. Insert a fold of the net into a 6" trench and tamp firmly. Staple at 12" intervals across the net. Lay the net smoothly on the surface of the soil - do not stretch the net, and do not allow wrinkles.



Anchoring Ends At Structures: Place the end of the net in a 6" slot on the up-channel side of the structure. Fill the trench and tamp firmly. Roll the net up the channel. Place staples at 12" intervals along the anchor end of the net.



From: Virginia Soil and Water Conservation Commission, 1985

FIGURE C-7
Installation of Blankets, Netting and Matting

R0017887

Whenever possible, topsoil should be salvaged for respreading on areas to be revegetated. The depth of soil stripping is determined by the depth of available topsoil. Areas near drainageways may have a considerable depth of topsoil, whereas lesser amounts may be available on the crowns of hills and flat slopes. Topsoil should be viewed as an important resource to be utilized for vegetation establishment, primarily due to its water-holding capacity. Native topsoil located on a construction site also have good soil structure, organic matter content, biological activity, and nutrient supply that supports vegetation.

The rooting zone of most semi-arid grasslands evident in the Denver metropolitan area is 6 to 18 inches. At a minimum, the upper six (6) inches of topsoil can be stripped and stockpiled, and respread to a thicker depth on surfaces not planned for buildings or impervious areas. If the surface is compacted, ripping of subsoils prior to topsoiling is recommended. Scarification will assist in placement of a stable topsoil layer on steeper slopes, and allow percolation and root penetration to greater depth.

Where topsoil is not available or utilized, subsoils can be treated to provide a plant-growth medium. Organic matter can be added to improve nutrient levels necessary for plant growth. Other treatments, such as liming, can be used to adjust soil conditions as necessary with amendments. Soil testing is recommended to determine appropriate amendments required.

A suitable seedbed will enhance the success of revegetation efforts. The surface should be rough and the seedbed should be firm, but neither too loose nor compacted. The upper layer of soil should be in a condition suitable for seeding at the proper depth and conducive to plant growth.

3.3.2 Temporary Revegetation. Temporary revegetation is required on all disturbed areas having a period of exposure prior to final stabilization of one year or longer. All temporary seeding shall be protected with mulch.

To provide temporary vegetative cover on disturbed areas which will not be paved, built upon, or fully landscaped within 12 months but will be completed within 24 months, plant an annual grass appropriate for the time of planting and mulch the planted areas. The annual grasses generally suitable for the Denver metropolitan area are listed in Table C-2. These are to be considered only as a general recommendation whenever specific design guidance for a particular site is not available.

3.3.3 Permanent Revegetation. To provide vegetative cover on disturbed areas not paved or built upon for a period of 2 years or longer, or for an indeterminate length of time, a perennial grass or grass mix should be planted. Each site will have different characteristics, and a landscape professional should be contacted to determine the most suitable species or seed mix for a specific site. In lieu of a specific recommendation and for planning purposes, one of the perennial grass mixes appropriate for site conditions listed in Table C-3 can be used. The pure live seed (PLS) rates of application recommended in these tables are considered to be absolute minimum rates for seed applied using proper drill-seeding equipment. All permanent seeding shall be protected with mulch. See Table C-4 for appropriate seeding dates.

TABLE C-2

Minimum Drill Seeding Rates for Annual Grasses[a]

Species (Common name)	Growth Season[b]	Pounds of Pure Live Seed (PLS)/acre[c]	Planting Depth (inches)
1. Oats	Cool	35 - 50	1 - 2
2. Spring wheat	Cool	25 - 35	1 - 2
3. Spring barley	Cool	25 - 35	1 - 2
4. Annual ryegrass	Cool	10 - 15	½
5. Millet	Warm	3 - 15	½ - ¾
6. Sudangrass	Warm	5 – 10	½ - ¾
7. Sorghum	Warm	5 - 10	½ - ¾
8. Winter wheat	Cool	20 - 35	1 - 2
9. Winter barley	Cool	20 - 35	1 - 2
10. Winter rye	Cool	20 - 35	1 - 2
11. Triticale	Cool	25-40	1 - 2

[a] Successful seeding of annual grass resulting in adequate plant growth will usually produce enough dead-plant material residue to provide protection from wind and water erosion for an additional year. This assumes that the cover is not disturbed or mowed closer than 8 inches.

Hydraulic seeding may be substituted for drilling only where slopes are steeper than 3:1 or where access limitations exist. When hydraulic seeding is used, hydraulic mulching should be done as a separate operation to prevent the seeds from being encapsulated in the mulch.

[b] See Table C-4 for seeding dates. Irrigation, if consistently applied, may extend the use of cool season species during the summer months.

[c] Seeding rates should be doubled if seed is broadcast; or increased by 50 percent if done using a Brillion Drill or by hydraulic seeding.

If desired for wildlife habitat or landscape diversity, shrubs such as rubber rabbitbrush (*Chrysothamnus nauseosus*), fourwing saltbush (*Atriplex canescens*) and skunkbrush sumac (*Rhus trilobata*) could be added to the upland seedmixes at .25, .5 and 1 pounds per acre, respectively. In riparian zones, planting root stock of such species as American plum (*Prunus americana*), woods rose (*Rosa Woodsii*), plains cottonwood (*Populus sargentii*), and willow (*Populus spp.*) may be considered. On non-topsoiled upland sites, a legume such as Ladak alfalfa at 1 lb. PLS per acre can be included as a source of nitrogen for perennial grasses.

[a] All of the above seeding mixes and rates are based on drill seeding followed by crimped hay or straw mulch. These rates should be doubled if seed is broadcast and should be increased by 50 percent if the seeding is done using a Brillion Drill or is applied through hydraulic seeding. Hydraulic seeding may be substituted for drilling only where slopes are steeper than 3:1. If hydraulic seeding is used, hydraulic mulching should be done as a separate operation.
[b] See Table 3-4 for seeding dates.
[c] Crested wheatgrass should not be used on slopes steeper than6H to 1V.
[d] If site is to be irrigated, the transition turf seed rates should be doubled.
[e] Could substitute 0.5 lbs PLS of Blue grama for the 2.0 lbs PLS of Vaughn sideoats grama.

R0017891

TABLE C-4
Seeding Dates for Annual and Perennial Grasses

	Annual Grasses		Perennial Grasses	
Seeding Dates	Warm	Cool	Warm	Cool
January 1 - March 15				
March 16 - April 30	4	1,2,3		
May 1 - May 15	4			
May 16 - June 30	4,5,6,7			
July 1 - July 15	5,6,7			
July 16 - August 31				
September 1 - September 30		8,9,10,11		
October 1 - December 31				

Notes:

See Table C-2 and C-3 for growth season of annual and perennial grasses, respectively. Number codes for annual species refer to specific seeding periods for: (1) oats; (2) spring wheat; (3) spring barley; (4) annual ryegrass; (5) millet; (6) sudangrass; (7) sorghum; (8) winter wheat; (9) winter barley; (10) winter rye; and, (11) triticale.

To provide temporary erosion control between the seeding dates specified, utilize surface roughening (on the contour or perpendicular to prevailing winds) and/or apply a mulch.

The seeding dates for perennial species are generally in the spring from March through early May, and in the fall after mid-October until snow cover precludes planting. Fall seeding is referred to as "dormant seeding" because the seeds will lie dormant through the winter and germinate in the spring.

Perennial grasses can be seeded using a drill seeder in areas previously planted with a temporary grass cover. In this case, the annual grass may need to be mowed for the drill to operate. Broadcast seeding or hydroseeding of permanent grasses should not be done with a live crop of annual grasses without first reworking and preparing the topsoil.

3.4 Roads and Soil Stockpiles

Road cuts, road fills, and parking lot areas should be covered with the appropriate aggregate base course on the surfaces to be paved in lieu of mulching. Early application of road base is suitable where a layer of course aggregate is specified for final road or parking lot construction. This practice may not be desirable in all instances, and is not needed when final pavement construction will take place within 30 days of grading to final contours. All non-paved portions of road cut, fill, and parking lot areas should be seeded and mulched as soon as possible after final grading has occurred, but in no case later than 14 days after grading has been completed.

Soils stockpiled for more than 60 days should be seeded with a temporary or permanent grass cover within 14 days after completion of stockpile construction. Mulching is recommended to ensure vegetation establishment. If stockpiles are located within close proximity to a drainageway (i.e., 100 feet), additional sediment control measures, such as a temporary diversion dike or silt fence, should be provided (see Section 4).

4.0 SEDIMENT CONTROL

The installation of sediment entrapment and control facilities has to begin before major land disturbance activities begin on a construction site.

Sediment control will be site specific and can include vehicle tracking controls; sod buffer strips around the lower perimeter of the land disturbance; sediment barriers, filters, dikes, sediment basins; or a combination of any or all of these measures.

Sediment controls must be constructed before land disturbance takes place. Earthen structures such as dams, dikes, and diversions should be mulched within 14 days of installation. Earthen structures that are expected to remain in place for more than one year must be seeded and mulched.

Dams must address stable embankment design and water rights considerations. Consult with the State Engineer's Office on these requirements prior to constructing any dam.

4.1 Vehicle Tracking

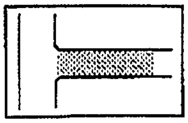
Wherever construction vehicles enter onto paved public roads, provisions must be made to prevent the transport of sediment (mud and dirt) by runoff or by vehicles tracking onto the paved surface. It is recommended that coarse-aggregate rock surfacing be provided to keep most construction traffic from coming into contact with mud and dirt. In other words, stabilized access, parking, staging, and loading/unloading areas will reduce the likelihood that vehicles will come in contact with mud.

For sites greater than two (2) acres, a stabilized vehicle tracking control must be constructed (see Figure C-8). Whenever deemed necessary by the city or county of jurisdiction, wash racks shall be installed to remove mud and dirt from the vehicle and its tires before it enters onto public roads (see Figure C-8A).

Whenever sediment is transported onto a public road, regardless of the size of the site, the road shall be cleaned at the end of each day. Sediment shall be removed from roads by shoveling or sweeping and be transported to a controlled sediment disposal area. Street washing shall not be allowed until after sediment is removed in this manner. Storm sewer inlet protective measures should be in place at the time of street washing.

4.2 Slope-Length and Runoff Considerations

Cut-and-fill slopes must be designed and constructed to minimize erosion. This requires consideration of the length and steepness of the slope, the soil type, upslope drainage area, groundwater conditions and other applicable factors. Slopes which are found to be eroding excessively will require additional slope



VTC

VEHICLE TRACKING CONTROL

Definition

A stone stabilized pad located at points of vehicular ingress and egress on a construction site.

Purposes

To reduce the amount of mud transported onto public roads by motor vehicles or runoff.

Note: Only applicable for sites greater than 2 acres in size

stabilization until the problem is corrected. The following guidelines should assist site planners and plan reviewers in developing an adequate design:

1. Rough soil surfaces are preferred over smooth surfaces on slopes (Section 3.1).

2. Temporary diversion dikes (Section 4.2.1) can be constructed at the top of long or steep slopes, or hillslopes that have an upslope tributary drainage area over five acres. Diversion dikes or terraces (Section 4.2.3) may also be used to reduce slope length within the disturbed area.

   Temporary diversion dikes shall be provided whenever:

$$S^2L > 2.5$$

   where: S = slope of the upstream tributary area (in feet/foot); and,
   L = length of the upstream slope (in feet).

3. Concentrated stormwater should not be allowed to flow down cut or fill slopes unless contained within an adequately-sized temporary channel diversion, a permanent channel, or temporary slope drain (Section 4.2.4).

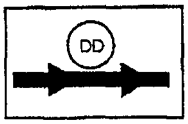
4. Wherever a slope face crosses a water seepage plane which endangers the stability of the slope, adequate drainage should be provided.

5. Provide sediment basins or barriers (silt fences or straw bale dikes) below slopes to reduce offsite sediment transport or to reduce slope lengths (Section 4.3).

4.2.1 Slope Diversion Dikes. A temporary diversion dike is a horizontal ridge of soil placed perpendicular to the slope and angled slightly to provide drainage along the contour. Temporary diversion dikes can be constructed by excavation of a V-shaped trench or ditch and placement of the fill on the downslope side of the cut. A design of a temporary diversion dike is shown on Figure C-9.

There are two types of temporary slope diversion dike:

1. A diversion dike located at the top of a slope to divert upland runoff away from the disturbed area. The discharge from undisturbed or previously-developed upland areas collected by these diversion dikes may be directed to a permanent channel or temporary channel diversion (Section 5.2).



DD

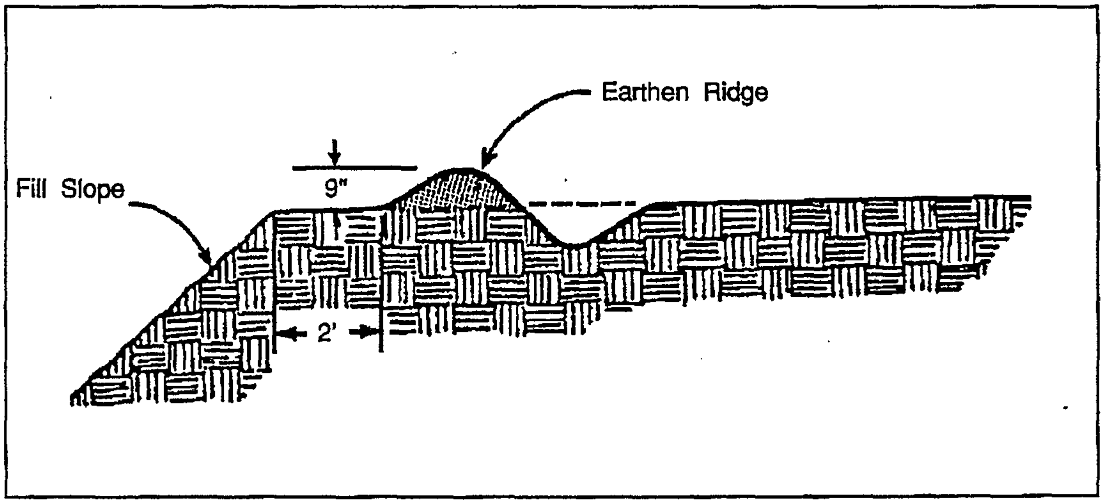
TEMPORARY DIVERSION DIKE

Definition

A temporary ridge of compacted soil located at the top, midslope, or base of a disturbed area.

Purposes

1. To divert storm runoff from higher drainage areas away from unprotected slopes to a permanent channel or temporary channel diversion.
2. To divert sediment-laden runoff from the midslope of a disturbed area to a temporary slope drain.
3. To divert sediment-laden runoff from the base of a disturbed area to a sediment trapping facility.



From: Virginia Soil and Water Conservation Commission, 1985

FIGURE C-9
Temporary Diversion Dike

R0017898

2. A diversion dike located at the base or midslope of a disturbed area to divert sediment-laden water to a sediment basin. These diversions are also very useful at road intersections during the construction phase. The discharge from these diversion dikes may be directed to a temporary slope drain or sediment basin.

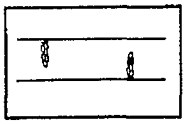
4.2.2 Roads and Roadside Swales. The drainage system provided for roads will define to some extent the length and area of individual slope segments within the disturbed area. A number of smaller hillslope segments will be created by construction of roads. These areas will require erosion control as described in Section 3.4, and sediment controls dependent on the size of upslope tributary area (Section 4.3).

For road areas that are not paved within 30 days of final grading, and have not received early application of roadbase (Section 3.4), rough-cut street controls should be used. These are runoff barriers that are constructed at intervals down the road. The barrier projects perpendicular to the longitudinal slope from the outer edge of the roadside swale to the crown of the road. The barriers are positioned alternately from the right and left side of the road to allow construction traffic to pass in the lane not barred. If construction traffic is expected to be congested and a vehicle tracking control has been constructed, rough-cut street controls may be omitted for 400 feet from the entrance. The design and spacing of temporary rough-cut road controls are shown on Figure C-10.

4.2.3 Terracing. Sediment can be controlled on slopes that are particularly steep by the use of terracing. During grading, relatively flat sections, or terraces, are created and separated at intervals by steep slope segments. The steep slope segments are prone to erosion, however, and must be stabilized in some manner. Retaining walls, gabions, cribbing, deadman anchors, rock-filled slope mattresses and other types of soil retention systems are available for use. These should be specified in the plan and installed according to manufacturer's instructions.

4.2.4 Slope Drains. There are certain instances when runoff must be directed down a slope within the disturbed area. A temporary slope drain can be used to protect these hillslope areas from scour and additional erosion. A number of alternative designs and materials can be used for a slope drain. These are illustrated in Figures C-11 and C-11A.

The sizing of temporary slope drains must be defined but do not need rigorous hydraulic analysis. Criteria for sizing are given in the design criteria. The discharge from all slope drains must be directed to a stabilized outlet (Section 5.3).



RCS

ROUGH-CUT STREET CONTROL

Definition

A temporary sediment barrier placed on alternate sides of a rough cut street.

Purposes

To divert sediment-laden runoff from rough-cut streets and slow the velocity of storm runoff.

Note:
1. Alternate materials such as curb socks or silt fences may be used where large flows are not expected.
2. Requirements for and spacing of velocity reducers for streets with grades of less than 4% shall be as shown on the erosion control plan.

4.3 Sediment Entrapment Facilities

Sediment entrapment facilities are necessary to reduce sediment discharges to downstream properties and receiving waters. Sediment entrapment facilities include straw bale barriers, silt fences, and sediment basins. The type of sediment entrapment facility to be used depends on the tributary area, basin slope and slope length of the upstream area. Table C-5 summarizes the recommended maximum tributary areas, slope lengths and slopes for three (3) types of sediment entrapment facilities.

All runoff leaving a disturbed area shall pass through a sediment entrapment facility before it exits the site and flows downstream.

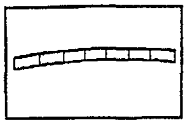
TABLE C-5
Sediment Entrapment Facility Limitations

Sediment Control Facility	Allowable Maximum Limit: Tributary Drainage Area (ac)	Tributary Slope Length (ft)	Tributary Slope Gradient
Straw Bale Barrier or Silt Fence	0.5-1.0 per 100 lineal ft	150	2:1 (50%)
Sediment Basin	n/a	n/a	n/a

Straw bale barriers or silt fences may be used for small sites. When the tributary area is greater than that allowed for straw bale barriers or silt fences, runoff shall be collected in diversion dikes and routed through temporary sediment basins.

4.3.1 Straw Bale Barriers. Straw bales can be placed at the base of a hillslope to act as a sediment barrier. These are not recommended for use within a swale or channel. Straw bales are temporary in nature and may only perform for a period of weeks or months. Proper installation and maintenance is necessary to ensure their performance. These limitations should be considered when selecting straw bales for use. Guidance on design and installation of straw bales is given on Figures C-12 and C-12A.

4.3.2 Silt Fence. A silt fence is made of a woven synthetic material and acts to filter runoff. Silt fence can be placed as a temporary barrier along the contour at the base of a disturbed area but is not recommended for use in a channel or swale. The material is durable and will last for more than one season if properly installed and maintained. Silt fence is not intended to be used as a perimeter fence, particularly on ridges or transverse to the contours, or in areas of concentrated flow. If concentrated flow conditions exist, the use of a rack overtopping berm is recommended. Silt fence design criteria and construction techniques are shown on Figure C-13 and C-14.



STB

STRAW BALE BARRIER

Definition

A temporary sediment barrier consisting of a row of entrenched and anchored straw bales.

Purposes

1. To intercept and detain small amounts of sediment from disturbed areas of limited extent in order to reduce sediment in runoff from leaving the site.
2. To decrease the velocity of sheet flows from hillslope areas

4.3.3 Sediment Basins. Areas draining more than 1 acre must be routed through a sediment basin similar to one shown in Figures C-15, C-15A, and C-16. Sediment basins in the Denver region shall be designed to a minimum 1,800 cubic feet of volume per tributary acre and shall be cleaned out prior to becoming half full.

If the site is to include a stormwater quality or flood detention basin, the permanent detention facility may be used as the temporary sediment basin, provided the outlets are modified upon completion for this purpose. Such permanent detention facilities shall be restored to design grades, volumes, and configurations after site development is completed and the project is finalized.

The outlet from a sediment basin should be designed to empty its volume in 40 hours. The basin's length shall be no less than twice the basin's width. The inflow structures at the entrance of the basin should be designed to dissipate inflow energy and to spread the flow so as to achieve uniform flow throughout the basin's width.

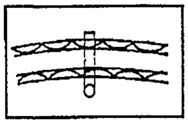
A recommended design procedure is shown below:

4.3.4 Design Procedure: Sediment Basin

The following steps outline the temporary sediment basin design procedure and criteria:

- Basin Storage Volume: Provide a design storage volume that is greater than or equal to 1800 cubic feet per acre of drainage area.
- Dam Embankment: Embankment slopes should be no steeper than 3:1, preferably 4:1 or flatter.
- Emergency Spillway: Design an emergency spillway to convey flows over the embankment when the design storage volume of the basin is exceeded (100 year events or larger). Set the crest at or slightly above the water surface elevation resulting from the design storage volume. The entire emergency spillway should be protected with riprap. Do not construct the spillway over fill material.
- Outlet Works: Design the outlet works in accordance with Figure C-15A. A perforated riser pipe (8-inch or larger PVC) shall be installed to release the design storage volume over a 40-hour period. The perforations in the riser pipe should be sized as follows:
  - Refer to Figure EDB-3 in the *Structural BMP* section to calculate the required perforation area per row of the riser pipe (for purposes of this application, the design storage volume is the same as the water quality capture volume).

R0017908



SB

TEMPORARY SEDIMENT BASIN

Definitions

A temporary basin with a controlled stormwater release structure, formed by excavation or construction of an embankment of compacted soil. Required for all drainage areas greater than 1 area.

Purposes

To detain sediment-laden runoff from distributed areas to allow the majority of the sediment to settle out.

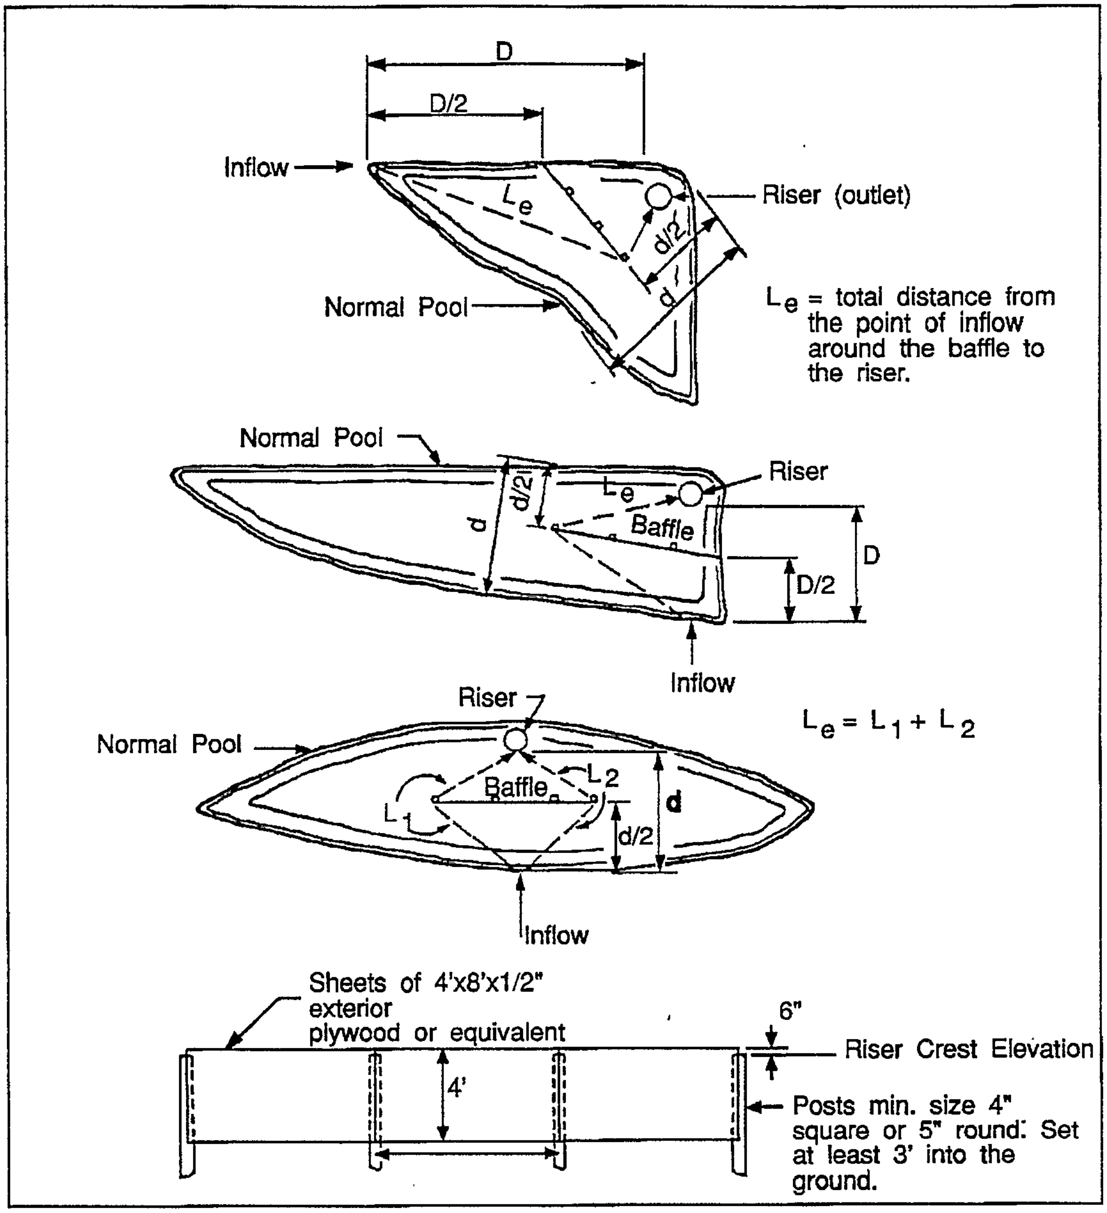
BAFFLE LOCATIONS IN SEDIMENT BASINS



From: Environmental Protection Agency, 1976

FIGURE C-16
Baffle Locations in Sediment Basins

- See Figures 4 and 5 in the *Typical Det*ails section to determine the appropriate perforation geometry (Note: Although Figures 4 and 5 are based on a flat orifice plate, the resulting hole sizes and patterns may be applied to the cylindrical riser pipe.).

The outlet pipe (8-inch or larger PVC) shall extend through the embankment at a minimum slope of 0.5%. A riprap apron shall be provided at the outfall. A baffle should be constructed to protect the outlet and improve sedimentation in the basin if the length-to-width ratio is less than 2 to 1 (D to D/2) for various geometrys to provide Le greater than or equal to D as shown in Figure C-16.

- Maintenance: The basin shall be dredged out prior to the design storage volume becoming half filled with sediment.

R0017912

5.0 DRAINAGEWAY PROTECTION

At times construction activities must occur adjacent to or within a drainageway. Whenever this occurs, bottom sediments will be disturbed and transported downstream. The goal of these criteria is to minimize the movement of sediments resulting from construction activities that take place within any drainageway. Temporary facilities can be installed to divert flowing water around such sediment-generating construction activities within drainageways.

Some construction activities within a waterway are short lived, namely a few hours in duration, and are minor in nature. These are typically associated with maintenance of utilities and stream crossings and minor repairs to outfalls and eroded banks. In these cases, construction of temporary diversion facilities may cause more soil disturbance than the maintenance activity itself. If it can be reasonably determined that any channel work is maintenance related, is of very short duration, and will result in only a small disturbance of bottom sediment, it is reasonable to exempt these from the requirement to construct temporary diversion facilities.

5.1 Working Within or Crossing a Waterway

Whenever work occurs within a waterway, the following should be considered as appropriate:

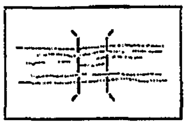
1. Construction vehicles should be kept out of a waterway to the maximum extent practicable. Where in-channel work is necessary, steps, such as temporary channel diversions, must be taken to stabilize the work area during construction to control erosion. The channel (including bed and banks) must be restabilized immediately after in-channel work is completed.

2. Where an actively-flowing watercourse must be crossed regularly by construction vehicles, a temporary crossing should be provided. Two primary methods are available: (1) a culverted crossing; and, (2) a stream ford.

   A culverted crossing should be designed to pass the 2-year design flow. A typical temporary stream crossing is shown on Figure C-17. For additional discussion on design of box culverts and pipes, see Sections 3 and 4, *Major Drainage*, of the *USDCM*.

   A ford should be lined with a minimum 6-inch thick layer of 1-1/2 inch diameter rock. A typical stream ford is shown on Figure C-18.

   A permit is required for placement of fill in a waterway under Section 404 of the Clean Water Act. The U.S. Army Corps of Engineers has issued nationwide general permit Number 14 for Minor Road Crossing Fills. This is defined as placement of less than 200 cubic yards of fill



SC

TEMPORARY STREAM CROSSING

Definition

A temporary structural span installed across a flowing watercourse for use by construction traffic. Structures may include bridges, round pipes or pipe arches.

Purposes

To stabilize stream crossings and reduce erosion created by construction traffic.

FIGURE C-17
Temporary Culvert Stream Crossing

R0017914

SC

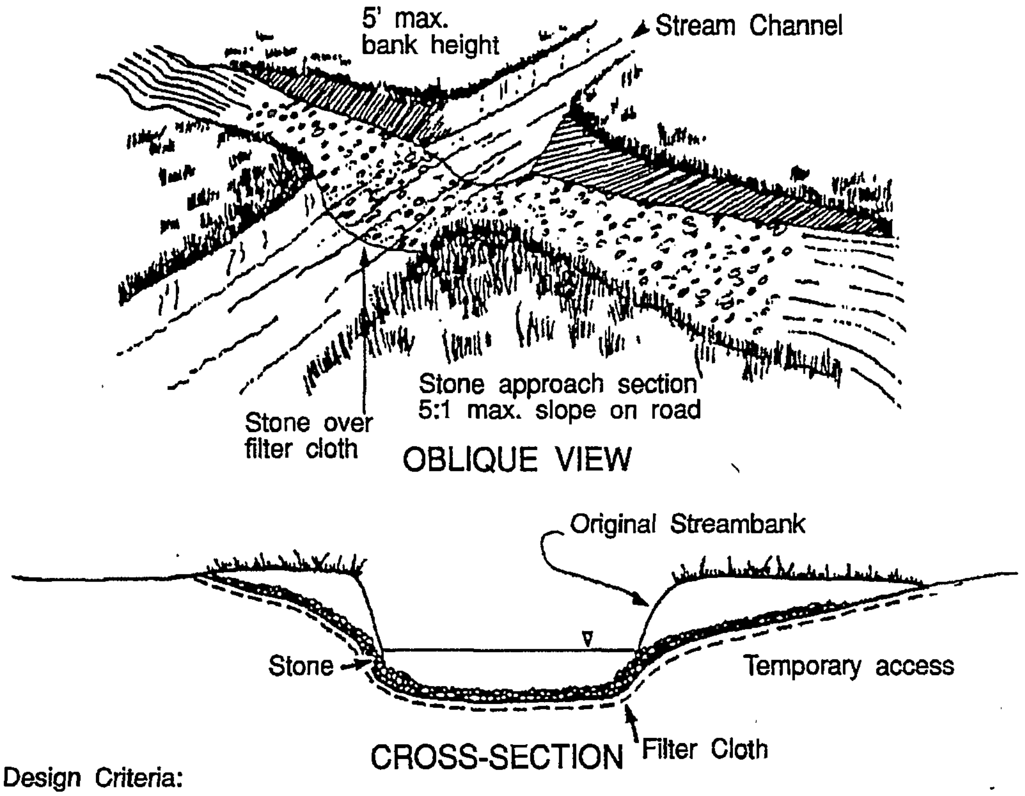
TEMPORARY STREAM CROSSING

Definition

A temporary at-grade stream crossing installed across a normally dry watercourse for use by construction traffic.

Purposes

To stabilize stream crossings and reduce erosion created by construction traffic.



Design Criteria:

- As a minimum, design the structure to pass bankfull flow or peak flow, whichever is less, from a 2-year peak storm, without overtopping.
- Ensure that design flow velocity at the outlet of the crossing structure is nonerosive for the receiving stream channel. See Vol. II, Major Drainage, Section 5.3

From: North Carolina Sediment Control Commission, 1988

FIGURE C-18
Typical Ford Stream Crossing

R0017915

material below the plane of ordinary high water. The local office of the Corps should be contacted about the requirements for obtaining a 404 permit. The city or county of jurisdiction should also be consulted and can provide assistance. A further discussion on the need for 404 permits is included in Section 2.1, *Major Drainage*, of the *USDCM*.

3. Whenever feasible, use a temporary water diversion (Section 5.2) to bypass the work areas when work takes place within a channel itself.
4. Whenever possible, construction in a waterway should be sequenced to begin at the most downstream point and work progressively upstream installing required channel and grade control facilities.
5. Complete work in small segments, exposing as little of the channel at a time as possible.
6. Where possible, perform all in-channel work between September 15 and April 15.

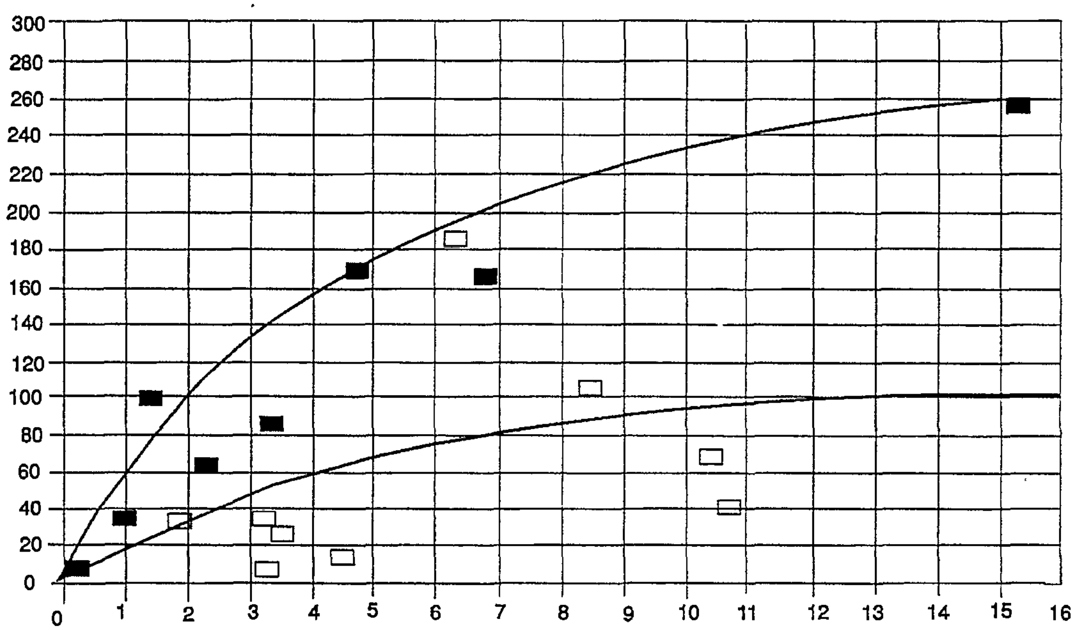
5.2 Temporary Channel Diversions

Limiting construction activities within actively-flowing water will significantly reduce sediment movement downstream from these activities. This can be done by using a temporary diversion facility that carries water around construction activities taking place within a waterway.

Permanent drainage channels should be constructed at the earliest possible stage of development. Temporary channel diversions should not remain in place for more than two years prior to removal or replacement by permanent facilities.

5.2.1 Temporary Diversion Sizing. Figure C-19 must be used to determine the minimum design discharge to size temporary diversions. The two curves in Figure C-19 were developed using monthly peak flow data for the months of April through September collected at 17 watersheds within the Urban Drainage and Flood Control District. Data for these watersheds were collected over periods that ranged from six years to eleven years and, as a result, provide reasonable statistical foundation for Figure C-19. The designer of a temporary diversion facility and the construction contractor must recognize that the design flows taken from Figure C-19 are for sediment control and not job-site protection from large runoff events, since these flow values are not representative of major or minor floods. However, all temporary channel diversions shall be sized to convey no less than the flows provided by Figure C-19. Since each construction project is unique, it is recommended that the contractor consider the use of larger temporary water diversion facilities to protect the job site from higher runoff.

ADJUSTED TRIBUTARY AREA VS. 50 PERCENTILE COMPUTED OUTFLOW



This figure covers the April through September period. When construction is expected to be totally completed within October through March period without a possibility of extending into the April through September period, temporary diversion design can be based on 50% of these flows.

FIGURE C-19
Temporary Diversion Facility Sizing Nomograph for Denver Region

R0017917

While Figure C-19 suggests minimum design flows for April through September, the chances of high runoff decrease substantially during the months of October through March. During these months, much of the precipitation is snow that produces snowmelt runoff rates that are low when compared to runoff from rainstorms. As a result, it is suggested that temporary channel diversion structures for projects scheduled to be performed and completed during October through March be designed to carry no less than one-half of the flow values taken from Figure C-19.

5.2.2 Stability Considerations. Temporary channels are not likely to be in service long enough to establish adequate vegetative lining. Temporary channel diversions must be designed to be stable for the design flow with the channel shear stress less than the critical tractive shear stress for the channel lining material. Unlined channels should not be used unless it can be demonstrated that an unlined channel will not erode during the design flow. Table C-6 gives allowable channel lining materials for a range of slope and flow depth. Table C-7 gives Mannings 'n' values for lining materials. Design procedures for temporary channels are described in detail in the Hydraulic Engineering Circular No. 15 published by the Federal Highway Administration. The methods presented in this section are greatly simplified and are based on information developed using only the most commonly used erosion control materials.

TABLE C-6
Lining Materials for Temporary Channels[a]

	Maximum Flow Depth	
Slope Range	**1 ft.**	**3 ft.**
0% - 0.005%	Jute Netting	Straw or Wood Fiber Erosion Control Netting or Plastic Membrane
0.005% - 1.0%	Straw or Wood Fiber Erosion Control Netting or Plastic Membrane	Straw or Wood Fiber Erosion Control Netting
1.0% - 2.0%	Straw or wood Fiber Erosion Control Netting	Type VL Riprap
2.0% - 3.0%	Type VL Riprap	Type L Riprap
3.0% - 4.0%	Type VL Riprap	Type M Riprap

[a]See Table C-7 for channel design parameters.

5.2.3 Example: Temporary Diversion Design. A simplified method for designing a non-erosive channel is given as follows:

Step One: Using the tributary area A (in acres) determine peak flow according to Figure C-19.

R0017918

Step Two: Determine depth of flow, one foot maximum for flows less than 20 cfs and three feet maximum for flows less than 100 cfs. (Flows in excess of 100 cfs should be designed in accordance with the *Major Drainage* Section of the *USDCM*.)

Step Three: Determine channel slope based on existing and proposed site conditions.

Step Four: Select lining material from Table C-6.

Step Five: Determine the channel geometry and check the capacity using Manning's Equation and the "n" value given in Table C-7. The steepest side slope allowable for a temporary channel is two horizontal to one vertical (i.e., 2:1). It is suggested that the design for temporary bypass channels include an additional 0.5 feet of freeboard.

TABLE C-7
Temporary Channel Design Criteria

Lining Material	Flow Depth 0 ft to 1.0 ft	Flow Depth 1.0 ft to 3.0 ft
Plastic Membrane	0.011	0.010
Jute Netting	0.028	n/a
Straw or Curled Wood Mats	0.035	0.025
Riprap, Type VL	0.070	0.035
Riprap, Type L	0.073	0.037
Riprap, Type M	0.075	0.040

Notes: Maximum depth is 1 foot for flows less than 20 cfs.

Maximum depth is 3 feet for flows equal to or greater than 20 cfs but less than 100 cfs (flows than 100 cfs should be designed in accordance with the Major Drainage Section of the *USDCM*).

Determine the channel bottom width by using Manning's Equation and the "n" value given above.

See Table 5-1 in the Major Drainage Section of the *USDCM* for riprap gradation.

Unless structurally reinforced, side slopes shall be two horizontal to one vertical (2:1) or flatter.

Erosion protection should extend to 0.5 feet above the design depth.

5.3 Outlet Protection

To protect adjacent downstream properties from erosion due to concentrated flows, a stable outlet or channel is necessary. If there is no stable outlet, one may have to be constructed. In lieu of constructing a temporary or permanent outlet to the storm drainageway system, temporary total retention of the runoff from a 24-hour, 100-year storm may be provided. Written approval by the local city or county must be obtained for total retention of stormwater.

The outlets of slope drains, culverts, sediment traps, and sediment basins must be protected from erosion and scour. Outlet protection should be provided where the velocity of flow will exceed the maximum permissible velocity of the material where discharge occurs. This may require the use of a riprap apron at the outlet location. Design guidance on outlet protection is provided on Figure C-20.

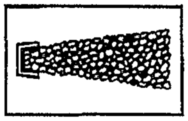
Check dams can be used in ditches or swales and downstream of the outlets of temporary slope drains, culverts, sediment traps, and sediment basins. Check dams reduce the velocity of concentrated flows and trap sediment eroded from the upstream ditch or swale. They are not a primary sediment trapping facility and are a temporary flow-control structure.

Check dams may be used under the following conditions:

- In temporary or permanent swales that need protection during the establishment of grasses
- In permanent swales that need protection prior to installation of a non-erodible lining
- In temporary ditches or swales that need protection where construction of a non-erodible lining is not practicable.

Check dams should be constructed of four- to six-inch angular rock to a maximum height of two-feet. The center of the top of the dam should be six-inches lower than the sides to concentrate the flow to the channel center. Where multiple check dams are used, the top of the lower dam should be at the same topographical elevation as the toe of the upper dam. Cross-sections of a loose-rock check dam and the spacing between a series of check dams are illustrated on Figure C-21.

Sediment that collects behind a check dam shall be removed when the sediment reaches the spillway level. Check dams constructed in permanent swales should be removed when perennial grasses have become established, or immediately prior to installation of a non-erodible lining. All of the rock and accumulated sediment should be removed, and the area seeded and mulched, or otherwise stabilized.



OP

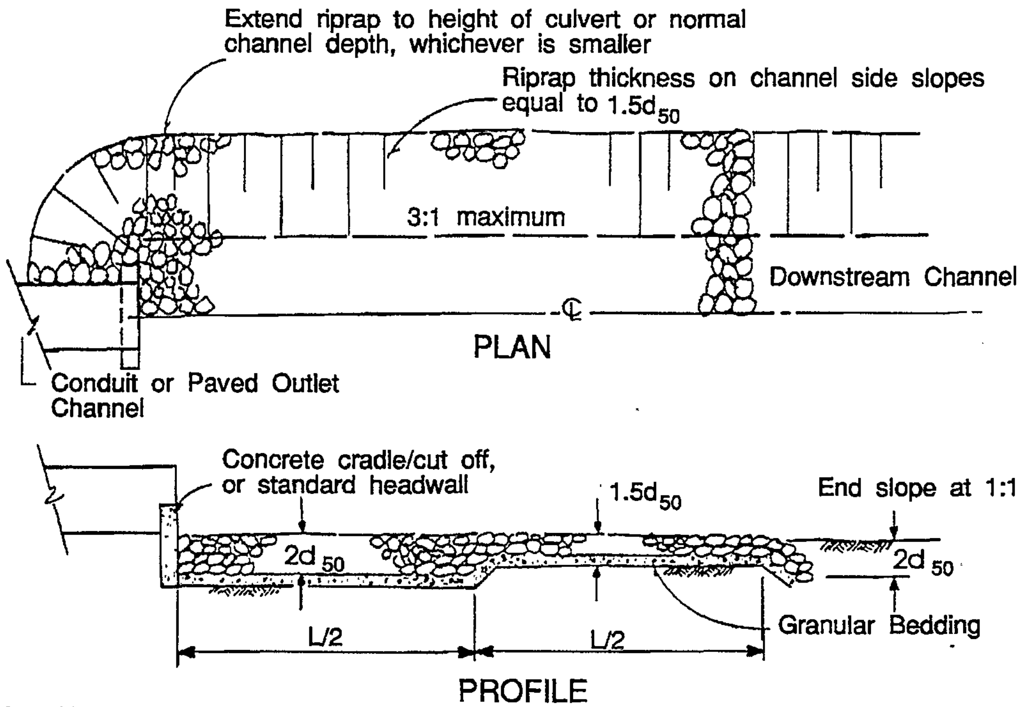
OUTLET PROTECTION

Definition

Structurally lined aprons or other acceptable energy dissipating devices placed at the outlets of pipes or paved channel sections.

Purposes

To prevent scour at stormwater outlets and to minimize the potential for downstream erosion by reducing the velocity of concentrated stormwater flows.



See Urban Storm Drainage Criteria Manual, Vol. 2, "Major Drainage", Section 5.6 for design criteria.

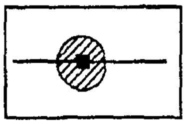
5.4 Inlet Protection

All storm sewer inlets which are made operable during construction must be protected to prevent sediment-laden runoff from entering the conveyance system without first being filtered or otherwise treated to remove sediment. A number of alternate inlet protection designs are available for use as shown on Figures C-22 through C-27.

An important consideration in construction of curb-opening inlets is that their maximum height should be less than the top of the curb opening. This is to allow overflows to occur during large rainfall events even though sediment-laden runoff will enter the storm drainage system. If the inlet protection height is greater than the curb elevation, particularly if the filter is clogged from previous sediment deposits, runoff will not be allowed to enter the inlet and will bypass the inlet. If downstream inlets are constructed similarly, runoff amounts that are bypassed accumulate rapidly. Significant erosion will occur at the downstream location where curb flows eventually level the gutter and travel across unprotected soil on a hillslope.

Inlet protection devices that are easy to construct, portable, and reusable, such as the "gravel sock" shown in Figure C-27, offer many advantages. These can also be placed upstream of an inlet at intervals in the gutter flow line and also at the entrance to the inlet. Sediment removal and re-construction is facilitated with this portable device. Inlet protection measures may be removed after upstream disturbed areas are stabilized.

R0017923



IP

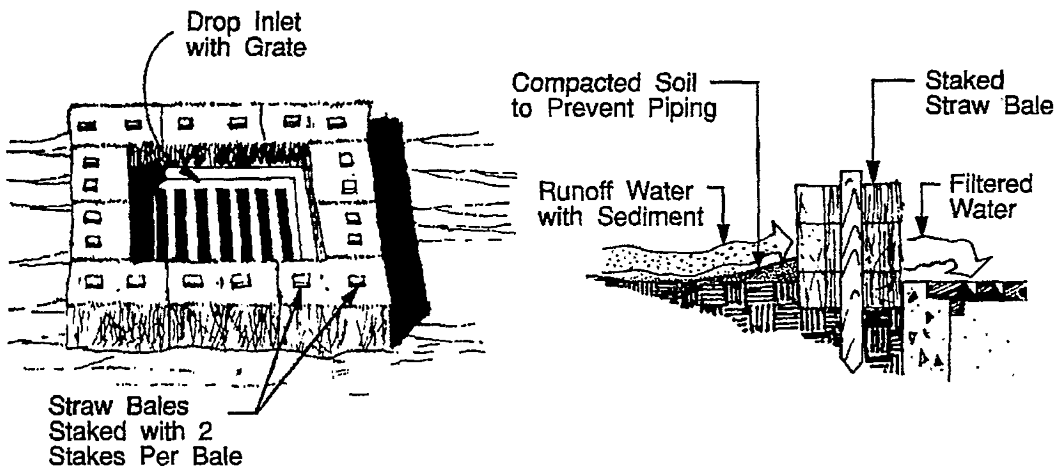
INLET PROTECTION

Definition

A sediment filter or an excavated impounding area around a storm drain drop inlet or curb inlet.

Purposes

To reduce sediment from entering storm drainage systems prior to permanent stabilization of disturbed areas.



Specific Application

This method of inlet protection is applicable where the inlet drains a relatively flat area (slopes no greater than 5 percent) where sheet or overland flows (not exceeding 0.5 cfs) are typical. The method shall not apply to inlets receiving concentrated flows, such as in street or highway medians.

6.0 MATERIAL STORAGE

Materials are sometimes used at a construction site that present a potential for contamination of stormwater runoff. These include fuel, oil, lubricants, paints, solvents, concrete-curing compounds and other liquid chemicals such as fertilizers, herbicides and pesticides. Practices that can be used to prevent or minimize toxic materials in runoff from a construction site are described in this section.

6.1 Chemical and Petroleum Products Storage

Areas at the construction site that are used for storage of toxic materials and petroleum products should be designed with an enclosure, container, or dike located around the perimeter of the storage area to prevent discharge of these materials in runoff from the construction site. These barriers will also function to contain spilled materials from contact with surface runoff.

Measures to prevent spills or leaks of fuel, gear oil, lubricants, antifreeze, and other fluids from construction vehicles and heavy equipment should be considered to protect groundwater and runoff quality. All equipment maintenance should be performed in a designated area and measures, such as drip pans, used to contain petroleum products. Spills of construction-related materials, such as paints, solvents, or other fluids and chemicals, should be cleaned up immediately and disposed of properly. For additional guidance on spill prevention and response, and material storage practices, see the appropriate sections in the *Nonstructural BMPs* chapter of the *Manual.*

6.2 Waste Storage

Areas used for collection and temporary storage of solid or liquid waste should be designed to prevent discharge of these materials in runoff from the construction site. Collection sites should be located away from the storm drainage system. Consideration should be given to covering waste storage areas, fencing these areas, if necessary, to contain windblown materials, and construction of a perimeter dike to exclude runoff. These measures may not be necessary if all waste is placed immediately in covered waste containers at the site and is otherwise controlled in an effective manner. All waste should be disposed at an approved landfill. For additional guidance on waste storage and disposal practices, see the appropriate sections in the *Nonstructural BMPs* chapter of the *Manual.*

7.0 UNDERGROUND UTILITY CONSTRUCTION

The construction of underground utility lines that are not exempted (see Section 1.3.4) shall be subject to the following criteria:

1. No more than 200 feet of trench are to be opened at one time (local criteria may be more restrictive).
2. Where consistent with safety and space considerations, excavated material is to be placed on the uphill side of trenches.
3. Trench dewatering devices must discharge in a manner that will not adversely affect flowing streams, wetlands, drainage systems, or off-site property. Site dewatering permit requirements should be discussed with the Colorado Department of Public Health and Environment.
4. Provide storm sewer inlet protection (Section 5.4) whenever soil erosion from the excavated material has the potential for entering the storm drainage system.

8.0 DISPOSITION OF TEMPORARY MEASURES

All temporary erosion and sediment control measures shall be removed and disposed within 30 days after final site stabilization is achieved, or after the temporary measures are no longer needed, whichever occurs earliest, or as authorized by the city or county of local jurisdiction. For example, a site containing only one building will have temporary erosion control measures removed after building construction is complete and final landscaping is in place. Temporary erosion control measures may be removed from a commercial construction site or residential subdivision only after streets are paved and all areas have achieved final stabilization. Trapped sediment and disturbed soil areas resulting from the disposal of temporary measures must be returned to final plan grades and permanently stabilized to prevent further soil erosion.

The Professional Engineer preparing the erosion and sediment control plan shall submit, as part of the narrative report, a schedule of removal dates for temporary control measures. The schedule should be consistent with key construction phases such as street paving, final stabilization of disturbed areas, or installation of structural stormwater controls.

9.0 MAINTENANCE

All temporary and permanent erosion and sediment control practices shall be maintained and repaired by the owner during the construction phase as needed to assure continued performance of their intended function. Straw bale barriers, silt fences, and inlet protection devices may require periodic replacement and all sediment accumulated behind them must be removed and disposed of properly. Sediment basins will require periodic sediment removal when the design storage level is one-half full. All facilities must be inspected by the owner or owner's representative following each heavy precipitation or snowmelt event that results in runoff.

The Professional Engineer preparing the erosion and sediment control plan shall submit, as part of the narrative report, a schedule of planned maintenance activities for temporary and permanent erosion and sediment control measures. The schedule should be consistent with the level of maintenance required for the control measures proposed in the plan.

APPENDIX A

MODEL ORDINANCE FOR EROSION AND SEDIMENTATION CONTROL
(Revised August 28, 1991)

AN ORDINANCE TO AMEND THE CODE OF THE CITY (COUNTY) OF ____________________ BY ADDING A NEW CHAPTER RELATING TO EROSION AND SEDIMENT CONTROL, AND ADOPTING BY REFERENCE THE PUBLISHED CRITERIA FOR "EROSION AND SEDIMENT CONTROL FOR CONSTRUCTION ACTIVITIES" OF THE URBAN DRAINAGE AND FLOOD CONTROL DISTRICT, BY ADDING A NEW CHAPTER, WHICH NEW CHAPTER SHALL BE DESIGNATED AS CHAPTER _____ OF TITLE _________ OF SAID CODE.

THE CITY (COUNTY) OF __________________________________, ORDAINS;

Title ________ of the Code of the City (County) of __________________________, is amended by adding a new Chapter _______ - Grading and Soil Erosion Control, which shall read as follows:

CHAPTER NO.

GRADING AND SOIL EROSION CONTROL

Section 1. Legislative Findings. The City Council (Board of County Commissioners) hereby finds that excessive quantities of soil are eroding from certain areas that are undergoing development for non-agricultural uses such as housing and commercial developments, industrial areas, recreational facilities, and roads. This erosion makes necessary costly repairs to gullies, washed out fills, roads and embankments. The resulting sediment clogs storm sewers and road ditches, and leaves deposits of silt in streams, lakes and reservoirs and is considered a significant water pollutant.

Section 2. Purposes. The purpose of this Ordinance (Resolution) is to prevent soil erosion and sedimentation from leaving construction sites that occur from non-agricultural development and construction activities within the City (County) by requiring proper provisions for water disposal and the protection of soil surfaces during and after construction, in order to promote the safety, public health, convenience and general welfare of the community (County).

Any person who undertakes or is responsible for an undertaking which involves earth disturbance is ultimately responsible to see that soil erosion and sedimentation as well as changed water flow characteristics resulting therefrom are controlled to the extent necessary to avoid damage to property and to avoid pollution of receiving waters. Nothing in this Ordinance (Resolution) shall be taken or construed as lessening or modifying the ultimate responsibility of such persons. Nor do the permit requirements of this Ordinance (Resolution) imply the assumption of any liability therefor on the part of the City (County). The standards, criteria and requirements of this Ordinance (Resolution) are to be seen as minimum standards which are not necessarily adequate to meet the highly variable conditions which must be covered by effective control measures. Compliance with the requirements of this Ordinance (Resolution) may not, therefore, of itself discharge such person's responsibility to provide effective control measures.

Section 3. Definitions. The following definitions shall apply in the interpretation and enforcement of this Chapter.

(1) "Accelerated soil erosion" - The increased migration and movement of soils on all land surfaces that occur as a result of man's activities.

(2) "Inspector" - The chief of the __________ Department (insert department title) of the City (County) or his duly authorized representative.

(3) "Certificate of completion" - A signed written statement by a licensed professional engineer working for the applicant stating that all construction, all earth disturbance work, and all permanent soil erosion control measures were inspected by the engineer and were installed in strict compliance with the approved plans and specifications.

(4) "City (County) Engineer" - The City (County) Engineer of the City (County) or his duly authorized representative.

(5) "Earth disturbance" - A man-made change in the natural cover or topography of land, including all grading, cut and fill, building, paving and other activities, which may result in or contribute to soil erosion or sedimentation of the waters of the State.

(6) "Erosion" - The process by which the ground surface is worn away by action of wind, water, gravity, or a combination thereof.

(7) "Excavation" - Any act by which soil or rock is cut into, dug, quarried, uncovered, removed, displaced, relocated, or stockpiled, and also included shall be the conditions resulting therefrom.

(8) "Filling" - Any act by which soil, rock or other construction materials are placed, stockpiled, dumped, or a combination thereof onto the surface of the earth that may exposed to rain or wind.

(9) "Flood plain" - An area adjacent to a watercourse, which area is subject to flooding as the result of the occurrence of the 100-year flood and which area thus is so adverse to past, current, or foreseeable construction or land use as to constitute a significant hazard to public health and safety or property.

(10) "Grading" - Any stripping, excavating, filling, stockpiling, or any combination thereof, and also included shall be the land in its excavated or filled condition.

(11) "Grading permit" - A permit issued to authorize work to be performed under this Ordinance.

(12) "Land use" - A use of land which may result in an earth disturbance, including, but not limited to, subdivision, residential, commercial, industrial, recreational, or other development, private and public highway, road and street construction, drainage construction, logging operations, agricultural practices, and mining.

(13) "Limits of allowable erosion" - The natural or historic rate of soil loss.

(14) "Permanent soil erosion control measures" - Those control measures which are installed or constructed to control soil erosion and which are maintained after completion of all grading and earth disturbance activities.

(15) "Person" - A natural person, firm, corporation, partnership, or association.

(16) "Slope" - Slope of land measured in horizontal distance necessary for the land to fall or rise one foot, expressed by horizontal distance in feet to one vertical foot.

(17) "Stripping" - Any activity which removes or significantly disturbs the vegetative surface cover including clearing and grubbing operations.

(18) "Temporary soil erosion control measures" - Interim control measures which are installed or constructed and maintained whenever grading or other earth disturbance is to occur for the purpose of control soil erosion until permanent soil erosion control is effected.

Section 4. Compliance with Chapter Required for Site Plan or Plat Approval. No site plan, plot plan, or plat shall be approved under Chapters ______ and ______ of this Code unless said site plan, plot plan, or plat shall include soil erosion and sediment control measures consistent with the requirements of this Chapter and related land development regulations.

Section 5. Compliance with Chapter Required for Occupancy. No certificate of occupancy for any building shall be issued under Chapter ______ of this Code unless the applicant for said Certificate of Occupancy submits a Certificate of Completion to the City (County) and said Certificate of Completion is approved by the City (County) Engineer.

Section 6. Adoption by reference of Erosion and Sediment Control Criteria. There is hereby adopted by reference, as a part of this ordinance (resolution), as if fully set forth herein, that certain code consisting of the published criteria of The Urban Drainage and Flood Control District, adopted by said District on ______________ 1991, effective on the _______ day of _______________, 1991, known as "Erosion and Sediment Control for Construction Activities," published on _________________, 1991, which shall be known and referred to in this ordinance (resolution) by that name. The Inspector and the City (County) Engineer shall be guided by and shall apply the criteria contained in said code in the administration of this ordinance (resolution).

Section 7. Permits and Fees.

(1) Permit requirement. Except as exempted by sections of this ordinance (resolution), no person shall do any grading, stripping, excavating, or filling, or undertake any earth disturbance, unless a valid grading permit is issued by the City (County). Issuance by City (County) does not exempt the parties from obtaining any permits required by State of Colorado or the Federal Government.

(2) Permit application. A separate application shall be required for each grading permit, along with plans, specifications, and timing schedules for all earth disturbance. The plans shall be prepared under the supervision of a professional engineer licensed in the State of Colorado experienced in soil erosion and sedimentation control methods and techniques.

(3) Application data required. The plans and specifications shall include an Erosion and Sedimentation Control Plan and a Site Plan, which shall include and contain all of the requirements of Section 1.4 of the "Erosion and Sediment Control for Construction Activities".

(4) Fees. At the time of filing an application for a grading permit, a non-refundable filing fee of _______________________________________ Dollars $__________________ shall be paid to the City (County) Treasurer. An additional non-refundable fee of ______________________________ Dollars per acre of site area involved will be charged for plan review and site inspections (with a minimum fee of _______________________________ Dollars $___________________ for such review and inspection).

Section 8. Bond Requirement. A grading permit shall not be issued unless the permittee shall first post with the City (County) Engineer a bond executed by the landowner and a corporate surety with authority to do business in this State as a surety, or at the option of the City (County) Engineer, secured by a letter of credit drawn upon a bank doing business in Colorado, or having a Colorado correspondent bank at which such letter of credit may be collected.

The bond and letter of credit, whichever is used, shall be in a form approved by the City (County) Attorney, payable to the City (County), and in the amount of the estimated total cost of all temporary or permanent soil erosion control measures. The total cost shall be estimated by the City (County) Engineer or Building Inspector. The bond, and letter of credit, whichever is used, shall include penalty provisions for failure to complete the work on schedule as specified on the grading permit. In lieu of a surety bond or letter of credit, the applicant may file with the City (County) a cash bond or other instrument of credit which gives the City (County) at least equal security protection, approved by the City (County) Attorney in the amount equal to that which would be provided for in the surety bond or letter of credit.

Every bond and letter of credit or other instrument of credit shall include and every cash deposit shall be made on the conditions that the permittee shall comply with all of the provisions of this ordinance (resolution) and all of the terms and conditions of the grading permit, and shall complete all of the work contemplated under the grading permit within the time limit specified in the grading permit, or if no time limit is specified, within 180 days after the date of issuance of the grading permit.

A bond and surety thereon, or letter of credit, whichever is used, will be released to applicant four hundred ten (410) days after the Certificate of Completion has been approved by the City (County) Engineer, provided the City (County) Engineer, after field inspection, is satisfied the work completed under the grading permit is functioning as represented by applicant, or in the event defects are identified by the City (County) Engineer the applicant satisfactorily corrects all the defects identified in writing by the City (County) Engineer and said corrections are accepted in writing by the City (County) Engineer.

Section 9. Extension of Time. If the permittee is unable to complete the work within the specified time, at least ten (10) days prior to the expiration of the permit, a written request to the City (County) Engineer for an extension of time shall be submitted setting forth the reasons for the requested extension. In the event such an extension is warranted, the City (County) Engineer may grant additional time for the completion of the work, but no such extension shall release the owner or surety on the bond or the issuer of the letter of credit, or the person furnishing the instrument of credit or cash bond.

Section 10. Failure to Complete the Work. In the event of failure to complete the work or failure to comply with all the requirements, conditions, and terms of permit, the City (County) Engineer may order such work as is necessary to eliminate any danger to persons or property and to leave the site in a safe condition and he may authorize completion of all necessary temporary or permanent soil erosion control measures. The permittee and the surety executing the bond or the issuer of the letter of credit, or person issuing the instrument of credit or making the cash deposit shall continue to be firmly bound under a continuing obligation for the payment of all necessary costs and expenses that may be incurred or expended by the City (County) in causing any and all such work to be done. In the case of a cash deposit, any unused portion thereof shall be refunded to the permittee.

Section 11. Denial of Permit. Grading permits shall not be issued where:

(1) The proposed work would cause hazardsto the public safety and welfare; or

(2) The work as proposed by the applicant will damage any public or private property or interfere with any existing drainage course in such a manner as to cause damage to any adjacent property or result in the deposition of debris or sediment on any public way or into any waterway or create an unreasonable hazard to persons or property; or

(3) The land area for which grading is proposed is subject to geological hazard to the extent that no reasonable amount of corrective work can eliminate or sufficiently reduce settlement, slope instability, or any other such hazard to persons or property; or

(4) The land area on which the grading is proposed may lie within the designated flood plain of any stream or watercourse (not specifically designated by the City (County) as an area subject to flood hazard), unless a hydrologic report, prepared by a professional engineer, is submitted to certify that the proposed grading will have, in his professional opinion, no detrimental influence on the public welfare or upon the total development of the watershed and is also consistent with flood plain ordinances and Federal Emergency Management Agency regulations.

Section 12. Modifications of Approved Plans. All proposed modifications of the approved grading plan must be submitted along with all supporting materials, to the City (County) Engineer. No work in connection with the proposed modifications shall be permitted without prior approval of the City (County) Engineer, approval for which may be issued if the applicant can demonstrate that the modifications will provide soil erosion controls equivalent to, or better that the originally approved soil disturbance plans.

Section 13. Responsibility of Permittee. During grading operations the permittee shall be responsible for:

(1) The prevention of damage to any public utilities or services within the limits or grading and along any routes of travel of the equipment;

(2) The prevention of damage to adjacent property (No person shall grade on land so close to the property line as to endanger any adjoining public street, sidewalk, alley, or any public or private property without supporting and protecting such property from settling, cracking, or other damage which might result).

(3) Carrying out the proposed work in accordance with the approved plans and in compliance with all the requirements of the permit and this ordinance (resolution);

(4) The prompt removal of all soil, miscellaneous debris, materials applied, dumped, or otherwise deposited on public streets, highways, sidewalks, or other public thoroughfares or any other non-authorized offsite location, during transit to and from the construction site, or otherwise, where such spillage constitutes a public nuisance, trespass or hazard in the determination of the City (County) Engineer or a Court of competent jurisdiction.

Section 14. General Requirements.

(1) All temporary erosion control facilities and all permanent facilities intended to control erosion of any earth disturbance operation shall be installed before any earth disturbance operations take place.

(2) Any earth disturbances shall be conducted in such a manner so as to effectively reduce accelerated soil erosion and resulting sedimentation, and should not exceed the erosion expected to occur for the site in is totally undeveloped state.

(3) All persons engaged in earth disturbances shall design, implement, and maintain acceptable soil erosion and sedimentation control measures, in conformance with the erosion control technical standards adopted by the City.

(4) All earth disturbances shall be designed, constructed and completed in such a manner so that the exposed area of any disturbed land shall be limited to the shortest possible period of time.

(5) Sediment cause by accelerated soil erosion shall be removed from runoff water before it leaves the site of the earth disturbance.

(6) Any temporary or permanent facility designed and constructed for the conveyance of water around, through, or from the earth disturbance area shall be designed to limit the water flow to a non-erosive velocity.

(7) Temporary soil erosion control facilities shall be removed and earth disturbance areas graded and stabilized with permanent soil erosion control measures pursuant to standards and specifications prescribed in accordance with the provisions of the "Erosion and Sediment Control for Construction Activities" and in accordance with the permanent erosion control features shown on the soil stabilization plan approved by the City (County).

(8) Permanent soil erosion control measures for all slopes, channels, ditches, or any disturbed land area shall be completed within fourteen (14) calendar days after final grading or the final earth disturbance has been completed. When it is not possible to permanently stabilize a disturbed area after an earth disturbance has been completed or where significant earth disturbance activity ceases, temporary soil erosion control measures shall be implemented within fourteen (14) calendar days. All temporary soil erosion control measures shall be maintained until permanent soil erosion measures are implemented.

Section 15. Maintenance Requirements. Persons carrying out soil erosion and sediment control measures under this Chapter, and all subsequent owners of property concerning which such measures have been taken, shall maintain all permanent erosion control measures, retaining wall, structures, plantings, and other protective devices. Should the applicant or any of the subsequent property owners fail to adequately maintain the permanent erosion control facilities, retaining walls, structures, plantings, and other protective devices, the City (County) reserves the authority, after properly notifying the owner of needed maintenance and the owner failing to respond to the City's (County's) demand for such maintenance to enter affected property, provide needed maintenance and to charge the owner for the work performed by the City (County) or its contractors.

Section 16. Minimum Design Standards for Erosion and Sediment Control. All erosion control plans and specifications including extensions of previously approved plans shall include provisions for erosion and sediment control in accordance with the "Erosion and Sediment Control for Construction Activities". Erosion control plans are required on sites which are:

(1) Five (5) acres in size or larger, and all sites smaller than five (5) acres if they are a part of a total development or subdivision that is larger than five (5) acres in size; or

(2) Any development containing 15 dwelling units; or

(3) Where physical features have a cumulative effect and will create erosion problems such as:

a. Steep slopes - 8-feet (horizontal) to 1-foot (vertical) or steeper, and

b. Significantly erodible soils - "K" in the universal soil loss equation is greater than or equal to 0.25;

Section 17. Variances and Exceptions.

(1) No permits shall be required for the following:

(a) Agricultural use of land zoned agricultural.

(b) Grading or an excavation below finished grade for basements, footings, retaining walls, or other structures on plots zoned R1 - R3 of less than five (5) acres in size unless required otherwise under Section 16 above.

(c) A sidewalk or driveway authorized by a valid permit under Chapters ________ of ________.

(d) Gravel, sand, dirt or topsoil removal as authorized pursuant to approval of the Colorado Mined Land Reclamation Board, provided said approval includes an erosion plan that meets the minimums specified by this ordinance.

(e) Sites smaller than five (5) acres which are not a part of a larger development and which constitute an infill of an established older development within the City.

(f) Where the City (County) Engineer certifies in writing that the planned work and the final structures or topographical changes will not result in or contribute to soil erosion or sedimentation and will not interfere with any existing drainage course in such a manner as to cause damage to any adjacent property or result in the deposition of debris or sediment on any public way, will not present any hazard to any persons or property and will have no detrimental influence upon the public welfare or upon the total development of the watershed.

(g) Even though no permits are required under subsections (1)(a), (b), (c), (d), and (e) of this section, those operations and construction activities which are exempted from obtaining permits must comply with the rules and regulations concerning grading and erosion specified in this Chapter, and shall provide appropriate controls to retain soil erosion on the construction site.

(2) Where it is alleged that there is error or misinterpretation in any order, requirements, decisions, grant or refusal made by the City (County) Engineer, the (chose as appropriate: Deputy City Manager, Manager of Public Works, Public Works Director, County Manager, Chairman of the Board of County Commissioners) may appoint a technical hearing board that shall have the power to hear specific applications and all complaints regarding the decisions of the City (County) Engineer and to determine if the decisions of the City (County) Engineer were based on a misinterpretation of the requirements of this Chapter and referenced criteria. Whenever it is determined that an interpretation error was made, the case will be returned to City (County) Engineer, along with the board's recommendations on how the Engineer's decision could be modified to made consistent with the provisions of this Chapter.

* *In absence of this, or another similar appeals process, resort directly to court would be the only remedy, which may not be desired as a matter of policy. If such policy is desired, however, it is suggested it be spelled out by substituting for (2) above, the following, or a similar subsection:*

(2) Review of any order, requirement, decision, grant or refusal made by the City (County) Engineer, and claimed to be illegal, shall be by the District Court pursuant to the Colorado Rules of Civil Procedure.

Section 18. Inspection. The requirements of this Chapter shall be enforced by the City (County) Engineer. The City (County) Engineer shall inspect the work and shall require the owner to obtain services to provide adequate on-site inspection and/or compaction testing by a soil engineer, approved by the City (County) Engineer, unless he determines that such inspection requirements may be waived due to the non-hazardous nature of the grading.

Upon satisfactory execution of all approved grading plans and other requirements, the City (County) Engineer shall issue a certification of completion. If the City (County) Engineer finds any existing conditions not as stated in any application, grading permit or approved plan, he may refuse to approve further work until a revised grading plan which will conform to the existing condition has been prepared and approved.

If the City (County) Engineer finds that eroded soils are leaving the construction site, the City (County) Engineer may direct the owner(s) or his agents or his contractor on the site by written order to install any and all erosion controls that are deemed necessary to prevent said soil erosion from migrating off site. It shall be the duty of the owner(s) and his agent(s) and contractor(s) immediately to take all necessary steps to comply with such order and otherwise to take all necessary steps to prevent such migration off premises or entering receiving waters. Delivery of such a written order by the City (County) Engineer to the owner's agent or contractor shall be deemed to be notice thereof to and binding upon the owner.

Section 19. Enforcement. Notwithstanding the existence or pursuit of any other remedy, the City (County) may maintain an action in its own name in any court of competent jurisdiction for an injunction or other process against any person to restrain or prevent violations of this ordinance (resolution).

The City (County) Engineer, or his duly authorized agents, may enter at all reasonable times in, or upon, any private or public property for the purpose of inspecting and investigating conditions and practices which may be a violation of this ordinance (resolution).

Project Description

The Project consists of the development of a 6.2 acre parcel with two office buildings. The project is located in the SW quarter of Section #, Township, Range of the 6th principal meridian located in County, Colorado. The project involves grading of 5.2 acres of the parcel, constructing two office buildings, two parking lots, an access road, a box culvert over Dry Creek and associated site utilities.

Existing Site Conditions

Most of the existing site is vegetated with native grass. The plant density is estimated to be 50% coverage of the ground surface. Cottonwood trees and other riparian vegetation are found adjacent to Dry Creek. The site drains to Dry Creek except the southeast portion which drains offsite to the southeast. About 0.2 acres of wetlands are found next to Dry Creek. The riparian and wetland vegetation will not be disturbed by the site development. The existing slopes on the site range from 2% to 19% adjacent to the Creek.

Adjacent Areas

Surrounding development consists of office and commercial development. The site is bounded by Broadway and Monroe Streets. Dry Creek bisects the site. The proposed improvements to Dry Creek are limited to a box culvert and preservation of the 100-year floodplain (Refer to the Drainage Report for the Site).

Soils

Existing site soils consists of Ascalon sandy loam and Nunn sandy clay loam on the uplands and alluvial soils next to Dry Creek. Ascalon sandy loam is well drained with moderate permeability (Hydrologic soil group B) and has a slight erosion hazard. Nunn sandy clay loam is well drained with moderately slow permeability (Hydrologic soil group C) and presents a moderate erosion hazard. The alluvial soils adjacent to the Creek will not be disturbed.

II. Erosion and Sediment Control Plan

Volumes and Areas Impacted

The site will be graded with topsoil stripped and stockpiled. The total quantity of cut and fill is 3,500 cubic yards. The cut and fill is balanced, that is, no fill will be imported to the site. The access road, building site and parking areas will be graded, then covered with granular base course. Other graded areas will be mulched until permanent landscaping is installed.

Erosion and Sediment Control Measures

The erosion control measures for the site are shown on the "Sample Erosion and Sedimentation Control Plan." (Note: Proposed contours are not shown on this example plan for clarity; however, proposed contours are required to be shown on the site plan.) Offsite drainage from the north is diverted to the east along Broadway Avenue. Offsite drainage from the west is diverted to the south along Monroe Road. The area southeast of the proposed parking lot for Building "B" drains offsite. This area will remain undisturbed and will be protected with a silt fence. A stabilized construction entrance will be provided at the access point off Monroe Road. Diversion channels will be constructed near Dry Creek to collect runoff from the building areas and route flows to sediment basins. Each sediment basin collects runoff from 1.0 acre and will be excavated below grade. The sediment basins will be about 30 feet square and about two feet deep (show details) below the outlet. Sediment basins will have a surcharge

R0017972

volume of 1,800 cubic feet above the outlet. Straw bale barriers will be anchored next to the creek for the areas where runoff is not intercepted by the diversion channels.

Schedule

The construction schedule is as follows:

Install Construction Entrance, Sediment basins and Straw Bale Barriers:	September 15 - September 30
Site Grading:	September 30 - October 15
Install Base Course and Mulch All Exposed Soil Areas:	October 15 - October 20
Utility and Building Construction:	October 20 - April 1
Paving and Landscaping:	April 1 - April 15
Removal of Erosion Control Measures:	April 15 - April 20

The schedule will minimize the exposure of unprotected areas to less than 30 days. The perimeter controls will be installed prior to site grading.

Permanent Stabilization Measures

Permanent landscaping will include bluegrass sod, zeriscape plantings and trees and shrubs. The two sediment traps will be converted to the site detention ponds after sod is installed (Refer to the site Drainage Report for the detention requirements). The box culvert will be constructed early in the construction period to provide access across the creek during construction.

Stormwater Management Considerations

Stormwater will sheet flow from the building areas towards the creek, then be intercepted and routed to sediment traps during construction. All areas that will not be intercepted by the diversions will be protected with straw bale barriers. Post-development stormwater quality control will be provided by the vegetated filter strip adjacent to Dry Creek.

Construction Materials and Equipment

The contractor shall store all construction materials and equipment and shall provide maintenance and fueling of equipment in confined areas on site from which runoff will be contained and filtered.

Maintenance

The erosion control measures will be inspected weekly during construction. Sediment traps will be cleaned of excessive sediment if necessary. Erosion control blankets in the diversion channels will be checked after runoff events. Straw bale barriers will be checked for undermining and bypass and repaired or expanded as needed. Mulching of bare soils will be checked regularly and areas where it was lost or damage will be remulched within seven working days when needed.

Cost Estimate

The estimated cost of the erosion control measures is $7,320. A total of 780 linear feet of silt fences and straw bale barriers will be constructed at an estimated cost of $4.00 per foot. The two sediment traps involve excavation at a cost of $250 each. The diversion channels will be lined with a coconut fiber blanket at an estimated cost for grading and the blanket of $7.50 per linear foot for the 400 linear feet to be installed. The construction entrance will require 10 cubic yards of material at $10 per cubic yard. Site mulching and it maintenance prior to final revegetation is estimated to cost $500,000.

Calculations

Calculations for the diversion channels and sediment traps are provided herein. Details for the erosion control measures can be found in Figures C-5, C-6, C-7, C-8, C-9, C-12, C-13, C-15, and C-15A of the *Erosion Control Chapter* of Volume 3 of the *Urban Storm Drainage Criteria Manual*. (The figures are not included with this example to save space but shall be included with the erosion and sediment control plans submitted to the local jurisdiction.)

Slope Diversion Channel Sizing:

$Q = C\ I\ A$

$C = 0.2$ (From Table 3-1, USDCM, Runoff)

(Weighted average of undeveloped and parking areas.)

$I_{2\text{-yr}} = 2.6''/\text{hour}$ (From Fig. 5-1, USDCM, Rainfall)

$A = 2.0$ acres each

$Q = 0.2 \times 2.6 \times 2.0 =$ 1.04 cfs

Try a triangular channel with depth of 0.5 ft and four to one sideslopes. (Actual depth will be 1.0 ft. allowing 0.5 ft. as freeboard.)

Proposed Slope = 0.75%

$A = 1\ \text{ft}^2$, $P = 4.47$ ft. $R = 0.224$ ft.

Use a fiber blanket for erosion control.

$n = 0.035$

from Manning's Equation:

$V = 1.486/0.035 \times (.0075)^{1/2} = 1.35$ feet per second

$Q = A\ V = 1.35$ cfs

(more than 1.04 so this channel section is acceptable)

Check Erosion potential:

$\tau = \gamma\ d\ s$ (Shear Stress Formula)

$\tau = 62.4 \times 0.5 \times 0.0075 = 0.23\ \text{lb/ft}^2$

from HEC-15, $\tau_{allowable} = 0.65\ \text{lb/ft}^2$

τ_{actual} is less than $\tau_{allowable}$ so the diversions should be stable.

Sediment Basins

Tributary Area = 1.0 acres

Required Volume = $1{,}800\ \text{ft}^3/\text{acre} \times 1.0\ \text{acre} = 1{,}800\ \text{ft}^3$

Use a 30 ft. x 30 ft. x 2.0 ft. deep sediment basin

APPENDIX C

GLOSSARY OF TERMS

Erodibility - The susceptibility of a particular soil type to erosion by water or wind.

Erosion - The wearing away of the land surface by water, wind, ice or other geological agents, including the detachment and movement of soil or rock fragments by water, wind, ice, or gravity.

Erosion Control Measures - Practices that slow or stop erosion.

Final Stabilization - Completion of all land disturbing activities, removal of all temporary sediment controls, establishment of vegetative cover on exposed soil areas, and installation of permanent roads and structural stormwater quality best management practices.

Land Disturbing Activity - Grading, cut, fill, stockpiling of dirt, removal of vegetation, or any other alteration or disturbance of the ambient land surface.

Mapping Unit - Soil name and symbol given in the Soil Conservation Service Soil Survey for each soil type. Most areas of the Denver metropolitan area are included in a soil survey. In older urban portions of the City and County of Denver, soils analysis will be needed to determine soil types.

Permanent - Installation of land-surface cover, or erosion and sediment control measures, that will remain in place for a long period of time.

Sedimentation - The process of solid materials, both inorganic (mineral) and organic, coming to rest on the earth's surface either above or below sea level.

Sediment - Particulate solid material, either inorganic or organic, that will settle or be deposited in a liquid under the force of gravity.

Sediment Barrier - Straw bale barrier (dike) or a silt fence.

Sediment Basin - A depression, either excavated or formed by a dam, that holds water and debris and facilitates sedimentation of soil particles. Normally used for drainage areas equal to and greater than 1.0 acre.

Temporary - Installation of erosion or sediment control measures, either structural or nonstructural, that are planned to be removed or inactivated after a period of time.

Viable Vegetative Cover - A measure of performance for establishment of appropriate vegetative cover (or density) on sites planned for revegetation for the period of duration of successful growth as approved by the city and county of jurisdiction.

I. INTRODUCTION

A. PURPOSE OF REPORT TO CONGRESS

EPA provides this Report to Congress in compliance with Section 431(a) of the Departments of Veterans Affairs and Housing and Urban Development and Independent Agencies Appropriations Act of 2000, Pub. L. No. 106-74 (1999) ("Appropriations Act"). The Appropriations Act directs the Administrator of the Environmental Protection Agency ("EPA") to submit two reports to the Committee on Environment and Public Works in the Senate and the Committee on Transportation and Infrastructure in the House of Representatives. The first of the reports is to address several issues related to EPA rulemaking to implement Section 402(p)(6) of the Clean Water Act ("CWA"). This rulemaking is also referred to as the Storm Water Phase II rule. Section 431(a) of the Appropriations Act directs the Administrator to submit a report containing:

> (1) an in-depth impact analysis on the effect the final regulations will have on urban, suburban, and rural local governments subject to the regulations, including an estimate of --
>
> > (A) the costs of complying with the 6 minimum control measures described in the regulations; and
> >
> > (B) the costs resulting from the lowering of the construction threshold from 5 acres to 1 acre;
>
> (2) an explanation of the rationale of the Administrator for lowering the construction site threshold from 5 acres to 1 acre, including --
>
> > (A) an explanation, in light of recent court decisions, of why a 1-acre measure is any less arbitrarily determined than a 5-acre measure; and
> >
> > (B) all qualitative information used in determining an acre threshold for a construction site;
>
> (3) documentation demonstrating that storm water runoff is generally a problem in communities with populations of 50,000 to 100,000 (including an explanation of why the coverage of the regulation is based on a census-determined population instead of a water quality threshold); and
>
> (4) information that supports the position of the Administrator that the Phase II storm water program should be administered as part of the National Pollutant Discharge Elimination System under section 402 of the Federal Water Pollution Control Act (33 U.S.C. 1342).

Section 431(c) of the Appropriations Act directs EPA to publish the reports in the Federal Register for public comment. The Appropriations Act does not specify whether EPA should seek and respond to public comment on the reports prior to submitting them to the Committees. Section 431(a) does provide, however, that the Administrator shall not promulgate the Phase II rule until submitting the Section 431(a) report to the Committees. EPA is subject to a judicial consent decree in NRDC v. Browner, (D.D.C., Civ. No. 95-634 PLF) to take final action by October 29, 1999 on the Phase II rule proposed earlier. The Appropriations Act does not relieve EPA from the timing of this rulemaking obligation. Therefore, EPA will invite public comment on the Section 431(a) report after submitting it to the Committees. EPA will carefully review and evaluate comments received and determine whether the comments warrant further action regarding the October 29, 1999, final rule.

As noted above, on October 29, 1999, the Administrator of EPA will take final action on a notice of proposed rulemaking under CWA section 402(p)(6), 33 U.S.C. § 1342(p)(6). On January 9, 1998, at 63 Fed. Reg. 1536, EPA proposed to expand the National Pollutant Discharge Elimination System (NPDES) permitting program for storm water to apply to discharges from certain small municipal separate storm sewer systems (MS4s) and from construction activity generally disturbing between one and five acres of land surface. Although EPA designated for regulation discharges from these two categories, the rulemaking would also allow for waivers (for subsequent exclusion from regulation of certain sources in these categories) and designation (for subsequent inclusion of certain sources that fall outside of the categories). Waivers would be available based on criteria by which the NPDES permitting authority would determine a low potential for adverse water quality impact, and the permitting authority would designate additional sources on a localized basis when necessary to protect or remedy localized adverse water quality impacts.

Rulemaking under CWA section 402(p)(6) is to be based on a study that EPA was directed to provide to Congress under CWA section 402(p)(5). Section 402(p)(5) provides that:

> The Administrator, in consultation with the States, shall conduct a study for the purposes of -
>
> (A) identifying those stormwater discharges or classes of stormwater discharges for which permits are not required pursuant to [CWA sections 402(p)(1) and (p)(2)];
>
> (B) determining, to the maximum extent practicable, the nature and extent of pollutants in such discharges; and
>
> (C) establishing procedures and methods to control stormwater discharges to the extent necessary to mitigate impacts on water quality.

CWA section 402(p)(5) directed EPA to provide reports to Congress on the different components of this study. In proposing the regulations under CWA section 402(p)(6), EPA identified the reports to Congress comprising the study described in CWA section 402(p)(5), specifically, *Storm Water Discharges Potentially Addressed by Phase II of the National Pollutant Discharge Elimination System Storm Water Program: Report to Congress* (U.S. EPA, 1995, EPA 833-K-

94-002). Today's report under section 431(a) of the Appropriations Act is a supplement to the study described in CWA section 402(p)(5).

B. PURPOSE OF THE PHASE II RULE

The Phase II rule would establish a cost effective, flexible approach for reducing environmental harm by storm water discharges from many point sources of storm water that are currently unregulated. Some of the costs of implementing the Phase II rule are discussed in Chapter II of this report. A summary of the rule's benefits are described below. EPA's Economic Analysis of the Final Phase II Storm Water Rule fully analyzes the costs and benefits expected from implementation of the rule.

The environmental harm currently caused by discharges from municipal separate storm sewer systems (MS4s) and construction activity is well documented:

- Urbanization alters the natural infiltration capability of the land and generates a host of pollutants that are associated with the activities of dense populations, thus causing an increase in storm water runoff volumes and pollutant loadings in storm water discharged to receiving water bodies.

- The National Urban Runoff Program (NURP) Study (U.S. EPA 1983) indicated that discharges from MS4s draining runoff from residential, commercial, and light industrial areas carried more than ten times the annual loadings of total suspended solids as did discharges from municipal sewage treatment plants that provide secondary treatment, and somewhat higher annual loadings of chemical oxygen demand (COD), total lead, and total copper.

- The National Water Quality Inventory (305(b)), 1996 report to Congress shows that urban runoff/storm sewer discharges affect 13% of impaired rivers, 21% of impaired lakes and 45% of impaired estuaries.

- Urban storm water runoff, sanitary sewer overflows, and combined sewer overflows have become the largest causes of beach closings in the United States in the past three years. A survey of coastal and Great Lakes communities found that more than 1,500 beach closings and advisories were attributable to storm water runoff in 1998 based on EPA data supplemented with additional data (Natural Resources Defense Council. 1998. "Testing the Waters Volume VIII-Has Your Vacation Beach Cleaned Up Its Act?" New York, NY). Recreational bathers are at the highest risk for contracting illnesses such as gastroenteritis, typhoid, dysentery, hepatitis, skin rashes, and respiratory infections.

- The MS4 program will address illicit discharges, which can contribute high levels of pollutants, including heavy metals, toxic substances, oil and grease, solvents, nutrients, viruses and bacteria into receiving water bodies.

- The NURP study found that pollutant levels from illicit discharges were high enough to significantly degrade receiving water quality and threaten aquatic, wildlife, and human health.

- Discharges from construction activity impact the biological, chemical, and physical integrity of receiving waters. A number of pollutants are preferentially absorbed onto particles found in fine sediment. Estimates indicate that 80 percent of the phosphorus and 73 percent of the Kjeldahl nitrogen in streams is associated with eroded sediment from construction and other activities.

- Sediment yields from smaller construction sites are as high as or higher than the 20 to 150 tons/acre/year measured from larger sites.

- Siltation is the largest cause of impaired water quality in rivers and the third largest cause of impaired water quality in lakes, according to the 305(b) Report to Congress.

The implementation of the six minimum measures identified for small MS4s should significantly reduce pollutants in urban storm water compared to existing levels and do so in a cost effective manner. Similarly, the implementation of best management practice ("BMP") controls at small construction sites should also result in a significant reduction in pollutant discharges and an improvement in surface water quality. EPA's Economic Analysis of the Final Phase II Storm Water Rule details the expected benefits from implementation of the rule. These benefits include:

- Enhanced Commercial Fishing: Commercial fisheries are a significant part of the nation's economy. In 1997, the commercial shellfish catch was worth $1.04 Billion and the finfish catch was worth $581 Million. 18% of surveyed estuary miles identified storm water as a significant source of impairment.

- Enhanced Recreational and Subsistence Fishing: The potential value of marine recreational fishing is $1.1 Billion to $11.3 Billion annually. Pollutants in storm water may result in eliminating or decreasing the numbers or size of sport fish or shellfish in receiving waters. In September 1996, there were 2,196 fish consumption advisories and about 25% of waters designated for fishing did not support that use.

- Enhanced Opportunities for Boating: Storm water controls offer benefits to boaters by reducing sediment and other pollutants in waters, increasing water clarity and enhancing the experience for boating users. EPA estimates that pollution reduction due to Phase II controls may result in 3,000 currently non-boatable miles of river becoming boatable.

- Enhanced Opportunities for Swimming: EPA estimates that Americans participated in 1.3 billion non-pool swimming days. EPA estimates that at least 28% of these trips are to either marine or fresh water that is impacted by runoff from Phase II sources. For example, in 1998, storm water runoff caused beach closures that resulted in the loss of an estimated 86,000 individual trips to beaches impacted by Phase II sources.

- Enhanced Opportunities for Noncontact Recreation: Activities like picnicking, jogging, biking, camping and hunting do not necessitate direct contact with water, but water quality affects the ability to enjoy these activities when in close proximity to water. Storm water controls reduce turbidity, odors, floating trash and other pollutants and allow waters to be used as focal points for recreation, enhancing the experience of current and future users.

- Enhanced Nonconsumptive Wildlife Uses: An estimated 76.1 million people participated in observing wildlife and waterfowl in 1991. Storm water controls that result in greater numbers or diversity of viewable wildlife species will produce benefits.

- Reduced Flood Damage: Storm water runoff controls may mitigate flood damage by addressing problems due to the diversion of runoff, insufficient storage capacity, and reduced channel capacity from sedimentation.

- Drinking Water Benefits: Storm water was identified as a major source of impairment in rivers, streams, lakes, reservoirs and ponds. Pollutants from storm water runoff, such as solids, toxic pollutants (including pesticides) and bacteria, may impose additional costs for treatment or even render the water unusable for drinking.

- Water Storage Benefits: Storm Water is a major source of impairment for reservoirs. The heavy load of solids deposited by storm water runoff can lead to rapid sedimentation of reservoirs and the loss of needed water storage capacity.

- Navigational Benefits: Storm water also delivers high sediment loads to rivers and harbors critical to navigation and commerce. Where waters are used for navigation, solids must be dredged and disposed of to maintain the utility of the waterway. An estimated 5% of these sediments (12.6 million cubic yards of material) is attributed to storm water runoff from roads and constructions sites. Storm water controls will reduce the rate and amount of sediment loadings.

- Reduced Illness from Consuming Contaminated Seafood: Storm water controls may reduce the presence of pathogens in seafood caught by commercial or recreational anglers. Researchers have estimated 2,700 cases of illness annually from raw or partially cooked contaminated seafood.

- Reduced Illness from Swimming in Contaminated Water: Epidemiological studies have indicated that swimmers in water contaminated by storm water runoff are more likely to experience illness than those that swim farther from a storm water outfall. By reducing illicit connections and other sources of pathogens in storm water, EPA estimates that up to 500,000 cases of illness will be avoided annually.

- Enhanced Aesthetic Value: When storm water affects the appearance or quality of a water body, the desirability of working, living, traveling or owning property near that water body is similarly affected. Improvements in water quality due to reductions in storm water pollution will result in benefits as these waters recover and become more desirable locations near which people want to live, work, travel or own property.

Thus, the rule will result in significant monetized financial, recreational and health benefits, as well as benefits that EPA has been unable to monetize.

II. IMPACT OF PHASE II RULE ON LOCAL GOVERNMENTS

This section responds to the Appropriations Act's direction to provide a report containing:

"(1) an in-depth impact analysis on the effect the final regulations will have on urban, suburban, and rural local governments subject to the regulations, including an estimate of-
(A) the costs of complying with the 6 minimum control measures described in the regulations; and
(B) the costs resulting from the lowering of the construction threshold from 5 acres to 1 acre;"

A. SUMMARY OF PHASE II RULE REQUIREMENTS

EPA conducted an in-depth impact analysis of the effect of the final Storm Water Phase II Rule on local governments. Two provisions of the Phase II rule are expected to result in compliance costs for local governments. These are the provision requiring certain municipalities to regulate discharges from their municipal separate storm sewer systems (MS4s) and the provision which extends the storm water construction program to cover sites between one and five acres in size. The analysis considers potential cost impacts to all local governments, including urban, suburban and rural governments, and provides insight into the differing situations of small or very small local governments. Based on this analysis, EPA determined that the Phase II rule is not expected to have a significant impact on a substantial number of local governments.

<u>Municipal Storm Water Program:</u>

The Phase II Rule would automatically designate for regulation discharges from small MS4s located in urbanized areas, and require that NPDES permitting authorities examine for potential designation, at a minimum, a particular subset of discharges from small MS4s located outside of urbanized areas. The MS4 provision would result in costs primarily for local governments in urbanized areas. An urbanized area is defined by the U.S. Census Bureau as an area with a population of at least 50,000 and a minimum average population density of more than 1,000 people per square mile. Thus, this rule would primarily affect suburban and urban local governments, because these MS4s are more likely to be located in urbanized areas. Rural local governments may be designated on a case-by-case basis if the permitting authority determines that they have a significant impact on water quality. The Phase I storm water program addressed runoff from "medium" and "large" MS4s, generally those discharges from governmental jurisdictions serving populations of 100,000 or more people. The Phase II Storm Water regulations will address discharges from smaller MS4s. The rule also would allow MS4s that are automatically designated because they are within an urbanized area to obtain a waiver from the otherwise applicable requirements if the discharges from small MS4s are not causing impairment of a receiving water body. Qualifications for the waivers vary depending on whether the MS4 serves a population under 1,000 or a population under 10,000.
