R0011952

EXECUTIVE SUMMARY

Since the 1994-95 storm season, the County of Los Angeles Department of Public Works has endeavored to monitor and characterize stormwater water quality under the Los Angeles NPDES Municipal Stormwater Permits. The first two years of monitoring fell under the 1990 Permit, while the current monitoring program is defined in the 1996 Permit. The current monitoring program has consisted of four major elements: Santa Monica Bay receiving water impacts study, mass emission monitoring, land use runoff monitoring, and critical industry monitoring. Other peripheral and supportive studies were conducted since 1996. Those consisted of a study of sampling in wide channels (see Appendix E), a study of the feasibility of sampling storms down to 0.1" rainfall (see Appendix D), an El Niño season supplemental study (see Appendix F), and freshwater toxicity studies on the Los Angeles and San Gabriel Rivers (see Appendix G). In 1999, the County also voluntarily funded half of a study of impacts on stormwater quality from aerial deposition (see Appendix H for progress reports).

HYDROLOGIC CONDITIONS AND SAMPLING SUCCESS

The last six years have experienced a range of climatological events, ranging from the 1997-98 El Niño season (twice the normal annual rainfall) to the 1998-99 La Niña season (less than half the normal annual rainfall). Nevertheless, the County's resourcefulness allowed it to respond to many different and unexpected circumstances as they arose. Since January 1995, 212 mass emission and 396 land use monitoring station events have been sampled. The major objective of runoff characterization of mass emission, land use, and critical industry drainage areas was achieved.

OBJECTIVES ACHIEVED

The goal of the monitoring program has been to provide technical data and information to support effective watershed stormwater quality management programs in Los Angeles County. The monitoring program has been successful in meeting those goals, namely:

- Track Water Quality Status, Pollutant Trends and Pollutant Loads, and Identify Pollutants of Concern

  Water quality status, pollutant trends and loads were successfully addressed by all of the major monitoring program elements: the Santa Monica Bay receiving waters impact study, the mass emission monitoring element, the land use monitoring element, and the critical source monitoring element. The total cost incurred by the monitoring program to date has been more than $4.8 million.

- Monitor and Assess Pollutant Loads from Specific Land Uses and Watershed Areas

  Both the mass emission and land use monitoring elements were successful at assessing loading, and the County's GIS Loading Model has been recognized as an innovative solution to estimating loading in unmonitored watersheds.

- Identify, Monitor, and Assess Significant Water Quality Problems Related to Stormwater Discharges Within the Watershed

  The monitoring program was successful at identifying toxic levels of zinc and copper from Ballona Creek discharge, toxicity in the Los Angeles and San Gabriel Rivers, and the extent and severity of bacterial indicators in both dry and wet weather.

- Identify Sources of Pollutants in Stormwater Runoff

  In addition to the Bay receiving water impacts study's identifying Ballona Ck., and not Malibu Ck., as a contributor of stormwater toxicity, the mass emission monitoring identified the Los Angeles River as consistently contributing the most zinc, copper, and suspended solids. The land use monitoring identified light industrial, transportation, and retail/commercial land uses as developing the highest median concentrations for total and dissolved zinc. Light industrial and transportation land uses displayed the highest median concentrations for total and dissolved copper, and light industrial produced the highest concentrations of suspended solids. Finally, the critical source monitoring program identified fabricated metal businesses as producing the highest median concentrations for zinc, copper, and suspended solids.

- Identify and Eliminate Illicit Discharges

  Each Permittee has a program to identify and eliminate illicit connections to the storm drain system to the maximum extent practicable. The County has been successful in the inspection of open channels and underground storm drains to identify illicit connections.

  Most Permittees perform random area surveillance during dry and wet weather to inspect for potential illegal discharges. The Permittees also conduct educational site visits at businesses. During these visits, flyers with information on Best Management Practices (BMPs) applicable to that business are distributed.

  The Department has also been successful in developing and implementing a standard program for public reporting of illicit discharges and reporting hazardous substances via the 1-888-CleanLA hotline.

- Evaluate the Effectiveness of Management Programs, including Pollutant Reductions Achieved by Implementation of Best Management Practices (BMPs)

  The Critical Source element of the monitoring program was successful at examining the potential effectiveness of voluntary good housekeeping and preventive types of Best Management Practices at one critical source industry. There was no significant difference at other critical source industries at which BMPs were implemented. The inability to control the voluntary usage of good housekeeping BMPs at these critical industries may have compromized the study's effectiveness for those industries.

- Assess the Impacts of Stormwater Runoff on Receiving Waters

  The receiving waters impact study, one of the first in the nation to assess stormwater impacts on the marine environment, was very successful at assessing stormwater impacts on Santa Monica Bay. The study was able to discern the existence and extent of the stormwater plume in the Bay, identify two trace metals in Ballona Creek. stormwater discharge that are toxic to simple sea creatures, and conclude that sediments offshore of Ballona Creek generally had higher concentrations of urban contaminants. The findings related to toxicity and sediments, along with bacterial indicators, set the stage for the rest of this report.

WATER QUALITY CHEMICAL ANALYSES

Monitoring in Los Angeles county from 1994 to date has been performed in compliance with the Municipal Stormwater Permits of June, 1990, and July, 1996, which have required a broad suite of chemical analyses, including solids, minerals, bacteria, metals, organics, and nutrients. The Los Angeles county Department of Agricultural Commissioner/Weights and Measures, Environmental toxicology Laboratory, provided the water quality laboratory and related services to the Department of Public works. The laboratory implemented a Quality Assurance/Quality Control program to ensure that the analyses conducted were scientifically valid, defensible, and of known precision and accuracy.

WATER AND SEDIMENT QUALITY RESULTS

Conclusions on the status and trends of water quality over the past six years have been derived from the monitoring program's Santa Monica Bay receiving waters impact study, mass emissions monitoring element, land use runoff monitoring element, and critical industry monitoring element. Findings regarding sediment quality were derived from the Santa Monica Bay receiving waters impact study and the County's involvement with the California Sediment Task Force and the Corps of Engineers' Sediment Control Management Plan.

- The nonprofit Center for Watershed Protection has linked overall watershed imperviousness to stormwater quality problems. The Dominguez Channel/L. A. Harbor Watershed Management Area has the highest overall imperviousness (62%) based on 1993 SCAG land use distribution, followed by the Ballona Creek (45%), Los Angeles River (35%), San Gabriel River (30%), Malibu Creek (6%), and Santa Clara River (5%) Watershed Management Areas.

- The monitoring program has identified the nearly ubiquitous existence of indicator bacteria in both dry and wet weather throughout the urbanized part of the coastal basin. Total coliforms, fecal coliforms, fecal streptococcus, and fecal enterococcus were detected in all stormwater samples tested since 1994 at densities (or most probable number, MPN) between several hundreds to several million cells per 100 ml., exceeding the public health criteria of AB411.

- The Malibu Creek station appears to have consistently lower indicator bacteria counts than other mass emission stations and is consistently lower for all four groups of bacteria.

- The 1995-96 season appears to have higher mean densities of indicator bacteria than other years. At 75% of normal, this was not a particularly rainy season.

- In a number of instances, peak fecal coliform counts occurred at different monitoring stations in different parts of the county during the same storm. Further, in 1995-96, the highest fecal coliform readings at five stations coincided with the largest storm of the season. Also, in 1996-97, the highest fecal coliform readings at two stations coincided with the first storm of the season greater than 0.1" rainfall. These observations suggest that peak fecal coliform levels may be related to regional hydrologic conditions.

- Except for somewhat lower bacteria densities at Malibu Creek, there was no seasonal or regional consistency in cell densities. There was a very wide range of densities for all stations.

- There was one storm event, January 9, 1998, that yielded extremely high counts in all stations for all bacterial strains. The available data do not provide an explanation, or suggest whether this could be a contamination artifact.

- The 1996-97 season had one event, November 21, 1996, that yielded runoff with high counts in all stations for all bacteria species.

- During the 1998-99 season, the event of March 15, 1999 was associated with high bacterial counts for most stations and the events of March 25, 1999 and April 4, 1999, were associated with unusually low counts for most stations.

- Virtually every sample of Ballona Creek stormwater tested in the Santa Monica Bay receiving water impacts study was toxic to sea urchin fertilization.

- The first storms of the year produced the most toxic stormwater in Santa Monica Bay during the receiving water impacts study.

- The toxic portions of the observed stormwater plume were variable in size, extending from 1/4 to 2 miles offshore of Ballona Creek.

- Surface water toxicity caused by unidentified sources was frequently encountered during dry weather in Santa Monica Bay during the receiving water impacts study.

- Zinc was the most important toxic constituent identified in stormwater in Santa Monica Bay, but zinc concentrations in the toxic portion of the discharge plume were usually below levels shown to cause toxicity in the laboratory.

- Copper and other unidentified constituents may also be responsible for some of the toxicity measured in Santa Monica Bay.

- The measured concentrations of zinc and copper in Ballona Creek stormwater were estimated to account for only 5% - 44% of the observed toxicity.

- The fate of most stormwater constituents discharged to Santa Monica Bay is unknown.

- For two years in a row, wet weather toxicity was significant in the Los Angeles River. Dry weather toxicity was significant the second year, but not the first.

- For the San Gabriel River, wet weather toxicity was significant the first year, but not the second. Dry weather toxicity was not significant either year.

- For both the Los Angeles and San Gabriel Rivers, wet weather toxicity was higher for the first storm tested, suggesting a seasonal "first flush" phenomenon for toxicity.

- The sea floor is where stormwater particles, and associated contaminants, eventually settle.

- The sediments on the sea floor can accumulate runoff inputs over an entire storm, over several storms, or over several seasons.

- Sediments offshore of Ballona Creek generally had higher concentrations of urban contaminants, including common stormwater constituents such as lead and zinc.

- Sediments offshore of Ballona Creek showed evidence of stormwater impacts over a large area.

- Sampled biological communities offshore of Ballona Creek were similar to those offshore of Malibu Creek. Both areas had comparable abundance and similar species composition.

- Sampled biological communities offshore of Ballona and Malibu Creeks were also similar to background reference conditions established in previous studies of southern California.

- According to the Los Angeles Basin Contaminated Sediment Task Force, informal surveys of potential marina and harbor users and past dredging projects suggest that the major sources of contaminated dredge material will continue to be Marina del Rey, the ports of Los Angeles and Long Beach, and the mouth of the Los Angeles River.

- According to the Los Angeles Basin Contaminated Sediment Task Force, some of the sediments dredged from these harbors contain elevated levels of heavy metals, pesticides, and other contaminants. In most cases, the concentrations of these contaminants do not approach hazardous levels.

- According to the U. S. Army Corps of Engineers, four of 21 sites in the bottom of Ballona Creek and major tributaries were without any chemical concentration exceeding the National Oceanographic and Atmospheric Administration's "Effect Range-Low" (ERL) values: storm drain Bond Issue Project 9408, Project 425, Ballona Creek at Sawtelle Blvd., and Centinela Channel.

- According to the U. S. Army Corps of Engineers, sediments on the bottoms of storm drain Bond Issue Projects 648, 51, 494, and 503 ranked by dry weight most consistently as the most contaminated sites with respect to metals and polycyclic aromatic hydrocarbons (PAHs).

- According to the U. S. Army Corps of Engineers, the two areas of the main Ballona Ck. channel that ranked by dry weight as most contaminated and exceeding ERLs were just downstream of Madison Ave. and Fairfax Ave.

- According to the U. S. Army Corps of Engineers, with respect to the potential for contamination from PAHs, sites in Ballona Ck. at Pickford St. and Fairfax Ave., Higuera St. drain, Projects 51 and 3867, and Culver City Acquisition and Improvement District No. 4 drain appeared most contaminated.

- According to the U. S. Army Corps of Engineers, bed load sediment in the major tributary drains of Sepulveda and Centinela Channels were among the least contaminated samples.

- According to the U. S. Army Corps of Engineers, the area within the Ballona Ck. drainage area having expected highest stormwater loading of metals, oil, and grease extends from Hollywood to Culver City in a 1- to 2-mile wide, 5- to 6-mile long strip parallel and east of the San Diego (I-405) Freeway.

- Only two PAH compounds, phenanthrene and pyrene, exceeded the California Ocean Plan objective. This occurred at the Malibu Creek station. No other PAH compound exceedences appeared through the comparison of mass emission concentrations to the California Ocean Plan, although 1999-2000 was the first year of lower detection limits for PAHs.

- The Los Angeles River is the largest contributor of suspended solids of the five mass emission stations monitored.

- After exceedence of bacterial indicators, when compared to the California Ocean Plan, the Los Angeles Basin Plan, and the California Toxics Rule, the next most numerous "virtual" exceedences occurred with total and dissolved copper and bis(2-ethylhexyl)phthalate, followed by turbidity, total zinc, and total lead.

- The El Niño season, 1997-98, contributed the most virtual mass emission exceedences at all monitoring stations except Coyote Creek.

- The Los Angeles River produced the most virtual exceedences of any other mass emission monitoring station.

- Loading to the ocean was greatest during 1997-98, the El Niño season, during which the Los Angeles River delivered the highest loadings of total suspended solids (approx. 220,000 tons), dissolved copper (approx. 28 tons), total copper (approx. 40 tons), dissolved zinc (approx. 170 tons), and total zinc (approx. 230 tons).

- It appears that Los Angeles River loading for metals is disproportionate by drainage area to the other watersheds.

- According to the GIS Loading Model, the unmonitored Dominguez Channel/L. A. Harbor Watershed Management Area was estimated to contribute the highest loadings for dissolved zinc (approx. 2.3 tons) and dissolved copper (approx. 30 tons) and contribute the highest loadings of the unmonitored watersheds for each year since 1995. Comparison of loadings between monitored and unmonitored watersheds should not be made at this time because the model is not yet fully calibrated.

CONSTITUENTS OF CONCERN

- Sixteen chemical constituents were identified from the comparison of mass emission annual concentrations to the objectives of the California Ocean Plan, the Los Angeles Basin Plan, and the California Toxics Rule. Exceedence of these objectives, however, do not constitute noncompliance with the Permit.

- While Total Maximum Daily Loads (TMDLs) are not part of the Los Angeles Municipal Stormwater Permit, constituents identified by the 303d list that were not already identified through the comparison process, namely nutrients, are also constituents of concern. It should be noted, however, that a report by the Las Virgenes Municipal Water District found that beneficial use impairment due to algal growth is not a problem in Malibu Creek during storm season.

- Two organophosphate pesticides, diazinon and chlorpyrifos, are also among the constituents of concern due to their identification with stormwater toxicity in independent studies.

- Indicator bacteria (total coliform and fecal coliform, streptococcus, and enterococcus) are included as constituents of concern due their exceedence of AB411 (assembly bill).

IDENTIFICATION OF POSSIBLE SOURCES

- Light industrial, transportation, and retail/commercial land uses displayed the highest median values for total and dissolved zinc, with light industrial the highest at about 300 μg/l for

dissolved zinc and about 360 μg/l for total zinc. Runoff concentrations for metals from the high density single family residential, education, multifamily residential, and mixed residential land uses were significantly less.

- Light industrial and transportation land uses displayed the highest median values for total and dissolved copper, with transportation the highest at about 28 μg/l for dissolved copper and about 40 μg/l for total copper.

- Median concentrations of total suspended solids were highest coming off of the light industrial land use category, at about 130 mg/l.

- Among all the critical industry monitoring sites, the highest median value for total zinc (approx. 450 μg/l), dissolved zinc (approx. 360 μg/l), total copper (approx. 240 μg/l), and dissolved copper (approx. 110 μg/l) were produced at the fabricated metal business sites.

- Levels for total and dissolved zinc did not appear to be significantly different between any of the industry types.

- Levels for total and dissolved copper did appear significantly higher for the fabricated metals sites over the other critical industry categories.

- The highest median level for suspended solids was also produced at the fabricated metals sites, but no industry was significantly higher or lower than another for suspended solids.

EVALUATION OF CRITICAL INDUSTRY BMP EFFECTIVENESS

- Limited success was achieved in evaluating BMPs for the auto dismantling and auto repair industries. The reasons for no discernable differences in concentrations before and after BMP implementation at the two industries are not obvious, but may include the voluntary nature of the BMP usage.

- For total and dissolved zinc, the median concentration lowered or stayed nearly the same with the implementation of BMPs at the auto dismantling, auto repair, and fabricated metals industries.

- For total and dissolved copper, where the fabricated metal industry had displayed the highest median concentrations, levels were significantly reduced with the implementation of BMPs.

- The auto dismantling and auto repair businesses showed no significant difference for copper pre- and post-BMP.

RECOMMENDATIONS

The following recommendations are made based on all the monitoring and studies to date, from within the Los Angeles County Department of Public Works and other sources. These recommendations include monitoring, research, and studies that should be considered or undertaken to advance the understanding of stormwater quality science and support future TMDL development. Because of their scope, such studies should be undertaken by various entities, such as the Regional Water Quality Control Board, NPDES permittees, or collaborative efforts between private and public organizations.

- Mass emission monitoring should continue at the five existing sites for up to five storm events per season.

- Those constituents that have been detected in less than 25% of ten consecutive sampling events (Table ES-1a) should be removed from the analytical suite for the associated mass emission monitoring stations. However, the constituents of concern should remain.

- As a result of the 25% Event (or Seasonal) Mean Concentration error rate (Table ES-1b), land use monitoring should only sample the following constituents:

LAND USE SITE	CONSTITUENTS
Retail/Commercial	Ammonia, total and dissolved copper, nitrate, total lead, TSS, PAH, diazinon, chlorpyrifos
Vacant	TKN, TSS, PAH, diazinon, chlorpyrifos
High Density Single Family Residential	Total lead, PAH, diazinon, chlorpyrifos
Transportation	PAH, diazinon, chlorpyrifos
Light Industrial	Total copper, PAH, diazinon, chlorpyrifos
Education	Total copper, total zinc, TSS, PAH, diazinon, chlorpyrifos
Multifamily Residential	Ammonia, ammonia nitrogen, nitrite nitrogen, TSS, PAH, diazinon, chlorpyrifos
Mixed Residential	Ammonia, nitrate, total zinc, PAH, diazinon, chlorpyrifos

- Receiving water impact studies should be performed on significant impaired water bodies to identify impacts due to stormwater. Such impact studies could include assessments of bioassessment.

- Support and cooperation should continue with the Southern California Coastal Waters Research Project in conducting current research and calibrating water quality models for the Santa Monica Bay and Los Angeles River.

- Similar water quality models should be initiated for other parts of the County where indicator bacteria impair beneficial uses.

- Support and cooperation should continue with the Corps of Engineers' Sediment Control Management Plan and the Coastal Commission Sediment Task Force.

- Studies of receiving water and stormwater impacts due to aerial deposition should be conducted on inland watersheds.

- Major tributaries to Ballona Creek should be surveyed to find possible contributing areas and sources of trace zinc and copper.

- Two dry weather and two wet weather Toxicity Identification Evaluations should be conducted for a full range of constituents on freshwater species for the L. A. River and Dominguez Channel.

- Two wet weather Toxicity Identification Evaluations should be conducted for a full range of constituents on freshwater species for the San Gabriel River.

- Follow-up studies should be conducted in Santa Monica Bay that address the persistence of stormwater plumes following storm events, the toxicity of stormwater on other representative species, and the fate of sediments in the Bay.

- A study should be conducted assessing the impacts due to stormwater on San Pedro Bay.

- Support and cooperation should continue toward local and regional monitoring programs, including but not limited to the Santa Monica Bay Restoration Project, the City of Long Beach, and the developing Southern California Regional Stormwater Monitoring Coalition.

- Best Management Practices and impacts should be formally evaluated in controlled cases. Current examples might include the City of Santa Clarita demonstration projects, catch basin inserts and deflectors, groundwater impacts due to stormwater infiltration, the Department of Public Works' parking lot retrofit, and storm drain low flow diversions.

- Continue the IC/ID model program as approved by the Regional Board on March 23, 1999.

- Calibrate the GIS Loading Model between monitored and unmonitored watersheds.

R0011968

R0011969

The Integrated Receiving Water Impacts Report is a requirement of the Los Angeles County Municipal Stormwater Permit No. CAS0061654. Part VII.D of the Permit states:

"The Principal Permittee shall not later than July 31, 2000, prepare and submit an Integrated Receiving Water Impacts Report. The report shall include, but not be limited to a comprehensive analysis of the results of the different monitoring data (land use, mass emissions, critical source, load assessment, receiving waters, and other pertinent studies available), and feasible environmental indicators. It should also include recommendations on future monitoring requirements, e.g., integration of storm water receiving water monitoring with regional receiving water monitoring, if applicable. This report will be an integral part of the ROWD."

1.1 PURPOSE

The goal of the Monitoring Program is to develop information to support effective watershed stormwater quality management programs. The purpose of these management programs is to reduce pollutants in stormwater discharges to the maximum extent practicable. The major objectives of the Monitoring Program outlined in the Municipal Permit are to:

- track water quality status, pollutant trends and pollutant loads, and identify pollutants of concern;
- monitor and assess pollutant loads from specific land uses and watershed areas;
- identify, monitor, and assess significant water quality problems related to stormwater discharges within the watershed;
- identify sources of pollutants in the stormwater runoff;
- identify and eliminate illicit discharges;
- evaluate the effectiveness of management programs, including pollutant reductions achieved by implementation of BMPs; and
- assess the impacts of stormwater runoff on receiving waters.

These objectives are met through three major types of monitoring and additional studies as their need arises.

1.2 REPORT ORGANIZATION

Section 2 contains a brief history of the station selection process and site descriptions. Maps and tabular descriptions of the tributary areas of each monitored watershed are displayed as Figures 2-1 through 2-14. Section 3 covers methods used for measuring, sampling and analyzing stormwater. Section 4 presents and interprets results, and Section 5 draws conclusions and makes recommendations.

Tables and figures are labeled with two numbers. The first identifies their corresponding section number, and the second is for identification only.

Appendix A contains rainfall contour maps. Program costs are included in Appendix B. An Executive Summary of the Santa Monica Bay Receiving Waters Study by SCCWRP is included in Appendix C. Appendices D and E contain the Low Flow and Wide Channel Pilot Studies respectively. River Toxicity Test results are included in Appendix G. Aerial Deposition Progress Reports are included in Appendix H. A list of people to contact for more information is included in Appendix I.

1.3 RECAP OF MAJOR MONITORING ELEMENTS

The 1994-95 storm season was the first for which stormwater monitoring was accomplished under the 1990 Los Angeles County NPDES Municipal Stormwater Permit, No. CA0061654. During the 1994-95 and 1995-96 seasons, automated and manual sampling was conducted to characterize stormwater quality and quantity in accordance with the 1990 Municipal Permit. The 1994-95 monitoring data is summarized in *Report of Stormwater Monitoring, Winter of 1994-95* (LACDPW, 1996).

The 1996-97 season was the first storm season in which stormwater monitoring was conducted under the new 1996 Municipal Permit (No. CAS614001). For the 1996-97 season the scope of the Monitoring Program was expanded to incorporate further data collection and new pilot studies. The one-year pilot studies, consisting of "Wide Channel" and "Low Flow" analyses, were completed and reported in the *Los Angeles County 1996-97 Stormwater Monitoring Report, July 15, 1997* (LACDPW and Woodward-Clyde, 1997) and are reproduced in Appendices D and E.

The monitoring program, including the Mass Emission, Land Use, and Critical Source elements continued in the 1997-98, 1998-99 and 1999-2000 storm seasons. The 1998-99 storm season also included funding from the Los Angeles County Department of Public Works (LACDPW) to the Southern California Coastal Waters Research Project (SCCWRP) to study the impacts to receiving waters by aerial deposition of pollutants.

At the request of the Natural Resources Defense Council (NRDC), the 1998-99 and 1999-2000 reports include results of the industrial stormwater permit sampling within the county. Due to the limitations of the data set, only summaries of maximum and minimum results can be provided.

In an effort to analyze the presence of PAH in stormwater, Los Angeles County Public Works lowered the detection limit of semi-volatile organics in stormwater samples in the 1999-2000 season by using modified EPA method 625.

1.3.1 Santa Monica Bay Receiving Waters Impact Study

The Santa Monica Bay Receiving Waters Impact Study was conducted for three consecutive storm seasons (1995-98). Three components were studied:

- Stormwater plume characterization
- Water column biology
- Seafloor biology

High turbidity and low salinity characterized stormwater plumes. Generally, the stormwater plumes extended 2-10 meters below the surface and up to several miles offshore. They also persisted for several days.

Toxicity tests found toxic concentrations of dissolved materials in the water column. Zinc was the main toxicant identified in stormwater. There was also toxicity detected from sources other than stormwater.

The benthic community structure remained stable throughout the study. However, there was a high accumulation of contaminants in sea urchins offshore of Ballona Creek. The effects of the bioaccumulation are unknown.

The executive summary is presented in Appendix C, and is excerpted from the *Study of the Impact of Stormwater Discharge on the Beneficial Uses of Santa Monica Bay, July 8, 1999* (SCCWRP, 1999).

1.3.2 Mass Emissions

Mass emission stations capture runoff from major Los Angeles County watersheds that generally have heterogeneous land use. There were ten mass emission stations during the 1990 Municipal Permit and there were five under the 1996 permit. The objectives of the mass emissions stations are to update estimated pollutant loads to the ocean and to identify long term trends in pollutant concentrations, if possible. Four mass emission stations under the 1990 Municipal Permit were equipped with automated samplers to collect composite samples during storms. Grab samples were also taken at these stations. All five mass emission stations under the 1996 NPDES permit had automated samplers where composite and grab samples were taken in accordance with the Municipal Permit.

During the 1998-99 storm season, the station shelter on the Los Angeles River at Wardlow Road was under reconstruction during the entire season due to the raising of the levee walls by the Army Corps of Engineers (ACOE), and the automated sampling equipment was removed. Water quality samples from the Los Angeles River were collected manually at Wardlow Road and were not composited. Results from these manually collected samples were not included in event mean concentration (EMC) calculations. Stream flow data for the Los Angeles River at Wardlow Road was synthesized from three upstream flow stations.

R0011972

1.3.2.1 Pollutant Loading

Total pollutant loading, as a result of stormwater runoff was first calculated under the 1990 NPDES permit for the 1994-95 storm season. The results were presented in the *Report of Stormwater Monitoring, Winter of 1994-95* (Los Angeles County Department of Public Works, March 1996).

The 1996 NPDES permit in its Section B.4, Attachment C, states that a loads assessment for each of the six WMA's is to be conducted following the 1998-99 storm season. Results were presented in the *Los Angeles County 1998-99 Stormwater Monitoring Report* (Los Angeles County Department of Public Works, July 1999). For those rivers where mass emissions were monitored, loads were calculated from observed flow volumes and observed pollutant concentrations. For those drainage areas that were not monitored, a newly developed GIS model was employed to estimate loads.

Summaries of Total Pollutant Loading, including data from the 1999-2000 storm season, are included in this report.

1.3.3 Land Use Program

The drainage area tributary to each land use monitoring station is comprised predominantly of a single land use and is relatively homogeneous. The major objectives of this monitoring effort are to evaluate the effects of certain land uses on water quality, to identify the relative importance of specific land uses as pollution sources, and to provide data that can be used to project watershed loads from watersheds that do not have mass emission stations.

There were 14 land use monitoring stations under the 1990 Municipal Permit. Five of these stations were equipped with automated samplers to collect composite samples during storms. The 1996 NPDES permit required the re-evaluation of the location of land use specific monitoring stations. The land use monitoring program under the 1996 NPDES permit is a result of a site selection study entitled *Evaluation of Land Use Monitoring Stations* (Woodward-Clyde and Psomas and Associates, 1996). The study identified the most significant land use categories within the permit area regarding stormwater quality. The selection study yielded eight land use stations. These eight land use categories represent over 86% of all the land use within the permit area. These stations monitor flow and have automated samplers to collect flow weighted composite stormwater samples during storm events.

The Santa Monica Pier station was down due to construction during the 1999-2000 storm season.

1.3.4 Critical Sources

The Critical Source/BMP Monitoring Study was introduced under the 1996 NPDES permit and is designed to gather baseline water quality data and assess the effectiveness of BMP implementation for critical industries and businesses. A list of critical sources were identified and ranked by their potential significance to stormwater quality (Woodward-Clyde, 1997) and are listed below:

R0011973

Industrial Category	SIC code	Industrial Stormwater Permits*
• Wholesale trade (including scrap yards and auto dismantling)	50	Yes
• Automotive repair/parking	75	No
• Fabricated metal products (including electroplating)	34	Yes
• Motor freight (including trucking)	42	Yes
• Chemical manufacturing facilities	28	Yes
• Automotive dealers/gas stations	55	No
• Electric/gas/sanitary	49	No
• Miscellaneous manufacturing	39	Yes

* Industrial facilities requiring general industrial stormwater permits.

For each critical source industry, there is a multi-year study monitoring the stormwater runoff from six sites. During the first year of each study, runoff is sampled and analyzed from five storms. During subsequent years, BMPs are implemented at three of the six sites (test sites). BMP effectiveness is estimated from monitoring data gathered at the pooled test sites and pooled control sites during ten additional storms. A complete study plan is included in *Critical Source Selection and Monitoring Report* (Woodward-Clyde, 1997).

The first critical source monitoring was conducted during the 1997-98 storm season. Sites at six automotive repair shops and six auto dismantlers were monitored. These sites, plus six fabricated metal shops were monitored during the 1998-99 storm season. Six motor freight companies and six automobile dealers were added during the 1999-2000 storm season.

1.4 OTHER STUDIES

Two pilot studies were conducted during the 1996-97 storm season to identify a potential need for modifying monitoring practices. Both studies concluded that existing practices were satisfactory.

Other studies were conducted to explore the effects by aerial deposition, El Niño climatology on stormwater quality, and river toxicity.

1.4.1 Wide Channel Pilot Study

The Wide Channel Pilot Study was developed to evaluate the accuracy of a single point intake in wide channels. Samples were taken at the same time at various depths and widths across the channel to determine the level of mixing achieved.

1.4.2 Low Flow Pilot Study

The Low Flow Pilot Study was conducted to assess the feasibility of monitoring storms as small as 0.1 inches of rainfall. An existing land use monitoring station (Project 1202, Light Industrial) was used for this study.

1.4.3 Aerial Deposition

Data is currently being accumulated to estimate toxic loads deposited into the Santa Monica Bay and inland from atmospheric sources. The Data Assessment Report is scheduled for completion in September 2000. Quarterly progress reports are included in the 1998-99 Los Angeles County Stormwater Monitoring Report and herein Appendix H.

This year, the US EPA, Los Angeles County Department of Public Works, and Southern California Coastal Waters Research Project (SCCWRP) are funding the project. Other parties involved include UCLA's Institute of the Environment, the Santa Monica Bay Restoration Project (SMBRP), the US EPA's Great Water Program, and the South Coast Air Quality Management District (AQMD).

1.4.4 El Niño Study by SCCWRP

The objective of this research was to determine whether El Niño conditions influenced the toxicity of Ballona Creek stormwater or the characteristics of the stormwater discharge plume in Santa Monica Bay. The results indicated that storm size and cumulative amount of prior rainfall had little influence on stormwater toxicity. However, stormwater from rainfall preceded by more than 20 days of dry weather was found to have the highest toxicity. This relationship appeared to be independent of El Niño weather patterns.

The executive summary of the El Niño Study appears in Appendix F.

1.4.5 River Toxicity

During the 1997-98 and 1998-99 storm seasons, tests were conducted for toxicity of samples of dry and wet weather flow from the Los Angeles and San Gabriel Rivers. This testing was performed by the Southern California Coastal Waters Research Project. Toxicity was measured as impairment to sea urchin fertilization.

More details on the study are presented in Appendix G. A summary of finding is listed in Section 4.2.3.

SECTION 2

R0011976

To characterize the quality of stormwater runoff in Los Angeles County, sampling of single Land Use sites and large area Mass Emissions sites has been performed under the 1990 and the 1996 NPDES permits.

2.1 1990 NPDES PERMIT – SAMPLING SITES

2.1.1 Automated Sampling Program – 1990 NPDES permit

Starting in January 1995, in compliance with Phase I requirements of the 1990 NPDES stormwater permit, nine automated sampling stations began sampling runoff from combinations of mass emissions and land use specific watersheds within the Santa Monica Bay drainage area. Phases II and III added 15 more inland stations in 1995-1996. The 24 stations were:

Location	Land Use/ Mass Emission
Ballona Creek, Culver Dr. and Beloit Ave., City of Los Angeles.	Mass Emissions
Malibu Creek, Malibu Cyn. Rd. s/o Piuma Rd., Los Angeles Co.	Mass Emissions
Trancas Canyon, North end of Paseo Cyn. Dr., City of Malibu.*	Open Space/Rec.
Kenter Cyn. Drain, Main St. and Colorado Ave., City of Santa Monica.*	Mass Emissions
Bond Issue Proj. 1105, Herondo St. and Valley Dr., City of Redondo Beach.*	Mass Emissions
Bond Issue Proj. 558, Paseo Lunado and Via Anacapa, City of Palos Verdes Estates.*	Single Family Residential
Bond Issue Proj. 5401, Redondo Ave. and 11th St., City of Manahattan Beach.*	Single Family Residential
Santa Monica Pier Drain, Appian and Moss Ave, City of Santa Monica.	Commercial
Drain No. 2361, Grand Ave. and 21st St., City of Los Angeles.*	Industrial /Commercial
Coyote Creek, below Spring Street, City of Long Beach	Mass Emissions
Rio Hondo Channel, Above Beverly Blvd., Pico Rivera*	Mass Emissions
Los Angeles River, at Tujunga Ave., City of Los Angeles	Mass Emissions

R0011977

Location	Land Use/ Mass Emission
Bouquet Creek, Upstream of Newhall Ranch Rd., Private Drain No. 2225, Santa Clarita.	Mass Emissions
San Gabriel River, downstream of San Gebriel River Parkway, Pico Rivera	Mass Emissions
Browns Creek, Rinaldi Street, Chatsworth*	Open Space Recreation
Monrovia Creek/Sawpit Creek, Arcadia	Open Space Recreation
Project 1402, Near Foothill Blvd. And Don Diablo Dr., Arcadia*	Low Density Single Family Residential
Project 3857, Near Hamlin St. and Oso Ave., Warner Center*	High Density Single Family Residential
Project 620, near Glenwood Rd. and Bruce Ave., Glendale	High Density Single Family Residential
Project 1, near Alcoa Ave. and Randolph St, Vernon *	Industrial
Dominguez Channel, near 116th St. and Isis Ave. Lennox	Transportation
Private Drain 314, near Firestone Blvd. And Phoebe Ave., La Mirada*	Commercial
Project 1202, near Wilmington Ave. and 220th St., Carson	Industrial
Los Angeles River, between Willow St. and Wardlow Rd., City of Long Beach	Mass Emissions

* Discontinued under 1996 permit.

2.2 1996 NPDES PERMIT – SAMPLING SITES

2.2.1 SITE SELECTION

2.2.1.1 Mass Emission Site Selection

The Department of Public Works monitored four major drainage areas near their outfalls to the ocean. Four of the mass emission monitoring stations installed under the original 1990 Permit were retained under the 1996 Permit; specifically the Los Angeles River, San Gabriel River, Ballona Creek, and Malibu Creek. The Coyote Creek mass emission station, which was required under the 1990 Permit but not under the 1996 Permit, was also monitored during the 1997-98, 1998-99, and 1999-2000 seasons. This station was retained in the program to provide data for the calculation of mass loading in the San Gabriel River watershed. The five mass emission monitoring stations were used to collect water quality data from over 1619 square miles and have produced the data used to calculate total loading to the ocean from these watersheds.

During the 1998-99 season, the station shelter on the Los Angeles River at Wardlow Road was under reconstruction during the entire season due to the raising of the levee walls by ACOE, and the automated sampling equipment was removed. Samples from the Los Angeles River were collected manually and were not composited. This station has been reinstalled and was fully operational for 1999-2000 season.

For mass emission sites, the Permit requires sampling a minimum of five events per station per year. These sampling events may be either dry weather or wet weather events. The Los Angeles and San Gabriel River stations were also the sites of the freshwater toxicity testing required by the permit. The 1998-99 season was the final season for freshwater toxicity testing.

2.2.1.2 Land Use Site Selection

The following is a brief summary of the land use site selection process completed between the spring and fall of 1996. The complete methods and results of this study are provided in *Evaluation of Land Use Monitoring Stations* (Woodward-Clyde and Psomas and Associates, 1996).

An initial list of 104 land use types based on the Southern California Association of Governments (SCAG) database was sorted into 37 categories. Of these, the top 12 urban uses based on total area were chosen for a field survey. The survey was performed to identify characteristics that would assist in the aggregation or subdivision of the 12 top land use categories. For each of the 12 land uses, 8 representative areas no larger than a city block were selected for the field survey during the spring of 1996. One issue investigated in the field surveys was whether the age of a development of high-density single family residential areas warranted additional monitoring sites. However, the survey indicated that there were no apparent differences between the five different age categories for high-density single-family residential land use so this land use was considered one category.

A loading model for all land uses was applied for four constituents (copper, phosphorus, COD, and TSS). The model used local and regional field-derived estimates of imperviousness and water quality. For each constituent, the land use categories were ranked by total loading. A marginal benefit analysis was applied to the ranked land uses to determine the most important for monitoring. The top land use types that ranked above or equal to the land use with the maximum marginal benefit were identified for monitoring. They were:

- Vacant
- High Density Single Family Residential
- Light Industrial
- Transportation
- Retail/Commercial
- Multifamily Residential
- Educational Facilities

The first 5 of the 7 land use types listed above (Vacant, High Density Single Family Residential, Light Industrial, Transportation, and Retail/Commercial) were already being monitored under the

R0011979

1990 Municipal Permit. To comply with the terms of the 1996 Permit, one site for each of these land uses was retained for continued sampling; the remaining sites were dismantled. New stations to monitor the last two land use types, Multifamily Residential and Educational Facilities, were installed in February 1997 and were operational for the 1997-98, 1998-99, and 1999-2000 storm seasons.

In addition to the pollutant loading analysis, land uses were also ranked by total area within each of the six major Los Angeles County watershed management areas. Four land use types not already on the list were then identified as having significant area in one or more of the watersheds (i.e., ranking in the top five land uses), as follows:

- Heavy Industrial
- Rural Residential
- Utility Facilities
- Mixed Residential

On the basis of this analysis, one mixed residential land use station was installed in October 1997 and was operational for the 1997-98, 1998-99, and 1999-2000 storm seasons; all eight land use monitoring stations were operational during the 1998-99 and seven land use monitoring stations were operational during 1999-2000 season. The Retail/Commercial monitoring station on Pier Drain in Santa Monica (S08) was dismantled and not in use in 1999-2000 storm season, with prior approval from the RWQCB, to accommodate construction by the City of Santa Monica of its stormwater treatment plant.

2.2.1.3 Critical Source Site Selection

The following is a brief summary of the Critical Source selection process undertaken to identify five industrial and/or commercial critical source sites. Each critical source type is to be monitored for a minimum of two years, the first year without BMPs, and subsequent years with BMPs. The complete methods and results of this study are provided in *Critical Source Selection and Monitoring Report* (Woodward-Clyde, 1997).

Similar to the land use monitoring evaluation process, the County undertook a five step process to identify and prioritize a list of critical industries within the county that may contribute significant pollutants to stormwater runoff. Standard Industrial Classification (SIC) codes played a major role in the selection process. Once selected, appropriate sites would be monitored over a minimum two year period for the duration of the permit to measure runoff quality with and without remedial cleanup actions. These remedial actions are referred to as Best Management Practices, or BMPs.

The first step was to develop an initial list of candidate industries. This list contained industries both included and excluded under the State's General Industrial Activities Stormwater permit process. Initial candidate selection was based on prevalence in the county and the extent of outdoor activities. The resulting list yielded a group of 30 candidate industries ranked by the number of facilities.

The next step involved developing a set of criteria to prioritize the list. A number of empirical factors were used to assign levels of significance to each SIC category. Loading (Q) would be

R0011980

addressed by the number of sources at a site and the likelihood of release. Imperviousness (R) of a site would be represented by the percent of paved area. Pollutant toxicity (T) would be denoted by the number of toxic pollutants and the inherent toxicity of the mix. An exposure factor (E) signifies if activities are exposed to rainfall. And finally, number (N) would represent the total number of sites in the county. Each variable would be assigned a qualitative number from 1 to 10, with 10 representing the worst condition. The pollutant potential (P) used to rank the results would thus be the product of all the factors, or

$$P = Q \times R \times T \times E \times N$$

Based on this ranking scheme, the top "critical source" industries were:

- Wholesale Trade (scrap and auto dismantling)
- Automotive Repair/Parking
- Fabricated Metal Products
- Motor Freight
- Automobile Dealers
- Chemical Manufacturing
- Electric/Gas/Sanitary
- Miscellaneous Manufacturing

A literature search was simultaneously conducted to identify what "critical source" industries, if any, have already been analyzed. The search revealed that similar stormwater studies had yet to be performed.

After the identification and prioritization, the Department then had the task of finding six companies of any one of the top five industries to enlist for monitoring runoff from five storms during the 1996-97 storm season. However, all six companies could not be enlisted until the end of that storm season, too late for the collection of runoff data. In 1997-98, twelve companies from two industries, automobile repair and auto dismantling, were enlisted. In the 1998-99 storm season, six companies from the metal fabrication industry were added. In the 1990-2000 storm season, half of the first three critical source industries designated as test sites were fitted with structural or nonstructural BMP at the Department's expense. The other half will remain as controls in order to evaluate BMP effectiveness. In addition, twelve companies from two industries, motor freight and automobile dealers, were enlisted for the 1999-2000 season. Sampling will continue for six years until five critical source industries and remedial BMPs are tested and evaluated.

2.2.2 LOCATION AND DRAINAGE AREA DESCRIPTIONS

Figure 2-1 is an overview of the study area with all mass emission and land use monitoring sites shown. Table 2-1 also indicates the dominant land use associated with each monitoring site and the total drainage area.

R0011981

2.2.2.1 Mass Emission Monitoring Sites

Provided below is a description of the four mass emission stations required by the 1996 Municipal Permit (Ballona Creek, Malibu Creek, Los Angeles River, and San Gabriel River) and one additional mass emission station (Coyote Creek) which is not specifically required. Figures 2-2 through 2-6 show the location of each monitoring station along with a description of its land use and 1990 population.

Ballona Creek Monitoring Station (S01)

The Ballona Creek monitoring station is located at the existing stream gage station (Stream Gage No. F38C-R) between Sawtelle Boulevard and Sepulveda Boulevard in the City of Los Angeles. At this location, which was chosen to avoid tidal influences, the upstream tributary watershed of Ballona Creek is 88.8 square miles. The entire Ballona Creek Watershed is 127.1 square miles. At the gauging station, Ballona Creek is a concrete lined trapezoidal channel.

Malibu Creek Monitoring Station (S02)

The Malibu Creek monitoring station is located at the existing stream gage station (Stream Gage No. F130-9-R) near Malibu Canyon Road, south of Piuma Road. At this location, the tributary watershed to Malibu Creek is 104.9 square miles. The entire Malibu Creek Watershed is 109.9 square miles.

Los Angeles River Monitoring Station (S10)

The Los Angeles River Monitoring Station is located at the existing stream gage station (Stream Gage No. F319-R) between Willow Street and Wardlow Road in the City of Long Beach. At this location, which was chosen to avoid tidal influences, the total upstream tributary drainage area for the Los Angeles River is 825 square miles. This river is the largest watershed outlet to the Pacific Ocean in Los Angeles County. At the site, the river is a concrete lined trapezoidal channel.

San Gabriel River Monitoring Station (S14)

The San Gabriel River Monitoring Station is located at an historic stream gage station (Stream Gage No. F263C-R), below San Gabriel River Parkway in Pico Rivera. At this location the upstream tributary area is 450 square miles. The San Gabriel River, at the gauging station, is a grouted rock-concrete stabilizer along the western levee and a natural section on the eastern side. Flow measurement and water sampling are conducted in the grouted rock area along the western levee of the river. The length of the concrete stabilizer is nearly 70 feet. The San Gabriel River sampling location has been an active stream gauging station since 1968.

Coyote Creek Monitoring Station (S13)

The Coyote Creek Monitoring Station is located at the existing ACOE stream gage station (Stream Gage No. F354-R) below Spring Street in the lower San Gabriel River watershed. Although this site is not required for monitoring per the NPDES Permit, the site was added to assist in determining mass loading for the San Gabriel River watershed. At this location, the

upstream tributary area is 150 square miles (extending into Orange County). The sampling site was chosen to avoid backwater effects from the San Gabriel River. Coyote Creek, at the gauging station, is a concrete lined trapezoidal channel. The Coyote Creek sampling location has been an active stream gauging station since 1963.

2.2.2.2 Land Use Monitoring Sites

The following is a description of the locations selected to monitor runoff from land-use specific drainage areas. Figures 2-7 through 2-14 show the location and drainage area of each monitoring station along with a description of its land use and 1990 population.

Santa Monica Pier Storm Drain Monitoring Station (S08)

The Santa Monica Pier Storm Drain Monitoring Station monitors runoff from land use that is predominantly commercial. The monitoring site is located near the intersection of Appian Way and Moss Avenue in Santa Monica. This storm drain discharges below the Santa Monica Pier. The Santa Monica Mall and Third Street Promenade dominate this watershed. The remaining land uses include: commercial office buildings, small shops, restaurants, hotels, and high density apartments. However, This station was dismantled and not in use in the 1999-2000 storm season to accommodate construction by city of Santa Monica's stormwater treatment plant.

Sawpit Creek Monitoring Station (S11)

The Sawpit Creek Monitoring Station is located in the Los Angeles River Watershed in the City of Monrovia. The monitoring station is in Sawpit Creek, downstream of Monrovia Creek. Sawpit Creek is a natural watercourse at this location. The overall watershed land use is predominantly vacant.

Project 620 Monitoring Station (S18)

The Project 620 Monitoring Station is located in the Los Angeles River Watershed in the City of Glendale. The monitoring station is at the intersection of Glenwood Road and Cleveland Avenue. The overall watershed land use is predominantly high density single family residential.

Dominguez Channel Monitoring Station (S23)

The Dominguez Channel Monitoring Station is located within the Dominguez Channel/ Los Angeles Harbor Watershed in Lennox, near Los Angeles International Airport (LAX). The monitoring station is near the intersection of 116th Street and Isis Avenue. The overall watershed land use is predominantly transportation, and includes areas of LAX and Interstate 105.

Project 1202 Monitoring Station (S24)

The Project 1202 Monitoring Station is located in the Dominguez Channel/Los Angeles Harbor Watershed in the City of Carson. The monitoring station is near the intersection of Wilmington Avenue and 220th Street. The overall watershed land use is predominantly industrial.

R0011983

Project 474 Monitoring Station (S25)

The Project 474 Monitoring Station is located in the Los Angeles River Watershed in the Northridge section of the City of Los Angeles. The monitoring station is located along Lindley Avenue, one block south of Nordhoff Street. The station monitors runoff from the California State University of Northridge. The land use of the drainage area is primarily education.

Project 404 Monitoring Station (S26)

The Project 404 Monitoring Station is located within the Los Angeles River Watershed in the City of Arcadia. The monitoring station is located along Duarte Road, between Holly Avenue and La Cadena Avenue. The land use of the drainage area is primarily multi-family residential.

Project 156 Monitoring Station (S27)

The Project 156 Monitoring Station is located within the Los Angeles Watershed in the City of Glendale. The monitoring station is located along Wilson Avenue, near the intersection of Concord Street and Wilson Avenue. The land use of the drainage area is classified as mixed residential.

2.2.2.3 Critical Source Monitoring Sites

The general locations of the critical source monitoring sites are shown in Figure 2-15. For purposes of anonymity, the agreement reached with each of the businesses keeps the exact locations confidential. Sites C01, C02, and C03 are the control sites for the wholesale trade (auto dismantlers); T01, T02, and T03 are the sites where Best Management Practices (BMPs) will be installed for the wholesale trade industry. Similarly, C04, C05, and C06 are the control sites for automotive repair, while T04, T05, and T06 are the BMP sites for the automotive repair industry. Sites C07, C08, and C09 are the control sites for fabricated metal products; T07, T08, and T09 are the BMP sites for the fabricated metal products industry. Sites C10, C11, and T12C are the control sites for motor freight companies; T10, T11A, T11B, T12A, T12B, and T12C are the BMP sites for the motor freight companies. Sites C13, C14, and C15 are the control sites for the auto dealers; T13, T14, and T15 are the BMP sites for the auto dealers.

SECTION 3

R0011985

This section describes the field and laboratory methods used to conduct the Monitoring Program, which includes precipitation and flow monitoring, stormwater sampling, and laboratory analyses. It also includes statistical test criteria as described in the NPDES permit.

3.1 PRECIPITATION AND FLOW MEASUREMENT

3.1.1 Precipitation Monitoring

For every monitoring station, a minimum of one automatic tipping bucket (intensity measuring) rain gage is located nearby or within the tributary watershed. Large watersheds may require multiple rain gages to accurately characterize the rainfall. The Los Angeles County Department of Public Works operates various automatic rain gages throughout the county. Existing gages near the monitored watersheds are also utilized in calculating stormwater runoff and are essential to develop runoff characteristics for these watersheds.

3.1.2 Flow Monitoring

Flow monitoring equipment is needed to trigger the automated samplers because the Monitoring Program requires flow-weighted composites for many constituents. Flows are determined from measurements of water elevation as described below.

The water elevation in a storm drain is measured by the stage monitoring equipment, and the flow rate is derived from a previously established rating table for the site or calculated with an equation such as Manning's. The Los Angeles County Department of Public Works uses rating tables generated from analysis of storm drain cross sections and upstream/downstream flow characteristics. The rating tables are modified if it is demonstrated in the field through stream velocity measurements that calculated table values are incorrect. Previous stormwater flow measurement efforts indicates that all stations will require multiple storm events to gather the data necessary for calibration of the measurement devices.

The automatic samplers utilize pressure transducers as the stage measurement device. However, pressure transducers are only accurate as flow measurement devices in open channel flow regimes. Therefore, for stations monitoring flows in underground storm drains, efforts were made to select drains that do not surcharge (flow under pressure) during events smaller than a 10-year storm event.

3.2 STORMWATER SAMPLING

3.2.1 Sample Collection Methods

Grab and composite sample collection methods, defined below, are used to collect samples.

- **Grab Sample** - a discrete, individual sample taken within a short period of time, usually less than 15 minutes. This method is used to collect samples for constituents that have very short holding times and specific collection or preservation needs. For example, samples for coliforms are taken directly into a sterile container to avoid non-resident bacterial contamination.

R0011986

- **Composite Sample** - a mixed or combined sample created by combining a series of discrete samples (aliquots) of specific volume, collected at specific flow-volume intervals. Composite sampling is ideally conducted over the duration of the storm event.

During a storm event, grab samples were collected during the initial portion of the storm (on the rising limb of the hydrograph) and taken directly to the laboratory.

Flow composite storm samples were obtained using an automated sampler to collect samples at flow-paced intervals. Samples collected at each station were combined in the laboratory to create a single flow-weighted sample for analysis.

During the storm season, the sampler was programmed to start automatically when the water level in the channel or storm drain exceeded the maximum annual dry weather stage. A sample was collected each time a set volume of water had passed the monitoring point (this volume is referred to as the pacing volume or trigger volume). The sample was stored in glass containers within the refrigerated sampler. A minimum of eight liters of sample was required to conduct the necessary laboratory analyses for all the constituents. The automated sampler was deactivated by field personnel when the water level in the channel or storm drain fell to about 120 percent of the observed maximum annual dry weather flow stage.

Samples were retrieved from the automated samplers as soon as possible to meet laboratory analysis holding time requirements. As samples were collected, rainfall and runoff data were logged and stored for transfer to the office.

Critical Source sampling procedures and equipment are described in the *Critical Source Selection and Monitoring report* (LACDPW and Woodward-Clyde, January 8, 199).

3.2.2 Field Quality Assurance/Quality Control Plan

Properly performed monitoring station set up, water sample collection, sample transport, and laboratory analyses are vital to the collection of accurate data. Quality Assurance/Quality Control (QA/QC) is an essential component of the monitoring program.

Evaluation of Analytes and QA/QC Specifications for Monitoring Program (Woodward-Clyde, 1996a) describes the procedures used for bottle labeling, chain-of-custody tracking, sampler equipment checkout and setup, sample collection, field blanks to assess field contamination, field duplicate samples, and transportation to the laboratory.

An important part of the QA/QC Plan is the continued education of all field personnel. Field personnel were adequately trained from the onset and informed about new information on stormwater sampling techniques on a continuing basis. Field personnel also evaluate the field activities required by the QA/QC Plan, and the Plan is updated if necessary.

Bottle Preparation

For each monitoring station, a minimum of three sets of bottles was available so that up to two complete bottle change-outs could be made for each storm event. Bottle labels contained the following information:

- LADPW Sample ID Number
- Station Number
- Station Name
- Sample Type (Grab or Composite)
- Laboratory Analysis Requested
- Date
- Time
- Preservative
- Temperature
- Sampler's Name

Bottles were cleaned at the laboratory prior to use, then they were labeled and stored in sets. Each station was provided with the same number, types, and volumes of bottles for each rotation unless special grab samples were required. Clean composite sample bottles were placed in the automated sampler when samples were collected. This practice ensured readiness for the next storm event. All bottles currently not in use were stored and later transported in plastic ice chests. Composite sample bottles were limited to a maximum of 2-1/2 gallons each, to ensure ease of handling.

Chain-of-Custody Procedure

Chain-of-custody forms were completed to ensure and document sample integrity. These procedures establish a written record which tracks sample possession from collection through analysis.

Field Setup Procedures

All field sampling locations were fixed sites, with the sampler placed on a public road or flood control right-of-way. After sample collection, field staff prepared the sampler for collection of the next set of samples either in storm mode or in dry weather mode. Inspection of visible hoses and cables was performed to ensure proper working conditions according to the site design. Inspection of the strainer, pressure transducer, and auxiliary pump was performed during daylight hours in nonstorm conditions.

The automated sampler was checked at the beginning of the storm (during grab sample collection) to ensure proper working condition and to see if flow composite samples were being collected properly. Dry weather collection techniques were similar, with grab and 24-hour composite samples being collected.

Bottles were collected after each event and packed with ice and foam insulation inside individually marked ice chests. Chain-of-custody forms were completed by field staff before

R0011988

transportation of the samples to the laboratory. Under no circumstance were samples removed from the ice chest during transportation from the field to the laboratory.

Travel Blanks and Field Duplicates

Potential field contamination was assessed through analysis of travel blanks and duplicate grab samples. Field travel blanks were collected for each monitoring station during every sampling event to quantify post sampling contamination. The monitoring program also included field duplicates to assess the precision of laboratory results. A field duplicate, the origin of which was unknown to the laboratory, was collected for each sampling event. This methodology for assessing post sampling contamination and laboratory testing procedures provided data to measure the precision and accuracy of the laboratory results.

3.2.3 Sampling Frequency

During the 1996-97 storm season, the Permit required the Department to sample up to 100 "station events" for the land use sites. During subsequent years (1997-98, 1998-99, 1999-2000), the Department was required to sample up to 200 "station events". A station event is defined as collection of one sample at one station. The Municipal Permit specifies sampling at mass emission stations to total five events per year during dry weather, storm, or a combination of both for all years.

3.3 LABORATORY ANALYSES

The Department of Agricultural Commissioner/Weights and Measures (ACWM) Environmental Toxicology Laboratory provides water quality laboratory and related services to the LACDPW. The ACWM lab is state certified to perform the water quality analyses contracted by LACDPW. The ACWM Lab maintains a laboratory analysis program that includes Quality Assurance and Quality Control protocols consistent with the objectives of the monitoring program required by the Permit (Section 3.3.3).

3.3.1 Possible Constituents of Concern

Possible constituents of concern for each element of the Monitoring Program are specified in the Municipal Permit. The constituents of concern for land use station monitoring are:

- Total Suspended Solids
- Total Nitrogen
- Total Phosphorus
- Cadmium
- Chromium
- Copper
- Lead
- Mercury
- Nickel
- Selenium
- Silver
- Zinc
- Chlordane
- Chlorpyrifos
- Diazinon
- Malathion
- Simazine
- Total DDT
- Total PAHs
- Total PCBs

Constituents of concern for mass emission monitoring include those listed above plus:

- Bacteria
- Total Phenols
- TPH
- Oil and Grease
- Cyanide

3.3.2 Analytical Suite and Analytical Methods

The suite of analytes and associated detection limits for samples collected at the land use stations and mass emission stations are specified in the Municipal Permit. Constituents of concern for derivation of event mean concentrations are also specified by the Permit. All the laboratory methods used for analysis of the stormwater samples are approved by the California Department of Health Services and are in conformance with USEPA approved methods.

The laboratory made an effort to provide the lowest detection limits attainable without compromising the reliability of the data. "Detection limit" (DL) is defined by the USEPA as "the concentration above which we are 99% confident that the analyte is present at a concentration greater than zero" (40 CFR Part 136 Appendix B). For this project the laboratory made some allowance for interference in the analysis due to the complex nature of the sample matrix by performing a DL study using a water sample collected from a channel during dry weather. These 'matrix specific' DLs are the reported DLs in the data tables. Data below the DL are reported as zero. The Practical Quantitation Limit (PQL) is the concentration above which the analyte can be accurately quantified. Reported PQLs were developed by the laboratory during the analysis of stormwater runoff samples using professional judgment to account for matrix interferences. Data that fall between the DL and PQL are reported by the laboratory at the apparent concentrations. When reviewing these data it should be noted that the concentrations below the PQL are estimated.

For some pollutants, the EPA Water Quality Criteria were lower than the required Monitoring Program method detection limits. As a result, detection limits for some constituents were lowered (beginning in the 1996-97 storm season) to a level below the EPA Criteria concentrations. This also enhanced the value of the data by improving the quality of the data sets and allowed for more rigorous statistical analyses and data interpretation techniques.

Detection limits of many semi-volatile organic compounds (SVOCs) were lowered in the 1999-2000 storm season, including all PAHs, for the land use and mass emission studies at the request of the Los Angeles Regional Water Quality Control Board. Modifications to detection limits are presented in Table 3-1.

3.3.3 Quality Assurance and Quality Control

The primary objective of the laboratory quality assurance/quality control program is to ensure that the analyses are scientifically valid, defensible, and of known precision and accuracy. The ACWM laboratory maintains quality assurance/quality control procedures (as described in their Quality Assurance Manual) in accordance with requirements of the California Department of Health Services. The ACWM laboratory standard operation procedures include method validation, equipment calibration, preventive maintenance, data validation procedures, assessment of accuracy and precision, corrective actions, and performance and system audits.

R0011990

The QA/QC review and data validation for the monitoring data was conducted by ACWM Lab, and the QA/QC documentation is available within the ACWM Lab files. The validated data as provided by the ACWM Lab were used for data analysis and interpretation with no further QA/QC review.

3.4 STATISTICAL TEST CRITERIA

3.4.1 Land Use

There are two provisions in the Permit which allow for discontinuing monitoring of specific land use constituents. The first is achieving an event mean concentration (EMC) at an error rate of 25% (Criteria 1). The second is detecting less than 25% of any constituent in 10 consecutive samples (Criteria 2).

Criteria 1

Section B.1.c of Attachment C of the NPDES Permit states: "The land use stations shall be monitored during the term of this Order or until such time that event mean concentrations (EMC) are derived, at the 25% error rate, for the following constituents of concern:"

PAHs	Chlordane	Cadmium
Copper	Nickel	Lead
Chromium	Silver	Zinc
Selenium	Mercury	Total Nitrogen
Total Phosphorus	Total Suspended Solids	Diazinon
Chlorpyrifos	Malathion	Simazine
Total DDT	Total PCBs	

The RWQCB agreed to substitute the mean standard error in place of the error rate (Swamikannu, 1999). The findings are presented in Table 4-14. Constituents appearing have at least 10 samples and an 80% detection rate.

Criteria 2

Section B.1.e of Attachment C of the NPDES Permit states: "If a constituent is not detected at the method detection limit (MDL) for its respective test method listed in Attachment C-3 in more than 25 percent of the first ten sampling events or on a rolling basis using ten consecutive sampling events, it will not be further analyzed unless the observed occurrences show high concentrations and are cause for concern." The results of this test are presented in Table 4-13.

Constituents meeting this criteria (with an X corresponding to a site) can be considered for discontinuation. However, if there is still concern for the constituent, monitoring will continue. Specific constituents of concern are marked with an asterisk in the table.

3.4.2 Mass Emissions

The only criteria required to discontinue monitoring constituents at mass emissions sites is the detection of less than 25% in 10 consecutive samples (Section B.2.c of Attachment C of the NPDES Permit). The results of this test are presented in Table 4-7.

Constituents meeting this criteria (with an X corresponding to a site) can be considered for discontinuation. However, if there is still concern for the constituent, monitoring will continue. Specific constituents of concern are marked with an asterisk in the table.

R0011992

SECTION 4

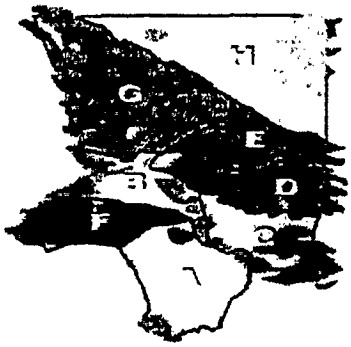
R0011993

4.1 HYDROLOGY: PRECIPITATION AND FLOW

Over the past six years, Los Angeles County has experienced weather patterns that have resulted in very diverse storm seasons. The two most significant seasons were the 1997-98 El Niño and the 1998-99 La Niña storm seasons.

The term El Niño refers to the disruption of the entire oceanic-atmospheric system in the tropical Pacific Ocean. This occurrence often causes a major departure from average temperatures and precipitation amounts on a global scale. During El Niño, the trade winds relax in the central and eastern Pacific and upwelling of deep colder ocean water is inhibited. Therefore, in the eastern Pacific, the water temperature rises. Increases in temperature in the central and eastern Pacific result in an increase of evaporation and convection, or thunderstorm activity. This activity can be observed, especially in the winter, as the subtropical jet stream flows from Southern California, through the Gulf Coast region.

The effects of the 1997-98 El Niño were the strongest observed for the past 40 years (National Oceanic and Atmospheric Administration). Rainfall associated with El Niño was greater later in the storm season as compared to previous years. The month of February of 1998 produced over fifteen inches of rain at the downtown Los Angeles raingage compared to the 110 year average of 3.17 inches for the same raingage. The previous year, the same raingage recorded only 0.06 inches of rain.



Furthermore, the total wet season runoff volume at the Los Angeles River station as of March, 1998, was nearly 300,000 acre-ft. By comparison, the 1996-97 storm season runoff volume at the same location was 58,309 acre-ft, approximately one-fifth.

In contrast, the 1998-99 storm season was considered a La Niña storm season. La Niña climatology is characterized by unusually cold ocean temperatures in the eastern equatorial Pacific that impact global weather patterns. La Niña tends to bring nearly opposite effects of El Niño to the United States. It often features drier than normal conditions in the Southwest in late summer trough the subsequent winter. La Niña conditions recur every few years and can persist as long as two years.

The month of February of 1999 produced only 0.4 inches of rain at the downtown Los Angeles raingage compared to the 110 year average of 3.17 inches for the same raingage. The same raingage during the El Niño season, by contrast, produced over 15 inches of rain. Similarly, the total rainfall for the 1998-1999 season at the Ballona Creek station was only 9.48 inches, and the total wet season runoff volume at the Ballona Creek station was 10,700 acre-ft. By comparison, the rainfall total during the previous storm season at this station was 28.28 inches and the runoff volume was 18,300 acre-feet.

Figures 4-20 and 4-21 respectively show the Los Angeles annual and monthly wet season rainfall at the downtown Los Angeles station.

Furthermore, the figure and table below display aerial weighted rainfall totals for the Los Angeles County by area. As expected, the San Gabriel and Santa Monica Mountains recorded the highest precipitation totals throughout the years while the dessert areas recorded the lowest. San Gabriel and San Fernando Valleys recorded very similar precipitation values. Again, it can be seen that El Niño season of 1997-98 produced twice as much rainfall as the seasonal normal, while La Niña season of 1998-99 recorded less than half the seasonal normal.

RAINFALL INDICES USING SELECTED STATIONS
for the period of October 1 through September 30

	Seasonal Normal (inches)	94-95 Season (inches)	95-96 Season (inches)	96-97 Season (inches)	97-98 Season (inches)	98-99 Season (inches)	99-00 Season* (inches)
A. Coastal Plain	13.71	25.19	11.38	13.91	29.08	7.73	8.94
B. San Fernando Valley	17.62	35.01	13.22	18.58	39.55	10.35	15.64

County**	15.65	27.27	11.69	13.72	33.01	8.02	11.17

Notes: * Rainfall from October 1, 1999 through April 30, 2000
** Seasonal Normal and Season sections of this line are derived from Areal Weighted Average.

Table 4-1 summarizes the hydrological data for each station for the 1994-95, 1996-97, 1997-98, 1998-99, and 1999-2000 seasons.

A collection of rainfall contour maps for the 1994-95, 1995-96, 1996-97, 1997-98, 1998-99, and 1999-2000 storm seasons are included in Appendix A.

Refer to Appendices of preceding annual Stormwater Monitoring Reports for hydrographs of monitored sites and rainfall contour maps for each storm event.

4.2 STORMWATER QUALITY

4.2.1 Overall Imperviousness

Overall watershed imperviousness has been linked to stormwater quality problems (Center for Watershed Protection, 1996). The following table gives the overall imperviousness of each of the major Watershed Management Areas under the 1996 Municipal Stormwater Permit:

Imperviousness of Watershed Management Areas

WATERSHED MANAGEMENT AREA	AREA, Sq. Mi.	OVERALL IMPERVIOUSNESS, %
Dominguez Channel/ L. A. Harbor	110	62
Ballona Creek	211	45
Los Angeles River	834	35
San Gabriel River	683	30
Malibu Creek	203	6
Santa Clara River	1029	5

Notes. - Values were calculated using the DPW GIS Pollutant Loading Model
- Land use distribution is based on 1993 SCAG data
- Imperviousness values for each land use were taken from the LACDPW Hydrology Manual, 1991

4.2.2 Bacterial Indicators

Los Angeles County has been monitoring a selection of bacterial indicators, including total coliforms and fecal bacteria (fecal coliforms, fecal streptococcus, and fecal enterococcus), at two of the mass emission monitoring stations (Ballona Creek and Malibu Creek) since the 1994-95 rainy season. Bacteria monitoring in 1994-95 and 1995-96 also involved land use sampling. All four of the mass emission monitoring stations currently required by the Permit (Ballona Creek, Malibu Creek, Los Angeles River, and San Gabriel River) have been sampled for bacteria since the 1995-96 storm season. Bacteria were not sampled at the Coyote Ck. station, which was not a requirement of the Permit, and land use sampling for bacteria was also not a requirement under the current Permit.

In addition to wet weather sampling, a number of dry weather samples were analyzed since 1994 to support other in-house studies, most notably for the low flow diversion projects at various locations along the shore line in Los Angeles County. Dry weather bacteria results are presented in Tables 4-5b and 4-5c.

Fecal bacteria are normal residents of the digestive tracts of humans and other warm-blooded animals. They are usually not pathogenic themselves but they can serve as indicators for the presence of potential pathogens (including bacteria, viruses, and protozoa that may cause human health problems) if contamination of surface waters with sewage had occurred. Fecal coliforms are a subgroup of the total coliform group.

Fecal coliforms, fecal streptococcus, and fecal enterococcus are three independent residents of the gastro-intestinal tracts of warm-blooded animals, and their distribution among warm-blooded species varies. Unfortunately, none of the bacteria is totally specific to humans, so none can serve as the ultimate indicator and warning signal for the presence of potential human pathogens.

Total coliforms and fecal bacteria (fecal coliforms, fecal streptococcus, and fecal enterococcus) were detected in all stormwater samples tested since 1994 at densities (or most probable number, MPN) between several hundreds to several million cells per 100 ml. Table 4-8 and Figure 4-4 show the wet weather sample results obtained between 1994 and 2000 for the different bacterial groups. The geometric mean (labeled as "log mean" for consistency with reports from other Los Angeles agencies) for each storm season is shown as one bar. Results are shown for the four mass-emission stations tested. Dry weather bacteria results are presented in Tables 4-5b and 4-5c.

The Malibu Creek station appears to have consistently lower counts than other mass emission stations and is consistently lower for all four groups of bacteria. There is no apparent pattern of differences between monitoring years, although the 1995-96 season appears to have higher mean densities than other years. At 75% of normal, this was not a particularly rainy season.

A study of the raw microbial data for wet weather and dry weather from 1994 to 2000 indicates the following:

- Every wet weather mass emission bacteria sample taken exceeded the public health criteria for indicator bacteria. All of the dry weather bacteria samples taken for the low flow diversion projects exceeded the public health criteria. Most of the dry weather mass emission bacteria samples taken exceeded the public health criteria. Wet weather flows

contained bacteria densities at much higher levels (three to four orders of magnitude) than dry weather flows.

- Except for 1996-97, densities observed during the first storm of each rainy season were not necessarily higher than during consecutive storm events, suggesting that there was no consistent "first-flush" effect in these watersheds. Peak densities were observed at different times each year. In 1995-96, the peak density at all four mass emission stations and one land use station coincided with the peak storm of the season.

- Except for somewhat lower densities at Malibu Creek, there was no seasonal or regional consistency in cell densities. There was a very wide range of densities for all stations.

- There was one storm event, January 9, 1998, that yielded extremely high counts in all stations for all bacterial strains. The available data do not provide an explanation, or suggest whether this could be a contamination artifact.

- The 1996-97 season had one event, November 21, 1996, that yielded runoff with high counts in all stations for all species.

- During the 1998-99 season, the event of March 15, 1999 was associated with high bacterial counts for most stations and the events of March 25, 1999 and April 4, 1999 were associated with unusually low counts for most stations.

The following table gives the storm date when the peak fecal coliform reading was observed for that season:

[SEE TABLE ON NEXT PAGE]

Comparison of Storm Dates to Peak Fecal Coliform Dates

		1994-1995	1995-1996	1996-1997	1997-1998	1998-1999	1999-2000
Date of First Storm > 0.1"		10/04/94	12/13/95	10/29/96	11/10/97	11/08/98	11/08/99
Date of Largest Storm		01/07/95	02/20/96	01/20/97	02/21/98	04/11/99	03/03/00
Depth of Largest Storm (inches)		6.65	4.39	3.54	5.08	1.15	2.01
MONITORING STATION	Ballona Creek	01/10/95	02/20/96	10/29/96	01/09/98	02/09/99	02/10/00
	Malibu Creek	03/03/95	02/20/96	10/29/96	01/09/98	03/15/99	02/23/00
	Los Angeles River	N/A	02/20/96	11/21/96	01/09/98	03/15/99	02/23/00
	San Gabriel River	N/A	02/20/96	11/21/96	01/09/98	03/15/99	03/08/00
	Retail/Commercial	03/21/95	12/23/95	N/A	N/A	N/A	N/A
	Vacant	N/A	12/23/95	N/A	N/A	N/A	N/A
	HDSFR	N/A	03/12/96	N/A	N/A	N/A	N/A
	Transportation	N/A	12/23/95	N/A	N/A	N/A	N/A
	Light Industrial	N/A	02/20/96	N/A	N/A	N/A	N/A

It appears from the table that in a number of instances, peak fecal coliform counts occurred at different monitoring stations in different parts of the county during the same storm. Further, in 1995-96, the highest fecal coliform readings at five stations coincided with the largest storm of the season. Also, in 1996-97, the highest fecal coliform readings at two stations coincided with the first storm of the season greater than 0.1" rainfall. These observations suggest that peak fecal coliform levels may be related to regional hydrologic conditions.

4.2.3 Stormwater Toxicity

Two studies required by the 1996 Municipal Stormwater Permit examined stormwater toxicity. The Santa Monica Bay Receiving Waters study examined water column and sediment toxicity impacts on Santa Monica Bay from stormwater from Ballona and Malibu Creeks. The Southern California Coastal Waters Research Project (SCCWRP), the University of Southern California, and the University of California Santa Barbara were the principal investigators. In addition, dry and wet weather toxicity tests were performed on the Los Angeles and San Gabriel Rivers in 1997-98 and 1998-99. This testing was performed by the Southern California Coastal Waters Research Project. Toxicity was measured as impairment to sea urchin fertilization.

An Executive Summary of the Bay Receiving Waters study is included in Appendix C. Major findings of the stormwater toxicity studies (SCCWRP, 1999) are repeated below:

- Virtually every sample of Ballona Creek stormwater tested was toxic to sea urchin fertilization.

- The first storms of the year produced the most toxic stormwater in Santa Monica Bay during the study.
- The toxic portions of the stormwater plume were variable in size, extending from 1/4 to 2 miles offshore of Ballona Creek.
- Surface water toxicity caused by unidentified sources was frequently encountered during dry weather in Santa Monica Bay.
- Zinc was the most important toxic constituent identified in stormwater in Santa Monica Bay, but zinc concentrations in the toxic portion of the discharge plume were usually below levels shown to cause toxicity in the laboratory.
- Copper and other unidentified constituents may also be responsible for some of the toxicity measured in Santa Monica Bay.
- The measured concentrations of zinc and copper in Ballona Creek stormwater were estimated to account for only 5% - 44% of the observed toxicity.
- The fate of most stormwater constituents discharged to Santa Monica Bay is unknown.
- For two years in a row, wet weather toxicity was significant in the Los Angeles River. Dry weather toxicity was significant the second year, but not the first.
- For the San Gabriel River, wet weather toxicity was significant the first year, but not the second. Dry weather toxicity was not significant either year.
- For both rivers, wet weather toxicity was higher for the first storm tested, suggesting a seasonal "fist flush" phenomenon for toxicity.

4.2.4 Contaminated Sediments and Total Suspended Solids

Sea floor habitat and sediment contamination were studied in the Santa Monica Bay Receiving Waters study and were investigated by the Southern California Coastal Waters Research Project. Major findings of the sea floor habitat and sediment contamination study (SCCWRP, 1999) are repeated below:

- The sea floor is where stormwater particles, and associated contaminants, eventually settle.
- The sediments on the sea floor can accumulate runoff inputs over an entire storm, over several storms, or over several seasons.
- Sediments offshore of Ballona Creek generally had higher concentrations of urban contaminants, including common stormwater constituents such as lead and zinc.
- Sediments offshore of Ballona Creek showed evidence of stormwater impacts over a large area.
- Sampled biological communities offshore of Ballona Creek were similar to those offshore of Malibu Creek. Both areas had comparable abundance and similar species composition.
- Sampled biological communities offshore of Ballona and Malibu Creeks were also similar to background reference conditions established in previous studies of southern California.

The County of Los Angeles Department of Public Works has also participated on the Los Angeles Basin Contaminated Sediment Task Force. The management committee of the Task Force is comprised of the U. S. Army Corps of Engineers, the U.S. Environmental Protection Agency (Region IX), the California Water Quality Control Board (Los Angeles Region), and the California Coastal Commission. One of the goals of the Task Force is to promote and implement region-wide efforts at source reduction through watershed management. The Task Force, in its Long Term Management Strategy Action Plan (no date), states:

- Informal surveys of potential users and past projects suggest that the major sources of contaminated dredge material will continue to be Marina del Rey, the ports of Los Angeles and Long Beach, and the mouth of the Los Angeles River.
- Some of the sediments dredged from these harbors contain elevated levels of heavy metals, pesticides, and other contaminants. In most cases, the concentrations of these contaminants do not approach hazardous levels.

The Corps of Engineers, in a draft study (2000) sought to identify possible inland sources of contaminated sediments in the Ballona Creek watershed by sampling dry weather sediments in the bottom of Ballona Creek and major tributaries. The draft study found:

- Four of 21 sites were without any chemical concentration exceeding the National Oceanographic and Atmospheric Administration's "Effect Range-Low" (ERL) values: storm drain Bond Issue Project 9408, Project 425, Ballona Creek at Sawtelle Blvd., and Centinela Channel.
- Sediments on the bottoms of storm drain Bond Issue Projects 648, 51, 494, and 503 ranked by dry weight most consistently as the most contaminated sites with respect to metals and polycyclic aromatic hydrocarbons (PAHs).
- The two areas of the main Ballona Ck. channel that ranked, by dry weight, as most contaminated and exceeding ERLs were just downstream of Madison Ave. and Fairfax Ave.
- With respect to the potential for contamination from PAHs, sites in Ballona Ck. at Pickford St. and Fairfax Ave., Higuera St. drain, Projects 51 and 3867, and Culver City Acquisition and Improvement District No. 4 drain appeared most contaminated.
- Bed load sediment in the major tributary drains of Sepulveda and Centinela Channels were among the least contaminated samples.
- According to a Corps geographic information system used to model unit aerial loading, the area within the Ballona Ck. drainage area of expected highest stormwater loading of metals, oil, and grease extends from Hollywood to Culver City in a 1- to 2-mile wide, 5- to 6-mile long strip parallel and east of the San Diego (I-405) Freeway.

In an effort to analyze the presence of PAH in stormwater, Los Angeles County Public Works lowered the detection limit of semi-volatile organics in stormwater samples in the 1999-2000 season by using modified EPA method 625 (see Table 3-1). An analysis of stormwater mass emission mean concentrations (Table 4-6b) shows that two PAH compounds, phenanthrene and pyrene, exceeded the California Ocean Plan objective at the Malibu Creek station. No other PAH compound exceedences appeared through this comparison.

Given the connection between contaminated sediments and suspended solids (Stenstrom et al, 1997, in U. S. Army Corps of Engineers, 2000), we calculated suspended solids loadings at the five mass emission monitoring stations from 1994 to present (Table 4-10 and Fig. 4-5a) where data was available. The data shows that the Los Angeles River is the largest contributor of suspended solids. This finding is expected because the L. A. River drainage area is the largest monitored watershed (825 square miles at the monitoring station). However, during the El Niño season of 1997-98, suspended solid loading was disproportionately higher than Ballona Creek loading (88.8 square miles at the monitoring station). It should be noted, however, that the Ballona Ck. monitoring station was out of service during February of 1998.

Total suspended solids were high during the 1999-2000 storm season at the vacant land use site. This may have been due to modifications to the Sawpit Dam located upstream of the sampling station.

4.2.5 Comparison of Mass Emissions Concentrations to the Ocean Plan, Basin Plan, and California Toxics Rule

Table 4-6a shows the list of constituents analyzed from the stormwater mass emission monitoring sites since 1994. Both the annual mean and median of the analyses of these constituents were compared to the water quality objectives outlined in the California Ocean Plan, the Los Angeles Basin Plan, and the California Toxics Rule. Stormwater bacteria indicators were compared to the standards in AB411. It should be noted that, except for bacteria indicators, there are no numerical water quality standards that apply to stormwater or nonpoint source pollution. Current federal and state numerical standards apply only to point source pollution, such as sanitary sewage, industrial and point source discharges to the ocean and other water bodies. Water quality standards described in the 1995 Los Angeles Region Basin Plan or the 1997 California Ocean Plan do not apply to stormwater runoff, and any exceedence of values should not indicate violation nor noncompliance with the plans. Furthermore, a direct comparison of the sampling results with the Ocean Plan standards cannot be made since the results presented in the table are detected values before dilution, a factor allowed by the Ocean Plan.

Table 4-6b shows those constituents whose annual mean or median virtually exceeded the three objectives described above. For bacteria indicators, the log mean of the Most Probable Number per 100 ml was compared to the objectives of AB411. The table shows that the bacteria indicator standards were exceeded at every monitoring station where sampled for every year. The next most prominent virtual exceedences occurred with total and dissolved copper and bis (2-ethylhexyl) phthalate, followed by turbidity, total zinc, and total lead. The table also shows that 1997-98, the El Niño season, contributed the most virtual exceedences at all monitoring stations except Coyote Creek. Finally, the table shows that the Los Angeles River produced the most virtual exceedences of any other mass emission monitoring station.

4.2.6 Loading

The above discussion points to dissolved zinc and copper and total suspended solids as constituents worthy of further examination. If these are important constituents, it would be helpful to look at what watersheds are producing the greatest amounts of these constituents. A loading analysis, that is pounds of constituent per season, would make this indication. To

calculate annual loading, the annual mean concentration of the constituents of interest are multiplied by the annual volume of runoff measured at each mass emission station. Loading results are shown in Table 4-10 and Figures 4-5a through 4-12.

As expected, loading was greatest during 1997-98, the El Niño season. This analysis indicates that the Los Angeles River delivered the highest loadings of total suspended solids (approx. 220,000 tons), dissolved copper (approx. 28 tons), total copper (approx. 40 tons), dissolved zinc (approx. 170 tons), and total zinc (approx. 230 tons). Further, it appears that Los Angeles River loading for the metals is disproportionate by drainage area to the other watersheds.

Total and dissolved zinc loading is also prevalent among unmonitored watersheds. The Dominguez Channel/L. A. Harbor watershed contributed the highest loadings for dissolved zinc (approx. 2.3 tons) and dissolved copper (approx. 30 tons) and was the highest for each year.

Loading calculations from unmonitored watersheds were accomplished by a GIS model (Table 4-11 and Figures 4-16 through 4-19). Comparison of loadings between monitored and unmonitored watersheds should not be made at this time because the model is not fully calibrated.

4.2.6.1 GIS Model

To assist in implementing this requirement, the Department developed a GIS application called the Pollutant Loading Model. A brief description of the model follows:

Hardware Requirements

- IBM-compatible, running Windows NT 4.0 or Windows 95
- 8 MB hard disk space (data/project on network); 600MB hard disk space (local)
- 64 MB RAM or higher

Software Requirements

- ArcView 3.1
- Spatial Analyst 1.1 for ArcView

Data Requirements

Geographic -

- Thomas Brothers Maps® data sets, County of Los Angeles
- Southern California Association of Governments Land Use
- Watershed Management Area Boundaries
- Rain gage locations and depths
- Watershed sub-basin boundaries
- Municipal Boundaries
- Water Quality Monitoring Station locations

Tabular -

- Rain gage data for each rainfall event
- Event Mean Concentration data

The Pollutant Loading application computes total pollutant loading for selected pollutants originating in user-defined watersheds or political boundaries. It draws upon many existing data sources, such as predetermined drainage subbasins, land use, historical and event rainfall data, water quality monitoring station results, and multiple underlying geographic data including political boundaries, natural boundaries, census tracts, forest boundaries, streets, and drains.

The user is given the option of hand-digitizing a study area or graphically selecting a predetermined drainage subbasin, monitoring station watershed, city, or other municipal boundary to use as a study area. The user can also locate an area of interest by typing an address or selecting a Thomas Brothers Maps® page.

The user selects a rainfall event from historical records. Rainfall data comes in the form of a previously processed grid of the user-selected storm event or as a rain gage data file, in which case, the model will prepare a rainfall grid using the Spatial Analyst extension. There is also an option to use average annual rainfall.

The application uses the rainfall data to calculate the amount of runoff, based on the imperviousness of the land use polygons it intersects. See equations used at the end of this Section.

The user then has the ability to choose the pollutants for the study from over 257 constituents. The Water Quality data comes from over 24 monitoring stations the County has operated at some point since the 1994-95 storm season. The user can quickly select constituents from pre-classified groups such as General Minerals, Heavy Metals, Pesticides, etc. By default the model will select the 25 pollutants of concern (made up of 61 constituents) listed in the NPDES permit.

The model will then tabulate total pollutant load for the study area using previously calculated Event Mean Concentrations of the selected pollutants. A report of the results is generated in Crystal Reports. The application also produces maps as ArcView layouts showing the area of study, rainfall isohyets, landuse distribution, rain gage locations and values.

Equations Used

- Runoff Volume = (Rainfall Volume)*(Runoff Coefficient)
  Where:
  Runoff Coefficient = (0.8*Imperviousness) + 0.1
- Load = (Pollutant concentration)*(Runoff Volume)

Assumptions and Limitations

- An imperviousness value used for the calculations is associated with 104 different landuse categories.
- The 104 SCAG land use categories have been aggregated into 34 categories covering 100% of the County.

Critical Industry Land Use Types

Critical Source Industry	SCAG Land Use
Auto Dismantling (Wholesale Trade)	Heavy Industrial
Auto Repair	Retail/Commercial
Metal Fabrication	Heavy Industrial
Motor Freight	Transportation
Auto Dealerships	Retail Commercial

Table 4-15 and Figure 4-3 show the highest median value for total zinc (approx. 450 μg/l), dissolved zinc (approx. 360 μg/l), total copper (approx. 240 μg/l), and dissolved copper (approx. 110 μg/l) were produced at the fabricated metal sites (labeled "control"). This finding holds true for those critical source industries added and sampled in 1999-2000, namely motor freight and auto dealerships, which are discussed in the 1999-2000 annual monitoring report. However, levels for total and dissolved zinc did not appear to be significantly different between the industry types.

By contrast, levels for total and dissolved copper did appear significantly higher for the fabricated metals sites over the other critical industry categories. The highest median level for suspended solids was also produced at the fabricated metals sites, but no industry was significantly higher or lower than another for suspended solids.

Bacteria indicators were analyzed for the first time from the critical source sites in 1999-2000.

4.2.9 Best Management Practices for Critical Source Industries

In the 1999-2000 season, items of equipment called Best Management Practices (BMPs) were purchased by the County for installation at half of the companies from the auto dismantling, auto repair, and metal fabrication industries. These preventive-type BMPs took the form of good housekeeping and spill containment measures (Table 4-16). Each business owner agreed to be responsible for installing and using the BMPs. The County encouraged the business owners to utilize the BMPs during the storm season, but the County had no jurisdiction or control over how or when they were used.

Table 4-15 and Fig. 4-3 compare the results of those companies fitted with BMPs to those without. For total and dissolved zinc, the median concentration lowered or stayed nearly the same with the implementation of BMPs at the auto dismantling, auto repair, and fabricated metals industries. (For the auto dismantling and auto repair industries, the median actually increased slightly.) In none of the circumstances was the difference significant.

For total and dissolved copper, however, where the fabricated metal industry had displayed the highest median concentrations, levels were significantly reduced with the implementation of BMPs. The auto dismantling and auto repair businesses showed no significant difference.

- Water quality data collected from 8 different landuse monitoring stations yields Event Mean Concentration (EMC) values. The remaining landuse categories (34-8 = 26) use assumed EMC values based on their association with the 8 monitored landuse types.
- All polygons of the same landuse type are assumed to have the same EMC value regardless of their spatial location within the county.
- Annual pollutant loadings use previously calculated seasonal EMCs for their calculation.
- Rainfall grid cell sizes are 500 feet by 500 feet. Rainfall depth does not vary within the grid cell.
- The model does not account for variation over time in soil permeability which influences surface runoff in undeveloped watersheds. In other words, a given coefficient of discharge for a particular land use type will not change regardless of previous soil conditions (saturated soil versus dry soil)

The primary operations that are inherent to both observed and modeled methods are described below.

Comparison of Observed and Modeled Load Calculation Methods

ITEM	OBSERVED METHOD	MODEL CALCULATIONS
STORM RUNOFF VOLUME	Flow rate taken directly from stream gage data and integrated over duration of storm to develop runoff volume. Note that this parameter includes base flow and storm runoff. Calculations can be made to estimate a base flow and separate it from the observed runoff.	Rain gage rainfall depths are used to prepare a rainfall grid surface. Rainfall grid cells are 500' x 500'. Equations: (1) Runoff coeff. = (0.8 x Imperviousness) + 0.1 (2) Rainfall volume = (Rainfall depth) x Area (3) Runoff volume = (Rainfall vol.) x (Runoff coeff.)
POLLUTANT EVENT MEAN CONCENTRATION (EMC)	Flow composited samples obtained at the mass emission monitoring sites are analyzed by the lab. Resulting pollutant concentrations are EMCs.	(1) The entire county is comprised of 34 general land use types. Storm runoff from the 8 most significant types is flow-weight sampled by automated equipment. The monitored watersheds of the eight significant types are chosen to represent typical examples of that land use. (2) Water quality results from the 8 monitored land use stations are assigned to the remaining 26 unmonitored land use types based on similarities of land use. (3) Any given land use type is assumed to yield the same EMC anywhere in the county (i.e. a given polygon defined as Single Family Residential (SFR) is assumed to yield the same EMC as any other SFR polygon in the county).
POLLUTANT LOAD	Observed concentration (EMC) multiplied by observed runoff volume.	Observed and assigned concentrations (EMC) for each land use multiplied by the modeled runoff volume for each land use summed within the area of study.

The model does not take into account possible degradation or adsorption of the pollutant as it is transported downstream. These results therefore should not be taken as absolute; rather, they should be used for unmonitored watersheds or smaller portions of monitored watersheds for comparative purposes only.

4.2.7 Constituents of Concern

Table 4-6b includes sixteen chemical constituents that were identified from the comparison of mass emission annual concentrations to the objectives of the California Ocean Plan, the Los Angeles Basin Plan, and the California Toxics Rule. Two organophosphate pesticides, diazinon and chlorpyrifos, are also included in Table 4-6b because of their identification of stormwater toxicity in other independent studies (Lee, 1998). Indicator bacteria (total coliform and fecal coliform, streptococcus, and enterococcus) are also included due their exceedence of AB411.

As of yet, Total Maximum Daily Loads (TMDLs) are not part of the Los Angeles Municipal Stormwater Permit. However, constituents identified by the 303d list that were not already identified through the comparison process, namely nutrients, are also included in Table 4-6b. It should be noted that there were no virtual exceedences by nutrients (compounds of nitrogen and phosphorus) of the three water quality objectives. Further, a report by the Las Virgenes Municipal Water District (May, 2000) found that beneficial use impairment due to algae growth is not a problem during storm season in Malibu Creek.

4.2.8 Identification of Possible Sources

With the identification of dissolved zinc and copper as stormwater toxicants in the Santa Monica Bay receiving water study (SCCWRP, 1999), and the implication of suspended solids (U. S. Army Corps of Engineers, 2000), it is helpful to look at land use and critical source runoff quality data (Tables 4-12 and 4-15 and Figures 4-1 and 4-3) to see if any particular land uses or industries could be singled out as notable or significant for those constituents. Figures 4-22 and 4-23 also show which constituents were prevalent at which land use.

Light industrial, transportation, and retail/commercial land uses displayed the highest median values for total and dissolved zinc, with light industrial the highest at about 300 μg/l for dissolved zinc and about 360 μg/l for total zinc. Runoff concentrations from the remaining land use types (high density single family residential, education, multifamily residential, and mixed residential) were significantly less.

Light industrial and transportation land uses displayed the highest median values for total and dissolved copper, with transportation the highest at about 28 μg/l for dissolved copper and about 40 μg/l for total copper.

Median concentrations of total suspended solids were highest coming off of the light industrial land use category, at about 130 mg/l.

These land use observations, particularly from the light industrial and retail/commercial categories, can be narrowed down by looking at the stormwater zinc, copper, and suspended solids sampled under the Critical Source program. The critical source industries sampled to date fall under the following SCAG land use categories:

SECTION 5

R0012007

5.1 OBJECTIVES ACHIEVED

Since 1994, the goal of the Monitoring Program has been to develop information to support effective watershed stormwater quality management programs. The primary objectives of the Monitoring Program, as outlined in the Permit and Section 1 of this report, follow.

5.1.1 Track Water Quality Status, Pollutant Trends and Pollutant Loads, and Identify Pollutants of Concern

Water quality status and pollutant trends and loads were successfully addressed by all of the major monitoring program elements: the Santa Monica Bay receiving waters impact study, the mass emission monitoring element, the land use monitoring element, and the critical source monitoring element.

The Santa Monica Bay receiving waters impact study extended from the 1996-97 through the 1998-99 storm seasons and focused on discharge from Ballona and Malibu Creeks.

The five mass emission stations located on major tributaries to the Pacific Ocean sampled runoff from 1220 of 2086 square miles of the Los Angeles coastal basin. The only major watershed not monitored for mass emissions was the largely undeveloped Santa Clara River watershed in the northwest part of the permit area. The mass emission data was also used to identify pollutants of concern and to calculate seasonal loads. Since January 1995, 212 station events have been sampled. Generally, sampling activities were conducted according to plan, and attempts were made to capture as many storms as possible. Initial mechanical difficulties with the sampling equipment were overcome over the years of use.

The siting of these stations was dictated in large part by accessibility and the availability of public right of way. All five mass emission stations were set up in existing Department of Public Works stream gauge shelters. Two of the mass emission stations, Ballona Creek and Malibu Creek, have the longest record, sampling since January 1995, and the balance of the mass emission stations have been sampling since the 1995-96 storm season. The automated equipment also provided the collection of flow-weighted composite samples, which reflect and allow for varying constituent concentrations throughout the storm event.

The sampling of runoff from land use specific drainage areas also began in January 1995 with the installation of automated equipment in the Santa Monica Pier drain (retail/commercial). By the 1995-96 season, four more of the current land use monitoring stations were installed (high density SFR, vacant, light industrial, and transportation). When the current permit came into effect in July, 1996, two more land use stations were installed (multifamily residential and educational). The final land use monitoring station (mixed residential) was installed by the 1997-98 storm season. Similar flow-weighted compositing was accomplished through the use of automated equipment for sampling runoff from land use-specific drainage areas.

In contrast to the mass emission stations, land use monitoring stations are largely located in underground drains. Their siting was therefore more complicated, requiring the identification of locations where the drainage area was the predominant land use, where there was a manhole near available power in available right-of-way, where the drain was not surcharged in a moderate storm, and where personnel would be relatively safe. Since 1995, 396 station events have been sampled.

The land use monitoring was successful at characterizing runoff from land use specific drainage areas and developing seasonal mean concentrations. Seasonal mean concentrations (also called Event Mean Concentrations) were used for calculating loading from unmonitored watersheds. It was found that seasonal mean concentrations were below the 25% error rate in 77% of circumstances.

Monitoring at the land use stations and mass emission stations included a broad constituent suite including bacteria, metals, organics, major ions, and nutrients. The laboratory analytical efforts achieved detection limits (DL) as required by the Permit for all constituents, and achieved DLs that were lower than Permit requirements for many analytes, particularly for constituents of concern.

5.1.2 Monitor and Assess Pollutant Loads from Specific Land Uses and Watershed Areas

The mass emission and land use monitoring elements were successful at assessing loading. Loading was first reported in the 1994-95 Los Angeles County Stormwater Monitoring Report. Subsequent loading based on both observed and modeled data was also reported in the 1998-99 and 1999-2000 Reports. The County's GIS Loading Model has been recognized as an innovative solution to estimating loading in unmonitored watersheds.

5.1.3 Identify, Monitor, and Assess Significant Water Quality Problems Related to Stormwater Discharges Within the Watershed

The monitoring program was successful at identifying significant water quality problems associated with stormwater discharge. First, the Santa Monica Bay receiving waters impacts study identified zinc and copper from Ballona Creek discharge as being toxic to the fertilization rate of simple marine animals. Toxicity testing of dry and wet weather flow in the Los Angeles and San Gabriel Rivers also identified toxicity problems. The extent and severity of bacterial indicators was better understood through wet weather mass emission sampling and ad hoc dry weather sampling.

5.1.4 Identify Sources of Pollutants in Stormwater Runoff

All of the major monitoring program elements were used successfully to identify stormwater pollutant sources. The Santa Monica Bay receiving waters study identified Ballona Ck., and not Malibu Ck., as a contributor of stormwater toxicity. Further, it identified zinc and copper as two metals contributing to the toxicity. The mass emission monitoring identified the Los Angeles River as consistently contributing the most zinc, copper, and suspended solids.

The land use monitoring identified light industrial, transportation, and retail/commercial land uses as developing the highest median concentrations for total and dissolved zinc. Light industrial and transportation land uses displayed the highest median concentrations for total and dissolved copper, and light industrial produced the highest concentrations of suspended solids.

Finally, the critical source monitoring program identified fabricated metal businesses as producing the highest median concentrations for zinc, copper, and suspended solids.

5.1.5 Identify and Eliminate Illicit Discharges

Each Permittee has a program to identify and eliminate illicit connections to the storm drain system to the maximum extent practicable. One of the programs developed for the elimination of illicit connections is open channel and underground storm drain inspections.

Most Permittees perform random area surveillance during dry and wet weather to inspect for potential illegal discharges. The Permittees also conduct educational site visits at businesses. During these visits, flyers with information on Best Management Practices (BMPs) applicable to that business are distributed.

The County, maintaining the majority of the storm drains within Los Angeles County, conducts routine inspections of the storm drain system for illicit connections/illicit discharges. Maps and connection inventory reports for 1,304 storm drains have been prepared to facilitate these inspections, which have resulted in the discovery of 1,993 undocumented connections as of July of 1999. These connections are either removed or permitted.

A toll free number 1-888-CleanLA was created for the public to report observed illicit connections/illicit discharges to the storm drain system.

It is recommended that the IC/ID model program approved by the Regional Board on March 23, 1999, be continued.

5.1.6 Evaluate the Effectiveness of Management Programs including Pollutant Reductions Achieved by Implementation of Best Management Practices (BMPs)

The Critical Source element of the monitoring program was successful at examining the potential effectiveness of good housekeeping and preventive types of voluntary Best Management Practices at one critical source industry. While two of the industries showed no significant improvement as the result of implementing BMPs, the fabricated metal industry showed significant improvement for total and dissolved copper.

5.1.7 Assess the Impacts of Stormwater Runoff on Receiving Waters

The receiving waters impact study, one of the first to assess stormwater impacts on the marine environment, was very successful at assessing stormwater impacts on Santa Monica Bay. The study was performed by the Southern California Coastal Waters Research Project, the University of Southern California, and the University of California Santa Barbara. The plume study found that freshwater plumes extended for a number of miles out to sea and often persisted for a number of days after a storm. The toxicity study found that the stormwater discharge from Ballona Creek was toxic to sea urchin fertilization and that dissolved zinc and copper were contributors to the toxicity. The study also found that sediments offshore of Ballona Creek generally had higher concentrations of urban contaminants, including common stormwater constituents such as lead and zinc.

5.2 WIDE CHANNEL PILOT STUDY

The purpose of the wide channel pilot study (Woodward-Clyde et al, 1996) was to evaluate the accuracy of a single point water quality intake in representing the water quality in wide channels. Ballona Creek, Los Angeles River, San Gabriel River, and Coyote Creek can be considered wide

channels. The pilot study found the water homogenous through the depth and the width of the channel. Thus, the single point intake produces a representative sample, and no adjustments were made to the monitoring stations. A complete report of this pilot study may be found in Appendix E.

Additional analysis was conducted in 1998 confirming that vertical mixing was achieved.

5.3 LOW FLOW PILOT STUDY

The purpose of the low flow pilot study (Woodward-Clyde et al, 1996) was to assess the feasibility of modifying the automated sampling equipment at land use stations in order to sample storms as small as 0.1 inch rainfall. The pilot study concluded that: operational effectiveness of automated equipment dropped significantly for storms as low as 0.1" rainfall, the feasibility and effectiveness of sample retrieval and transport became very difficult for such storms, and the ability to program and maintain low flow settings at other automated samplers could only be accomplished through large investments in telemetry. A complete report of this pilot study may be found in Appendix D.

Further analysis was conducted in 1998 that concluded 94 percent of total runoff volumes are monitored using the 0.25 inch threshold. Therefore, monitoring continued unaltered.

5.4 FUTURE MONITORING RECOMMENDATIONS

The following recommendations include monitoring, research, and studies that should be considered or undertaken to advance the understanding of stormwater quality science and support future TMDL development. Because of their scope, such studies should be undertaken by various entities, such as the Regional Water Quality Control Board, NPDES permittees, or by collaborative efforts between private and public organizations.

5.4.1 Mass Emission Element

Because the Pacific Ocean is a primary resource to Southern California, it is recommended that mass emission monitoring continue at the five existing sites for up to five storm events per season.

Non-Detection Test: The Permit states that if a given constituent is not detected in at least 25% of the samples taken in ten consecutive storm events at a given station, then that constituent may qualify for removal from the analytical suite for the associated station. For mass emission stations, several constituents met this criterion (see Table 4-7). Carbonate, the majority of heavy metals (24 of the 38), and all of the pesticides met the criteria in each of the mass emission sites. All of the semi-volatile constituents that had more than 10 samples met the criteria in each mass emission site as well. (Due to the change in detection limits of many SVOCs, there were fewer than 10 samples tested under the new limit.) Cyanide, total phenols, MBAS, dissolved aluminum, dissolved nickel, and total lead had less than 25% detection in four of the five sites. It is recommended that these constituents be removed from the analytical suite for the associated stations.

5.4.2 Land Use Element

One of the goals of the land use monitoring element was to develop Event Mean Concentrations (EMCs) for constituents of concern. The EMCs are used in the County's GIS Loading Model to calculate seasonal loading from unmonitored watersheds.

EMC Test: The Permit allows the discontinuation of monitoring at a land use station for specific constituents once the event mean concentration (EMC) is derived with an error rate of 25% or less. We used the mean standard error as a substitute for error rate as mutually agreed upon with the RWQCB (Swamikannu, 1999). Nitrate-Nitrogen achieved the 25% error rate at each of the land use monitoring sites. Total kjeldahl nitrogen (TKN) and total phosphorus met the criteria at seven of the eight land use sites. Dissolved copper, total zinc, dissolved zinc, ammonia-nitrogen, nitrate, and dissolved phosphorus met the criteria at six of the eight sites.

Of 115 station-constituents under investigation, 26 of them had an EMC with a mean standard error higher than 25% (Table 4-14). In other words, there were 26 station-constituents which had a standard error (standard deviation of the mean) larger than 25% of their corresponding mean concentrations. Carbonate, the majority of heavy metals (24 of the 38), and all of the pesticides met the criteria in each of the land use sites. All of the semi-volatile constituents that had more than 10 samples met the criteria in each land use site as well. (Due to the change in detection limits of many SVOCs, there were fewer than 10 samples tested under the new limit.) Flouride, MBAS, dissolved aluminum, and total lead had less than 25% detection in seven of the eight sites.

Given the findings of both the non-detect test and the EMC test, it is recommended that the following land use stations monitor the following constituents only:

Constituents for Future Land Use Monitoring

LAND USE STATION	DRAINAGE SYSTEM	FUTURE MONITORING
Retail/Commercial	Santa Monica Pier Drain	Ammonia, total and dissolved copper, nitrate, total lead, TSS, PAH, diazinon, chlorpyrifos.
Vacant	Sawpit Wash	TKN, TSS, PAH, diazinon, chlorpyrifos.
High Density Single Family Residential	Bond Issue Project 620	Total Lead, PAH, diazinon, chlorpyrifos.
Transportation	Dominguez Channel	PAH, diazinon, chlorpyrifos.
Light Industrial	Bond Issue Project 1202	Total Copper, PAH, diazinon, chlorpyrifos.
Education	Bond Issue Project 474	Total Copper, Total Zinc, TSS, PAH, diazinon, chlorpyrifos.
Multifamily Residential	Bond Issue Project 404	Ammonia, Ammonia Nitrogen, Nitrite Nitrogen, TSS, PAH, diazinon, chlorpyrifos.
Mixed Residential	Bond Issue Project 156	Ammonia, Nitrate, Total Zinc, PAH, diazinon, chlorpyrifos.

Note that the retail/commercial site was removed in 1999 for construction of the City of Santa Monica's stormwater treatment plant. Future monitoring at this site may be in jeopardy.

5.4.3 Critical Source Element

Limited success was achieved in evaluating BMP effectiveness for two of the first three industries. The reasons for no discernable differences in concentrations before and after BMP implementation at the two industries are not obvious, but may include the voluntary nature of the BMP usage. However, valuable baseline data has been collected to date, and success was seen at one critical source industry. Therefore, it is recommended that the critical source program continue as described in the 1996 Municipal Stormwater Permit until eight critical industries are studied.

5.4.4 TMDLs in Los Angeles County

By March, 2006, at least 22 impaired water bodies in Los Angeles County will come under Total Maximum Daily Load (TMDL) regulation due to the recent Consent Decree (Los Angeles Regional Water Quality Control Board et al, 1999). The pollutants claimed to be causing impairment include trash, nutrients, coliform, nitrogen, metal, PCBs, pesticides, and chlordane. It is recommended that receiving water impact studies be performed on significant impaired water bodies to identify impacts due to stormwater. Such impact studies could include assessments of bioassessment.

5.4.5 Constituents of Concern

The following recommendations are based on the observation of problems identified by the monitoring program, namely: dry and wet weather bacteria indicators, zinc and copper toxicity in Ballona Ck., suspended solids linked to contaminated sediments, and toxicity in the Los Angeles and San Gabriel Rivers. These recommendations also recognize the concerns regarding possible stormwater impairment to water bodies under the forthcoming TMDL regulations.

5.4.5.1 Bacteria

Wet weather observations suggest that peak coliform levels may be related to regional hydrologic conditions. In an effort to characterize the presence and persistence of indicator bacteria in dry and wet weather, the Southern California Coastal Waters Research Project is conducting research and calibrating water quality models. Participation in these studies is recommended. It is further recommended that similar studies be initiated for other parts of the County where indicator bacteria impair beneficial uses.

5.4.5.2 Contaminated Sediments

Because contaminated sediments can be linked to suspended solids in stormwater, participation in the Corps of Engineers' Sediment Control Management Plan and the Coastal Commission Sediment Task Force is recommended. It is further recommended that receiving water impacts due to aerial deposition studies be conducted on inland watersheds.

5.4.5.3 Stormwater Toxicity

With the identification of zinc and copper in Ballona Creek stormwater discharge, it is recommended that major tributaries to Ballona Creek be surveyed to find possible contributing areas and sources.

It is recommended that two dry weather and two wet weather Toxicity Identification Evaluations be conducted for a full range of constituents on freshwater species on the L. A. River and Dominguez Channel.

It is recommended that two wet weather Toxicity Identification Evaluations be conducted for a full range of constituents on freshwater species on the San Gabriel River.

5.4.6 Receiving Waters Impacts

It is recommended that follow-up studies be conducted in Santa Monica Bay that address the persistence of stormwater plumes following storm events, the toxicity of stormwater on species other than sea urchins, and the fate of sediments in the Bay.

It is further recommended that a study be conducted assessing the impacts due to stormwater on San Pedro Bay.

5.4.7 Other Monitoring Activities

Participation and cooperation with local and regional monitoring programs is recommended, including but not limited to the Santa Monica Bay Restoration Project, the City of Long Beach, and the developing Southern California Regional Stormwater Monitoring Coalition.

It is also recommended that Best Management Practices and impacts be formally evaluated. Examples would include the City of Santa Clarita demonstration projects, catch basin inserts and deflectors, groundwater impacts due to stormwater infiltration, the Department of Public Works' parking lot retrofit, and storm drain low flow diversions.

Notes:

All land use percentages are rounded to the nearest whole number.
Land use percentages less than 0.1% are represented with a dash (--).
(1) HDSFR = High density single-family residential.
(2) Coyote Creek is not required under the Municipal Stormwater Permit, but is included in the Monitoring Plan.
(3) The Retail/Commercial sampling site on Pier Drain in Santa Monica (S08) was dismantled and not in use in the 1999-2000 season, with prior approval from the RWQCB, to accommodate construction by city of Santa Monica of its stormwater treatment plant.

CV = Coeffiecient of variation

DL = Detection Limit

S.I.D. = Statistically Invalid Data, not enough data above detection limit collected

a) Criteria based on daily maximum

b) Criteria based on 30-day average

c) Criteria for the sum of acenaphthylene, anthracene, 1,2-benzanthracene, 3,4-benzofluoranthene, benzo(k)fluoranthene, 1,12-benzoperylene, benzo(a)pyrene, chrysene, dibenzo(ah)anthracene, fluorene, indeno(1,2,3-cd)pyrene, phenanthrene and pyrene.

d) Criteria continuous concentration which equals the highest concentration of pollutant to which aquatic life can be exposed for an extended period time (4 days) without deleterious effects.

e) Criterion expressed in the total recoverable form.

f) Criteria maximum concentration which equals the highest concentration of pollutant to which aquatic life can be exposed for a short period time without deleterious effects.

g) Except for indicator bacteria, there are no numerical water quality standards that apply to stormwater or "non-point source" pollution. Current federal and state numerical standards apply only to "point source pollution," such as sanitary sewage, industrial and commercial discharges to the ocean, and other waterbodies. Water quality standards described in the 1995 Los Angeles Region Basin Plan or the 1997 California Ocean Plan do not apply to stormwater runoff, and any exceedance of values should not indicate violation nor noncompliance with the plans. Furthermore, a direct comparison of the sampling results with the Ocean Plan standards cannot be made since the results presented in the table are detected values before dilution, a factor allowed by the Ocean Plan.

h) Detection limits have changed throughout the monitoring process. Only data matching the current detection limit is displayed in this table. The *Data Included Since* field indicates the first year of the storm season with the current detection limit.

CV = Coefficient of variation

DL = Detection Limit

S.I.D. = Statistically Invalid Data, not enough data above detection limit collected

a) Detection limits have changed throughout the monitoring process. Only data matching the current detection limit is displayed in this table. The *Data Included Since* field indicates the first year of the storm season with the current detection limit.

Fecal Enterococcus	20	MPN/100ml	24[a]		104			7	0	100	2,647	300	1.52

a) Criteria based on 30-day average

b) Criteria continuous concentration which equals the highest concentration of pollutant to which aquatic life can be exposed for an extended period time (4 days) without deleterious effects.

c) Except for indicator bacteria, there are no numerical water quality standards that apply to stormwater or "non-point source" pollution. Current federal and state numerical standards apply only to "point source pollution," such as sanitary sewage, industrial and commercial discharges to the ocean, and other waterbodies. Water quality standards described in the 1995 Los Angeles Region Basin Plan or the 1997 California Ocean Plan do not apply to stormwater runoff, and any exceedance of values should not indicate violation nor noncompliance with the plans. Furthermore, a direct comparison of the sampling results with the Ocean Plan standards cannot be made since the results presented in the table are detected values before dilution, a factor allowed by the Ocean Plan.

X = Greater than objective[1]. Except for indicator bacteria, there are no numerical water quality standards that apply to stormwater or "non-point source" pollution. Current federal and state numerical standards apply only to "point source pollution," such as sanitary sewage, industrial and commercial discharges to the ocean, and other waterbodies. Water quality standards described in the 1995 Los Angeles Region Basin Plan or the 1997 California Ocean Plan do not apply to stormwater runoff, and any exceedance of values should not indicate violation nor noncompliance with the plans. Furthermore, a direct comparison of the sampling results with the Ocean Plan standards cannot be made since the results presented in the table are detected values before dilution, a factor allowed by the Ocean Plan.

* Required by Permit

^ = Rain gage not active

~ = Statistically invalid data, not enough samples or data above detection limit collected

NS = Not Sampled

Blank = No Exceedance

1 = Objectives are presented in Table 4-3.

CV = Coefficient of variation
DL = Detection Limit
S.I.D. = Statistically invalid Data, not enough data above detection limit collected

a) Detection limits have changed throughout the monitoring process. Only data matching the current detection limit is displayed in this table. The *Data Included Since* field indicates the first year of the storm season with the current detection limit.

CV = Coefficient of variation

DL = Detection Limit

S.I.D. = Statistically invalid Data, not enough data above detection limit collected

a) Detection limits have changed through out the monitoring process. Only data matching the current detection limit is displayed in this table. The Data Included Since field indicates the first year of the storm season with the current detection limit.

CV = Coefficient of variation
DL = Detection Limit
S.I.D. = Statistically Invalid Data, not enough data above detection limit collected
a) Detection limits have changed through out the monitoring process. Only data matching the current detection limit is displayed in this table. The Data Included Since field indicates the first year of the strom season with the current detection limit.

1 Indicator Bacteria tested during 1999-2000 storm season only

2 PAHs tested during 1999-2000 storm season only

S.I.D. = Statistically Invalid Data, not enough data above detection limit collected

& = Statistically valid data in the control sites but detected in less than 20% of the samples in the BMP sites

CV = Coefficient of variation

DL = Detection Limit

Possible Decrease = Less than 20% detects BMP, but existing data shows a possible lowered median.

ACKNOWLEDGMENTS

The authors wish to acknowledge the Los Angeles County Department of Public Works and the Natural Resources Defense Council who helped design the workplan, guide the study elements, and evaluate the results. We also acknowledge the expertise in sample collection and laboratory analysis provided by the following organizations: City of Los Angeles (R/V *Le Mer* and R/V *Marine Surveyor*), Southern California Ocean Studies Consortium (R/V *Sea Watch*), University of California Los Angeles (R/V *Sea World*), CRG Laboratories, Inc. (analytical chemistry), and MEC Analytical Systems, Inc. (benthic taxonomy). This project was funded by the Los Angeles County Department of Public Works, the University of Southern California Sea Grant, and the Southern California Coastal Water Research Project. The conclusions presented in this document are the views of the authors and do not necessarily represent positions of the Los Angeles County Department of Public Works, the Natural Resources Defense Council, or other collaborating agencies.

R0012199

INTRODUCTION

Stormwater runoff is widely believed to be one of the largest sources of contaminants to coastal waters.

Urban stormwater runoff is now regarded as one of the largest sources of pollution to the coastal waters of the United States. In southern California, point source control and advanced sewage treatment have greatly reduced the emissions of contaminants from sewage treatment plant and industrial discharges into the ocean. As a consequence, mass emissions from stormwater runoff now constitute a much larger portion of the constituent inputs to receiving waters and may represent the dominant source of some contaminants such as lead and zinc.

While stormwater runoff can produce impacts in both freshwater and seawater environments, effects on the ocean are of greatest concern in urban southern California. Our coastal waters provide many beneficial uses, including recreation, aesthetic enjoyment, fishing, marine habitat, fish reproduction, industrial water supply, and navigation. Ocean-dependent activities contribute approximately $9 billion annually to the economies of coastal communities in southern California.

Current water quality monitoring programs do not assess the effects of stormwater runoff on the environment.

Substantial resources are spent monitoring the chemical constituents in stormwater runoff, yet little is known about the effects of these inputs once they enter the ocean. Of greatest concern to the public are whether impairments are occurring to the beneficial uses that relate to human health (safety of swimming and seafood consumption) or ecosystem health (presence of a natural balance of species). Stormwater discharge has the potential to impair these beneficial uses through 1) contamination of recreational waters or seafood with disease-causing microbes, 2) aesthetic degradation from trash and reduced water clarity, and 3) ecosystem degradation from contaminants or other stormwater constituents.

Understanding the effects of stormwater on beneficial uses is essential. Information about the extent and type of adverse impacts is useful to guide and refine management actions to improve water quality. The monitoring programs of various agencies collect information that is useful for assessing some beneficial use impairments, primarily those related to human health. For example, public health and sanitation agencies regularly conduct shoreline microbiological monitoring near storm drain discharges, which indicates impacts to swimming and shellfish consumption. However, very little information is available to assess the impacts of urban stormwater on ecosystem health. Studies of

R0012200

impacts to freshwater systems (particularly in the west) are rare; impacts to the coastal ocean have never been assessed.

This study is one of the first to assess stormwater impacts on the marine ecosystem.

This report summarizes a three-year study, funded by the Los Angeles County Department of Public Works, Southern California Coastal Water Research Project (SCCWRP), and University of Southern California Sea (USC) Grant Program, to assess the impacts of urban stormwater runoff to the receiving waters of Santa Monica Bay. The goal of this study was to examine impacts that were relevant to ecosystem health, rather than impacts related to human health or recreation issues. This effort was conducted by an interdisciplinary team of scientists from SCCWRP, the University of Southern California, and the University of California at Santa Barbara.

This study examined plume characteristics, water column and seafloor biology.

The Santa Monica Bay Receiving Waters Study incorporated four design elements. The first element used physical and optical oceanographic instruments to characterize the size, composition, and mixing of stormwater plumes, providing information on the impacts to beneficial uses that are associated with water clarity. The second element used toxicity tests to assess the biological effects of runoff on water column biota and to identify the responsible toxicants. The third element examined seafloor biota and chemistry in order to assess the long-term effects of storm-discharged particles with their associated contaminants.

Comparisons between Ballona and Malibu Creeks evaluated effects of different watershed types.

The fourth element of the study design was a comparison of stormwater impacts from different watershed types. Land use patterns and development within a watershed are thought to influence the composition and quantity of stormwater runoff. The influence of watershed type was investigated by comparing stormwater impacts in the receiving water offshore of the highly urbanized Ballona Creek watershed with impacts in the receiving water offshore of the less-urbanized Malibu Creek watershed (Figure 1).

Sampling and analyses were conducted over three wet seasons (1995/96 to 1997/98). This document provides a summary of the study and focuses on major concepts and important findings. For the detailed results and raw data, we encourage readers to consult the Annual Progress Reports available through USC Sea Grant.

R0012202

STORMWATER PLUME CHARACTERIZATION

The impact of stormwater on the coastal ocean is determined by the composition of the stormwater and the dynamics (mixing, transport, and persistence) of the stormwater plume once it enters the coastal ocean. These dynamics influence the location, duration, and magnitude of impacts from stormwater.

The research team mapped the three-dimensional distribution of the stormwater plumes resulting from several winter storm events during 1996-1998. Mapping was performed using a towyo system, which carried sensors to measure temperature, salinity, light transmission (turbidity), chlorophyll fluorescence (plant biomass), and ambient visible light. The towyo was towed through the water in a vertical zigzag pattern that enabled us to map the horizontal and vertical distributions of the measured parameters. In addition, surface water was pumped to similar sensors on the boat so that the distribution of these parameters at the water's surface could be mapped. Maps were constructed for two regions of Santa Monica Bay, the receiving waters offshore of Ballona Creek and those offshore of Malibu Creek.

The low salinity and high turbidity of stormwater provide markers that allow plumes to be mapped in the ocean.

The characteristics of stormwater discharged into Santa Monica Bay from the two watersheds were similar in several respects. The most obvious and important physical characteristic was that the stormwater, being primarily composed of freshwater, had very little salinity. This low salinity enabled us to trace the stormwater plume in the ocean and differentiate it from the ambient seawater, which was not directly influenced by stormwater discharge. The stormwater also contained high concentrations of suspended particulate material, derived from various sources such as land erosion, street dust, aerial deposition, and litter. Suspended particulate material increased the turbidity of water by scattering and absorbing light. The turbidity and salinity together allowed the differentiation of seawater influenced by stormwater discharge from seawater containing freshwater from direct rainfall input.

Understanding the dispersion and fate of stormwater plumes is a complex task. The distribution of dissolved components such as nutrients and small particles is dependent upon the amount of rainfall, the coastal currents, and the winds, which can drive currents and cause vertical mixing (Figure 2). Large stormwater particles often have a different fate; they settle out of the low salinity plume, become incorporated into bottom sediments, and may be redistributed later by wave resuspension and transport. As

R0012203

the plume disperses, the components of stormwater mix with other sources of suspended particles, nutrients, and freshwater in the receiving water. These sources include bottom resuspension, phytoplankton growth, and wastewater discharge.

The stormwater plume was most concentrated in the surface layer.

Stormwater plumes usually formed relatively thin layers at the surface of the ocean that are 2-10 m deep (Figure 3). The depth of penetration increased with time as winds mixed the upper layer vertically. The horizontal scales of the plumes studied in Santa Monica Bay were variable, with plumes extending from 1 to 6 miles cross-shelf (offshore) for storms of 1- to 2-year frequencies (0.8 to 4 in. of rainfall). During the February 19-21, 1996 storm (4 in. of rainfall), the plume spread approximately 4 miles offshore of Ballona Creek (Figure 4).

The speed and direction of coastal currents determine the cross-shelf scale of the plume. The Coriolis force (an apparent force that acts on oceans and lakes) also has an influence on the distribution of stormwater plumes. This force is due to the rotation of the earth and its motion through space, resulting in a tendency for currents to turn toward the right in the Northern Hemisphere. If the plume is carried to the north when it enters the ocean, it will be more likely to remain near the coast due to the influence of the Coriolis force.

The distribution of stormwater plumes along the coast depended upon the tidal variations in the currents, the presence of additional runoff sources, and the amount of runoff. Longshore distances of up to 6 miles were measured for plumes within Santa Monica Bay.

Suspended stormwater particles reduced surface water clarity.

Spatial gradients in the dissolved and particulate components of the plume occurred as it was diluted through mixing with the receiving water. Although larger stormwater particles tended to settle out from the plume rapidly, smaller, lighter particles remained in suspension near the surface (Figures 3 and 4), where they can reduce the amount of light available for photosynthesis by marine plants. Measures of primary production were not part of this study, so adverse effects on phytoplankton in Santa Monica Bay resulting from turbid stormwater plumes were not determined.

R0012204

Stormwater plumes persisted for several days after a storm.

The duration of stormwater plumes depends upon the rate of plume dispersion and particle sinking. Stormwater plumes were observed to persist in Santa Monica Bay for at least three days, even for the smallest storm sampled (0.8 in. rainfall). The maximum duration of stormwater plumes could not be assessed in this study because measurements did not extend more than three days after a storm.

High concentrations of the plant pigment chlorophyll were present in the surface layer during some storm events, indicating the presence of increased phytoplankton populations. Phytoplankton growth may have been stimulated by stormwater discharge due to the addition of nutrients to the surface layer, where light is readily available. Dense patches of phytoplankton were observed off of Malibu Creek on the boundary of stormwater plumes 1-2 days after rain events. Off of Ballona Creek, we observed increased phytoplankton in the plume even while a large proportion of suspended particulate material was still present in the surface water. The ecological effects of these changes in phytoplankton density were not determined in this study.

R0012205

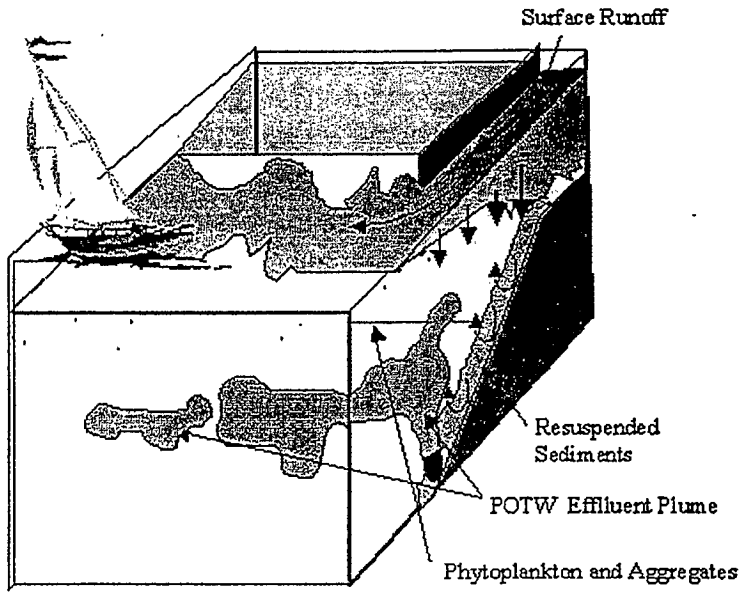

FIGURE2. A three-dimensional representation of the dispersion of the dissolved and particulate Components in surface runoff and municipal (POTW) wastewater effluent.

R0012206

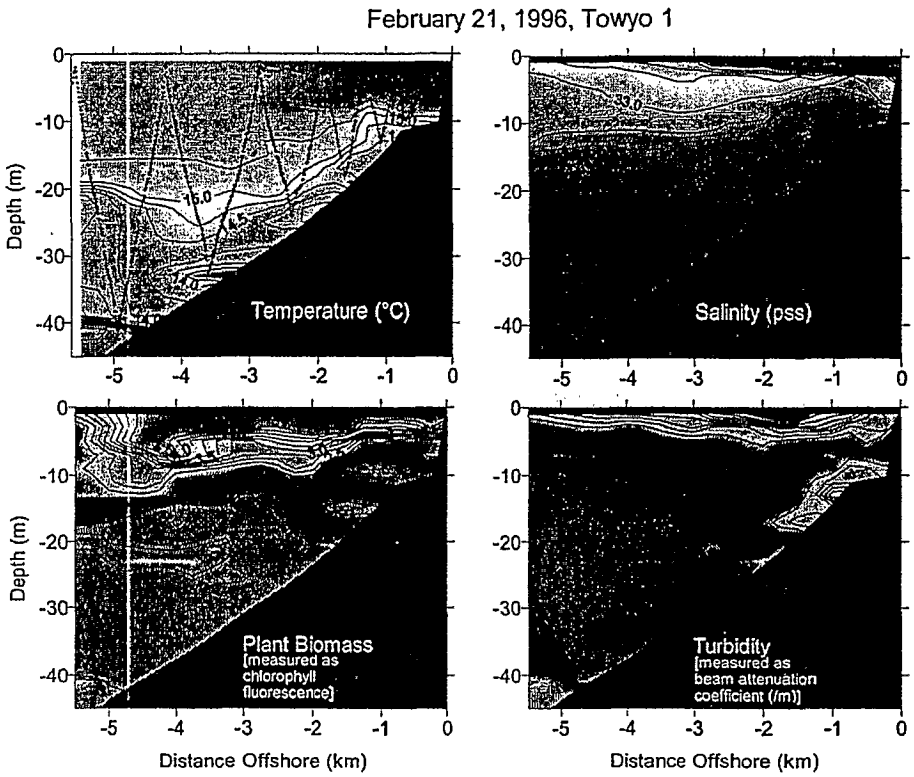

FIGURE 3. Vertical cross-shelf sections of the Ballona Creek discharge plume following a storm event in February, 1996. The maps were generated using a towyo system, which carried sensors for temperature, salinity, turbidity (beam attenuation), and plant biomass (chlorophyll fluorescence). The zigzag pattern on the temperature section indicates the path of the towyo system. The stormwater plume is indicated by water with a salinity less than 33.0 practical salinity units (psu).

R0012207

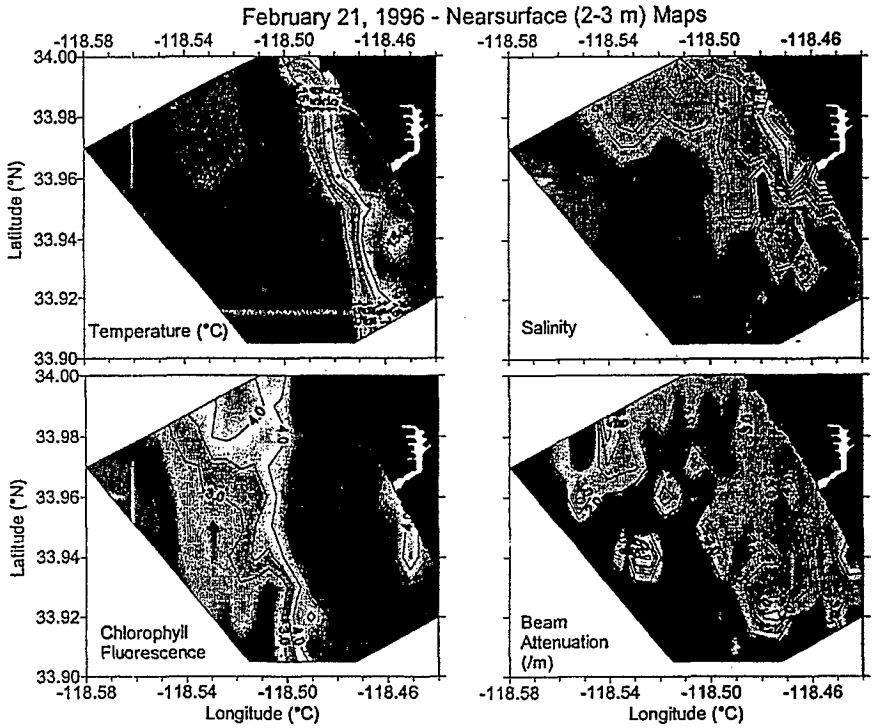

FIGURE 4. Near surface map of the February, 1996 stormwater plume from a 2-year storm off of Ballona Creek. The plume (surface water with a salinity less than 33.0 psu) extended approximately 4 miles offshore.

R0012208

WATER COLUMN BIOLOGY

The initial and most concentrated exposure to stormwater occurs in the upper few meters of the water column. A diversity of organisms occupies this habitat, ranging from mobile fish and mammals to drifting microscopic plants and animals (plankton). Plankton have a relatively high potential to be affected by stormwater toxicants because they have a limited ability to avoid the plume and are often more sensitive to contaminants than larger animals. Changes in the abundance and type of plankton present can have important consequences for the marine ecosystem. This group of organisms constitutes the base of the food chain for most marine life, so changes in plankton numbers may affect populations of other species. The larvae of many fish and other animals such as sea urchins, clams, and shrimp occur in the plankton, providing the potential for diminished reproductive success if their survival is reduced by water column toxicity.

Water column effects were measured using toxicity tests.

Toxicity tests were used to determine whether stormwater plumes contained harmful concentrations of dissolved constituents. Surface water samples were collected offshore of the two study sites in conjunction with measurements of the plume characteristics so that the data could be related to the concentration of the stormwater discharge plume. Samples of stormwater collected from Ballona Creek were also measured for comparison. The toxicity tests used sensitive stages of marine species that occur in southern California. Most samples were measured using the sea urchin fertilization test, in which the effect of the sample on the ability of sea urchin sperm to fertilize eggs is measured. Sea urchin sperm are highly sensitive to some types of dissolved metals. The fertilization test is appropriate for stormwater monitoring because it is rapid (40 min exposure) and uses an organism which spends a portion of its life cycle in the water column of Santa Monica Bay. All tests were adjusted to the appropriate salinity prior to exposure so only the effect of chemical constituents were evaluated.

Virtually every sample of Ballona Creek stormwater tested was toxic.

Undiluted samples of urban stormwater collected from drainage channels (before discharge into the ocean) usually contained toxic concentrations of constituents. Toxicity was detected in virtually every sample obtained from Ballona Creek and this toxicity was often present even after the sample was diluted 10-fold in the laboratory. The results indicated that even though a large portion of the constituents present in stormwater may be bound to particles, the dissolved concentrations of some materials are high enough to cause toxicity. Prior research by SCCWRP and

R0012209

others has detected toxicity in stormwater from other watersheds in Los Angeles, Orange, and San Diego Counties.

The first storms of the year produced the most toxic stormwater.

The results showed that time of year was an important variable influencing stormwater toxicity (Figure 5). Samples of Ballona Creek stormwater, obtained from the first storm of the season, were between two and ten times more toxic than samples from later storms. These data indicated that the first storms of the year provide the most concentrated inputs of toxicants to the environment.

Toxicity was frequently detected in surface water within the stormwater plume offshore of Ballona Creek, indicating that the initial dilution of stormwater discharge from this watershed was not sufficient to reduce the concentrations of stormwater toxicants below levels that are harmful to marine organisms. The magnitude of toxicity was greatest in the portion of the plume nearest the mouth of Ballona Creek (Figure 6), where the highest concentrations of stormwater were present. Within the plumes studied, toxicity was usually present whenever stormwater concentrations above 10% were present. The duration of toxicity in surface waters was not specifically addressed in this study, but can be expected to be determined by the rate of plume dispersion. In this study, toxicity was detected in surface water near the mouth of Ballona Creek 2 days after a storm event.

Toxic portions of the stormwater plume were variable in size, extending from ¼ to 2 miles offshore of Ballona Creek.

The spatial extent of surface water toxicity varied between storms, and was influenced by the amount of storm flow, the degree of toxicity of the stormwater, and the amount of mixing that occurred upon discharge. The greatest offshore extent of toxicity was measured following a storm on February 21, 1996, a two-year event, when toxicity was detected 2 miles offshore of Ballona Creek. For other storms, the toxic portion of the plume extended ¼-1 mile offshore. The distribution of toxicity along the shoreline was not determined in this study. The boundaries of stormwater plumes can be described using a number of parameters (*i.e.*, salinity, turbidity, and toxicity) each with different thresholds of detection. Because a relatively high concentration of stormwater is needed to produce toxicity, the area of potential biological impact within a plume will be smaller than the region defined by physical characteristics such as salinity (Figure 6).

An unexpected result of this study was the detection of toxicity in receiving waters that appeared to be due to sources other than urban runoff. An average of 53% of the surface water samples

R0012210

Surface water toxicity caused by unidentified sources was frequently encountered during dry weather.

collected offshore of Ballona and Malibu Creeks during periods of dry weather were found to be toxic. The location of the toxic samples was variable and there was no relationship between toxicity and the amount of freshwater in the samples, indicating that dry weather urban runoff was not the cause. Additional sources of receiving water toxicity were also indicated during the wet weather sampling, as some water samples were more toxic than could be accounted for by the amount of stormwater present.

The dry weather toxicity results suggest that factors other than stormwater discharge have a major influence on surface water quality in Santa Monica Bay. While the cause of dry weather toxicity was not determined, its frequent detection indicates that impaired surface water quality in Santa Monica Bay extends beyond the spatial and seasonal boundaries associated with stormwater discharge. Potential sources of dry weather toxicity include the deposition of contaminants from the atmosphere, biological events such as red tides, and inputs from boating activities.

Dissolved metals in stormwater were identified as important contributors to impaired water quality in Ballona Creek stormwater plumes. This conclusion was the result of experiments that combined chemical treatments designed to remove specific types of constituents in water samples with sea urchin toxicity tests, a process known as Toxicity Identification Evaluation (TIE). The toxicity of Ballona Creek stormwater and receiving water samples was usually eliminated when treatments were applied that neutralized toxic trace metals by complexation (Figure 7). Chemical analyses confirmed that dissolved concentrations of zinc, and occasionally copper, were at toxic levels in undiluted stormwater. The dissolved concentrations of other metals were below toxic levels for the sea urchin test. Measurements of receiving water also detected elevated concentrations of zinc (but not copper) in the stormwater plume offshore of Ballona Creek.

Zinc was the most important toxic constituent identified in stormwater. Copper and other unidentified constituents may also be responsible for some of the toxicity measured.

Chemical analyses were unable to attribute all of the toxicity measured to zinc and copper, indicating that additional constituents may contribute to the toxicity of stormwater discharged into Santa Monica Bay. The measured concentrations of zinc and copper in Ballona Creek stormwater were estimated to account for only 5-44% of the observed toxicity. Zinc concentrations in the toxic portion of the discharge plume were usually below levels shown to cause toxicity in the laboratory. The unaccounted-for toxicity may be due to synergistic interactions between toxic metals, variability in the chemical analyses, or the influence of other toxic chemicals,

R0012211

such as pesticides. Additional research is needed before these alternatives can be evaluated. TIE studies have not been completed for other stormwater discharges into the Bay, so we do not know if the pattern demonstrated for Ballona Creek is representative of other sites.

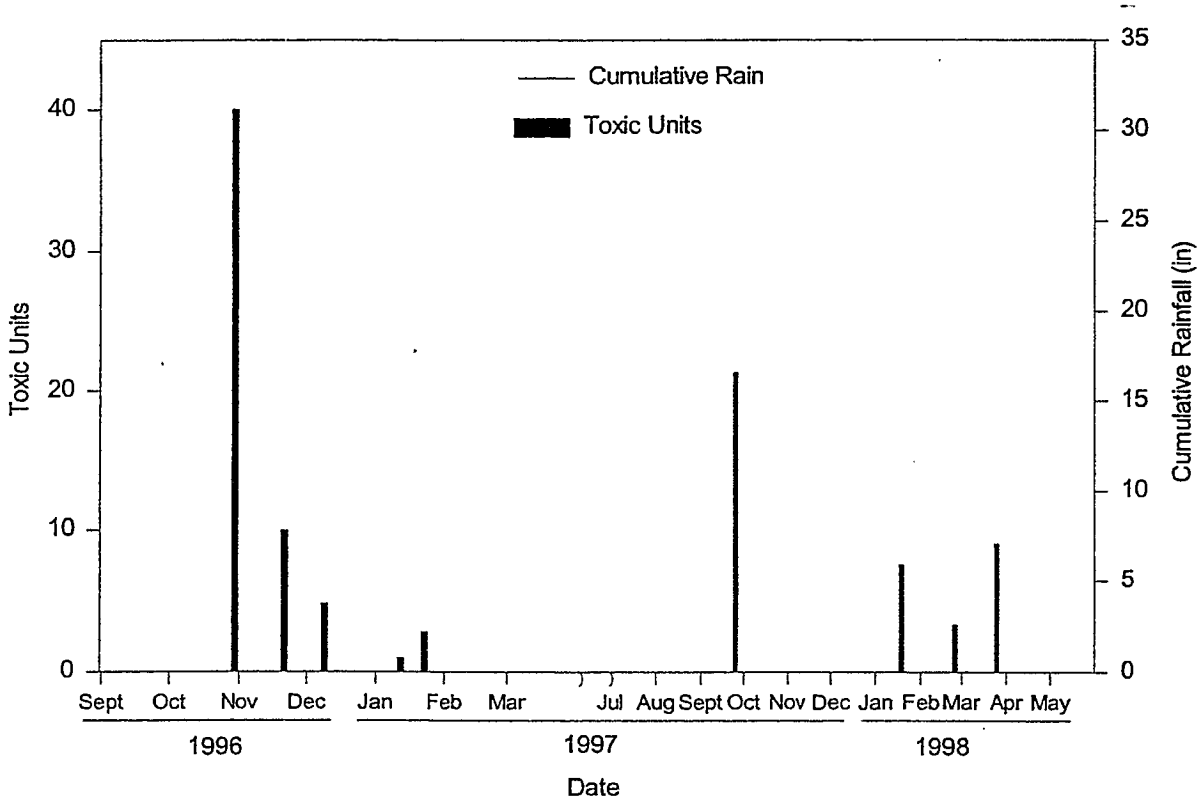

FIGURE 5. Seasonal changes in the toxicity of Ballona Creek stormwater over two storm seasons. Toxicity was measured using the sea urchin fertilization test (Toxic Units = 100/EC50). The greatest toxicity was observed in stormwater obtained from the first storm of each year.

R0012212

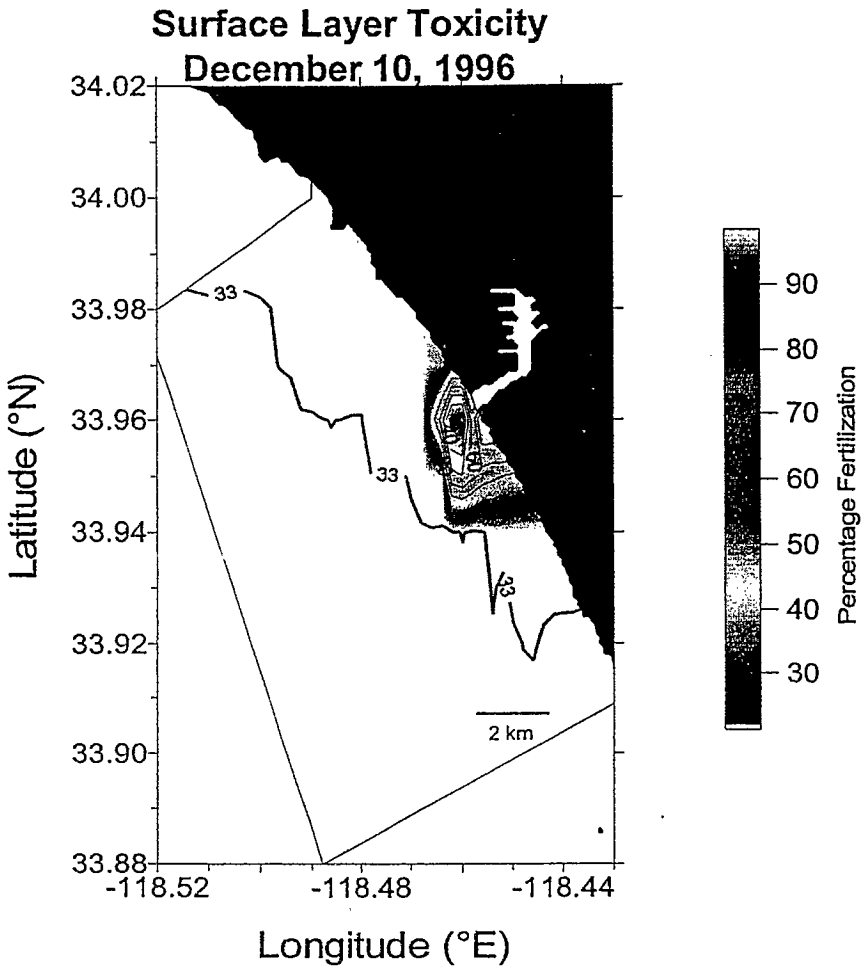

FIGURE 6. Map of surface layer toxicity (effect on sea urchin fertilization) from Ballona Creek stormwater discharge following a 2-year storm in December, 1996 (3.1 in. rainfall). Expected toxicity was calculated from measurements of salinity (indicates concentration of stormwater) and the concentration dose-response curve for the effects of stormwater on sea urchin fertilization. The greatest toxicity (lowest fertilization percentage) was present closest to the point of discharge. The area of toxicity was smaller than the physical extent of the plume, as indicated by the solid line showing a salinity of 33 psu. This figure illustrates the relative size of the toxic portion of the plume for a single storm, but does not represent the largest plume studied. Toxic portions of the plume were found to extend greater and smaller distances offshore for other storms.

R0012213

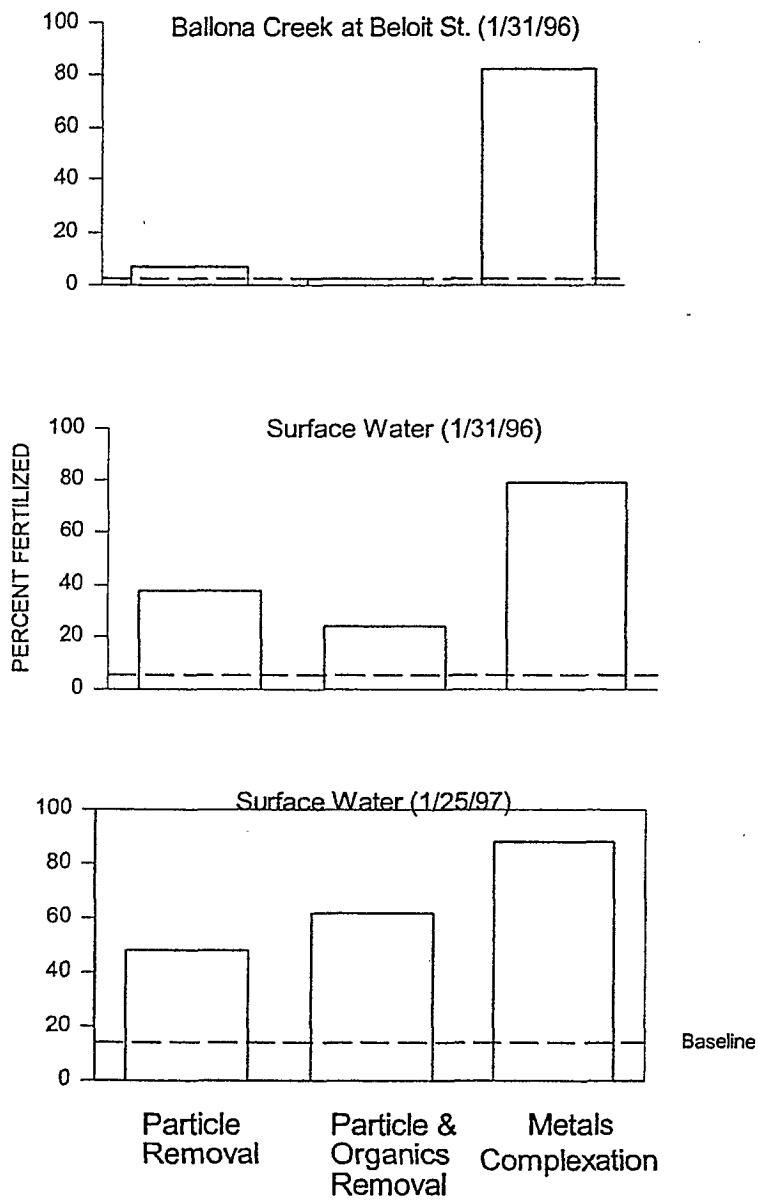

FIGURE 7. Effect of toxicity identification evaluation treatments on the toxicity of Ballona Creek stormwater and two samples of surface water collected within the Ballona Creek discharge plume. Complexation of metals by addition of EDTA usually eliminated toxicity, as shown by the large increase in sea urchin fertilization above the untreated (baseline) value. Other treatments, removal of particles by filtration and removal of organic compounds, were of limited effectiveness. Similar results were found for other samples of stormwater and surface water.

R0012214

SEAFLOOR BIOLOGY

The deposition of stormwater particles influences the physical and chemical characteristics of the seafloor.

Much of the natural diversity and many of the commercially important species in the ocean occur on the seafloor. Clams and shrimp live in this environment, as well as worms and starfish, all of which serve as food for fish. This is also the location where stormwater particles, and associated contaminants, eventually settle. Unlike the water column, where a stormwater plume eventually mixes and disperses, the sediments on the seafloor can accumulate runoff inputs over an entire storm, over several storms, or over several seasons. These inputs can alter the seafloor biology by either changing the habitat, such as altering sediment grain size, or by the build-up of pollutants. The potential for impacts to seafloor organisms is great because they are not mobile and are therefore subjected to the accumulated stormwater inputs for long periods of time. Typically, these seafloor organisms are relatively sensitive and changes to the number or types of organisms may result in changes to fish populations.

We estimated impacts of stormwater runoff discharges on the seafloor by collecting samples from the ocean bottom between one and two weeks following large storm events, after the stormwater plumes had dispersed and particles had time to settle, and then again during dry weather. Seafloor samples were collected directly offshore of Ballona and Malibu Creeks at 75 ft. depth in the heart of the stormwater plumes, along intervals upcoast and downcoast representing gradients of plume impact, and then outside the area of the plume. The top 2 cm (< 1 inch) of these seafloor samples, which represented the most recent seafloor accumulations, were collected for contaminant analysis and toxicity testing. Sediment samples were analyzed for contaminants including trace metals, chlorinated hydrocarbons (DDTs and PCBs), and petroleum hydrocarbons (PAHs). The toxicity tests included survival of crustaceans (an amphipod) and sea urchins, fertilization success and development of sea urchin embryos, and bioaccumulation of contaminants from seafloor mud in adult sea urchins. A second sediment sample was collected, sieved through a fine mesh screen, and the organisms were enumerated to determine the abundance and diversity of the native seafloor fauna.

An increase in sediment constituents was present on the seafloor offshore Ballona Creek.

Alterations to the seafloor habitat and sediment constituent concentrations had occurred offshore of the Ballona Creek watershed (Table 1). The sediments offshore of Malibu Creek generally had higher concentrations of naturally abundant constituents including fine-grained particles, organic carbon, and

R0012215

trace metals such as chromium. In contrast, the sediments offshore of Ballona Creek generally had higher concentrations of urban contaminants including common stormwater constituents such as lead and zinc, as well as other rarely detected constituents in routine stormwater monitoring programs, such as DDTs, PCBs, and PAHs. Moreover, sediments offshore of Ballona Creek showed evidence of stormwater impacts over a large area. Concentrations of copper, lead, zinc, DDTs, PCBs, and PAHs were highest directly offshore of the creek mouth and then decreased in both the upcoast and downcoast directions at distances up to 3 miles away (Figure 8). The increased sediment contamination was also observed more than 1 mile offshore, where water depths reached over 100 feet.

Biological communities offshore of Ballona Creek were similar to those offshore of Malibu Creek (Table 2). Both areas had comparable abundance and similar species composition. Seventeen of the 19 most commonly found taxa offshore of Ballona Creek were present offshore of Malibu Creek, and both watersheds had a low abundance of so-called "pollution indicator" organisms. Both areas had healthy benthic communities, as measured by the Benthic Response Index, which is a tool for assessing the relative importance of pollution indicator species at a site. Species richness and diversity were statistically higher near Malibu Creek than Ballona Creek.

Biological communities offshore of Ballona and Malibu Creeks were also similar to background reference conditions established in previous studies of southern California (Table 2). The mean abundance, mean number of taxa per sample, and mean diversity at the creek sites were comparable to reference sites located in waters of similar depth, but distant from river and creek mouths. The present study was limited to the area offshore of the Ballona Creek jetty; previous studies by other scientists have shown impacts to benthic communities and the presence of pollution indicator organisms inside of the jetty (adjacent to Marina del Rey).

The seafloor biology results were consistent with the results from sediment toxicity tests. Seafloor sediments offshore of Ballona Creek did not kill amphipods or impair the fertilization success or normal embryo development of sea urchins. However, seafloor sediments were found to be a potential source of contaminants that bioaccumulate in seafloor organisms such as adult sea urchins. Concentrations of lead, DDTs, and PCBs were three to ten times higher in sea urchins exposed to sediments

R0012216

collected offshore of Ballona Creek than in sea urchins living on sediments from our reference location. While the effect of this bioaccumulation on the sea urchin is not known, it does represent a mechanism by which sediment-associated pollutants can enter the food chain and biomagnify within fish.

The fate of most stormwater constituents is unknown.

One significant finding of this study was that the fate of most stormwater constituents discharged to Santa Monica Bay is unknown. Although we documented the accumulation of contaminants on the seafloor offshore of Ballona Creek, these amounts were not permanent and represent only a fraction of the total mass emissions discharged. Further, reductions in constituent concentrations were observed at some locations that may have resulted from the resuspension and transport of sediments by waves and currents. Until the location where this material eventually settles is known, we cannot be certain that we have examined the seafloor areas having the greatest influence from stormwater or dry weather discharges. An additional concern is that constituents from other sources may have similar transport and fate mechanisms, producing enhanced impacts from the cumulative effects of multiple sources.

R0012217

TABLE 1. Average concentrations of sediment constituents offshore (75 ft. depth) of creek mouths in Santa Monica Bay following storm events between 1995 and 1997. Boxed numbers indicate significantly higher concentrations. Sediment offshore of the less urbanized watershed (Malibu Creek) had higher levels of naturally occurring constituents such as aluminum and iron. Higher concentrations of anthropogenic constituents such as lead and PAHs were present offshore of the more urbanized watershed (Ballona Creek).

		Sediment Concentration	
		Ballona Ck (n=8)	Malibu Ck (n=7)
Fines	% dry	31.6	**53.1**
TOC	% dry	0.594	**0.963**
Aluminum	µg/dry g	11492	**17280**
Arsenic	µg /dry g	5.1	5.6

TABLE 2. Biological community parameters offshore of a highly urbanized watershed (Ballona Creek), a less urbanized watershed (Malibu Creek), and other reference areas in near-coastal waters of southern California at similar depths (30 to 75 feet). Values are the mean (±95% confidence limits).

	Ballona (n=6)	Malibu (n=5)	Reference (n=29)
Abundance (No. organisms/ 0.1 m^2)	238 (±51)	316 (±55)	276 (±61)
No. Species (No. taxa/ 0.1 m^2)	75 (±6)	91 (±8)	71 (±9)
Diversity (Shannon-Wiener H')	1.65 (±0.02)	1.73 (±0.04)	1.55 (±0.15)
Benthic Response Index (BRI units)	24.0 (±1.7)	30.5 (±0.7)	3.0 – 30.6

R0012219

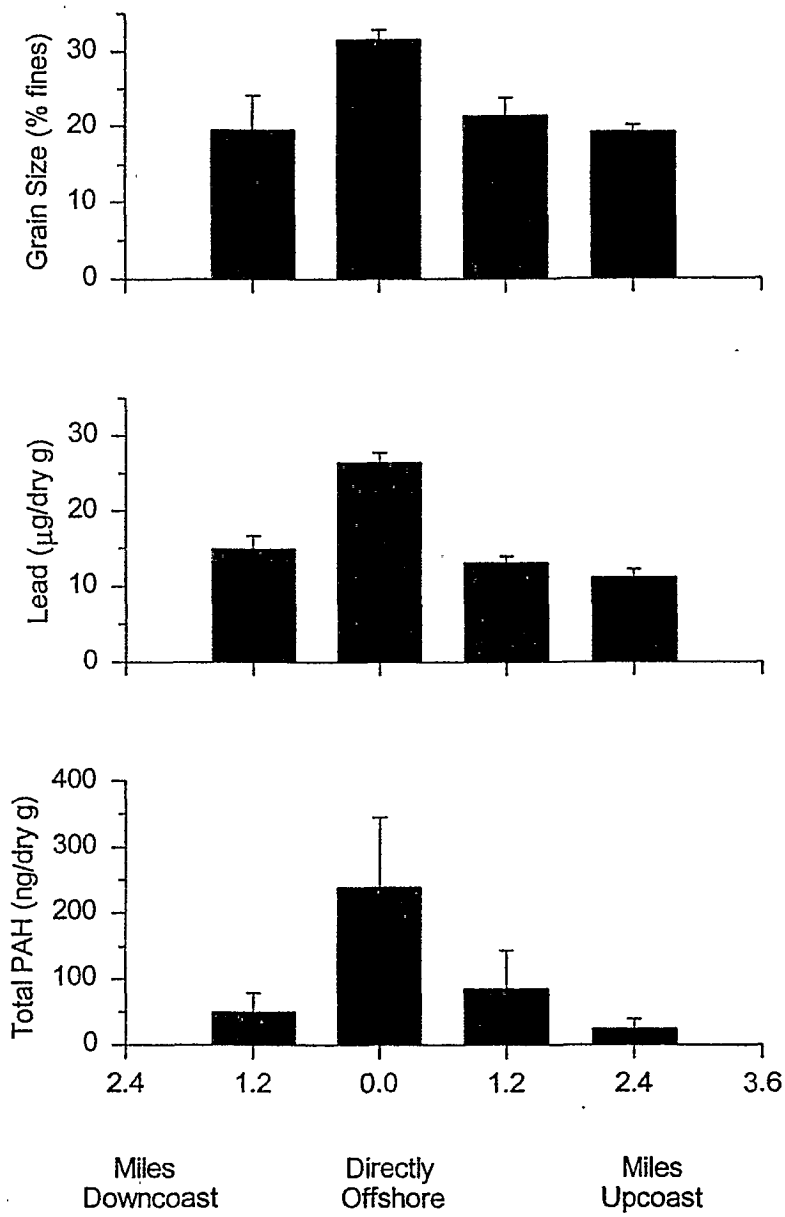

FIGURE 8. Grain size and contaminant concentrations in surface sediments across the gradient of stormwater influence offshore of Ballona Creek. Sampling stations were located 1.5 miles offshore (25 m depth) and at various distances upcoast or downcoast of the creek. Each value represents the mean (+95% confidence interval) of eight samples, each collected after a storm event. The influence of stormwater particle deposition is shown by the elevated values directly offshore of Ballona Creek.

R0012220

EFFECTS OF WATERSHED TYPE ON BENEFICIAL USES

Different impacts to Santa Monica Bay were produced by an urbanized and an unurbanized watershed.

The comparison of receiving water impacts from different watersheds is a powerful tool to distinguish between natural and man-made effects. Although the Ballona Creek and Malibu Creek watersheds are similar in size and discharge into the same body of water (Santa Monica Bay), they differ in their degree of urbanization (Figure 1). The measurement of similar parameters in each receiving water area provides the information needed to distinguish between natural processes and impairment due to man-made factors. This approach also identifies which monitoring methods are most useful for detecting man-made impacts.

The characteristics and impacts of stormwater from the Ballona Creek and Malibu Creek watersheds were found to differ in a number of respects (Table 3). The impacts observed were the result of the interaction of three key factors: land use, flow characteristics, and receiving water conditions. Receiving water impacts were less near Malibu Creek and were related to the discharge of less toxic stormwater and lower peak flows.

R0012221

TABLE 3. Characteristics of a highly urbanized watershed (Ballona Creek) and a less urbanized watershed (Malibu Creek) adjacent to Santa Monica Bay, California.

	Ballona Creek	Malibu Creek
Watershed Characteristics	The largest watershed draining to Santa Monica Bay, 83% of its 130 square miles is developed. The principal land use is residential.	Similar in size to Ballona Creek (110 square miles), 88% of this watershed is undeveloped.
Flow Characteristics	The largely impermeable surface area (41% overall) and concrete channel drainage system results in rapid changes in flow following rainfall. Peak flows are relatively high and of shorter duration compared to other areas.	More permeable surface area (96% overall) absorbs early season rainfall and increases lag time between rainfall and peak flow. Discharges have relatively lower peak flows but duration can be days longer than concrete channelized systems. Discharge into Malibu Lagoon may reduce flows and particle loads to ocean.
Plume Characteristics	The stormwater plume in both areas consisted of a thin buoyant layer of low salinity water floating at the surface. The dissolved and particulate components of stormwater were most concentrated in the upper 2 m of the water column. Plumes extended up to 6 miles offshore and were widely distributed along the shore.	
	Higher flows and less mixing produced well-defined plumes that contained higher concentrations of stormwater near Ballona Creek.	Lower flows, more mixing, and discharges from adjacent canyons resulted in more complex and ill-defined plume boundaries near Malibu Creek.
Debris	Floating debris was often concentrated near the margins of the plume and contained many items of man-made origin, such as plastic.	Floating debris was dominated by organic materials of natural origin, such as twigs and charred wood.

TABLE 3. Continued.

R0012222

	Ballona Creek	Malibu Creek
Water Clarity	Less mixing of stormwater usually produced larger areas of reduced water clarity.	Stormwater inputs were often more turbid, but lower flows and greater dilution near the mouth resulted in better clarity.
Stormwater Toxicity	Samples from the creek were always toxic to sea urchins. Concentrations higher than 10% stormwater usually produced adverse effects in laboratory tests.	Samples were less toxic than Ballona Creek stormwater and occasionally nontoxic. High concentrations (>25%) usually needed to produce toxicity.
Receiving Water Toxicity	Surface water in most concentrated portion of plume was often toxic to sea urchins. Toxicity was detected in receiving waters up to 2 miles from discharge.	Toxicity in water column was rarely present and was not related to plume concentration.
Cause of Toxicity	Zinc is responsible for a portion of the stormwater toxicity. The influence of pesticides and other organics is uncertain.	Metals are implicated but have not been confirmed as important toxicants.
Seafloor Habitat	Sediments were higher in urban stormwater associated contaminants, such as lead and zinc.	Higher concentrations of constituents were derived from natural sources, such as fine sediments and organic carbon.
Sediment Toxicity	Changes in sediment toxicity were minor and not related to stormwater discharges.	
Seafloor Biological Communities	Biological communities were similar among Malibu Creek, Ballona Creek, and background reference sites.	

R0012223

RECOMMENDATIONS FOR FUTURE STUDIES

The Santa Monica Bay receiving waters study produced the first integrated assessment of impacts from stormwater discharges into the Bay. The presence of well-developed plumes containing toxic materials demonstrates the need for continued studies of the impacts from urban stormwater runoff in Santa Monica Bay and elsewhere. Additional information regarding the sources, characteristics, and extent of the receiving water impacts should be determined in order to refine management actions.

A high priority should be placed upon locating sources of toxicity and contamination within the Ballona Creek watershed. Identification of the land uses or regions of the watershed that contribute most to the impacts will enable management actions to be targeted where they will have the greatest beneficial impact. Source identification studies should include sampling of systems tributary to Ballona Creek for measurement of toxicity and chemical constituents.

Additional receiving water studies are recommended for Santa Monica Bay to provide a more complete understanding of the nature and magnitude of stormwater impacts. Future studies should include constituents of concern that were not emphasized in this study, such as bacteria, nutrients, pesticides, and trash. These constituents should be incorporated into studies of plume persistence, cause of toxicity, and constituent fate.

Information on the duration, size, and cause of adverse impacts is needed to identify appropriate stormwater management actions.

Plume persistence information is needed to estimate the duration of exposure of: 1) swimmers to bacteria and 2) marine life to stormwater toxicants and nutrients. Improved information on plume persistence can be obtained by the use of moored sensors in the discharge area in combination with data from remote sensing instruments (e.g., satellites). A goal of these studies should be to develop plume dilution and/or tracking models of plume duration and magnitude. This information is valuable because different management responses may be appropriate for stormwater discharges that produce short- versus long-lived impacts.

A suite of species should be used to identify toxicants in stormwater.

Toxicity testing using multiple marine species is also needed to provide a more complete assessment of the causes of toxicity in stormwater discharged into Santa Monica Bay. Identification of zinc and copper as contaminants of concern was based primarily on studies with a single species (sea urchin). Because different species vary in their sensitivity to contaminants, tests with multiple species

R0012224

are needed to determine if other contaminants are present at toxic concentrations. Tests with crustaceans (e.g., shrimp) are especially recommended as they are likely to be sensitive to pesticides such as diazinon and chlorpyrifos, which have been found to be important factors in the toxicity of stormwater from other watersheds. These tests should include toxicity identification procedures so that potential constituents of concern (e.g., metals and pesticides) can be confirmed and others can be discounted. Toxicant identification is needed to prioritize chemical-specific management actions.

The fate of stormwater particles must be determined in order to assess seafloor impacts.

Chemical and oceanographic studies are needed to determine the fate of stormwater particles discharged into Santa Monica Bay. Although some of the particles in Santa Monica Bay stormwater plumes may be deposited near the mouth of an urban watershed, they do not necessarily persist there for long periods of time. Since the spatial extent of particle dispersal in Santa Monica Bay was not determined, there may be areas of significant accumulation that were not investigated. Studies of currents, sediment resuspension, and sediment transport, coupled with chemical source identification methods, should be conducted to determine whether stormwater discharge is a significant source of adverse sediment contamination within Santa Monica Bay. This information is needed to identify areas of the seafloor with the greatest potential for biological impacts from stormwater discharge.

Additional receiving water systems should be studied to identify impairments from other watersheds.

The impacts of stormwater runoff on other receiving water systems should also be studied. This is because differences in watershed size and land use patterns will likely result in different levels of risk to the receiving water beneficial uses. For example, changes in land use may contribute different toxicants, and changes in watershed size will influence the magnitude of the toxicant input. The nature of the receiving water environment is also important. Semi-enclosed water bodies, such as most bays and harbors, do not have the mixing and dilution capacity of the open coastal environment studied in Santa Monica Bay. The potential for impairment will be greater in these areas because organisms will have an increased exposure to the stormwater plume and more stormwater particles will settle nearby and influence sediment quality. Until the effects of variations in watershed or receiving water characteristics can be accurately predicted, additional integrated studies will be necessary to assess impacts to receiving waters in other areas.

R0012225

Appendix D
Low Flow Pilot Study

D.1 INTRODUCTION

The purpose of the Low Flow Pilot Study was to assess feasibility of modifying the sampling equipment at land use stations to monitor storms as small as 0.1 inches of rainfall. Currently the land use monitoring equipment is designed to monitor storms greater than 0.25 inches of rainfall. To conduct the assessment the equipment at a single land use monitoring station was modified to capture events as small as 0.1 inches. The feasibility assessment was based on the following criteria:

- the operational effectiveness of the sampler at low storm volumes;
- the feasibility and effectiveness of sample retrieval and transport; and
- the ability to reprogram and maintain this setting at other samplers.

Based on these criteria, a decision will be made whether to set some or all of the remaining land use samplers to monitor storms totaling 0.1 inches of rainfall or greater.

D.2 EQUIPMENT AND METHODS

Stormwater Monitoring Site 24, known as Project 1202 Monitoring Station, was selected for the Low Flow Pilot Study. The Project 1202 site is located at a concrete box culvert. The site catchment drains based on an evaluation conducted in Monitoring Plan for 1996/1997 Low Flow Pilot (Woodward-Clyde and Larry Walker Associates, 1996) a 1.07 square mile watershed that is approximately 74 percent impervious. The land use in the watershed is approximately 42 percent commercial, 49 percent industrial and 9 percent vacant. Project 1202 was selected for this pilot study because, compared to the other land use stations, it produced the best runoff response to small events, it had high imperviousness, and it had the lowest and most consistent dry weather flows.

The sampling was conducted with the existing automatic water sampler. The sampler was programmed to start automatically based on the water depth reaching 0.125 feet (1.5 inches) as measured by the existing pressure transducer, and detection of 0.02 inches of rainfall by a tipping bucket rain gage. The sampler drew 1.0 liter aliquots on a flow-proportioned basis. An initial daily volume of 10,000 cubic feet of flow between

aliquot collections was selected. Ten aliquots were sampled per bottle, and the sampler housed four 10 liter bottles. The sample collection pacing volume was changed to 5,000 cubic feet after receiving poor results from the first small storm of the season (Storm 2A). Sampling discontinued when either all sample aliquots were taken or when the sampler was manually turned off.

Rainfall estimates for storm volume were not available until two to three hours before an event. With the required set-up for the other elements of the Monitoring Program (i.e., bottle and ice placement, equipment problem solving, and field team mobilization), the sampler pacing volume could not be set based on anticipated storm size. The sampler pacing volume was, therefore, maintained at 5,000 cubic feet (that is after Storm 2A, see above) to ensure proper sampling of storms down to 0.1 inches.

The automatic sampler does not have telemetric communications. All programming and data transfer is conducted in the field. For this and other reasons discussed above, the sample collection pacing volume could not be modified in response to changes in forecasted rainfall amounts.

The sampler bottles were checked frequently, starting several hours after sampling began, to evaluate whether the bottles were full and needed to be changed. To sample any events with more than 0.25 inches of rain, the composite bottles were changed at least once during the sample collection. In the 1996-97 storm season, 8 of 11 storms were greater than 0.25 inches of rain.

The samples collected for the Low Flow Pilot Study were stored, handled and analyzed in accordance with the currently approved Storm Water/Urban Runoff Monitoring Plan. The analytical methods for the constituents analyzed in this study are listed in Table B-1. The complete methods are presented in Monitoring Plan for 1996/1997 Low Flow Pilot Study (Woodward-Clyde and Larry Walker Associates, 1996).

D.3 RESULTS

During the 1996-97 storm season, eleven events were monitored at the Project 1202 site. Of these eleven events, ten were sampled. The monitored storm events ranged in size from 0.13 inches to 4.25 inches of rainfall. In the 1996-97 storm season, 8 of 11 storms were greater than 0.25 inches of rain. Hydrographs for each event are presented in Attachment D-1. A summary of the events is presented below in Table D-2. Water quality results are presented in Table D-3.

Table D-2. Summary of the events monitored for the Low Flow Pilot Study.

Event No.	Date	Precipitation (in)	Runoff Volume (1000's of c.f.)	Antecedent Dry Period (days)	No. of Bottle Replacements[1]
1	10/29/96	0.75[2]	1,658	231	4
2	11/20/96	2.00	2,282	22	3
2A	12/5/96	0.16	113	13	1
3	12/9/96	4.25	5,205	3	3

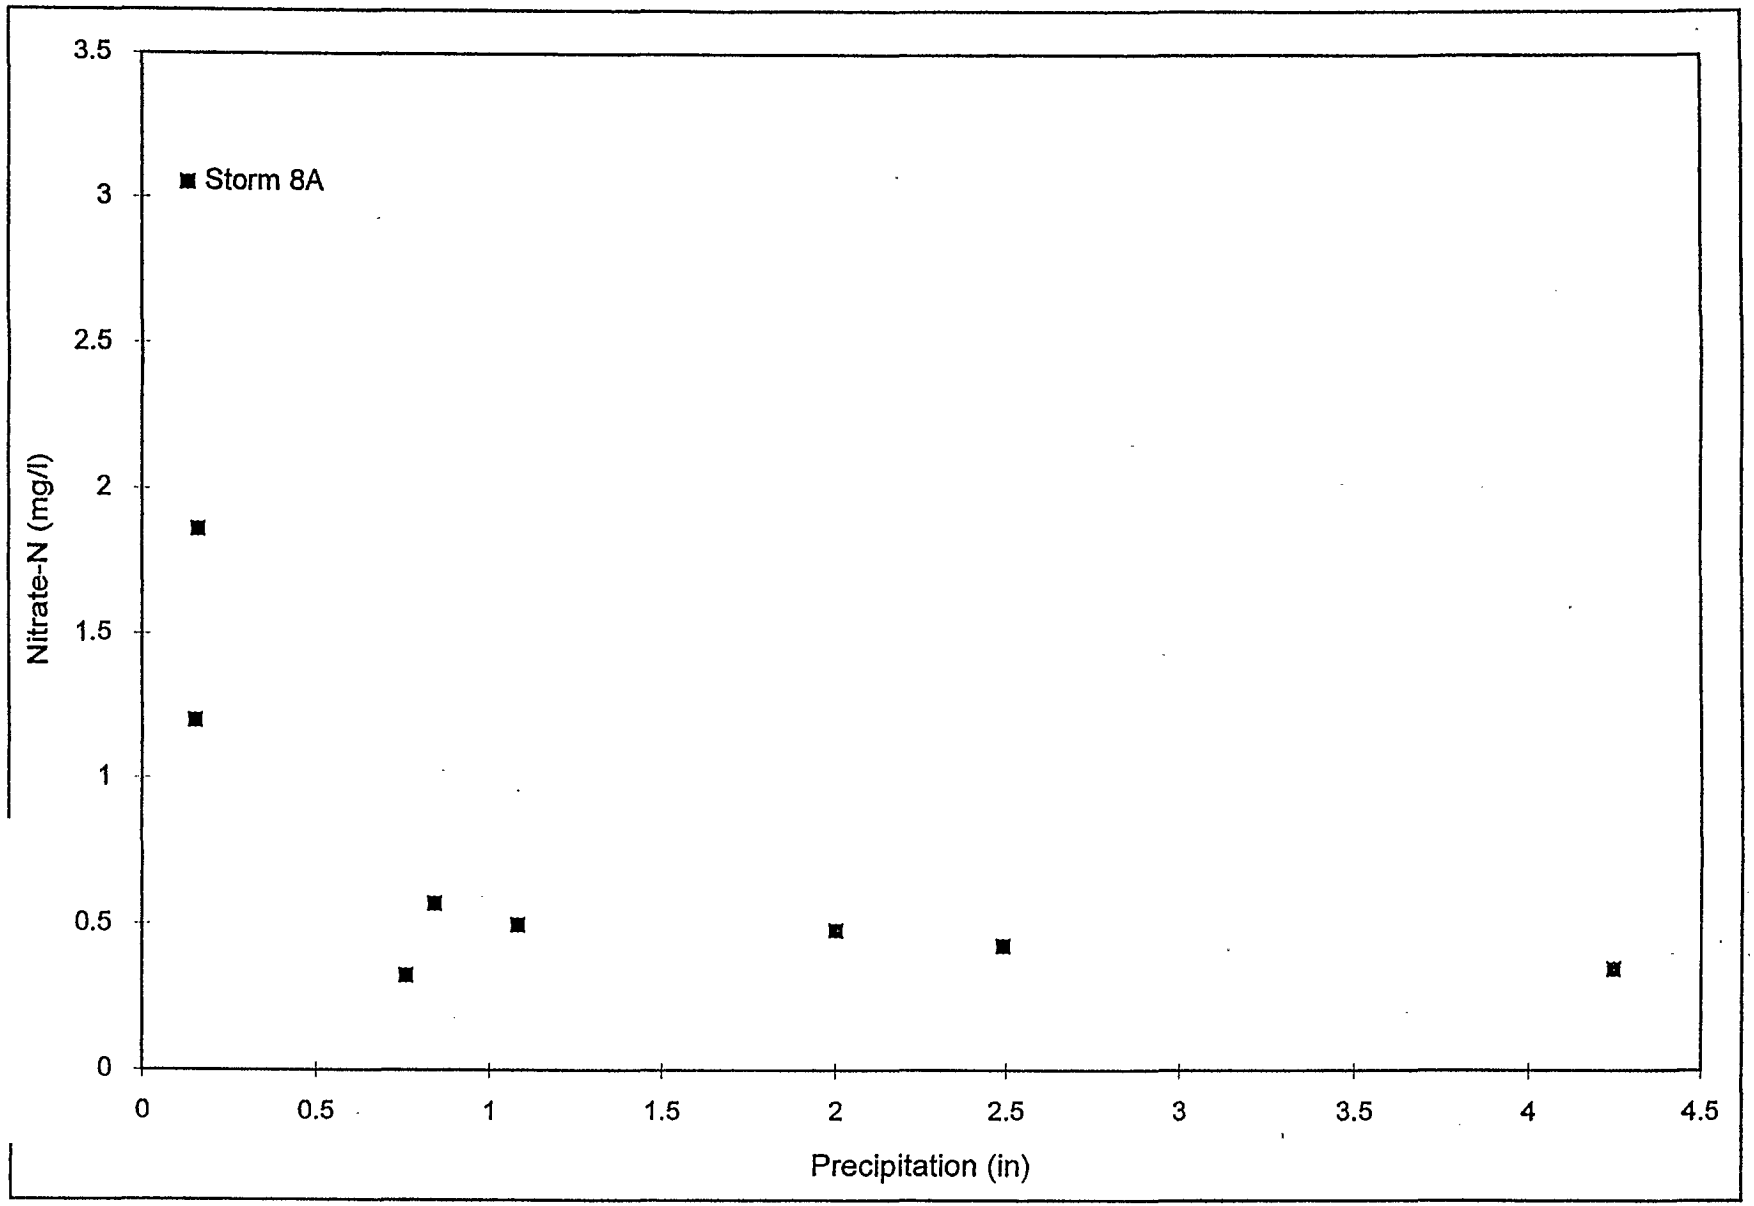
R0012233

The following problems occurred with the sampling equipment. For Storm 1, the adjacent triggering precipitation gauge was not yet operational. The flow record was inconsistent during Storm 7, which was the result of a calibration problem. For this event, data were analyzed for the first portion of the stormflow (shaded dark in the hydrograph in Attachment D-2). The calibration problem continued through Storm 8 and was fixed in early February before Storm 8A.

During the larger events the small pacing volume prevented the samplers from taking the correct number of samples. The sampler typically spends 2.5 minutes in the sampling mode once triggered by the flow meter. The flow meter will not begin to accumulate runoff volume for the next sample until the 2.5 minute sampling cycle is complete. There is, therefore, a down time following each pumping cycle. When the pacing volume is small and the runoff is high, the number of samples obtained is less than the target. This occurred in many of the larger events.

The sampler pacing for Storms 4, 5A, and 6 has been plotted to show this effect (Attachment D-2). In these figures the diamonds represent the theoretical sampler pacing assuming no down time. The triangles represent the theoretical sampler pacing with a 2.5 minute down time after each sample. Finally, the actual pacing is plotted with tick marks on the x-axis. All numbers above the symbols represent the number of samples taken during one hour.



During Storm 4 (0.15 inches of rain) the sampler collected three less samples than the calculated theoretical pacing. For Storm 5A (0.76 inches of rain) the sampler took one less sample than desired. However, for Storm 6 (2.49 inches of rain) the sampler took over 40 samples less than it theoretically should have. This figure does not include the periods of time not sampled when the bottles were completely filled and not yet replaced.

The water quality constituents analyzed showed some trends with storm size. A few higher concentrations than normal were seen in Storm 8A (0.13 inches rain). The composite sample for this event had the highest measured values of total suspended solids (TSS), turbidity, nitrate, total phosphorus, and hardness, while all other constituents were within the ranges of the other samples (Table D-3).

R0012234

In terms of concentration of the constituents monitored, the smaller storms produced higher levels of some of the constituents than the medium to large storms. This effect is shown in Figures D-1 through D-4. It can be seen that the concentrations of nitrate and total phosphorus are higher in the smaller storms than the larger storms (Figures D-1 and D-2). The concentration of total suspended solids was highest for one of the small rainfall events (Storm 8A), but otherwise there is no trend with storm size (Figure D-3). The concentration of total metals (total zinc shown as an example) do not exhibit a trend with storm size (Figure D-4).

R0012239

Field crews generally spent more time (by a factor of 2-3) on the sampling for this pilot study than any other sampling element of the Monitoring Program. Due to the small requirements for sampler pacing volume, sample bottles needed to be changed frequently throughout an event. During one event the crews needed to set up new bottles eight times (Table D-2). Transportation to and from sites during wet weather proved to be extremely time consuming. During the larger events, field crews had to handle and label many more bottles. The laboratory had to composite many more 2.5 gallon sample bottles, which also was very labor intensive.

Often the sample bottles were entirely filled and sampling discontinued for some time when field crews arrived at the sites. Thus, storm event coverage for the medium and large storm events was sacrificed to accommodate the 0.1 inches criterion.

D.4 CONCLUSIONS AND RECOMMENDATION

The conclusions presented below address the three criteria used to evaluate the effectiveness of 0.1 inches and greater event monitoring.

The operational effectiveness of the sampler

Sampler operational effectiveness dropped significantly for the Low Flow Pilot Study site. Although equipment failures were generally not a factor in this study, the equipment was not effective when the pacing volume was set so low. Due to the down time of the flow meter during the sampling cycle, samples were often missed during the highest flow rates. With the required pacing, bottles filled quickly and needed to be replaced frequently during events. With telemetry at the station and a trained staff person, the pacing volume could be charged depending on anticipated storm size. The sampling equipment should operate effectively for small storms, as evidenced by Storms 2A (0.16 inches), 4 (0.15 inches), and 8A (0.13 inches).

The feasibility and effectiveness of sample retrieval and transport

Overall, requiring that the smallest monitored storm be reduced from 0.25 inches to 0.1 inches resulted in extremely difficult sample retrieval and transport for field crews. Bottles needed to changed frequently during events, resulting in extensive travel on wet

R0012240

roads during the storms. For medium to large events the laboratory had to composite numerous 2.5 gallon bottles. If the pacing problem could be solved with telemetry and extra staff, the sample retrieval and transport would not be as burdensome for sampling events down to 0.1 inches.

The ability to reprogram and maintain this setting at other samplers

It would be relatively easy to reprogram other land use stations to sample 0.1 inches and larger storms. However, as shown in *Monitoring Plan for 1996/1997 Low Flow Pilot Study* (Woodward-Clyde and Larry Walker Associates, 1996), most of these stations would not effectively monitor the storms in the 0.1 to 0.25 inches range. This is because the flow at many stations do not respond well to small storms and also have excessive dry weather flows. There is only one other station that could potentially handle the 0.1 inches criteria as reported in the monitoring plan report. This station is Dominguez Channel (S23). Note that telemetry, tipping bucket rain gauges, and new samplers would need to be added to this station to perform the low flow monitoring. The current samplers cannot accommodate telemetry so they would need to be replaced.

Recommendation

Based on the three criteria discussed above, we recommend that all land use sites be monitored for storms 0.25 inches and greater for the duration of the 1996 Municipal Permit. It is our opinion that the 0.1 inches sampling will not be effective unless stations can be provided with telemetry. To convert stations to telemetry, sampling units will need to be replaced, which will be expensive, due to an incompatibility with telemetry. In this case, only two of the seven existing stations (Project 1202 and Dominguez Channel) could be monitored for storm over 0.1 inches, since the five other sites either have inadequate hydrologic responses to small events, low imperviousness, or high and variable dry weather flows.

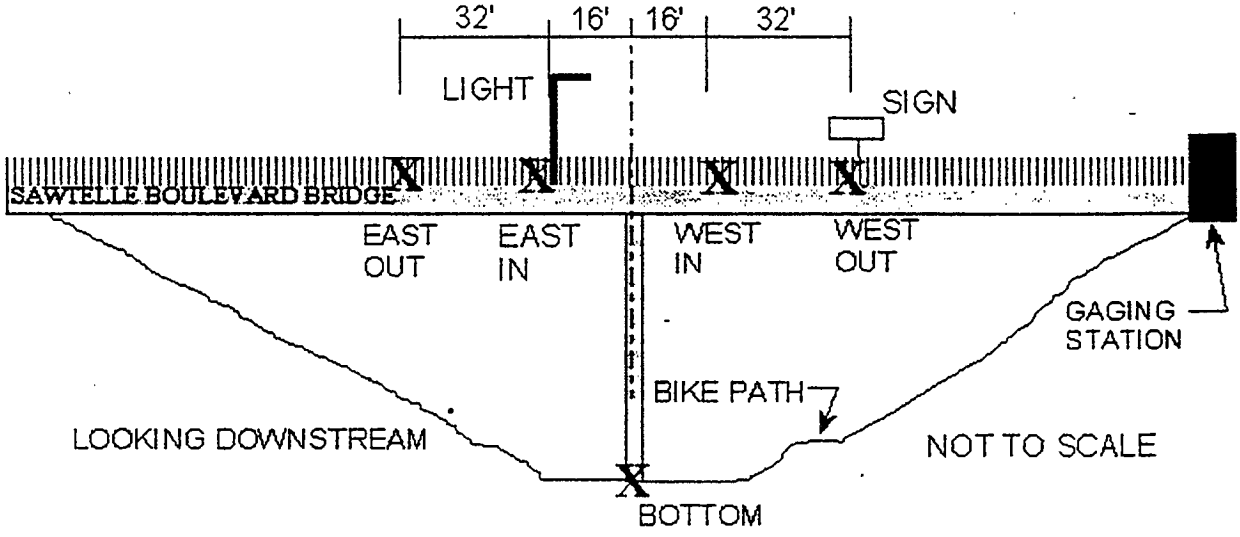
Appendix E
Wide Channel Pilot Study

E.1 INTRODUCTION

The purpose of the Wide Channel Pilot Study is to evaluate the accuracy of a single point water quality intake in representing the water quality in wide channels. The primary focus of this study was the comparison of a series of surface water grab samples collected across the width of a representative channel to investigate horizontal variations in water quality within wide channels. The secondary focus was to compare the surface grab samples with water samples collected near the bottom of the channel by an automated sampling station to evaluate the vertical variability in water quality.

The pilot study was conducted at the Ballona Creek mass emission monitoring station, located between Sawtelle and Sepulveda Boulevards at LACDPW stream gage No. F38C-R. The Ballona Creek station was selected because it provided the most suitable conditions for conducting the pilot study.



E.2 EQUIPMENT AND METHODS

This section provides a summary of the Wide Channel Pilot Study methods. The complete methods for this pilot study are included in *Monitoring Plan for 1996-97 Wide Channel Pilot Study* (Woodward-Clyde, November 1996).

In order to characterize the lateral variability in water quality within Ballona Creek, water quality sampling was conducted at five stations across the channel. The sampling pattern included four sampling stations along the Sawtelle Boulevard bridge that were spaced equidistant from each other, and an automated sampling station at the existing monitoring station at the side of the channel. All samples obtained from the four bridge stations were taken from the water surface. Stations located along the bridge are identified as West-Out, West-In, East-In, and East-Out (the In/Out designation described whether the station was inside or outside of the low-flow channel). Grab samples were also collected from the automated monitoring station, which takes samples from the water at the bottom of the channel. These samples are identified as Bottom samples (Figure E-1).

R0012260

Figure E-1
Cross Section of Ballona Creek
At Sawtelle Blvd. looking downstream

Each station was sampled three times during each of three events at a 2-3 hour recurrence interval. Therefore, for each event a maximum of fifteen samples were collected if channel conditions allowed. The Monitoring Plan included the sampling of at least three events sampled, thereby potentially resulting in 45 data points.

Grab samples from the four stations along the bridge were taken manually from the water surface using a clean, polyethylene bucket and rope. One bucket was used for each station. Water temperature in all samples was measured in the field along with observations of water color, odor, and presence of oil sheen. All samples were analyzed at the Department of Agricultural Commissioner/Weights and Measure's Environmental Toxicology Laboratory for the following constituents: pH, nitrate-nitrogen, specific conductivity, total dissolved solids (TDS), total suspended solids (TSS), total and dissolved copper, and total and dissolved zinc. Analytical methods for the constituents analyzed are listed in Table E-1.

E.3 SUMMARY OF RESULTS

Sampling for the pilot study was conducted during three storms of the 1996-97 storm season. These events were:

Event No.	Date	Precipitation (in)
2	Nov. 20-22, 1996	1.77
3	Dec. 9-11, 1996	3.09
6	Jan. 12-16, 1997	2.16

Hydrographs for the sampled events, including grab sample collection times, are shown in Attachment E-1. Grab samples were taken at the required 2-3 hour intervals during the rising and falling limb portions of the hydrographs.

Table E-1. Analytical Methods for Constituents Analyzed in Wide Channel Pilot Study

Class	Constituent	Sample Type	Method	DL	PQL	Units	Preservation	Holding Time

DL = Detection limit
PQL = Practical quantitation limit
na = Not applicable
"-" = No preservation required other than cooling the sample to 4° C.

R0012263

E.3.1 WATER QUALITY DATA SUMMARY

A total of 39 samples were taken for the pilot study during the three sampling events. There were potentially a maximum of 45 samples, however six samples could not be taken due to low stages in the creek at the time of sampling. Therefore all possible samples were collected, resulting in 100 percent completeness.

The field observations and measurements of water temperature, color, odor, and presence of oil sheen show little variability in both the horizontal and vertical direction (Table E-2). Water temperature did not vary by more than 2 degrees Fahrenheit, water color had little variability, and the presence of odors or oil films did not vary between the samples in each round.

The laboratory water quality results show little variability in the constituents analyzed (Table E-3). No sampling station, including the bottom sample, stands out as having consistently greater or lesser concentrations of any of the analytes.

E.3.2 CHANNEL CROSS-SECTIONAL TRENDS IN WATER QUALITY

Analysis of variance (ANOVA) is a statistical technique that is used to evaluate the relationship between one or more effects on a particular parameter and to determine if the different levels of the effects are significantly different from each other. For this pilot study the storm event (or date) and sample location are the effects and the constituents copper, zinc, TSS, and nitrate-N are the parameters of interest. A two-way ANOVA model was applied to the natural logs of the data. Natural logs were used since checks for normality indicated that the data follow a log normal distribution, with the exception of zinc.

There are two tests that must be checked prior to considering the results from the ANOVA valid. The tests serve to check major assumptions that are inherent in the ANOVA process. They are performed on the residuals from the ANOVA. The residuals are calculated from the dataset by the ANOVA and represent the part of the data that are not explained by the effects used in the model. The residuals are tested for normal distribution and homogeneity of variance. If these assumptions are not met, the ANOVA is invalid as

DL - Detection limit
PQL - Practical quantitation limit

R0012266

performed and must be performed on the ranked averages of the data rather than the natural logs. Both zinc and nitrate-N failed to meet these assumptions. While an ANOVA using a ranked average dataset does not need to meet any assumptions, it is generally less sensitive.

The results of the two-way ANOVAs are presented in Tables E-4 through E-7. Each table includes: the sum of squares for the whole model and for each effect examined; the probability that the null hypothesis is correct; and profile plots for both effects (date and location). In addition, the least square mean, the standard error, and the mean for each level of each effect is also given.

For example, Table E-4 reveals that the whole model explains 67 percent of the variability and is significant (Prob>F less than 0.05). The date explains 54 percent of the variability and is significant while the location is not significant. This means that the concentration differences due to sample location are much less than the concentration differences due to characteristics of individual storm events.

In the end the ANOVA model indicated that concentrations of all constituents analyzed (copper, zinc, TSS, and nitrate-N) were significantly related to the storm event (or date) and not to sample location (including the bottom sample). In some cases the data suggest that additional samples might reveal a significant difference. However, using the existing data to make a projection indicates that approximately 1300 samples would be required to determine if the observed difference is in fact significant.

E.4 CONCLUSIONS AND RECOMMENDATIONS

The ANOVA analysis revealed that the water quality data did not vary significantly with respect to sample station. This shows that the water quality appears to be homogeneous across the channel and that the single point sampler at the bottom of the channel represents the water in the channel as a whole. It is therefore recommended that no modifications be made to the wide channel monitoring stations.

during the El Niño study period rapidly dispersed the stormwater plumes to nontoxic concentrations within 24 hours.

Toxicant characteristics

The results of the surface water toxicity characterization studies (using phase I TIE procedures) were similar to data from samples analyzed before the El Niño. In all cases, addition of the metal chelating agent EDTA eliminated most or all of the toxicity. Filtration of the sample was also highly effective in reducing toxicity. The TIE results over three years of study are consistent with a conclusion that trace metals, especially zinc, are responsible for the toxicity measured with the sea urchin test. Other stormwater constituents may also be present in toxic amounts in Ballona Creek stormwater, as there is some uncertainty associated with biological variability, chemical methods, and species-specific differences in toxicant sensitivity.

Chemical composition of the plume

This study has produced the first measurements of chemical concentrations in both the dissolved and particulate fractions of the Ballona Creek stormwater plume. The results indicate that stormwater produced increased concentrations of trace metals and organics in the receiving water near Ballona Creek. More data are needed before the variability in composition can be examined in relation to weather conditions.

EXECUTIVE SUMMARY

Introduction

Urban stormwater runoff constitutes one of the largest inputs of chemical constituents to southern California's coastal waters. Substantial resources are spent monitoring the constituents in stormwater runoff, yet little is known about the effects of these inputs once they enter the ocean. Understanding the effects of stormwater on the marine environment is essential, because it provides the information needed to justify management action and to identify the most effective actions to improve environmental quality.

In 1996, a three-year research project sponsored by the Los Angeles County Department of Public Works, USC Sea Grant and the Southern California Coastal Water Research Project (SCCWRP) was initiated to examine the impacts of urban stormwater runoff on the beneficial uses of Santa Monica Bay. This study, the first integrated assessment of the impacts of stormwater discharges on coastal receiving water, investigated the effects of stormwater discharge from the two largest watersheds draining into Santa Monica Bay: Ballona Creek and Malibu Creek. The results of this investigation have shown that stormwater discharges produce particle-laden plumes that are concentrated in the upper 5-10 m of the water column and extend up to 10 km offshore. The plume from the discharge of stormwater from the highly urbanized Ballona Creek watershed was found to contain dissolved constituents that were toxic to marine life. Toxicity identification studies indicated that the toxicity was due to trace metals, with zinc the element of greatest concern. Studies of the sediments offshore of Ballona Creek also detected alterations in physical and chemical characteristics. Although elevated concentrations of some contaminants (lead, DDTs, PCBs, PAHs) were measured, biological impairment of sediment-dwelling animals was not detected.

While the types of impacts associated with stormwater discharge from Ballona Creek, have been identified, relatively few storm events have been studied. Early in 1997, forecasters began predicting that an El Niño condition in the Southern Hemisphere would bring increased rainfall to southern California in the 1997-98 wet season. In anticipation of an extreme winter season, studies were conducted to determine the effect of El Niño on urban stormwater. The objective of this research was to determine whether the unusual oceanographic conditions and storm events produced by El Niño conditions had an influence on the toxicity of Ballona Creek stormwater or the characteristics of the stormwater discharge plume in Santa Monica Bay.

The physical and optical characteristics of the Ballona Creek stormwater discharge plume and its toxicity were measured for three storm events occurring in February and March. Selected samples of the runoff plume were also analyzed for chemical constituents. All samples of stormwater from the Ballona Creek channel and surface water from the discharge plume were tested for toxicity using the sea urchin fertilization test. Selected surface water samples were further evaluated using toxicity

R0012284

identification evaluation (TIE) methods in order to characterize the toxicants present. The sampling and measurement methods were similar to those used in previous years so that the data could be compared. The results were examined to evaluate the effect of El Niño storms on three aspects of toxicity: magnitude of stormwater toxicity, spatial extent of the toxic portion of the plume, and the characteristics of the toxicants.

Southern California received record or near record rainfall during the 1997-1998 storm season. All of the anomalous rainfall occurred after the beginning of February. The Los Angeles civic center recorded over 20 in. of rain between February and the end of May; the annual average rainfall for this area is 14.8 in.

Magnitude of stormwater toxicity

The 1998 El Niño event did not have an unusual influence on the magnitude of Ballona Creek stormwater toxicity. The toxicity of the three stormwater samples measured in this study were typical of previous Ballona Creek samples analyzed. The results indicated that storm size and cumulative amount of prior rainfall had little influence on stormwater toxicity. The magnitude of toxicity was found to be affected by the number of antecedent dry days, however. Stormwater from rainfall preceded by more than 20 days of dry weather was found to have the highest toxicity. This relationship produced a seasonal pattern of greater toxicity in the first storm of the year that appeared to be independent of El Niño weather patterns.

Spatial extent of receiving water toxicity

The 1998 El Niño produced changes water temperature and salinity throughout Santa Monica Bay as a result of the presence of a large warm water mass from the south. The increased rainfall that occurred in 1998 altered the typical wet weather salinity structure of Santa Monica Bay. Reductions in salinity associated with freshwater inputs, normally confined to the upper few meters of the water column, were observed to extend 10-30 m below the surface following February's heavy rainfall. Coastal freshwater inputs to the surface layer were also detected much further offshore of Ballona Creek.

In contrast to these changes in water column characteristics, the spatial extent of receiving water toxicity within stormwater discharge plumes was similar to that observed during non El Niño storms. Surface water toxicity associated with runoff plumes in 1998 was limited to an area within 2 km of Ballona Creek, with most of the toxic samples located within 1 km of the creek mouth. The similarity in spatial distribution of the toxic portion of the plume is not surprising, considering that the characteristics of El Niño storms (rainfall volume and intensity) were similar to previous storms.

Evaluation of the toxicity data collected over the past three years indicates that two factors, storm size and time after the storm, are important determinants of the spatial extent of receiving water toxicity. The toxic portion of the stormwater plume extends further offshore following larger storms. The strong winds and large swells encountered

TOXICITY MEASUREMENT OF NOVEMBER AND DECEMBER 1997 WET WEATHER RIVER SAMPLES

INTRODUCTION

This report presents results for the toxicity analysis of samples of wet weather flow from the Los Angeles and San Gabriel Rivers. The tests were conducted as partial fulfillment of the monitoring requirements mandated by NPDES Permit No. CAS614001 from the California Regional Water Quality Control Board (Los Angeles Region).

METHODS

Sampling was conducted during wet weather flow conditions at the Los Angeles and San Gabriel Rivers. The test samples were composites collected by autosampler on November 26 and December 6, 1997. Sampling locations were LACDPW mass emission stations S-10 (Los Angeles River) and S-14 (San Gabriel River). Samples were stored under refrigeration until tested on November 29 and December 9, respectively.

Toxicity was measured using the purple sea urchin fertilization test as described by Chapman *et al.*, 1995. Sea urchin gametes were obtained from specimens collected from a relatively uncontaminated area in northern Santa Monica Bay. In the test, sea urchin sperm are exposed to various concentrations of the test sample for 20 minutes at a temperature of 15 °C. Sea urchin eggs are then added to each sample and given 20 minutes for fertilization to occur. Preservative is then added to the samples, which are later examined with a microscope to determine the percentage of fertilized eggs.

Since the toxicity test uses a marine organism, the salinity of the river samples was adjusted to a typical seawater value by addition of hypersaline brine. Addition of the brine diluted the samples, restricting the highest concentration of sample tested to 50%. Additional test concentrations (25, 12, 6, 3, and 1.5%) were prepared by adding laboratory seawater (filtered natural seawater collected from offshore Redondo Beach) to the samples. A brine control was included in the experiment to check for toxicity introduced by the salinity adjustment procedure. The brine control consisted of deionized water, laboratory seawater, and brine at the same concentration found in the 50% and 25% river samples.

A reference toxicant test was conducted at the same time in order to document variability in test sensitivity. This test consisted of five concentrations of dissolved copper, ranging from 10 µg/L to 65 µg/L.

Water quality measurements (pH, dissolved oxygen, conductivity, and total ammonia) were made on the test samples at the beginning of the toxicity test. Due to a malfunctioning ammonia electrode, total ammonia measurements were not made on the November 26 samples.

R0012288

For the river samples, water quality was measured on the 50%, 12% and 3% concentrations. All measurements were made using electrodes. Sample salinity was calculated from the conductivity and temperature data. Un-ionized ammonia (NH_3) concentration was calculated from the total ammonia, pH, salinity, and temperature data.

A tiered approach was used to examine the river test samples. First, selected samples from the four highest concentrations (50, 25, and 12%) were examined to determine the pattern of dose response. Additional samples were then examined as needed to provide sufficient data for calculation of the EC_{50} (concentration producing a 50% reduction in fertilization) and NOEC (highest test concentration that does not produce a statistically significant reduction in fertilization). This procedure eliminated wasted effort spent examining samples that did not provide useful information about the level of toxicity.

RESULTS

Sea urchin fertilization was significantly reduced by exposure to the November samples from the Los Angeles and San Gabriel Rivers, as shown in Figure 1. The NOEC for each river was 25% sample, which represents 4 chronic toxicity units (TU_c=100/NOEC). The EC_{50} for the San Gabriel River was 32%, while the Los Angeles River was 27% (Table 1). There was no significant difference between the EC_{50} values, indicating that the magnitude of toxicity was similar for both sites.

Toxicity was again detected in samples from both rivers in December (Figure 2). While the NOEC was again 25% for each river, the EC_{50} data indicated a lower magnitude of toxicity was present. The EC_{50} for the Los Angeles River was 50%. The San Gabriel River could not be calculated since none of the samples produced less than 50% fertilization (Table 2).

Summaries of the fertilization counts for each experiment are shown in Tables 3 and 4. For the first sampling, the control seawater fertilization percentage averaged 87% and the 50% brine control averaged 89%, well above the minimum acceptable value of 70%. The second sampling also had good control results with the seawater control averaging 98% and the 50% brine control 99%.

The results of water quality measurements are shown in Tables 3 and 4. For the first exposure, we were unable to make ammonia measurements. The pH, dissolved oxygen, and salinity of the samples were within acceptable ranges. All parameters were within acceptable ranges for the second exposure. Total ammonia in the San Gabriel River sample was elevated relative to the control, but was less than 1% of that measured in a non-toxic dry weather sample from the same site.

The reference toxicant tests associated with each exposure produced a fairly typical dose response. An EC50 of 13 µg/L was calculated for the first test and 32 ug/L for the second. The data for the second test is within the range typically found in our laboratory. The results for the

R0012289

first exposure may indicate a slightly more sensitive test, but is within the range seen by other laboratories using the same methods (Chapman *et al.*, 1995).

Westminster, CA 92683

November 24, 1998

R0012297

TOXICITY MEASUREMENT OF OCTOBER DRY WEATHER AND NOVEMBER 1998 WET WEATHER RIVER SAMPLES

INTRODUCTION

This report presents results for the toxicity analysis of samples of dry and wet weather flow from the Los Angeles and San Gabriel Rivers. The tests were conducted as partial fulfillment of the monitoring requirements mandated by NPDES Permit No. CAS614001 from the California Regional Water Quality Control Board (Los Angeles Region).

METHODS

Sampling was conducted during dry weather flow conditions at the Los Angeles and San Gabriel Rivers and during the first storm of the season on the San Gabriel River. The San Gabriel River dry weather sample was a 24 h, time weighted composite collected by autosampler on October 22, 1998. The Los Angeles River sample was a composite of 9 grabs collected manually by bucket over an 8 h period between 0800 and 1600 on October 22, 1998. The wet weather sample was collected by autosampler from the San Gabriel River on November 8, 1998. Sampling locations were LACDPW mass emission stations S-10 (Los Angeles River) and S-14 (San Gabriel River). Samples were stored under refrigeration until tested on October 23 and November 11, respectively.

Toxicity was measured using the purple sea urchin fertilization test as described by Chapman *et al.*, 1995. Sea urchin gametes were obtained from specimens collected from a relatively uncontaminated area in northern Santa Monica Bay. In the test, sea urchin sperm are exposed to various concentrations of the test sample for 20 minutes at a temperature of 15 °C. Sea urchin eggs are then added to each sample and given 20 minutes for fertilization to occur. Preservative is then added to the samples, which are later examined with a microscope to determine the percentage of fertilized eggs.

Since the toxicity test uses a marine organism, the salinity of the river samples was adjusted to a typical seawater value by addition of hypersaline brine. Addition of the brine diluted the samples, restricting the highest concentration of sample tested to 50%. Additional test concentrations (25, 12, 6, 3, and 1.5%) were prepared by adding laboratory seawater (filtered natural seawater collected from offshore Redondo Beach) to the samples. A brine control was included in the experiment to check for toxicity introduced by the salinity adjustment procedure. The brine control consisted of deionized water, laboratory seawater, and brine at the same concentration found in the 50% and 25% river samples.

A reference toxicant test was conducted at the same time in order to document variability in test sensitivity. This test consisted of five concentrations of dissolved copper, ranging from 10 µg/L to 65 µg/L.

R0012298

Water quality measurements (pH, dissolved oxygen, conductivity, and total ammonia) were made on the test samples at the beginning of the toxicity test. For the river samples, water quality was measured on the 50%, 12% and 3% concentrations. All measurements were made using electrodes. Sample salinity was calculated from the conductivity and temperature data. Un-ionized ammonia (NH_3) concentration was calculated from the total ammonia, pH, salinity, and temperature data.

For each experiment, we attempted to calculate an EC_{50} (concentration producing a 50% reduction in fertilization) and NOEC (highest test concentration that does not produce a statistically significant reduction in fertilization). The EC_{50} was calculated by probit analysis of the raw percent fertilized data. If there was less than a 50% reduction in fertilization success, then an EC_{50} could not be calculated. The NOEC was calculated by first arcsine transforming the percent fertilized data, then subjecting it a one way analysis of variance (ANOVA). If a significant difference between treatments was detected ($p \Leftrightarrow 0.05$), a Dunnett's multiple range test was performed to test for differences between the control value and each of the concentrations. If there was not a significant reduction in fertilization relative to the control, then a NOEC could not be calculated.

RESULTS AND DISCUSSION

Sea urchin fertilization was significantly reduced by exposure to the dry weather sample from the Los Angeles River (the 50% concentration had 64% of the eggs successfully fertilized), but no toxicity was detected for the San Gabriel River (the 50% concentration had 99% fertilization) (Figure 1). The NOEC for the Los Angeles River was 25% sample, which represents 4 chronic toxicity units (TU_c=100/NOEC). A NOEC could not be calculated for the San Gabriel River since there was no significant reduction in fertilization. Since samples from neither river caused a 50% reduction in fertilization, an EC_{50} could not be calculated (Table 1).

No toxicity was detected in the wet weather sample from San Gabriel River in November (Figure 2). Since there was no reduction in fertilization caused by this sample, neither a NOEC nor an EC_{50} could be calculated.

Summaries of the fertilization counts for each experiment are shown in Tables 3 and 4. For the first sampling, the control seawater fertilization percentage averaged 94% and the 50% brine control averaged 97%, well above the minimum acceptable value of 70%. The second sampling also had good control results with the seawater control averaging 89% and the 50% brine control greater than 99%.

The results of water quality measurements are shown in Tables 5 and 6. The pH, dissolved oxygen, and salinity of the samples were within acceptable ranges for both sets of experiments. Total ammonia in the San Gabriel River (3.51 mg /L) wet weather sample was

R0012299

elevated relative to the control, but was well below of the level (>20 mg /L) that would be expected to cause toxicity in the sea urchin fertilization test.

The reference toxicant tests associated with each exposure produced a fairly typical dose response. An EC_{50} of 52 µg/L was calculated for the first test and 19 µg /L for the second. The mean EC_{50} for our previous reference toxicant tests is 27.8 µg/L. The data for both tests is within the range for an acceptable test (3.2 to 52.4 µg/L). The results for the first exposure may indicate on average a slightly less sensitive test and the second exposure a slightly more sensitive test, but are both within the range seen by our laboratory and others using the same methods (Chapman *et al.*, 1995).

TOXICITY MEASUREMENT OF JANUARY THROUGH MARCH 1999 WET WEATHER RIVER SAMPLES

INTRODUCTION

This report presents results for the toxicity analysis of samples of wet weather flow from the Los Angeles and San Gabriel Rivers. The tests were conducted as partial fulfillment of the monitoring requirements mandated by NPDES Permit No. CAS614001 from the California Regional Water Quality Control Board (Los Angeles Region).

METHODS

Sampling was conducted by LACDPW personnel during wet weather flow conditions at the Los Angeles and San Gabriel Rivers. Samples were taken during two storms for the Los Angeles River and one storm for the San Gabriel. The wet weather sample was collected by autosampler from the San Gabriel River on January 26, 1999. A single grab sample was taken from the Los Angeles River during storms on March 15 and March 20, 1999. Sampling locations were LACDPW mass emission stations S-10 (Los Angeles River) and S-14 (San Gabriel River). Samples were stored under refrigeration until tested on January 27, March 16 and March 22, respectively.

Toxicity was measured using the purple sea urchin fertilization test as described by Chapman *et al.*, 1995. Sea urchin gametes were obtained from specimens collected from a relatively uncontaminated area in northern Santa Monica Bay. In the test, sea urchin sperm are exposed to various concentrations of the test sample for 20 minutes at a temperature of approximately 15 °C. Sea urchin eggs are then added to each sample and given 20 minutes for fertilization to occur. Preservative is then added to the samples, which are later examined with a microscope to determine the percentage of fertilized eggs.

Since the toxicity test uses a marine organism, the salinity of the river samples was adjusted to a typical seawater value by addition of hypersaline brine. Addition of the brine diluted the samples, restricting the highest concentration of sample tested to 50%. Additional test concentrations (25, 12, 6, 3, and 1.5%) were prepared by adding laboratory seawater (filtered natural seawater collected from offshore Redondo Beach) to the samples. A brine control was included in the experiment to check for toxicity introduced by the salinity adjustment procedure. The brine control consisted of deionized water, laboratory seawater, and brine at the same concentration found in the 50% and 25% river samples.

A reference toxicant test was conducted concurrently with the river tests in order to document variability in test sensitivity. This test consisted of five concentrations of dissolved copper, ranging from 10 µg/L to 65 µg/L.

R0012310

Water quality measurements (pH, dissolved oxygen, conductivity, and total ammonia) were made on the test samples at the beginning of the toxicity test. For the river samples, water quality was measured on the 50%, 12% and 3% concentrations. All measurements were made using electrodes. Sample salinity was calculated from the conductivity and temperature data. Un-ionized ammonia (NH_3) concentration was calculated from the total ammonia, pH, salinity, and temperature data.

For each experiment, we attempted to calculate an EC_{50} (concentration producing a 50% reduction in fertilization) and NOEC (highest test concentration that does not produce a statistically significant reduction in fertilization). The EC_{50} was calculated by probit analysis of the raw percent fertilized data. If there was less than a 50% reduction in fertilization success, then an EC_{50} could not be calculated. The NOEC was calculated by first arcsine transforming the percent fertilized data, then testing for homogenity of variance and normal distribution of the data. Data that passed these tests were then subjected to a one way analysis of variance (ANOVA). If a significant difference between treatments was detected ($p \leq 0.05$), a Dunnett's multiple range test was performed to test for differences between the control value and each of the concentrations. Data that did not pass the test for homogenity of variance and/or normal distribution were subjected to a non-parametric Steel's Many-One Rank test. If there was not a significant reduction in fertilization relative to the control, then a NOEC could not be calculated.

RESULTS AND DISCUSSION

No toxicity was detected in the wet weather sample from San Gabriel River taken in January (Figure 1). Since there was no reduction in fertilization caused by this sample, neither a NOEC nor an EC_{50} could be calculated (Table 1). The lack of toxicity from this sample is consistent with the results of testing from another San Gabriel River sample taken earlier in the storm season (SCCWRP 1998).

Sea urchin fertilization was significantly reduced by exposure to samples from the Los Angeles River for both storms in (Figures 2 and 3). The greatest toxicity was present in the March 15 storm sample. The NOEC for this storm was 12.5%, which represents 8 chronic toxicity units (TU_c=100/NOEC). The March 20 sample had a NOEC of 25% (4 TU_c). The EC_{50} for the first storm was 24% sample. Since the sample from the second storm did not cause a 50% reduction in fertilization, an EC_{50} could not be calculated (Table 1).

All of the experiments met the test acceptability criteria. For the San Gabriel River sampling, the control seawater fertilization percentage averaged 91% and the 50% brine control averaged 98%, well above the minimum acceptable value of 70%. The Los Angeles River samples also had good control results with the seawater control averaging 89% and 100% respectively and the 50% brine control greater than 83% and 100%. Summaries of the fertilization counts for each experiment are shown in Tables 2-4.

R0012311

The results of water quality measurements are shown in Tables 5-7. The pH, dissolved oxygen, and salinity of the samples were within acceptable ranges for all of the experiments. Total ammonia in the San Gabriel River (2.01 mg /L) wet weather sample was elevated relative to the control, but was well below the level (>20 mg /L) that would be expected to cause toxicity in the sea urchin fertilization test.

The copper reference toxicant tests conducted with each experiment also met performance standards. The EC_{50} values for these tests ranged from 27-48 µg/L, which are similar to the historical average for our laboratory (27.6 µg/L). The data for all three of the tests are within the range for an acceptable test (4.2 to 51.0 µg/L) (Figure 4). The relatively high EC_{50} for the March 22 experiment may indicate a somewhat less sensitive test than we would normally achieve.

Aerial Deposition Study Progress Reports
by Southern California Coastal Waters Research Project

Quarterly Report of Progress
May 11, 1999

ESTIMATES OF POLLUTANT INPUTS TO SANTA MONICA BAY VIA AERIAL DEPOSITION

This is the first year of a three-year project. The first year is funded by the US EPA, the Los Angeles County Department of Public Works and SCCWRP. The project is being conducted in collaboration with UCLA's Institute of the Environment, the Santa Monica Bay Restoration Project (SMBRP), the US EPA's Great Water Program, and in cooperation with the South Coast Air Quality Management District (AQMD). The first year of this project intends to estimate the annual pollutant loads to Santa Monica Bay via aerial deposition, both directly to Bay waters, and indirectly by depositing onto land surfaces then washing off into the Bay during storm events.

We have successfully completed the winter phase of our sampling program. The sampling program included measurements of contaminants on aerosol particles from the atmosphere, dry deposition (what lands on a surrogate surface), and wet deposition (rain). Our master sampling site is located within the Santa Monica Bay watershed at UCLA. The AQMD samples eight other locations within the airshed (LA air basin) that can contribute to loading in Santa Monica Bay. We also sampled the sea surface microlayer and bulk seawater at nine stations located throughout Santa Monica Bay to estimate direct deposition. Sample analysis is currently underway for all of these samples. During the next quarter, SCCWRP staff will be mobilizing for our summer sampling season scheduled to begin in July.

Quarterly Report of Progress
April, 2000

ESTIMATES OF POLLUTANT INPUTS TO SANTA MONICA BAY VIA AERIAL DEPOSITION

This is the first year of a three-year project. The first year is funded by the US EPA, the Los Angeles County Department of Public Works and SCCWRP. The project is being conducted in collaboration with UCLA's Institute of the Environment, the Santa Monica Bay Restoration Project (SMBRP), the US EPA's Great Water Program, and in cooperation with the South Coast Air Quality Management District (AQMD). The first year of this project intends to estimate the annual pollutant loads to Santa Monica Bay via aerial deposition, both directly to Bay waters and indirectly by depositing onto land surfaces, then washing off into the Bay during storm events.

We have made progress on two phases of our project over the last quarter. The first phase was reporting. We have compiled a Data Report that includes objectives, rationale, methods, quality assurance/quality control, information management, and raw data for the entire study. The second area of activity is data analysis and assessment. We have had three meetings with the UCLA Institute of the Environment that have been focused on data analysis, integration of project data with AQMD data sets, and atmospheric transport and deposition modeling.

During the next quarter, SCCWRP staff will continue to make progress on the data analysis and assessment report. The timeline for completion of the Data Assessment Report is for September 2000. We will also continue to make additional air measurements. We have received a $50,000 grant from the US EPA Great Waters Program to complete this work. The additional sampling and analysis will address data gaps identified during the first year's work. This provides an excellent opportunity for the LACDPW to leverage any additional resources in the upcoming year against those being provided by the US EPA and SCCWRP.

Quarterly Report of Progress
February, 2000

ESTIMATES OF POLLUTANT INPUTS TO SANTA MONICA BAY VIA AERIAL DEPOSITION

This is the first year of a three-year project. The first year is funded by the US EPA, the Los Angeles County Department of Public Works and SCCWRP. The project is being conducted in collaboration with UCLA's Institute of the Environment, the Santa Monica Bay Restoration Project (SMBRP), the US EPA's Great Water Program, and in cooperation with the South Coast Air Quality Management District (AQMD). The first year of this project intends to estimate the annual pollutant loads to Santa Monica Bay via aerial deposition, both directly to Bay waters and indirectly by depositing onto land surfaces, then washing off into the Bay during storm events.

We have made progress on four different phases of our project over the last quarter. The first phase was sampling. Sampling for the year is now completed. We conducted two additional sampling cruises over the last quarter than was required in order to capture Santa Ana wind conditions, an event that moves the urban air mass offshore. The second phase of our project was completing sample analysis. We anticipate having all samples analyzed by early February including aerosol particulates, dry deposition surfaces, wet deposition, sea-surface microlayer, and bulk seawater samples. The third phase of our project is information management. As we receive data from the laboratory, we are checking to ensure accuracy and completeness. Also, we have requested data from AQMD to obtain complimentary aerosol measurements outside of the Santa Monica Bay watershed, but inside of the Los Angeles airshed. A third phase of our project was quality assurance. We have met with AQMD twice and have analyzed a set of split samples. The goal of this interlaboratory calibration is to assess comparability prior to combining data sets.

During the next quarter, SCCWRP staff will make progress on two more phases of our project. The first phase will be data analysis. We intend to start preliminary examination of our results beginning in February. We also intend to begin integrating our results with the AQMD data set. The combined data set will be delivered to UCLA for continued work by the atmospheric transport and transformation modelers. The second phase of our project that we anticipate progress will be reporting. Our goal is to begin compiling a data report that includes the data generated under this project by April 2000. After the modelers have completed their tasks, an assessment report integrated our results, AQMD results, and modeled predictions will be constructed by July 2000.

An invited workshop entitled "Where air and water meet: Atmospheric deposition to the Pacific Coast" has been scheduled for February 9-10, 2000 at UCLA. The

workshop will be co-sponsored by the Ecological Society of America, the UCLA Institute of the Environment, and SCCWRP and will include nationally prominent atmospheric deposition scientists as well as National Estuary Program managers from around the country.

WQC	water quality criteria
WY	water year

GOALS AND OBJECTIVES

The goal of the Los Angeles County Monitoring Program is to provide technical data and information to support effective watershed stormwater quality management programs in Los Angeles County. Specific objectives of the Program, as outlined in the Municipal Permit, are:

- tracking water quality status, pollutant trends and pollutant loads, and identifying pollutants of concern;
- monitoring and assessing pollutant loads from specific land uses and watershed areas;
- identifying, monitoring, and assessing significant water quality problems related to stormwater discharges within the watershed;
- identifying sources of pollutants in stormwater runoff;
- identifying and eliminating illicit discharges;
- evaluating the effectiveness of management programs, including pollutant reductions achieved by implementation of Best Management Practices; and
- assessing the impacts of stormwater runoff on receiving waters.

The 2000-2001 Monitoring Program was designed to address these objectives through the implementation of three elements: land use station monitoring, mass emission station monitoring, and critical source/BMP monitoring. The County also is addressing illicit discharges through an inspection program.

LAND USE AND MASS EMISSION STATION MONITORING

Stations and Equipment

Land use stations are defined as relatively small catchments (0.1 to over 5 square miles) that have one predominant land use. The objectives of land use monitoring are to evaluate possible effects of land use on water quality, to evaluate the relative importance of land uses as pollution sources; and to provide data that can be used, along with data from mass emission stations, to project watershed pollutant loads. Data were obtained from seven land use stations during the 2000-2001 storm season: one vacant, one single family high density residential, one multiple family residential, one mixed residential, one light industrial, one transportation, and one educational. Land use stations were equipped with automatic water samplers and stage (water depth) recorders so that flow composite samples could be obtained. Grab samples were not required from land use stations.

In contrast to land use stations, mass emission stations monitor relatively large (100 to 1000 square miles) mixed land use watersheds. Runoff from five mass emissions monitoring stations was sampled during the 2000-2001 storm season. These stations cumulatively represented a total of 1619 square miles of drainage area. The Permit requires mass emission monitoring of four major drainage areas, namely: Ballona Creek, Malibu Creek, Los Angeles River, and San Gabriel River. The purpose of the mass emission monitoring is to support stormwater load estimates and to provide a basis for long term water quality trend analysis. Therefore, the

monitoring stations are located as close as practical to where the creeks and rivers enter the ocean. Mass emission stations are equipped with automated water samplers and stage recorders to collect composite stormwater samples during storm events. Grab samples were also taken at these stations in accordance with the Municipal Permit. Composite samples only were collected from one additional mass emission station (Coyote Creek) to support loadings analyses for the San Gabriel River watershed. At least six storms were sampled at all the mass emission stations during the 2000-2001 storm season, satisfying the required five storm events per station minimum under the 1996 Permit.

Hydrologic Conditions and Sampling Success

Twelve storms were sampled during the season, compared to 13 last season.

Water Quality Chemical Analysis

Monitoring in Los Angeles County in 2000-2001 was performed in compliance with the Municipal Permit issued in July 1996 which requires a broad suite of chemical analyses, including solids, minerals, bacteria, metals, organics, and nutrients. The Los Angeles County Department of Agricultural Commissioner/Weights and Measures, Environmental Toxicology Laboratory provided the water quality laboratory and related services to the Department of Public Works. The laboratory implemented a Quality Assurance/Quality Control program to ensure that the analyses conducted are scientifically valid, defensible, and of known precision and accuracy.

Water Quality Results (Mass Emission Study)

- Malibu Creek had noticeably higher median concentrations of both total and dissolved phosphorus, while the San Gabriel River has the highest median concentration of nitrate.
- The median total dissolved solids concentration in Malibu Creek is more than twice that of any other mass emission site.
- Both total and fecal coliforms exhibited higher medians in the Los Angeles River. Ballona Creek had the greatest range of results for both total and fecal coliforms as well as fecal enterococcus, while the Los Angeles River had the greatest variability for fecal streptococcus results.
- Concentrations were similar among stations for a given metal. In other words, no station appeared to be "cleaner" or "dirtier" than any other with respect to metals.
- There were several individual exceedances of water quality objectives, either of the California Toxics Rule or of the Ocean Plan (or of both), for metals; and in fact, total aluminum, total copper, dissolved copper, and total zinc each had at least one seasonal mean or median exceed an objective.

Water Quality Results (Land Use Study)

- Runoff from the vacant catchment had high pH (8.0) and high alkalinity (median of 180 mg/l), while runoff from the light industrial, transportation, mixed residential, and high

density residential stations had lower median pH values (6.9, 6.8, 6.8, and 6.8 respectively) and lower median alkalinity concentrations (26, 21, 26, and 23 mg/l respectively). The educational and multiple family residential stations fell in between these two extremes with median pH values of 7.1 and 7.3 respectively, and median alkalinities of 31 and 48 mg/l respectively.

- Median hardness concentrations are similar to the alkalinity pattern: high (200 mg/l) at the vacant station; low in the transportation (30 mg/l), mixed residential (40 mg/l), and high density residential stations (20 mg/l); and in between (55, 60, and 75 mg/l) at the educational, light industrial, and multiple family residential stations.
- TSS results overlapped substantially among the different land uses; however, the light industrial station had the highest median for TSS (199 mg/l) being more than twice as high as the next highest median (84 mg/l for transportation).
- Total and dissolved copper concentrations overlapped among the different land uses, however, the dissolved copper median for the transportation station (31.6 μg/l) was more than twice as high as the next highest median (9.0 μg/l for mixed residential). Dissolved copper generally exceeds the 3.1 μg/l California Toxics Rule guideline while both mean and median concentrations of total copper exceed the Ocean Plan guideline in the transportation, light industrial, educational high density single family residential, and mixed residential stations.
- Total lead results are fairly consistent among land uses.
- Dissolved and total zinc exhibit similar patterns; there is substantial overlap among the different land uses although the mean and median for the light industrial station is highest in each case.

Water Quality Results (Critical Source/BMP Monitoring Study)

- Total and dissolved copper medians at the fabricated metal control sites (218 µg/l and 97 µg/l, respectively) were an order of magnitude higher than those at the motor freight sites (3 and 9 µg/l respectively).
- The highest concentrations of total and dissolved lead occurred at the fabricated metal control sites (medians of 109 µg/l and 42 µg/l, respectively) while there were "no meaningful" median values for the motor freight sites.
- The highest dissolved zinc concentration was observed at the auto repair test sites (median of 229 µg/l) as compared with the auto repair control sites (median of 56 µg/l). Total zinc had a median of 299 µg/l at the fabricated metal test sites and a median of 95 µg/l at the auto repair control sites.
- Dissolved nickel had a median of 18 µg/l at the fabricated metal control sites, and the median of dissolved nickel was not meaningful at the motor freight sites.

RECOMMENDATIONS

The Permit states that if a given constituent is not detected in at least 25% of the samples taken in ten consecutive storm events then that constituent may qualify for removal from the analytical suite for the associated station. For both mass emission and land use stations several constituents met this criterion. It is recommended that these constituents be removed from the analytical suite for the associated stations.

The Permit allows the discontinuation of monitoring at a land use station for specific constituents once the event mean concentration (EMC) is derived at the 25% error rate. As mutually agreed upon with the RWQCB, it was decided to use the mean standard error as a substitute for error rate (Swamikannu, 1999). Eighty-nine station-constituent combinations met the criterion and it is recommended that monitoring be discontinued for these constituents at the associated stations.

1.1 PURPOSE

The goal of the Monitoring Program is to develop information to support effective watershed stormwater quality management programs. The purpose of these management programs is to reduce pollutants in stormwater discharges to the maximum extent practicable. The major objectives of the Monitoring Program outlined in the Municipal Permit are to:

- track water quality status, pollutant trends and pollutant loads, and identify pollutants of concern;
- monitor and assess pollutant loads from specific land uses and watershed areas;
- identify, monitor, and assess significant water quality problems related to stormwater discharges within the watershed;
- identify sources of pollutants in the stormwater runoff;
- identify and eliminate illicit discharges;
- evaluate the effectiveness of management programs, including pollutant reductions achieved by implementation of Best Management Practices (BMPs); and
- assess the impacts of stormwater runoff on receiving waters.

The Monitoring Program, developed to address these objectives, has several elements: Mass Emission runoff monitoring; Land Use runoff monitoring; and Critical Source runoff monitoring. Each element conducted in 2000-2001 is described in Section 1.3, including the Permit objectives it addressed.

1.2 REPORT ORGANIZATION

The station selection process and the stations used in the Monitoring Program are described in Section 2.1. Maps and tabular descriptions of the tributary areas of each monitored watershed are displayed as Figures 2-1 through 2-13. The field and laboratory methods used in the program are presented in Section 3. The hydrologic and water quality results of the 2000-2001 storm season monitoring are described in Section 4, and the conclusions and recommendations based on the 2000-2001 results are presented in Section 5.

Runoff hydrographs from all the monitoring stations and rainfall contour maps are presented in Appendix A. The complete water quality data for the 2000-2001 season are provided in Appendix B and Appendix C contains tables of available data from the Los Angeles Regional Water Quality Control Board of the Industrial Stormwater Sampling Program. Appendix D is a table of monitoring costs incurred, and Appendix E contains a list of people to contact for more information.

Appendices C and D, though not specifically required by the Municipal Stormwater permit, are included here in the interest of information sharing.

Los Angeles County was the primary author of this report having performed the bulk of the data and statistical analyses and writing much of the report. URS's role was primarily to compile and edit text and assist with conclusions and recommendations.

1.3 BACKGROUND

The 1994-95 storm season was the first for which stormwater monitoring was required under the 1990 Los Angeles County NPDES Municipal Stormwater Permit No. CA0061654. During the 1994-95 and 1995-96 seasons, automated and manual sampling was conducted to characterize stormwater quality and quantity in accordance with the 1990 Municipal Permit. The 1994-95 monitoring data is summarized in *Report of Stormwater Monitoring, Winter of 1994-95* (LACDPW, 1996).

The 1996-97 season was the first storm season in which stormwater monitoring was conducted under the new 1996 Municipal Permit (No. CAS614001). The Permit area is depicted in Figure 1-1. For the 1996-97 season the scope of the Monitoring Program was expanded to incorporate further data collection and new pilot studies. The one-year pilot studies, consisting of "Wide Channel" and "Low Flow" analyses, were completed and reported in the *Los Angeles County 1996-97 Stormwater Monitoring Report, July 15, 1997* (LACDPW and Woodward-Clyde, 1997).

The monitoring program, including the Mass Emission, Land Use, and Critical Source elements continued in the 1997-98, 1998-99, 1999-2000, and 2000-2001 storm seasons.

At the request of the National Resources Defense Council, this report includes the latest results (Appendix C) of the industrial stormwater permit sampling within the county.

1.3.1 Mass Emission Monitoring Program

Five mass emission-monitoring stations were utilized for the Monitoring Program during the 2000-2001 storm season. Mass emission stations capture runoff from major Los Angeles County watersheds that generally have heterogeneous land use. These stations monitor flow and have automated samplers to collect composite samples during storm events. Grab samples are also taken at these stations in accordance with the Municipal Permit. At least six storms were sampled at each mass emission site. The objectives of the mass emissions stations are to update estimated pollutant loads to the ocean and to identify long term trends in pollutant concentrations, if possible.

1.3.2 Land Use Monitoring Program

Seven land use stations were monitored during the 2000-2001 storm season. The land use monitoring program is a result of a site selection study entitled *Evaluation of Land Use Monitoring Stations* (Woodward-Clyde and Psomas and Associates, 1996). The study identified the most significant land use categories within the permit area regarding stormwater quality. The drainage area tributary to each land use monitoring station is comprised predominantly of a single land use and is relatively homogeneous. The eight land use stations that were monitored up to the 1998-99 storm season represent over 86% of all the land use within the permit area. These stations monitor flow and have automated samplers to collect flow-weighted composite stormwater samples during storm events. The major objectives of this monitoring effort are to evaluate the effects of certain land uses on water quality, to identify the relative importance of specific land uses as pollution sources, and to provide data that can be used to project watershed loads from watersheds that do not have mass emission stations.

The 12 storms of the 2000-2001 season yielded 71 land use station-events.

The retail/commercial sampling site on Pier Drain in Santa Monica (S08) was dismantled and not in use in the 1999-2000 and 2000-2001 seasons, with prior approval from the RWQCB, to accommodate construction by the City of Santa Monica of its stormwater treatment plant.

1.3.3 Critical Source/BMP Program

The Critical Source/BMP Monitoring Study was designed to analyze baseline stormwater quality and assess the effectiveness of BMP implementation for critical industries and businesses. A number of critical source industries were identified and ranked by their potential significance to stormwater quality (Woodward-Clyde, 1997) and are listed in the following table:

Industrial Category	SIC Code	Industrial Stormwater Permits*
• Wholesale trade (including scrap yards and auto dismantling)	50	Yes
• Automotive repair/parking	75	No
• Fabricated metal products (including electroplating)	34	Yes
• Motor freight (including trucking)	42	Yes
• Chemical manufacturing facilities	28	Yes
• Automotive dealers/gas stations	55	No
• Electric/gas/sanitary	49	No
• Miscellaneous manufacturing	39	Yes

* Industrial facilities requiring general industrial stormwater permits.

Each critical source industry monitoring plan involves a multi-year study of stormwater runoff from six sites (three test sites and three control sites). During the first year of each study, runoff is sampled and analyzed from five storms to establish background levels. During subsequent years, BMPs are installed at three of the six sites (test sites). BMP effectiveness is estimated from monitoring data gathered from the pooled test sites and pooled control sites during ten additional storms. A complete study plan is included in *Critical Source Selection and Monitoring Report* (Woodward-Clyde, 1997). Sites at six automotive repair shops, six auto dismantlers, six fabricated metal shops, six motor freight companies, six auto dealers, four chemical manufacturing facilities, four industrial machinery manufacturing facilities, and five rubber and plastics manufacturers were monitored during the 2000-2001 storm season.

The required minimum of 5 storms to characterize runoff were not sampled at the industrial machinery manufacturing facilities and rubber and plastics manufacturers. Therefore, additional storms will need to be monitored in 2001-2002 in order to characterize runoff.

To characterize the quality of stormwater runoff in Los Angeles County, a combination of single land use sites and large area mass emissions sites have been selected for monitoring.

2.1 SITE SELECTION

2.1.1 Mass Emission Site Selection

The Department of Public Works monitored four major drainage areas near their outfalls to the ocean. Four of the mass emission monitoring stations installed under the original 1990 Permit were retained under the 1996 Permit; specifically the Los Angeles River, San Gabriel River, Ballona Creek, and Malibu Creek. The Coyote Creek mass emission station, which was required under the 1990 Permit but not under the 1996 Permit, was also monitored during the 2000-2001 season. This station was retained in the program to provide data for the calculation of mass loading in the San Gabriel River watershed. The five mass emission monitoring stations were used to collect water quality data from over 1619 square miles and have produced the data used to calculate total loading to the ocean from these watersheds.

For mass emission sites, the Permit requires sampling a minimum of five events per station per year. These sampling events may be either dry weather or wet weather events.

2.1.2 Land Use Site Selection

The following is a brief summary of the land use site selection process completed between the spring and fall of 1996. The complete methods and results of this study are provided in *Evaluation of Land Use Monitoring Stations* (Woodward-Clyde and Psomas and Associates, 1996).

An initial list of 104 land use types based on the Southern California Association of Governments (SCAG) database was sorted into 37 categories. Of these, the top 12 urban uses based on total area were chosen for a field survey. The survey was performed to identify characteristics that would assist in the aggregation or subdivision of the 12 top land use categories. For each of the 12 land uses, 8 representative areas no larger than a city block were selected for the field survey during the spring of 1996. One issue investigated in the field surveys was whether the age of a development of high density single family residential areas warranted additional monitoring sites. However, the survey indicated that there were no apparent differences between the five different age categories for high density single-family residential land use so this land use was considered one category.

A loading model for all land uses was applied for four constituents (copper, phosphorus, COD, and TSS). The model used local and regional field-derived estimates of imperviousness and water quality. For each constituent, the land use categories were ranked by total loading. A marginal benefit analysis was applied to the ranked land uses to determine the most important for monitoring. The top land use types that ranked above or equal to the land use with the maximum marginal benefit were identified for monitoring. They were:

- Vacant
- High Density Single Family Residential (HDSFR)
- Light Industrial

- Transportation
- Retail/Commercial
- Multifamily Residential
- Educational Facilities

The first 5 of the 7 land use types listed above (Vacant, High Density Single Family Residential, Light Industrial, Transportation, and Retail/Commercial) were already being monitored under the 1990 Municipal Permit. To comply with the terms of the 1996 Permit, one site for each of these land uses was retained for continued sampling; the remaining sites were dismantled. New stations to monitor the last two land use types, Multifamily Residential and Educational Facilities, were installed in February 1997 and were operational for the 1997-98, 1998-99, 1999-2000, and 2000-2001 storm seasons.

In addition to the pollutant loading analysis, land uses were also ranked by total area within each of the six major Los Angeles County watershed management areas. Four land use types not already on the list were then identified as having significant area in one or more of the watersheds (i.e., ranking in the top five land uses), as follows:

- Heavy Industrial
- Rural Residential
- Utility Facilities
- Mixed Residential

On the basis of this analysis, one mixed residential land use station was installed in October 1997 and was operational for the 1997-98, 1998-99, 1999-2000, and 2000-2001 storm seasons; seven land use monitoring stations were operational during the 2000-2001 season. The retail/commercial sampling site on Pier Drain in Santa Monica (S08) was dismantled and not in used in either the 1999-2000 or 2000-2001 season, with prior approval from the RWQCB, to accommodate construction by the City of Santa Monica of its stormwater treatment plant.

2.1.3 Critical Source Site Selection

The following is a brief summary of the Critical Source selection process undertaken to identify industrial and/or commercial critical source categories/types to be monitored. Each selected critical source type is to be monitored for a minimum of two years, the first year without BMPs, and subsequent years with BMPs. The complete site selection methods and results of this study are provided in *Critical Source Selection and Monitoring Report* (Woodward-Clyde, 1997).

Similar to the land use monitoring evaluation process, the County undertook a five-step process to identify and prioritize a list of critical industries within the county that may contribute significant pollutants to stormwater runoff. Standard Industrial Classification (SIC) codes played a major role in the selection process. Once selected, appropriate sites would be monitored over a minimum two-year period for the duration of the permit to measure runoff quality with and without remedial cleanup actions. These remedial actions are referred to as Best Management Practices, or BMPs.

The first step was to develop an initial list of candidate industries. This list contained industries both included and excluded under the State's General Industrial Activities Stormwater permit process. Initial candidate selection was based on prevalence in the county and the extent of outdoor activities. The resulting list yielded a group of 30 candidate industries ranked by the number of facilities.

The next step involved developing a set of criteria to prioritize the list. A number of empirical factors were used to assign levels of significance to each SIC category. Loading (Q) would be addressed by the number of sources at a site and the likelihood of release. Imperviousness (R) of a site would be represented by the percent of paved area. Pollutant toxicity (T) would be denoted by the number of toxic pollutants and the inherent toxicity of the mix. An exposure factor (E) signifies if activities are exposed to rainfall. And finally, number (N) would represent the total number of sites in the county. Each variable would be assigned a qualitative number from 1 to 10, with 10 representing the worst condition. The pollutant potential (P) used to rank the results would thus be the product of all the factors, or

$$P = Q \times R \times T \times E \times N$$

Based on this ranking scheme, some "critical source" industries are selected to be monitored as follows:

- Wholesale Trade (scrap and auto dismantling)
- Automotive Repair/Parking
- Fabricated Metal Products
- Motor Freight
- Automobile Dealers
- Chemical Manufacturing
- Electric/Gas/Sanitary
- Miscellaneous Manufacturing.

A literature search was simultaneously conducted to identify what "critical source" industries, if any, have already been analyzed. The search revealed that similar stormwater studies had yet to be performed.

After the identification and prioritization, the Department then had the task of finding six companies out of the selected critical source industries to enlist for monitoring runoff from five storms during the 1996-97 storm season. However, all six companies could not be enlisted until the end of that storm season, too late for the collection of runoff data. In 1997-98, twelve companies from two industries, automobile repair and auto dismantling, were enlisted. In the 1998-99 storm season, six companies from the metal fabrication industry were added. In the 1999-2000 storm season, nine of the eighteen companies from the automotive repair, auto dismantling, and metal fabrication industries were fitted with BMPs at the Department's expense. The remaining nine companies remained as control sites in order to evaluate BMP

effectiveness. Twelve companies from two industries, motor freight and automobile dealerships were added to the monitoring program in the 1999-2000 storm season.

Of the twelve companies from the motor freight and automobile dealership industries, six were fitted with BMPs in the 2000-2001 storm season. The remaining six companies remained as control sites for evaluating BMP effectiveness. In addition, 13 companies from three industries, chemical manufacturing, industrial machinery manufacturing, rubber/miscellaneous plastics manufacturing were added to the monitoring program in the 2000-2001 storm season. Sampling will continue into the sixth year of monitoring until the eight critical source industries and remedial BMPs are tested and evaluated.

2.2 LOCATION AND DRAINAGE AREA DESCRIPTIONS

Figure 2-1 is an overview of the study area with all mass emission and land use monitoring sites shown. Table 2-1 also indicates the dominant land use associated with each monitoring site and the total drainage area.

2.2.1 Mass Emission Monitoring Sites

Provided below is a description of the four mass emission stations required by the 1996 Municipal Permit (Ballona Creek, Malibu Creek, Los Angeles River, and San Gabriel River) and one additional mass emission station (Coyote Creek) which is not specifically required. Figures 2-2 through 2-6 show the location of each monitoring station along with a description of its land use and 1990 population.

Ballona Creek Monitoring Station (S01)

The Ballona Creek monitoring station is located at the existing stream gage station (Stream Gage No. F38C-R) between Sawtelle Boulevard and Sepulveda Boulevard in the City of Los Angeles. At this location, which was chosen to avoid tidal influences, the upstream tributary watershed of Ballona Creek is 88.8 square miles. The entire Ballona Creek Watershed is 211.6 square miles. At the gauging station, Ballona Creek is a concrete lined trapezoidal channel.

Malibu Creek Monitoring Station (S02)

The Malibu Creek monitoring station is located at the existing stream gage station (Stream Gage No. F130-9-R) near Malibu Canyon Road, south of Piuma Road. At this location, the tributary watershed to Malibu Creek is 104.9 square miles. The entire Malibu Creek Watershed is 202.9 square miles.

Los Angeles River Monitoring Station (S10)

The Los Angeles River Monitoring Station is located at the existing stream gage station (Stream Gage No. F319-R) between Willow Street and Wardlow Road in the City of Long Beach. At this location, which was chosen to avoid tidal influences, the total upstream tributary drainage area for the Los Angeles River is 822.5 square miles. This river is the largest watershed outlet to the Pacific Ocean in Los Angeles County. At the site, the river is a concrete lined trapezoidal channel.

San Gabriel River Monitoring Station (S14)

The San Gabriel River Monitoring Station is located at an historic stream gage station (Stream Gage No. F263C-R), below San Gabriel River Parkway in Pico Rivera. At this location the upstream tributary area is 450.6 square miles. The San Gabriel River, at the gauging station, is a grouted rock-concrete stabilizer along the western levee and a natural section on the eastern side. Flow measurement and water sampling are conducted in the grouted rock area along the western levee of the river. The length of the concrete stabilizer is nearly 70 feet. The San Gabriel River sampling location has been an active stream gauging station since 1968.

Coyote Creek Monitoring Station (S13)

The Coyote Creek Monitoring Station is located at the existing ACOE stream gage station (Stream Gage No. F354-R) below Spring Street in the lower San Gabriel River watershed. Although this site is not required for monitoring per the NPDES Permit, the site was added to assist in determining mass loading for the San Gabriel River watershed. At this location, the upstream tributary area is 148.6 square miles (extending into Orange County). The sampling site was chosen to avoid backwater effects from the San Gabriel River. Coyote Creek, at the gauging station, is a concrete lined trapezoidal channel. The Coyote Creek sampling location has been an active stream gauging station since 1963.

2.2.2 Land Use Monitoring Sites

The following is a description of the locations selected to monitor runoff from land-use specific drainage areas. Figures 2-7 through 2-13 show the location and drainage area of each monitoring station along with a description of its land use and 1990 population.

Sawpit Creek Monitoring Station (S11)

The Sawpit Creek Monitoring Station is located in the Los Angeles River Watershed in the City of Monrovia. The monitoring station is in Sawpit Creek, downstream of Monrovia Creek. Sawpit Creek is a natural watercourse at this location. The overall watershed land use is predominantly vacant.

Project 620 Monitoring Station (S18)

The Project 620 Monitoring Station is located in the Los Angeles River Watershed in the City of Glendale. The monitoring station is at the intersection of Glenwood Road and Cleveland Avenue. The overall watershed land use is predominantly high density residential.

Dominguez Channel Monitoring Station (S23)

The Dominguez Channel Monitoring Station is located within the Dominguez Channel/ Los Angeles Harbor Watershed in Lennox, near Los Angeles International Airport (LAX). The monitoring station is near the intersection of 116th Street and Isis Avenue. The overall watershed land use is predominantly transportation, and includes areas of LAX and Interstate 105.

Project 1202 Monitoring Station (S24)

The Project 1202 Monitoring Station is located in the Dominguez Channel/Los Angeles Harbor Watershed in the City of Carson. The monitoring station is near the intersection of Wilmington Avenue and 220th Street. The overall watershed land use is predominantly industrial.

Project 474 Monitoring Station (S25)

The Project 474 Monitoring Station is located in the Los Angeles River Watershed in the Northridge section of the City of Los Angeles. The monitoring station is located along Lindley Avenue, one block south of Nordhoff Street. The station monitors runoff from the California State University of Northridge. The land use of the drainage area is primarily education.

Project 404 Monitoring Station (S26)

The Project 404 Monitoring Station is located within the Los Angeles River Watershed in the City of Arcadia. The monitoring station is located along Duarte Road, between Holly Avenue and La Cadena Avenue. The land use of the drainage area is primarily multi-family residential.

Project 156 Monitoring Station (S27)

The Project 156 Monitoring Station is located within the Los Angeles Watershed in the City of Glendale. The monitoring station is located along Wilson Avenue, near the intersection of Concord Street and Wilson Avenue. The land use of the drainage area is classified as mixed residential.

2.2.3 Critical Source Monitoring Sites

The general locations of the critical source monitoring sites are shown in Figure 2-14. For purposes of anonymity, the agreement reached with each of the businesses prohibits us from revealing the exact locations.

Sites C01, C02, and C03 are the control sites for the wholesale trade (auto dismantlers); T01, T02, and T03 are the sites where Best Management Practices (BMPs) have been installed for the wholesale trade industry. Similarly, C04, C05, and C06 are the control sites for automotive repair, while T04, T05, and T06 are the sites where the BMPs were installed for the automotive repair industry. Sites C07, C08, and C09 are the control sites for fabricated metal products industry; T07, T08, and T09 are the sites where BMPs were installed for the fabricated metal products industry. Sites C10, C11, and C12 are the control sites for motor freight companies; T10, T11, and T12 are the sites where the BMPs were installed for the motor freight companies. Sites C13, C14, and C15 are the control sites for auto dealership industry; T13, T14, and T15 are the sites where the BMPs were installed for the auto dealership industry.

During the 2000-2001 season, three new industries were added as follows: C16 and C17 are the control sites for chemical manufacturing industry; T16 and T17 are the BMPs sites for the chemical manufacturing industry. Sites C19 and C20 are the control sites for the industrial machinery manufacturing companies, while T19 and T20 are the BMPs sites for the industrial machinery manufacturing companies. Sites C22 and C23 are the control sites for the rubber and

miscellaneous plastics industry; T22, T23 and T24 are the BMPs sites for the rubber and miscellaneous plastics industry.

R0012356

This section describes the field and laboratory methods used to conduct the Monitoring Program, which includes precipitation and flow monitoring, stormwater sampling, and laboratory analyses.

3.1 PRECIPITATION AND FLOW MEASUREMENT

3.1.1 Precipitation Monitoring

For every monitoring station, a minimum of one automatic tipping bucket (intensity measuring) rain gage is located nearby or within the tributary watershed. Large watersheds may require multiple rain gages to accurately characterize the rainfall. The Los Angeles County Department of Public Works operates various automatic rain gages throughout the county. Existing gages near the monitored watersheds are also utilized in calculating stormwater runoff and are essential to develop runoff characteristics for these watersheds.

3.1.2 Flow Monitoring

Flow monitoring equipment is needed to trigger the automated samplers because the Monitoring Program requires flow-weighted composites for many constituents. Flows are determined from measurements of water elevation as described below.

The water elevation in a storm drain is measured by the stage monitoring equipment, and the flow rate is derived from a previously established rating table for the site or calculated with an equation such as Manning's. The Los Angeles County Department of Public Works uses rating tables generated from analysis of storm drain cross sections and upstream/downstream flow characteristics. The rating tables are modified if it is demonstrated in the field through stream velocity measurements that calculated table values are incorrect. Previous stormwater flow measurement efforts indicates that all stations will require multiple storm events to gather the data necessary for calibration of the measurement devices.

The automatic samplers utilize pressure transducers as the stage measurement device. However, pressure transducers are only accurate as flow measurement devices in open channel flow regimes. Therefore, for stations monitoring flows in underground storm drains, efforts were made to select drains that do not surcharge (flow under pressure) during events smaller than a 10-year storm event.

3.2 STORMWATER SAMPLING

3.2.1 Sample Collection Methods

Grab and composite sample collection methods, defined below, were used during the 2000-2001 storm season.

- **Grab Sample** - a discrete, individual sample taken within a short period of time, usually less than 15 minutes. This method is used to collect samples for constituents that have very short holding times and specific collection or preservation needs. For example, samples for coliforms are taken directly into a sterile container to avoid non-resident bacterial contamination.

- **Composite Sample** - a mixed or combined sample created by combining a series of discrete samples (aliquots) of specific volume, collected at specific flow-volume intervals. Composite sampling is ideally conducted over the duration of the storm event.

During a storm event, grab samples were collected during the initial portion of the storm (on the rising limb of the hydrograph) and taken directly to the laboratory.

Flow composite storm samples were obtained using an automated sampler to collect samples at flow-paced intervals. Samples collected at each station were combined in the laboratory to create a single flow-weighted sample for analysis.

During the storm season, the sampler was programmed to start automatically when the water level in the channel or storm drain exceeded the maximum annual dry weather stage. A sample was collected each time a set volume of water had passed the monitoring point (this volume is referred to as the pacing volume or trigger volume). The sample was stored in glass containers within the refrigerated sampler. A minimum of eight liters of sample was required to conduct the necessary laboratory analyses for all the constituents. The automated sampler was deactivated by field personnel when the water level in the channel or storm drain fell to about 120 percent of the observed maximum annual dry weather flow stage.

Samples were retrieved from the automated samplers as soon as possible to meet laboratory analysis holding time requirements. As samples were collected, rainfall and runoff data were logged and stored for transfer to the office.

3.2.2 Field Quality Assurance/Quality Control Plan

Properly performed monitoring station set up, water sample collection, sample transport, and laboratory analyses are vital to the collection of accurate data. Quality Assurance/Quality Control (QA/QC) is an essential component of the monitoring program.

Evaluation of Analytes and QA/QC Specifications for Monitoring Program (Woodward-Clyde, 1996a) describes the procedures used for bottle labeling, chain-of-custody tracking, sampler equipment checkout and setup, sample collection, field blanks to assess field contamination, field duplicate samples, and transportation to the laboratory.

An important part of the QA/QC Plan is the continued education of all field personnel. Field personnel were adequately trained from the onset and informed about new information on stormwater sampling techniques on a continuing basis. Field personnel also evaluate the field activities required by the QA/QC Plan, and the Plan is updated if necessary.

Bottle Preparation

For each monitoring station, a minimum of three sets of bottles was available so that up to two complete bottle change-outs could be made for each storm event. Bottle labels contained the following information:

- LADPW Sample ID Number
- Station Number
- Station Name

- Sample Type (Grab or Composite)
- Laboratory Analysis Requested
- Date
- Time
- Preservative
- Temperature
- Sampler's Name

Bottles were cleaned at the laboratory prior to use, then they were labeled and stored in sets. Each station was provided with the same number, types, and volumes of bottles for each rotation unless special grab samples were required. Clean composite sample bottles were placed in the automated sampler when samples were collected. This practice ensured readiness for the next storm event. All bottles currently not in use were stored and later transported in plastic ice chests. Composite sample bottles were limited to a maximum of 2-1/2 gallons each, to ensure ease of handling.

Chain-of-Custody Procedure

Chain-of-custody forms were completed to ensure and document sample integrity. These procedures establish a written record which tracks sample possession from collection through analysis.

Field Setup Procedures

All field sampling locations were fixed sites, with the sampler placed on a public road or flood control right-of-way. After sample collection, field staff prepared the sampler for collection of the next set of samples either in storm mode or in dry weather mode. Inspection of visible hoses and cables was performed to ensure proper working conditions according to the site design. Inspection of the strainer, pressure transducer, and auxiliary pump was performed during daylight hours in non-storm conditions.

The automated sampler was checked at the beginning of the storm (during grab sample collection) to ensure proper working condition and to see if flow composite samples were being collected properly. Dry weather collection techniques were similar, with grab and 24-hour composite samples being collected.

Bottles were collected after each event and packed with ice and foam insulation inside individually marked ice chests. Chain-of-custody forms were completed by field staff before transportation of the samples to the laboratory. Under no circumstance were samples removed from the ice chest during transportation from the field to the laboratory.

Travel Blanks and Field Duplicates

Potential field contamination was assessed through analysis of travel blanks and duplicate grab samples. Field travel blanks were collected for each monitoring station during every sampling event to quantify post sampling contamination. The monitoring program also included field

duplicates to assess the precision of laboratory results. A field duplicate, the origin of which was unknown to the laboratory, was collected for each sampling event. This methodology for assessing post sampling contamination and laboratory testing procedures provided data to measure the precision and accuracy of the laboratory results.

3.2.3 Sampling Frequency

During the 2000-2001 storm season, the Permit required the Department to sample up to 200 "station events" for the land use sites. A station event is defined as collection of one sample at one station. The Municipal Permit specifies sampling at mass emission stations to total five events per year during dry weather, storm, or a combination of both.

3.3 LABORATORY ANALYSES

The Department of Agricultural Commissioner/Weights and Measures (ACWM) Environmental Toxicology Laboratory provides water quality laboratory and related services to the LACDPW. The ACWM lab is state certified to perform the water quality analyses contracted by LACDPW. The ACWM Lab maintains a laboratory analysis program that includes Quality Assurance and Quality Control protocols consistent with the objectives of the monitoring program required by the Permit (Section 3.3.3).

3.3.1 Possible Constituents of Concern

Possible constituents of concern for each element of the Monitoring Program are specified in the Municipal Permit. The constituents of concern for land use station monitoring are:

- Total Suspended Solids
- Total Nitrogen
- Total Phosphorus
- Cadmium
- Chromium
- Copper
- Lead
- Mercury
- Nickel
- Selenium
- Silver
- Zinc
- Chlordane
- Chlorpyrifos
- Diazinon
- Malathion
- Simazine
- Total DDT
- Total PAHs
- Total PCBs

Constituents of concern for mass emission monitoring include those listed above plus:

- Bacteria
- Total Phenols
- TPH
- Oil and Grease
- Cyanide

3.3.2 Analytical Suite and Analytical Methods

The suite of analytes and associated detection limits for samples collected at the land use stations and mass emission stations are specified in the Municipal Permit. Constituents of concern for derivation of event mean concentrations are also specified by the Permit. All the laboratory methods used for analysis of the stormwater samples are approved by the California Department of Health Services and are in conformance with USEPA approved methods.

Table 3-1 shows all the constituents monitored during the 2000-2001 season at the mass emissions and land use stations, including constituents analyzed with composite or grab samples. The table lists the method number, the detecting limit, the data quality objectives, and other relevant information for each constituent. The table also shows which constituents were monitored at the land use sites versus the mass emission sites. It should be noted that detection limits of many semi-volatile organic compounds (SVOCs) were lowered, including all PAHs, for the land use and mass emission studies at the request of the Los Angeles Regional Water Quality Control Board.

Analyses of constituents in samples collected for the Critical Source/BMP Monitoring Study were performed using the methods and reporting limits given in Table 3-2.

The laboratory made an effort to provide the lowest detection limits attainable without compromising the reliability of the data. "Detection limit" (DL) is defined by the USEPA as "the concentration above which we are 99% confident that the analyte is present at a concentration greater than zero" (40 CFR Part 136 Appendix B). For this project the laboratory made some allowance for interference in the analysis due to the complex nature of the sample matrix by performing a DL study using a water sample collected from a channel during dry weather. These 'matrix specific' DLs are the reported DLs in the data tables. Data below the DL are reported as zero. The Practical Quantitation Limit (PQL) is the concentration above which the analyte can be accurately quantified. Reported PQLs were developed by the laboratory during the analysis of stormwater runoff samples using professional judgment to account for matrix interferences. Data that fall between the DL and PQL are reported by the laboratory at the apparent concentrations. When reviewing these data it should be noted that the concentrations below the PQL are estimated.

3.3.3 Quality Assurance and Quality Control

The primary objective of the laboratory quality assurance/quality control program is to ensure that the analyses are scientifically valid, defensible, and of known precision and accuracy. The ACWM laboratory maintains quality assurance/quality control procedures (as described in their Quality Assurance Manual) in accordance with requirements of the California Department of Health Services. The ACWM laboratory standard operation procedures include method validation, equipment calibration, preventive maintenance, data validation procedures,

assessment of accuracy and precision, corrective actions, and performance and system audits. The QA/QC review and data validation for the 2000-2001 monitoring data was conducted by ACWM Lab, and the QA/QC documentation is available within the ACWM Lab files. The validated data as provided by the ACWM Lab were used for data analysis and interpretation with no further QA/QC review.

R0012362

4.1 HYDROLOGY: PRECIPITATION AND FLOW

Total annual rainfall during the 2000-2001 storm season in LA County was just below normal. The long term average annual rainfall at Station # 716, Ducommun Street in downtown Los Angeles is about 15.60 inches. For water year (WY) 2000-2001 the total rainfall from October 2000 through May 2001 was about 15.09 inches.

Figures 4-1a and 4-1b show the rainfall pattern for WY 2000-2001 compared to the long term pattern of rainfall. About 78% of the annual total fell during the month of January. This is reflected by the timing of the storms that were monitored. Seven of the 12 storms monitored occurred in January and February. The months of November and December were practically dry this season while February had more than twice the amount of rainfall compared to the long term average for that month.

Table 4-1 summarizes the hydrologic and meteorologic conditions of each station-event monitored this season. Table 4-2 summarizes total precipitation and runoff volume for each station on a seasonal basis from 1994 through 2001. These data will help define hydrologic and water quality trends after subsequent years of data are compiled. A collection of 2000-2001 season hydrographs for each storm event from the monitored sites and rainfall contour maps is included in Appendix A. Each hydrograph includes the time of grab sample collection when applicable, the time of the first and last composite sample aliquot collection, the number of aliquots per composite, the sample volume interval, and the percent of storm sampled.

Also included in Appendix A are contour maps of total rainfall for the 2000-2001 storm season. The dates given as "Storm Event Date" are the dates each storm began.

4.2 STORMWATER QUALITY

A summary of the composite and grab samples taken during the 2000-2001 season is included as Table 4-3.

4.2.1 Determination of Constituents of Concern for Analysis

The County analyzes for some 209 individual water quality constituents, the results of which are included in Appendix B. But while the Municipal Stormwater permit lists 25 of them as constituents of concern, some constituents were not detected or were detected at levels below a number of common water quality guidelines. Therefore, a comparison was made between mass emission water quality results and the water quality objectives outlined in the Ocean Plan, Basin Plan, and California Toxics Rule. If either the mean or median concentration of a constituent from mass emission sampling exceeded the objective, it was selected for further analysis. The 2000-2001 mass emission results were compared with the standards in Table 4-4a, while information about each site is included in Table 4-4b. A comparison was made of the 1994-2001 water quality concentrations, and 17 pollutants were identified (see Table 4-4c). A complete description of the comparison study is included in *Los Angeles County 1994-2000 Integrated Stormwater Monitoring Report* (Los Angeles County Department of Public Works). Thirteen additional constituents (total suspended solids, diazinon, chlorpyrifos, total coliform, fecal coliform, fecal streptococcus, fecal enterococcus, dissolved phosphorus, total phosphorus, ammonia nitrogen, nitrate nitrogen, nitrite nitrogen and TKN, which may have not exceeded

standards or did not have standards defined) were also included. The constituents used for analysis are:

- Total Aluminum
- Dissolved Cadmium
- Dissolved Copper
- Total Copper
- Dissolved Nickel
- Total Nickel
- Dissolved Lead
- Total Lead
- Total Mercury
- Dissolved Zinc
- Total Zinc
- Total Suspended Solids
- Total Dissolved Solids
- Total Kjeldalh Nitrogen
- Ammonia
- Cyanide
- Turbidity
- Diazinon
- Chlorpyrifos
- Dissolved Phosphorus
- Total Phosphorus
- Total Coliform
- Fecal Coliform
- Fecal Streptococcus
- Fecal Enterococcus
- Bis(2-ethylhexyl)phthalate
- Phenanthrene
- Pyrene
- Nitrate
- Nitrite

The above 30 constituents of concern were used in developing the percentile distribution (box and whisker) graphs, bacteria count trend analysis, and pollutant loading estimations.

There are no numerical effluent standards that apply to stormwater pollution. Current federal and state numeric effluent standards apply only to "point source pollution," such as sanitary sewage, industrial and commercial discharges to the ocean, and other waterbodies. Water quality standards described in the 1995 Los Angeles Region Basin Plan or the 1997 California Ocean Plan do not apply to stormwater runoff, and any exceedance of values should not indicate violation or noncompliance with the plans. The 2000 California Toxics Rule is, strictly speaking, applicable to industrial and sewage treatment plant point-source discharges, but not to stormwater runoff discharges, which do not have any effluent limits. Furthermore, a direct comparison of the sampling results with the Ocean Plan standards cannot be made since the results presented in the tables are detected values before dilution, a factor allowed by the Ocean Plan. At the same time, however, it should be noted that new stormwater permits are including the narrative guidelines and limitations prescribed in the local Basin Plans.

4.2.2 Mass Emission Element

The NPDES Municipal Stormwater Permit mandates that the County monitor the quality of its stormwater discharges and create various programs for managing and improving stormwater runoff quality. The permit specifically requires the County to assess the pollutant loading from all six of its Watershed Management Areas following the 2000-2001 storm season.

4.2.2.1 GIS Model

To assist in implementing this requirement, the Department developed a GIS application called the Pollutant Loading Model.

The Pollutant Loading application computes total pollutant loading for selected pollutants originating in user-defined watersheds or political boundaries. It draws upon many existing data sources, such as predetermined drainage subbasins, land use, historical and event rainfall data, water quality monitoring station results, and multiple underlying geographic data including political boundaries, natural boundaries, census tracts, forest boundaries, streets, and drains.

Assumptions and Limitations

- An imperviousness value used for the calculations is associated with 104 different land use categories.
- The 104 SCAG land use categories have been aggregated into 34 categories covering 100% of the County.
- Water quality data collected from 8 different land use monitoring stations yields Event Mean Concentration (EMC) values. The remaining land use categories (34-8 = 26) use assumed EMC values based on their association with the 8 monitored land use types.
- All polygons of the same land use type are assumed to have the same EMC value regardless of their spatial location within the county.
- Annual pollutant loadings use previously calculated seasonal EMCs for their calculation.
- Rainfall grid cell sizes are 500 feet by 500 feet. Rainfall depth does not vary within the grid cell.
- The model does not account for variation over time in soil permeability which influences surface runoff in undeveloped watersheds. In other words, a given coefficient of discharge for a particular land use type will not change regardless of previous soil conditions (saturated soil versus dry soil)

The model does not take into account possible degradation or adsorption of the pollutant as it is transported downstream. These results therefore should not be taken as absolute; rather, they should be used for unmonitored watersheds or smaller portions of monitored watersheds for comparative purposes only.

4.2.2.2 Mass Emission Water Quality

This section provides a description of wet-weather results generated during the 2000-2001 monitoring season (Figures 4-2a through 4-2u). The figures present several panels, one for each parameter, with a series of box and whisker plots, one for each constituent. This box and whisker presentation of the data provides information on the distribution and variability of each data set. It shows the median, mean, 25 and 75 percentiles, 10 and 90 percentiles, as well as the 5 and 95 percentiles. Common water quality objectives for each parameter are also provided where available.

The criteria and conventions used in generation of these statistics are as follows:

- Only datasets that had at least 20% "detections" (positive result, with value above the method detection limit), and at least three "detections", were included;
- For data sets that met the selection criteria, if a parameter was a "non-detect", i.e., under the method detection limit, it was included in the dataset as half the method detection limit.

Thus, absence of a plot for a specific station for a given parameter may indicate that the dataset did not meet the selection criteria. However, in some situations it may indicate lack of data (due to logistical constraints related to sampling activities). The reader is referred to Table 4-3 for data inventory information.

All data for mass emission stations are presented in Appendix B.

- Malibu Creek had noticeably higher median concentrations of both total and dissolved phosphorus, while the San Gabriel River has the highest median concentration of nitrate.
- The median total dissolved solids concentration in Malibu Creek is more than twice that of any other mass emission sites.
- Both total and fecal coliforms exhibited higher medians in the Los Angeles River. Ballona Creek had the greatest range of results for both total and fecal coliforms as well as fecal enterococcus, while the Los Angeles River had the greatest variablilty for fecal streptococcus results. Please see Table 4-5 and Figures 4-3a through 4-3d for bacteria counts from 1994-2001.
- Concentrations were similar among stations for a given metal. In other words, no station appeared to be "cleaner" or "dirtier" than any other with respect to metals.
- There were several individual exceedances of water quality objectives, either of the California Toxics Rule or of the Ocean Plan (or of both), for metals; and in fact, total aluminum, total copper, dissolved copper, and total zinc each had at least one seasonal mean or median exceed an objective.

The Permit states that if a given constituent is not detected in at least 25% of the samples taken in ten consecutive storm events at a given station then that constituent may qualify for removal from the analytical suite for the associated station. Several mass emission stations meet this criterion and are summarized in Table 4-6. It is recommended that these constituents be removed from the analytical suite for the associated stations.

4.2.2.3 Loadings for Constituents of Concern for 2000-2001 Storm Season

Derivation of Event Mean Concentrations

Section B.4 of Attachment C of the Municipal Stormwater Permit (CAS614001) requires the County to "perform a loads assessment analysis for each of the six Watershed Management Areas to determine pollutant loads entering the ocean from receiving waters in the county . . . using the collected monitoring data from the land use and mass emission stations . . . and employing the USEPA simplified model". The work plan for this assessment, submitted to the Regional Board on November 6, 1997, was described in detail in *Monitoring Task Report No. 2* (Woodward-Clyde, December 9, 1996b). Loads from monitored mass emission watersheds have been calculated from observed mass emission mean concentrations and runoff volumes. Loads

R0012366

from unmonitored watersheds have been estimated using the GIS loading model with mean concentrations derived from the land use monitoring program. Following is a brief explanation of how event mean concentrations were calculated.

The event mean concentration is based on flow-weighted composited samples. Numerous data sets were created comprised of laboratory results from each monitoring station for a given season. Data were screened and analyzed to determine the quality and amount of data present. The following criteria were applied:

- at least 20% of the sample results were detected concentrations;
- there were at least 3 detected sample concentrations.

If the set of data did not meet these criteria, it was not used to calculate an event mean concentration. If sufficient data existed to conduct the statistical analysis, two methods were followed to address non-detects.

Initially, the Hazen robust method was used to calculate land use EMCs. The robust method uses a combination of regression and probability analysis to determine the "assumed" concentration to assign to samples with concentrations below the method detection limit. The "assumed" concentration is the point along a probability distribution regression line (derived from detected data) where true concentrations of non-detected data have the highest probability of residing. Each non-detect result was assigned the value of the detection limit and ranked along with the other detected results in the data set. The cumulative frequency data were plotted on a logarithmic plot and a straight line regression was fitted to the points. The mean, m, and variance, σ^2, of the natural logarithm of each point of the data set were used to calculate the event mean concentration. The event mean concentration, which the loading model multiplies by the volume of the event runoff to develop total loading, is defined as follows:

$$\text{Event Mean Concentration} = \exp(m + 0.5\sigma^2).$$

In order to reduce analysis time, another method, which has been successfully implemented by other agencies, was also used to calculate EMCs for the mass emission water quality data. That second method assigned a value of half the detection limit to each non-detect result. The resulting data set of concentrations was analyzed as described above to develop the mass emission EMCs. A comparison of the two methods showed that differences between EMCs developed from the same data set were insignificant in most cases; therefore, the second method assumed a valid approach.

The calculated EMCs are summarized in Table 4-7 for specific land uses. These EMCs were used to estimate loadings for several watersheds.

The loadings calculated for the monitored watersheds are summarized in Tables 4-8a through 4-8e and Figures 4-4a through 4-10.

The locations of unmonitored watersheds are shown in Figures 4-11 through 4-13. The loadings calculated for the unmonitored watersheds are summarized in Tables 4-9a through 4-9c and Figures 4-14 through 4-16.

R0012367

4.2.3 Land Use Element

The land use element monitoring results for the 2000-2001 season are summarized in Table 4-10. This table includes the number of samples analyzed and the percentage of samples that had detectable concentrations, as well as summary statistics (the mean, median, and coefficient of variation (CV)). Box and whisker plots for several constituents are included as Figures 4-17a through 4-17v for the 2000-2001 season. This "box-and whisker" presentation of the data provides information on the distribution and variability of each data set. It shows the median, mean, 25 and 75 percentiles, 10 and 90 percentiles, as well as the 5 and 95 percentiles. Common water quality objectives for each parameter are also provided where available.

The criteria and conventions used in generation of these statistics are as follows:

- Only datasets that had at least 20% "detections" (positive result, with value above the method detection limit), and at least three "detections", were included;
- For data sets that met the selection criteria, if a parameter was a "non-detect", i.e., under the method detection limit, it was included in the dataset as half the method detection limit.

All data for land use monitoring stations are presented in Appendix B.

Thus, absence of a plot for a specific station for a given parameter may indicate that the dataset did not meet the selection criteria. However, in some situations it may indicate lack of data (due to logistical constraints related to sampling activities). The reader is referred to Table 4-3 and to the summary tables for data inventory information.

The median pH values were visibly different between catchment types, and this trend is also reflected in the median concentrations of bicarbonate. Runoff from the vacant catchment had high pH (8.0) and high alkalinity (median of 180 mg/l), while runoff from the light industrial, transportation, mixed residential, and high density residential stations had lower median pH values (6.9, 6.8, 6.8, and 6.8 respectively) and lower median alkalinity concentrations (26, 21, 26, and 23 mg/l respectively). The educational and multiple family residential stations fell in between these two extremes with median pH values of 7.1 and 7.3 respectively, and median alkalinities of 31 and 48 mg/l respectively.

Hardness is also an important variable of water quality because it diminishes the potential of dissolved metals to cause toxicity to aquatic life. Median hardness concentrations are similar to the alkalinity pattern: high (200 mg/l) at the vacant station; low in the transportation (30 mg/l), mixed residential (40 mg/l), and high density residential stations (20 mg/l); and in between (55, 60, and 75 mg/l) at the educational, light industrial, and multiple family residential stations.

Total suspended solids (TSS) measurements reflect the amount of sediment in the water. Sediment is a constituent of concern because of the potential to adversely affect the aquatic habitat and also cause sediment accumulation that ultimately may require dredging. Sediment also may be a carrier of other chemicals that have a tendency to adsorb to particulate matter. TSS results overlapped substantially among the different land uses; however, the light industrial station had the highest median for TSS (199 mg/l) being more than twice as high as the next highest median (84 mg/l for transportation).

Metals in stormwater runoff can be of concern because some metals are toxic to aquatic organisms and some can bio-accumulate in the tissues of aquatic organisms (e.g., fish and clams) and be a human health concern. Total and dissolved copper concentrations overlapped among

the different land uses, however, the dissolved copper median for the transportation station (31.6 μg/l) was more than twice as high as the next highest median (9.0 μg/l for mixed residential). Dissolved copper generally exceeds the 3.1 μg/l California Toxics Rule guideline while both mean and median concentrations of total copper exceed the Ocean Plan guideline in the transportation, light industrial, educational high density single family residential, and mixed residential stations. Total lead results are fairly consistent among land uses. Dissolved and total zinc exhibit similar patterns; there is substantial overlap among the different land uses although the mean and median for the light industrial station is highest in each case. All data for land use monitoring stations are presented in Appendix B.

The Permit states that if a given constituent is not detected in at least 25% of the samples taken in ten consecutive storm events at a given station then that constituent may qualify for removal from the analytical suite for the associated station. Several land use stations meet this criterion and are summarized in Table 4-11. It is recommended that these constituents be removed from the analytical suite for the associated stations.

The Permit allows the discontinuation of monitoring at a land use station for specific constituents once the event mean concentration (EMC) is derived at the 25% error rate. We used the mean standard error as a substitute for error rate as mutually agreed upon with the RWQCB (Swamikannu, 1999).

The constituents evaluated include:

- PAHs
- Copper
- Chromium
- Selenium
- Total Phosphorus
- Chlorpyrifos
- Total DDTs
- Chlordane
- Nickel
- Silver
- Mercury
- TSS
- Malathion
- Total PCBs
- Cadmium
- Lead
- Zinc
- Total Nitrogen
- Diazinon
- Simazine

We first identified 114 station-constituent combinations which had at least 10 detected samples and no more than 20% non-detected samples. Non-detects were replaced with half of the corresponding detection limit. Then, we performed the Shapiro-Wilk Normality Test at 5% significance level on each station-constituent to determine whether the concentrations were normally or lognormally distributed (Gibbons 1994, USEPA 1995). If the p-value of the normality test in raw scale of the constituent's concentration was greater than 0.05, such station-constituent was concluded to be normally distributed. Similarly, if the p-value of the normality test in log-transformed scale was greater than 0.05, it was concluded to be lognormally distributed. If a station-constituent was determined to be both normally and lognormally distributed (the p-values for both tests for normality were greater than 0.05), we assigned such station-constituent with a normal distribution. Similarly, if a station-constituent was neither normally nor lognormally distributed based on the normality tests (both p-values less than 0.05), we assumed that it had a normal distribution.

Based on the probability distribution determined above, we calculated the mean standard error as follows:

$$\text{Mean Standard Error} = \frac{\text{Standard Error}}{\text{Mean}} = \frac{\text{Standard Deviation}/\sqrt{\text{Sample Size}}}{\text{Mean}}$$

For those station-constituents with a normal distribution, the sample mean and standard deviation were used in the above formula. However, for station-constituents with a lognormal distribution, the mean and standard deviation were estimated as follows (Gilbert 1987):

$$\text{Mean, } \hat{\mu} = e^{\left(\bar{y} + \frac{s_y^2}{2}\right)}$$

$$\text{Standard Error, } s(\hat{\mu}) = \sqrt{e^{\left(2\bar{y} + \frac{s_y^2}{n}\right)}\left[\left(1 - \frac{2s_y^2}{n}\right)^{-\frac{(n-1)}{2}} \cdot e^{\left(\frac{s_y^2}{n}\right)} - \left(1 - \frac{s_y^2}{n}\right)^{-(n-1)}\right]}$$

where $\bar{y}$ and s_y^2 are the arithmetic mean and variance of the log-transformed values

n is the sample size

All results of this analysis are summarized in Table 4-12. Of 114 station-constituents under investigation, 25 of them had an EMC with a mean standard error higher than 25%. In other words, there were 25 station-constituents which had a standard error (standard deviation of the mean) larger than 25% of their corresponding mean concentrations. These station-constituents must continue to be monitored under the current Permit. The remaining 89 station-constituent combinations met the criteria and it is recommended that monitoring be discontinued for these constituents at the associated stations.

4.2.4 Critical Source Element

The following is a discussion of the results of the 2000-2001 critical source study results summarized in Table 4-13. This table includes the number of samples analyzed and the percentage of samples that had detectable concentrations, as well as summary statistics (the mean, median, and coefficient of variation (CV)). Box and whisker plots for several constituents are included as Figures 4-18a through 4-18q for the 2000-2001 season. This "box and whisker" presentation of the data provides information on the distribution and variability of each data set. It shows the median, mean, 25 and 75 percentiles, 10 and 90 percentiles, as well as the 5 and 95 percentiles. Common water quality objectives for each parameter are also provided where available. This was the second year BMPs were installed under the Critical Source Monitoring Program.

Note there are no numerical effluent standards that apply to stormwater pollution. Current federal and state standards apply only to "point source pollution," such as sanitary sewage, industrial and commercial discharges to the ocean and other water bodies. Water quality standards described in the 1995 Los Angeles Region Basin Plan or the 1997 California Ocean Plan do not apply to stormwater runoff, and any exceedance of values should not indicate

violation or noncompliance with the plans. The Toxic Rule is, strictly speaking, applicable to industrial and sewage treatment plant point-source discharges, but not to stormwater runoff discharges, which do not have any effluent limits. The Ocean Plan objectives apply to "instantaneous" grab samples. Furthermore, a direct comparison of the sampling results with the Ocean Plan standards is not directly applicable since the results presented in the tables are detected values before dilution, a factor allowed by the Ocean Plan. At the same time, however, it should be noted that new stormwater permits are including the narrative guidelines and limitations prescribed in the local Basin Plans.

The chemical constituents whose means were above the objectives of the Ocean Plan, Basin Plan, or California Toxics Rule are discussed below and are as follows:

- Bis(2-ethylhexyl)phthalate (a semi-volatile organic)
- Dissolved copper
- Total copper
- Total lead
- Dissolved nickel
- Dissolved zinc
- Total zinc

The testing methods for the critical source program are outlined in Section 3.

A comparison of control to test sites for the motor freight companies reveals the following.

- Median oil and grease concentrations were higher at the test sites (5.50 mg/l) than the control sites (1.80 mg/l).
- Median bacterial counts for all bacterial types examined were lower at the test sites than the control sites.

Sample sizes for the oil and grease samples as well as the bacterial samples were significantly higher (n=12 to n=21) than for the other analyses discussed (n=3). Therefore, caution must be used in applying the following observations.

- Median suspended solids concentrations were higher at the test sites (147 mg/l) than the control sites (73 mg/l).
- Median zinc concentrations, both total and dissolved, were higher at the test sites (245 and 178 mg/l ,respectively) than the control sites (157 and 110 mg/l, respectively).
- Median total aluminum concentrations were lower at the test sites (318 mg/l) than the control sites (635 mg/l).
- Median iron concentrations, both total and dissolved, were lower at the test sites (270 and 200 mg/l, respectively) than the control sites (920 and 320 mg/l, respectively).

A comparison of control to test sites for the auto dealers reveals the following.

- Median oil and grease concentrations were lower at the test sites (1.45 mg/l) than the control sites (3.7 mg/l).

- Median bacterial counts for all bacterial types examined were higher at the test sites than the control sites.

Sample sizes for the oil and grease samples as well as the bacterial samples were significantly higher (n=8 to n=16) than for the other analyses discussed (n=2 to n=3). Therefore, caution must be used in applying the following observations.

- Median suspended solids concentrations were lower at the test sites (46.5 mg/l) than the control sites (125 mg/l).
- Median zinc concentrations, both total and dissolved, were lower at the test sites (85.7 and 54.7 mg/l, respectively) than the control sites (150 and 133 mg/l, respectively).
- Median iron concentrations, both total and dissolved, were higher at the test sites (240 and 110 mg/l, respectively) than the control sites (110 and 50 mg/l, respectively).

The 2000-2001 season was the first year for which BMPs were implemented at the test sites for the motor freight and automobile dealership industries. Motor freight and automobile dealership industries had both active test and control sites this season for the first time. A list of initial BMPs purchased is included as Table 4-14. Individual business owners were encouraged throughout the storm season to use the BMPs at all times, although LACDPW had no control over this action on the part of the owners.

This report describes the results of the 2000-2001 Monitoring Program that was conducted in compliance with the Program's NPDES Municipal Stormwater Permit No. CAS614004. Elements of the Monitoring Program consisted of land use station monitoring, mass emission station monitoring, and the Critical Source/BMP Monitoring Study. The following are the principal conclusions and recommendations from this work.

5.1 OBJECTIVES ACHIEVED IN 2000-2001

The land use monitoring was conducted at seven stations and included flow composite sample data collected during 71 station events through April 7, 2001. The mass emission monitoring was conducted at 5 stations and consisted of 37 station events. Some grab sample data were also obtained at the mass emission stations. Generally, sampling activities were conducted according to plan, and attempts were made to capture as many storms as possible.

Monitoring at the land use stations and mass emission stations included a broad constituent suite including bacteria, metals, organics, major ions, and nutrients. The laboratory analytical efforts achieved detection limits (DL) as required by the Permit for all constituents, and achieved DLs that were lower than Permit requirements for many analytes, particularly for constituents of concern. Lower DLs are beneficial for two reasons: 1) to increase the probability of detection of potentially harmful substances at the concentrations of concern, and 2) to enhance the information value of the data by improving the quality of the data sets and allowing for more rigorous statistical analyses and data interpretation techniques. Thus, the major objective of runoff characterization at mass emission and land use catchments was achieved.

5.2 MASS EMISSION PROGRAM CONCLUSIONS

- Malibu Creek had noticeably higher median concentrations of both total and dissolved phosphorus, while the San Gabriel River has the highest median concentration of nitrate.
- The median total dissolved solids concentration in Malibu Creek is more than twice that of any other mass emission sites.
- Both total and fecal coliforms exhibited higher medians in the Los Angeles River. Ballona Creek had the greatest range of results for both total and fecal coliforms as well as fecal enterococcus. While the Los Angeles River had the greatest variability for fecal streptococcus results
- Concentrations were similar among stations for a given metal. In other words, no station appeared to be "cleaner" or "dirtier" than any other with respect to metals.
- There were several individual exceedances of water quality objectives, either of the California Toxics Rule or of the Ocean Plan (or of both), for metals; and in fact, total aluminum, total copper, dissolved copper, and total zinc each had at least one seasonal mean or median exceed an objective.

5.3 LAND USE PROGRAM CONCLUSIONS

- Runoff from the vacant catchment had high pH (8.0) and high alkalinity (median of 180 mg/l), while runoff from the light industrial, transportation, mixed residential, and high

density residential stations had lower median pH values (6.9, 6.8, 6.8, and 6.8 respectively) and lower median alkalinity concentrations (26, 21, 26, and 23 mg/l respectively). The educational and multiple family residential stations fell in between these two extremes with median pH values of 7.1 and 7.3 respectively, and median alkalinities of 31 and 48 mg/l respectively.

- Median hardness concentrations are similar to the alkalinity pattern: high (200 mg/l) at the vacant station; low in the transportation (30 mg/l), mixed residential (40 mg/l), and high density residential stations (20 mg/l); and in between (55, 60, and 75 mg/l) at the educational, light industrial, and multiple family residential stations.
- TSS results overlapped substantially among the different land uses; however, the light industrial station had the highest median for TSS (199 mg/l) being more than twice as high as the next highest median (84 mg/l for transportation).
- Total and dissolved copper concentrations overlapped among the different land uses, however, the dissolved copper median for the transportation station (31.6 μg/l) was more than twice as high as the next highest median (9.0 μg/l for mixed residential). Dissolved copper generally exceeds the 3.1 μg/l California Toxics Rule guideline while both mean and median concentrations of total copper exceed the Ocean Plan guideline in the transportation, light industrial, educational high density single family residential, and mixed residential stations.
- Total lead results are fairly consistent among land uses.
- Dissolved and total zinc exhibit similar patterns; there is substantial overlap among the different land uses although the mean and median for the light industrial station is highest in each case.

5.4 CRITICAL SOURCE PROGRAM CONCLUSIONS

A comparison of control to test sites for the motor freight companies reveals the following.

- Median oil and grease concentrations were higher at the test sites (5.50 mg/l) than the control sites (1.80 mg/l).
- Median bacterial counts for all bacterial types examined were lower at the test sites than the control sites.

A comparison of control to test sites for the auto dealers reveals the following.

- Median oil and grease concentrations were lower at the test sites (1.45 mg/l) than the control sites (3.7 mg/l).
- Median bacterial counts for all bacterial types examined were higher at the test sites than the control sites.

5.5 RECOMMENDATIONS

The Permit allows the discontinuation of monitoring at a land use station for specific constituents once the event mean concentration (EMC) is derived at the 25% error rate. We used the mean

standard error as a substitute for error rate as mutually agreed upon with the RWQCB (Swamikannu, 1999).

Of 114 station-constituents under investigation, 25 of them had an EMC with a mean standard error higher than 25%. In other words, there were 25 station-constituents which had a standard error (standard deviation of the mean) larger than 25% of their corresponding mean concentrations. These station-constituents must continue to be monitored under the current Permit. The remaining 89 station-constituent combinations met the criterion and it is recommended that monitoring be discontinued for these constituents at the associated stations.

Notes:

All land use percentages are rounded to the nearest tenth of a percent.
Land use percentages less than 0.1% are represented with a dash (--).
(1) HDSFR = High density single-family residential.
(2) The Retail/Commercial sampling site on Pier Drain in Santa Monica (S08) was dismantled and not in use in the 2000-2001 season, with prior approval from the RWQCB, to accommodate construction by city of Santa Monica of its stormwater treatment plant.
(3) Coyote Creek is not required under the Municipal Stormwater Permit, but is included in the Monitoring Plan.

Bentazon	96	2	µg/l		18				9	9	0	S I D	S I D	S I D

CV = Coefficient of variation

DL = Detection Limit

S I D = Statistically Invalid Data not enough data above detection limit collected

a) Detection limits have changed throughout the monitoring process Only data matching the current detection limit is displayed in this table The *Data Included Since* field indicates the first year of the storm season with the current detection limit

b) Except for indicator bacteria, there are no numerical water quality standards that apply to stormwater or "non-point source" pollution Current federal and state numerical standards apply only to "point source pollution," such as sanitary sewage, industrial and commercial discharges to the ocean, and other waterbodies Water quality standards described in the 1995 Los Angeles Region Basin Plan or the 1997 California Ocean Plan do not apply to stormwater runoff, and any exceedance of values should not indicate violation or noncompliance with the plans Furthermore, a direct comparison of the sampling results with the Ocean Plan standards cannot be made since the results presented in the table are detected values before dilution, a factor allowed by the Ocean Plan

c) Criterion represents the highest concentration of pollutant to which aquatic life can be exposed for an extended period time (4 days) without deleterious effects.

d) Criterion based on daily maximum

e) Criterion based on 30-day average

f) Criterion expressed in the total recoverable form.

g) Criterion represents the highest concentration of pollutant to which aquatic life can be exposed for a short period time without deleterious effects.

h) Criterion for the sum of acenaphthylene, anthracene, 1,2-benzanthracene, 3,4-benzofluoranthene, benzo(k)fluoranthene, 1,1,2-benzoperylene, benzo(a)pyrene, chrysene, dibenzo(ah)anthracene, fluorene, indeno(1,2,3-cd)pyrene, phenanthrene and pyrene.

CV = Coeffecient of variation

DL = Detection Limit

S I D = Statistically Invalid Data, not enough data above detection limit collected

a) Detection limits have changed throughout the monitoring process Only data matching the current detection limit is displayed in this table
The *Data Included Since* field indicates the first year of the storm season with the current detection limit

Appendix C
Industrial Stormwater Discharge

This Appendix includes, at the request of Natural Resources Defense Council and the Santa Monica Bay Keeper, industrial stormwater permit sampling data from the Regional Water Quality Control Board (RWQCB) for all industrial stormwater permitees in Los Angeles County for the 1999-2000 wet season, the latest season available. The data set contains sampling results for 9 constituents and three parameters. The data include the dates samples were taken. Furthermore, permittees may have more than one sampling location and are required to sample from all designated sampling locations.

The CRWQCB requires Industrial Stormwater permittees to obtain and report stormwater samples according to the document entitled ***Waste Discharge Requirements (WDR) for Discharges of Stormwater Associated with Industrial Activities Excluding Construction Activities***. Section B, *Monitoring Program and Reporting Requirements*, states:

Monitoring Program and Reporting Requirements

Section 5.c Facility operators shall collect stormwater samples during the first hour of discharge from (1) the first storm event for the wet season [Oct. 1st - May 1st], and (2) at least one other storm event in the wet season. All stormwater discharge locations shall be sampled. . . Facility operators that do not collect samples from the first storm event of the wet season are still required to collect samples from two other events of the wet season and shall explain in the Annual Report why the first storm event was not sampled.

Section 5.b Sample collection is only required of stormwater discharges that occur during scheduled facility operating hours and that are preceded by at least (3) three working days without stormwater discharge.

Section 5 further explains what constituents should be analyzed and what are valid sample collection locations.

The count, maximum, and minimum values are presented in the table.

Note.- At the time of printing, Industrial Stormwater Discharge data was still being compiled. Therefore, this appendix represents only a partial view of the complete data set. For more information on who to contact, refer to Appendix E (Contacts).

Nonpoint source pollution—that is, pollution from contaminants picked up and carried into surface water by water running over land—is known to be one of the leading causes of water quality problems in the United States. Water that runs over developed areas, including paved surfaces such as roads and parking lots, before reaching a water body is known as urban runoff and is an increasingly important category of water pollution. As urban areas have expanded over the past several decades, the amount of urban runoff has also increased. Although the overall quality of the nation's waters has improved since the passage of the Clean Water Act in 1972, a significant number of water bodies still suffer from poor water quality. Because the act brought discharges from "point sources," such as industrial plants and municipal treatment plants, under control, the continuing pollution of these waters suggests that other sources, including urban runoff, are contributing to water quality problems. As a result, the Environmental Protection Agency (EPA) now classifies urban runoff as a significant cause of impairment to water quality. The Water Quality Act of 1987, which amended the Clean Water Act, required EPA, among other things, to regulate as a point source urban runoff that reaches municipal sewer systems. EPA's National Pollutant Discharge Elimination System Program for storm water requires that certain local governments take measures to control storm water runoff.

R0012669

Concerned about the degradation of water quality in urban areas, you asked us to report on (1) the amount of runoff from urban areas, particularly from roads, highways, and other impervious surfaces,[1] and its effects on water quality and (2) the programs that federal regulations require local governments to develop to address urban runoff, and the costs and effectiveness of those programs. To address these issues, we reviewed federal and other studies and interviewed experts on the relationship between the amount of paved and other impervious surfaces and the amount of runoff, and on the types of materials typically contained in urban runoff. We also reviewed studies and interviewed experts on the sources of these materials and any actual or potential effects on water quality from urban runoff. We visited five urban areas and organizations that are affiliated with their watersheds[2] to obtain site-specific information about urban runoff problems, programs these areas have implemented in response to federal requirements, and the costs and effectiveness of these programs. Finally, we reviewed studies and estimates of the costs and investment requirements associated with implementing storm water management programs. Because this report focuses on local governments' actions, we did not review the portions of the National Pollutant Discharge Elimination System Storm Water Program that address industrial facilities and construction sites.

We performed our review from August 2000 through May 2001 in accordance with generally accepted government auditing standards.

Results in Brief

The volume of urban storm water runoff increased throughout the United States in the last half of the 20th century because of the growth in impervious surfaces that resulted from the development of urban and suburban areas. According to the U.S. Department of Agriculture, between 1945 and 1997, land devoted to urban areas in the United States has increased by about 327 percent; according to EPA, paved road mileage has increased by 278 percent. Because paved surfaces are almost impervious, they allow little storm water to infiltrate the ground; therefore, the storm water runs off into creeks, rivers, and lakes. As storm water runs across these impervious surfaces and land, it picks up pollutants from these surfaces and carries them to receiving bodies of water—either directly or

[1]An impervious surface keeps water from soaking into soils.

[2]A watershed is an area of land in which all surface water drains to a common point.

R0012670

through conveyances such as gutters, storm sewers, and culverts. EPA's 1998 *National Water Quality Inventory Report to Congress* showed that certain rivers, streams, lakes, and estuaries are impaired in terms of their ability to support such uses as aquatic life, swimming, and fish consumption, and concluded that urban runoff was a major source of this impairment. Studies have shown that urban runoff and the pollutants it carries can cause increases in sedimentation, water temperature, and pathogen levels and decreases in dissolved oxygen levels in bodies of water. These changes can lead to the degradation of habitat in these water bodies and a decline in diversity of aquatic life and can endanger public health. For example, metals, a pollutant typically found in urban runoff, can be toxic to aquatic organisms. Pathogens, such as bacteria from animal waste, another pollutant commonly found in urban runoff, can pose public health problems when present in waters used for recreational purposes. The magnitude and nature of these effects vary by region, depending on the type and concentration of pollutants in storm water, rainfall characteristics, land use, and other factors.

Local governments are required to address urban runoff through EPA's National Pollutant Discharge Elimination System Storm Water Program. Under permits that EPA and states issue through this program, over 1,000 local governments must meet EPA's requirements to implement storm water management programs to reduce contaminants in storm water to the "maximum extent practicable." EPA recommends that these cities use "best management practices" to reduce contaminants in storm water runoff. The most typical practices included controlling runoff through a combination of structural means, such as detention ponds, and nonstructural means, such as increasing the frequency of street sweeping and educating the public about how to prevent pollutants from reaching storm sewers. Cities also used specialized practices to address specific local runoff problems. For example, Baltimore, Maryland, has focused on reducing the level of nutrients, such as fertilizers, in its runoff because of its proximity to the Chesapeake Bay, which suffers from high nutrient levels.

Neither the overall costs of implementing the storm water program nor the program's effectiveness has been determined. EPA estimated in a 1996 report to congress that the potential need for spending on storm water runoff and overflows of sewage resulting from runoff was over $50 billion over 20 years, but the agency also believes this estimate will increase when it issues its next report in 2002. EPA's regulations require that permitted cities annually report the costs of implementing their storm water

R0012671

programs, along with the results of their monitoring of storm water runoff and water quality. However, in part because EPA has not established guidelines for reporting costs, these data have not been calculated or reported consistently and, therefore, are not currently useful in characterizing the program's overall cost. EPA, state, and city officials generally believe that managing storm water runoff will reduce the volume of runoff and concentrations of pollutants in the runoff, as well as improve water quality, but no systematic effort to evaluate the program's results has been started. EPA and the states have generally been unsuccessful in developing measurable program goals and in demonstrating program effectiveness through the review of water quality data reported by local governments.

We believe it is time for EPA to begin evaluating this program, which is directed at one of the nation's most significant water quality problems. Therefore, this report includes a recommendation to EPA to work with states to develop program goals, establish standards for reporting on program costs and effectiveness, and review reported water quality data to determine whether the current storm water management programs are having the intended effect of improving the quality of the nation's waters and how much the programs cost. We provided a draft of this report to EPA and the Department of Transportation (DOT). EPA generally agreed with the report and plans to take action to implement several parts of the recommendation; the agency did not comment on the other parts of the recommendation. DOT generally agreed with the report. (See the Agency Comments and Our Evaluation section of this report.)

Background

Nonpoint source pollution can result when water, such as precipitation, runs over land surfaces and into bodies of water. Significant nonpoint sources of pollution can include paved urban areas, agricultural practices, forestry, and mining. However, in urban and suburban areas, this runoff generally enters a sewer system that can be regulated as a point source of water pollution. For example, precipitation from rain or snowmelt may run into a municipal separate storm sewer system (MS4 or storm sewer) that eventually discharges into a body of water. The precipitation may also run into a combined sewer system, which carries a combination of storm water runoff, industrial waste, and raw sewage in a single pipe to a sewage treatment facility for discharge after treatment. Lastly, the precipitation may run off of land or paved surfaces directly into nearby receiving waters.

R0012672

EPA's Office of Wastewater Management, which is within the Office of Water, implements the National Pollutant Discharge Elimination System (NPDES) Program. The program was created in 1972 with the passage of the Clean Water Act. Created to control water pollution from point sources—those sources, such as a factory or wastewater treatment plant, that contribute pollutants directly into a body of water from a pipe or other conveyance—the NPDES Program did not specifically address storm water discharges. In 1987, the Congress amended the Clean Water Act with the Water Quality Act, which directed EPA to also control storm water discharges that enter MS4s—essentially requiring EPA to treat such storm water as a point source.[3] MS4s are defined as those sewers that collect and convey storm water; are owned or operated by the federal, state, or local government; and are not part of a publicly owned treatment (sewage) facility.

To regulate urban storm water runoff, EPA published regulations in 1990 that established the NPDES Storm Water Program and described permit application requirements. According to EPA, the program's objective, in part, is to preserve, protect, and improve water quality by, among other things, controlling the volume of runoff from paved surfaces and by reducing the level of runoff pollutants to the maximum extent practicable using best management practices (BMP).[4] The 1987 act also authorized EPA to implement a program that provides federal funds and technical assistance to states to develop their own nonpoint source pollution management programs. States can use the federal funds they receive for nonpoint source programs to address nonpoint sources of pollution as well as urban runoff.

Currently, EPA manages NPDES Storm Water programs in six states (Alaska, Arizona, Idaho, Massachusetts, New Hampshire, and New Mexico) and has delegated authority to the remaining 44 states to manage these programs. The storm water program is being implemented in two phases. Local governments meeting the following criteria must comply with EPA's storm water program regulations. First, Phase I of the program requires that municipalities with a population of 100,000 or more obtain a permit for their MS4 system; second, the program requires that entities obtain a

[3]Section 402(p) of the Clean Water Act.

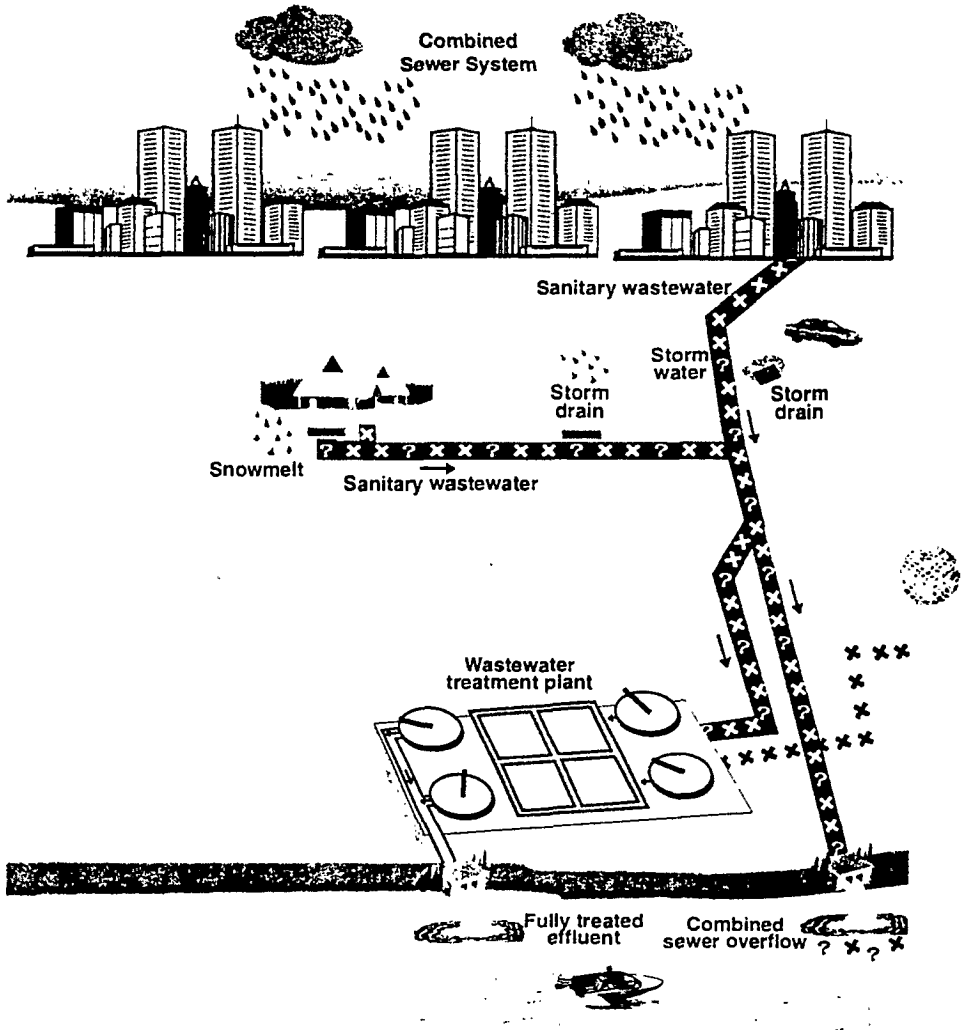
[4]According to EPA, a best management practice is a device, practice, or method for removing, reducing, retarding, or preventing targeted storm water runoff constituents, pollutants, and contaminants from reaching receiving waters.

R0012673

permit if they discharge storm water from sites with industrial activities, including construction activities that disturb 5 acres or more of land. In addition, NPDES permitting authorities may also bring other municipalities and industrial entities into the program if they deem it necessary. Municipalities that meet these conditions must submit a permit application to EPA or the governing regulatory state agency. In 1990, the regulations specifically identified 220 municipalities throughout the United States that were required to apply for a Phase I permit. According to EPA, as of April 2001, about 256 Phase 1 MS4 permits had been issued and about 17 more still needed to be issued. Because some permits cover more than one municipality, these permits cover about 1,000 medium and large municipalities nationwide.

The final rule for Phase II of the program was issued in December 1999. Phase II extends Phase I efforts by requiring that a storm water discharge permit be obtained by (1) operators of all MS4s not already covered by Phase I of the program in urbanized areas[5] and (2) construction sites that disturb areas equal to or greater than 1 acre and less than 5 acres of land. As with Phase I of the program, permitting authorities may require additional small MS4s and construction sites to obtain a permit if they are a significant contributor of pollutants. Currently, EPA anticipates that about 5,000 municipalities may be subject to permitting requirements under Phase II of the storm water program. These municipalities are required to obtain permits no later than March 10, 2003.

[5]The Bureau of the Census generally defines an urbanized area as a land area comprising one or more places—central place(s)—and the adjacent densely settled surrounding area—urban fringe—that together have a residential population of at least 50,000 and an overall population density of at least 1,000 per square mile.



R0012674

EPA also regulates combined sewer overflows (CSO) that can be caused by urban storm water runoff. Combined sewer systems, in which storm water enters pipes already carrying sewage, may overflow when rain or snowmelt entering the system exceeds the system's flow capacity. In the CSO that results, the mixture of untreated sewage and runoff bypasses the water treatment facility and is diverted directly into receiving waters. (See fig. 1 for an illustration of combined and separate sewer systems.) These combined systems generally serve the older parts of approximately 900 cities in the United States. Pipes carrying sewage and storm water separately generally serve newer parts of cities. EPA's 1994 CSO policy requires communities with combined sewer systems to take immediate and long-term actions to address CSO problems. The policy contains provisions for developing appropriate, site-specific NPDES permit requirements for all combined sewer systems that overflow because of wet-weather events. The Wet Weather Water Quality Act of 2000 requires that any permit, order, or decree issued for a CSO conform to the 1994 policy. Under this act, EPA is also required to submit a report to the Congress by September 2001 on the status of the program.[6]

[6]Sanitary sewer overflows, which are illegal under the Clean Water Act, can also result from rainfall. A sanitary sewer overflow may occur when rainwater or snowmelt leaks into sanitary sewage pipes, thereby exceeding the pipes' capacity and causing them to overflow. This discharge of raw sewage from municipal sanitary sewer systems can release untreated sewage into places such as streams, basements, and streets. EPA proposed regulations to require municipalities to reduce the number of overflows. However, these regulations have been withdrawn for further review.

R0012677

The Total Maximum Daily Load (TMDL) Program, established under the Clean Water Act, is intended to address water bodies that do not meet water quality standards because of pollutant loadings from point and nonpoint sources. Currently, it is unclear how and when this program will affect EPA's and states' issuance of storm water permits. A TMDL is a calculation of the maximum amount of a pollutant that a body of water can receive and still meet the water quality standard set by the state. Under EPA's regulations, the state is to allocate this "pollutant load" among the point and nonpoint pollutant sources that flow into the water body and then take steps to ensure that no source exceeds its assigned load. In 1996, EPA issued a policy that outlined an interim approach to including water quality standards in storm water permits. The policy promoted the use of BMPs in the first 5-year term permits, followed by a tailoring of BMPs in the second round of permits as necessary to comply with water quality standards. Until recently, few TMDLs had been established, and citizen organizations sued EPA for its lack of action. EPA issued a new set of regulations for the TMDL Program in 2000, but the Congress prevented EPA from spending money to implement the rule in 2000 and 2001. It is possible that establishing a TMDL for a body of water could result in the application of a numeric effluent limit to outfalls[7] that release storm water into that body of water. Some city officials we spoke with generally felt that numeric effluent limits would significantly increase the cost of managing storm water.

Volume of Urban Runoff Increases With the Expansion of Urban Development and Can Affect Water Quality

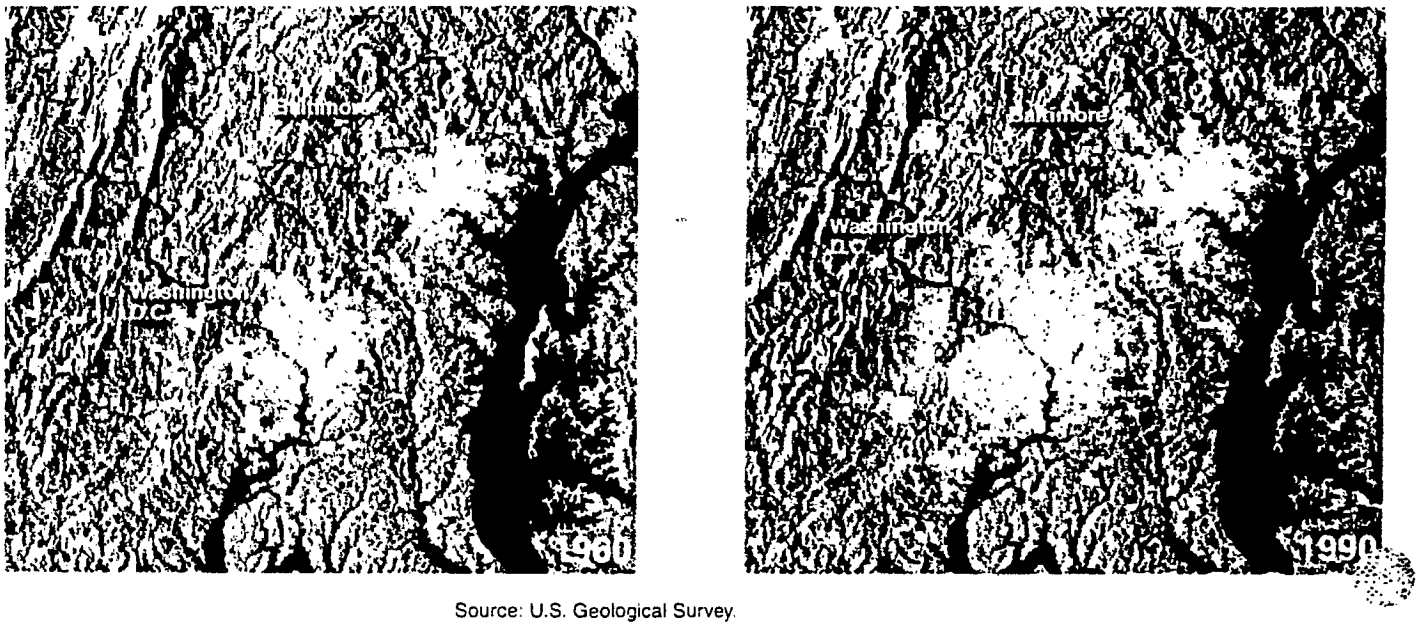
Since World War II, urban runoff has increased throughout the United States. This increase is directly related to growth in the amount of impervious surfaces due to urban and suburban development and the construction of roads, highways, and other impervious surfaces. Coinciding with this growth in impervious surfaces has been a reduction in wetlands and in the amount of storm water that infiltrates the ground to recharge aquifers. Moreover, the loss of vegetation due to development and related runoff can cause major erosion. Ultimately, much of this runoff is channeled into gutters, storm drains, and paved channels, and vegetation and sediment removed with the runoff may end up in receiving waters. EPA has identified urban storm water runoff as one of the leading sources of pollution to the nation's rivers, streams, lakes, and estuaries. Runoff from impervious surfaces picks up potentially harmful pollutants and

[7]An outfall is an outlet, such as a pipe, that allows storm water to flow into a river, lake, or other body of water.

R0012678

carries them into receiving waters. Studies have shown that urban runoff and the pollutants it carries can negatively affect water quality, aquatic life, and public health.

Paved Surfaces Have Increased With Urban and Suburban Expansion and Growth in Automobile Use



According to the U.S. Department of Agriculture, between 1945 and 1997, urban land area increased by almost 327 percent, from 15 million acres to about 64 million acres in the contiguous 48 states. From 1992 through 1997, the annual rate of development averaged about 1 million acres per year. The land developed between 1945 and 1997 came primarily from forestland and pasture and range.[8] For example, according to the Bureau of the Census, between 1960 and 1990, the amount of land used for urban purposes in Baltimore, Maryland, and Washington, D.C., grew by about 170 percent and 177 percent, respectively. As a result, urbanization, with its accompanying expansion of impervious surfaces like sidewalks, roofs, parking lots, and roads, has significantly increased the nation's total developed land and paved surface area.[9] Figure 2 demonstrates the growth in the urbanized areas of Baltimore and Washington, D.C., over the last half of the 20th century.

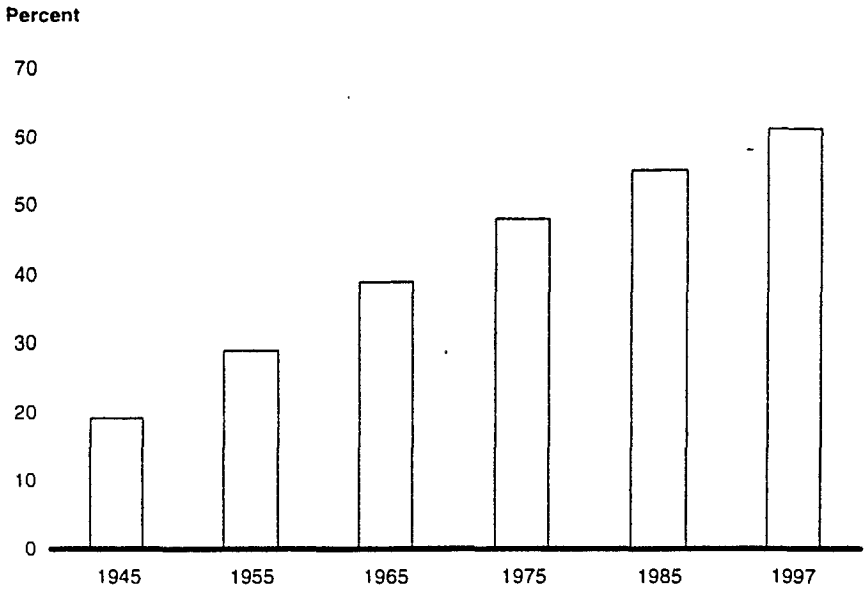
R0012679

Figure 2: Increase in Urbanized Land in Selected Cities, 1960-90



Source: U.S. Geological Survey.

The increase in paved surfaces has been spurred not only by urban and suburban development, but also by a steady increase in the use of automobiles, the primary mode of daily transportation for most Americans. Roads also play an important role in the economy of the United States, since trucks carry about 75 percent of the value of all goods shipped. According to EPA, paved road mileage in the United States increased by 278 percent from 1945 to 1997. In 1945, 19 percent of the public roads in the country were paved; by 1997, that percentage had increased to 61. (See fig. 3.) According to a 1999 study, motor-vehicle infrastructure, such as roads and parking lots, accounts for close to half of the land area in U.S. urban cities.[10]

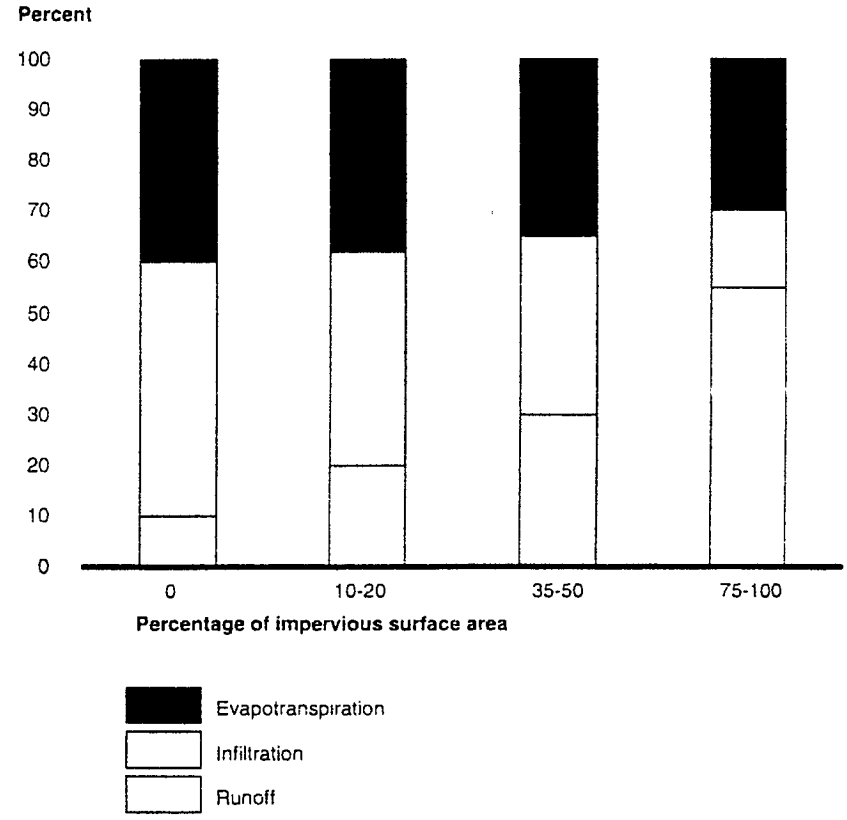
Increase in Impervious Surfaces Leads to Increased Runoff

The increase in impervious surfaces over the past several decades has led to an increase in storm water runoff. In part, this has occurred because highways and other developments have reduced the amount of wetlands and other undeveloped land. Wetlands mitigate the effects of storm water runoff by acting as a natural form of flood control, facilitating sediment replenishment, and improving water quality by removing excess nutrients and other chemical contaminants before the contaminants can affect receiving waters. According to a 2000 EPA report,[11] of the 12 states that listed wetland losses, six reported that they had significant losses due to highway construction, and 10 reported that they had significant losses due to residential growth and development. However, the effect of road building on wetland loss has been reduced in recent years. According to a Federal Highway Administration (FHWA) official, since 1996, wetlands have been replaced and restored under the Federal-Aid Highway Program

[11]See footnote 9.

R0012681



at an average rate of 2.7 acres for every acre lost to highway building. Other undeveloped land with vegetation also performs some of the roles that wetlands play in managing runoff, although to a lesser extent.

Furthermore, as impervious surfaces increase, less storm water is able to infiltrate through the soil to groundwater. Impervious areas allow only a very small amount of initial infiltration compared with unpaved areas whose infiltration capacity varies, depending on the soil type. Figure 4 demonstrates EPA's estimates of the impact of impervious surfaces on the percentages of storm water that runs off, infiltrates the ground, and is lost through evapotranspiration.[12] When natural ground cover is present over an entire site, normally 10 percent of precipitation runs off the land into nearby creeks, rivers, and lakes. In contrast, when a site is 75- to 100-percent impervious, 55 percent of the precipitation runs off into these receiving waters. However, according to an FHWA official, the runoff rates can be reduced if developers take mitigating actions to develop and implement BMPs to control flooding or runoff.

[12]Evapotranspiration represents water loss from evaporation and the absorption and eventual release into the atmosphere of water that plants and trees have collected. The extent to which evapotranspiration occurs is dependent primarily on the solar energy available to vaporize the water. As a result, the effect of evapotranspiration varies greatly across the country.

R0012682

Figure 4: Impact of Impervious Surfaces on the Amount of Storm Water That Runs Off, Infiltrates, and Evapotranspires

Source: EPA.

R0012683

The decrease in storm water infiltration that accompanies urbanization also reduces the amount of water that is available to recharge groundwater supplies. For this reason, reduced infiltration may lead to problems with the water table in certain urban areas. For example, a Massachusetts Department of Environmental Protection official noted that a low recharge rate affects water quality because it can result in a loss of wetlands and adversely affect aquatic habitat as water-table levels fall during dry weather.[13] In addition, officials from the Charles River Watershed Association in Massachusetts are concerned that the lack of infiltration might cause some communities to run short of drinking water in the next 20 years.

Urban Runoff Has the Potential to Impair Water Quality and Disrupt Biological Integrity

Urban runoff can adversely affect the quality of the nation's waters, and urban storm water runoff has been identified as one of the leading sources of pollution to rivers, streams, lakes, and estuaries.[14] Section 305(b) of the Clean Water Act requires states and other jurisdictions to report on the quality of their waters to EPA every 2 years. The 1998 *National Water Quality Inventory Report to Congress* showed that 35 percent of assessed river and stream miles, 45 percent of assessed lake acres, and 44 percent of assessed estuarine square miles were impaired in terms of their ability to support uses such as aquatic life, swimming, and fish consumption.[15] The report identified urban storm water runoff as one of the leading sources of impairment to the assessed waters.

[13]Dry weather is defined as a period when rainfall measuring at least 0.10 of an inch has not occurred for 72 hours.

[14]Other leading sources of pollution include agricultural runoff, municipal point sources, hydrologic modifications, and atmospheric deposition.

[15]Information contained in the 1998 report reflects only those waters assessed by states and other jurisdictions and cannot be used to characterize nationwide water quality. Furthermore, water quality standards among states are not identical, and the monitoring design used to collect data differed among states.

R0012684

Studies have shown that as the percentage of impervious cover increases within a watershed, biodiversity also declines. Research conducted by the Center for Watershed Protection found that, generally speaking, when a watershed has 10 percent or less impervious cover, the associated stream can be categorized as sensitive.[16] Sensitive streams are characterized as having high fish diversity and good water quality. Once the percentage of impervious cover exceeds 25 to 30 percent of the watershed, however, streams tend to become nonsupporting. Nonsupporting streams are highly unstable, have poor diversity of fish and aquatic life, and have poor water quality. For example, one study evaluated the relationship between the extent of impervious cover in watersheds to the number and diversity of fish populations in 47 small streams in southeastern Wisconsin between the 1970s and 1990s.[17] The results revealed that the number of fish species per site was highly variable for drainage areas that had less than 10-percent imperviousness. In contrast, sites that had greater than 10-percent imperviousness had consistently low numbers of fish species.

Other studies have associated urban runoff with basic changes in the receiving body of water. Runoff can carry sediment into surface water, and this sediment can carry contaminants, harm aquatic plants, and smother organisms. Runoff can also be warmed by the impervious surfaces it flows across. When sufficient amounts of warmed runoff enter a water body, the water temperature can rise. Less oxygen is then available for aquatic organisms because water holds less oxygen as it becomes warmer. These combined factors lead to the degradation of aquatic habitat. According to EPA, the common effects of these types of pollution on aquatic life include a decline in biodiversity and an increase in invasive species.

An increase in the volume of storm water runoff also increases the likelihood of erosion, which allows for transport of eroded sediment downstream into receiving waters. For example, during a site visit, we observed extensive erosion along the Gingerville Creek Subbasin in Anne Arundel County, Maryland, that was caused by urban runoff channeled into the creek. Figure 5 depicts the eroded banks and channel of this creek.

Contaminants in Urban Runoff Can Affect Aquatic Life and Human Health

There have been several efforts to characterize the chemicals and other constituents in urban runoff. The Nationwide Urban Runoff Program, conducted by EPA between 1978 and 1983, examined the characteristics of urban runoff. Another federal effort to characterize urban runoff is an ongoing joint project of the U.S. Geological Survey (USGS) and the FHWA to evaluate guidelines for highway runoff. As table 1 indicates, these studies and others have shown that the principal contaminants found in

R0012686

urban runoff include nutrients, solids, pathogens, metals, hydrocarbons, organics, salt, and trash. Water flowing over various surfaces, such as streets, parking lots, construction sites, industrial facilities, rooftops, and lawns, carries these pollutants to receiving waters. The contaminants have the potential to impair water quality, degrade aquatic ecosystems, and pose health risks to swimmers.

Table 1: Storm Water Pollutants in Urban Runoff, Including Sources and Potential Impacts

Contaminant	Source	Potential impact
Nutrients		
Nitrogen, phosphorous	Animal waste, fertilizers, failing septic systems, atmospheric deposition,[a] CSOs	Nutrient enrichment can cause an excessive growth of algae. Nuisance levels of algae are associated with dissolved oxygen deficiencies leading to fish kills, loss of submerged aquatic vegetation that serves as a habitat for aquatic organisms, and loss of natural biodiversity.
Solids		
Sediment	Construction sites, other disturbed and/or nonvegetated lands, eroding banks, road sanding	Sediment can cause infection and disease among fish, scour submerged aquatic vegetation, prevent sunlight from reaching aquatic plants, and bury bottom-dwelling aquatic organisms.
Pathogens		
Bacteria, viruses	Animal waste, failing septic systems, illicit connections and discharges to storm sewer system, CSOs	Pathogens entering waters used for recreational purposes can pose human health risks.
Metals		
Lead, cadmium, copper, zinc, mercury, chromium, aluminum, and others	Industrial processes, normal wear of automobile brake linings and tires, automobile emissions, automobile fluid leaks, metal roofs	Metals can cause acute or chronic toxicity for aquatic organisms.
Hydrocarbons		
Oil and grease, polycyclic aromatic hydrocarbons	Industrial processes, automobile wear, automobile emissions, automobile fluid leaks, waste oil	Hydrocarbons have the potential to be acutely toxic for aquatic organisms and several are suspected carcinogens.
Organics		
Pesticides, polychlorinated biphenyls (PCB), synthetic chemicals	Pesticides (herbicides, insecticides, fungicides, rodenticides, etc.), industrial processes	Low concentrations of some organics have the potential to bioaccumulate in the food chain.

R0012687

(Continued From Previous Page)

Contaminant	Source	Potential impact
Salt		
Sodium Chlorides	Road salting and uncovered salt storage	Salt can damage roadside vegetation, transport high levels of chlorides to receiving waters, and degrade aquatic ecosystems. Chloride can be harmful to some species of fish.
Trash		
	Street refuse and improperly discarded waste material	Trash impairs water quality by inhibiting the growth of aquatic vegetation and conveys nutrients, toxic substances, and other pollutants to aquatic ecosystems.

[a]Atmospheric deposition occurs when pollutants in the air fall on land or water.

R0012688

In our visits to cities with Phase I permits and their watersheds, we identified specific instances in which these contaminants had affected water quality. The Chesapeake Bay, for example, has been polluted with the nutrients nitrogen and phosphorus and with excess sediment caused, in part, by urban runoff. The excess nutrients cause algae blooms that block sunlight from reaching bay grasses—which are a source of food, shelter, and nursery grounds for many aquatic species. In an effort to control nutrient pollution in the Chesapeake Bay, the Executive Council of the Chesapeake Bay Program[19] established a goal to reduce the nitrogen and phosphorus entering the Chesapeake Bay by 40 percent, including through control of runoff from urban areas. In addition, an assessment of the status of chemical contaminant effects on living resources in the bay's tidal rivers found "hot spots" of contaminated sediment. As a result, the Baltimore Harbor and the Patapsco River in Maryland; the Anacostia River in Washington, D.C.; and the Elizabeth River in Virginia were designated as "regions of concern." Urban storm water runoff is a significant source of contaminants in the three regions. The Chesapeake Executive Council has committed to reduce by 30 percent the chemicals of concern in the regions of concern by 2010 through pollution prevention measures and other voluntary means.[20]

Pathogens such as bacteria and viruses, which are often present in urban runoff, can pose public health problems. For example, the Santa Monica Bay Restoration Project conducted a study to identify adverse health effects of untreated urban runoff by surveying over 13,000 swimmers at three bay beaches.[21] The study established a positive association between an increased risk of illness and swimming near flowing storm-drain outlets. Table 2 explains health outcome measures at various distances from storm drains. For example, the study found a 1-in-14 chance of fever for swimmers in front of the drain versus a 1-in-22 chance at 400 or more yards away.

Metals and polycyclic aromatic hydrocarbons (PAH) in urban runoff can present a threat to aquatic life. Studies have found the following:

- Storm water runoff from an urban area proved to be toxic to sea urchin fertilization in the Santa Monica Bay, and dissolved zinc and copper were determined to be contributors to this toxicity. [22]
- Brown bullheads (a bottom-dwelling catfish) in the Anacostia River developed tumors that were believed to be caused by PAHs associated in part with urban runoff.[23]
- High PAH and heavy metal concentrations were found in crayfish tissue samples from several urban streams in Milwaukee. The study associated these contaminants with storm water runoff.[24]

R0012690

In addition, USGS tracked trends in the concentrations of PAHs found in sediment in 10 lakes and reservoirs in six metropolitan areas over the last several decades. This study found that PAH concentrations in developed watersheds are increasing and that these increases may be linked to the amount of urban development and vehicle traffic in urban and suburban areas.[25] For example, from 1982 to 1996, PAH concentrations in the sediment core in Town Lake (Austin, Texas) and total miles driven in greater Austin both increased by about 2.5 times. Figure 6 illustrates this correlation.

Figure 6: Comparison of Town Lake PAHs and Traffic Trends

Note: According to USGS, irregularities in the date pattern are due to intervals at which sediment samples were collected.

R0012691

Although the studies we reviewed show that certain contaminants are likely to be present in urban runoff, factors such as land development practices, climate conditions, atmospheric deposition, and traffic characteristics all can affect the characteristics of runoff from a particular area. Therefore, given the diffuse nature of many storm water discharges and the variability of other contributing factors, characterizing the concentrations of pollutants contained in storm water runoff has been challenging. Recent USGS reports also suggest that improvements are needed in the methods used to analyze sediment and metals in runoff.[26]

Local Governments Take Actions to Manage Urban Storm Water Runoff, but Information Is Limited on the Cost and Effectiveness of These Actions

To comply with federal and state storm water management for Phase I permitting requirements, permitted municipalities must create and implement storm water management programs. The three primary activities used in these programs include efforts to characterize storm water runoff; BMPs aimed at reducing pollutants in storm water runoff to the maximum extent practicable; and reporting program activities, monitoring results, and costs of implementing the program. Some BMPs are structural—meaning that they are designed to trap and detain runoff until constituents settle or are filtered out. Other BMPs are nonstructural—meaning that they are designed to prevent contaminants from entering storm water through actions like street sweeping and inspections. Many permitted municipalities use specialized BMPs tailored to address particular runoff problems in their locations. Over 1,000 cities are undertaking these efforts under the NPDES Storm Water Program, but information on the overall costs of managing urban runoff and the effectiveness of the actions taken is limited. EPA's attempts to forecast costs have not encompassed the entire program or are out of date. In addition, the permitted municipal agencies we visited estimated their annual storm water management costs and reported them to state agencies or EPA, but the approaches they used to calculate these estimates varied considerably, making it difficult to draw any conclusions. Although EPA and state agencies believe that the program will be effective in improving water quality, EPA has not made a systematic effort to evaluate the program. Without such an effort, EPA cannot tell what effect the program is having on water quality nationally.

[26]The USGS reports indicate that certain methods used to analyze sediment and metals samples can be unreliable. For example, sample collection and processing methods can have an effect on measured concentrations of metals.

R0012692

Municipalities Comply With Federal and State Requirements Through Monitoring, Best Management Practices, and Reporting

The NPDES Storm Water Program requires municipalities operating under a Phase I MS4 permit to characterize and monitor storm water runoff, implement BMPs to reduce pollutants to the maximum extent practicable, and report costs and monitoring results to the permitting authorities. Because of these requirements, local governments have generally shifted the focus of their storm water management from water quantity control or flood management to water quality concerns.

Besides following the basic federal requirements, municipalities must follow any additional regulations developed by states that have been delegated the authority to manage the NPDES Storm Water Program. For example, Wisconsin's Department of Natural Resources broadened the requirements for determining which municipalities must get permits. The state requires local governments with storm sewer systems in priority watersheds (based on the significance of storm water runoff as a pollutant source) that serve a populace of 50,000 or more[27] to obtain a permit with requirements similar to those for a Phase I permit. Wisconsin's Department of Natural Resources also requires municipalities that are located in one of the state's five Great Lakes Areas of Concern[28] to obtain a state permit. Furthermore, in line with specific criteria in Wisconsin's Administrative Code, the state requires other municipalities to obtain a permit if the municipality is found to significantly contribute storm water pollutants to waters of the state. These various requirements increased the number of municipalities that must get permits from the two under federal requirements to over 70 under the states' requirements.

The local governments we reviewed were undertaking three primary activities when applying for permits and implementing their storm water management programs. Specifically, these activities were (1) characterizing storm water runoff; (2) developing BMPs to reduce discharges of pollutants to the maximum extent practicable; and (3) reporting program activities, monitoring results, and reporting program costs.

First, to characterize runoff, applicants are to provide quantitative data that describe the volume and quality of discharges from municipal storm

[27]For example, we visited West Allis, Wisconsin, which has a permit even though its population is under 100,000.

[28]Areas of concern have persistent water quality problems, which impair beneficial uses.

R0012693

sewers. For example, cities must map all storm sewer outfalls—an undertaking that one group representing cities described as significant. After the permit application is approved, additional monitoring is required throughout the life of the permit to facilitate the design of effective storm water management programs and to document the nature of the storm water. The local governments we visited were all monitoring for a variety of purposes, including characterizing runoff from different types of land use in order to target their BMPs, testing the effectiveness of a particular BMP, or establishing a baseline for their storm water quality evaluations.

Second, the storm water management programs that local governments develop focus on implementing BMPs. While active treatment, such as sending storm water through a treatment facility, is a possible BMP, the cities we visited were generally not using active treatment. EPA's February 2000 report[29] on the Phase I program described the program as based on the "use of low-cost, common-sense solutions." The five cities we visited were generally using similar types of structural and nonstructural BMPs, as follows:

- Structural BMPs are designed to separate contaminants from storm water. For example, detention ponds temporarily hold storm water runoff to allow solids and other constituents in the runoff to settle before the water is released at a predetermined rate into receiving waters. In addition, catch-basin inserts, placed in a storm drain, catch trash and other debris, and particle separators, placed beneath the surface of an impervious area such as a parking lot, separate oils from runoff and allow sediment and debris to settle. Structural devices such as these require regular maintenance to function properly and remain effective.
- Nonstructural BMPs are primarily designed to minimize the contaminants that enter storm water. These nonstructural BMPs include
  - "good housekeeping" practices by the local government, such as oil collection and recycling, spill response, household and hazardous waste collection, pesticide controls, flood control management, and street sweeping;

[29] *Report to Congress on the Phase I Storm Water Regulations*, U.S. Environmental Protection Agency, February 2000. This report includes information on the program for local governments, industries, and construction sites.

R0012694

- public education programs, such as storm-drain stenciling, to remind the public that trash, motor oil, and other pollutants thrown into storm drains end up in nearby receiving waters;[30]
- new ordinances to control pollution sources, such as prohibiting the disposal of lawn clippings in storm drains and requiring pet owners to clean up after their pets;[31]
- requirements that developers comply with storm water regulations and incorporate erosion and sediment controls at all new development sites;
- requirements that runoff from properties owned or activities sponsored by the municipality be properly controlled; and
- efforts to identify and eliminate illicit connections and illegal discharges to the storm sewer systems, such as those from pipes carrying sewage.

We found that the NPDES Program's requirements allowed local governments to tailor their storm water management efforts to prioritize local concerns, such as a particular type of contaminant, a particular climatic condition, or a particular body of water. Some cities also developed specialized BMPs to address these concerns. The following information highlights specific storm water-related concerns in the five cities we visited and the specialized BMPs these municipalities have developed to address these particular concerns. (See apps. I to V for additional information on these cities' storm water management programs.)

[30]Other public education programs we observed included in-school education programs, partnerships with grassroots organizations concerned with water quality issues, and the identification of commercial businesses and industries to educate owners on methods to control storm water runoff.

[31]According to Worcester, Massachusetts' April 2000 *City of Worcester DPW Stormwater Management Program Annual Report*, the city has proposed ordinances that prohibit the disposal of lawn clippings and other yard waste in catch basins and that require pet owners to clean up after their pets. As of April 2001, neither ordinance had been implemented.

R0012695

- In **Baltimore, Maryland**, excessive levels of nutrients, particularly phosphorus and nitrogen, are among the city's major water quality concerns because of the city's participation in the Chesapeake Bay Program. Baltimore City agreed to assist the state in reaching the Chesapeake Bay Program's goal to reduce nutrients discharged to the bay by 40 percent by the year 2000. According to a Chesapeake Bay Program Office representative,[32] as of March 2001, the program has not met this goal but expects to reach it within the next several years.
- In **Boston, Massachusetts**, the Boston Water and Sewer Commission, which holds the permit for Boston's storm sewer system, is concerned about runoff from roadways, especially runoff containing salt and sand used in the winter months and dissolved metals (copper and zinc) from automobiles. In September 2000, the commission began a 3-year program to develop and implement a citywide catch-basin inspection, cleaning, and preventive maintenance program. The program will also include the development of a database and map that can be linked to the commission's Geographic Information System.
- **Los Angeles County, California**, is responding to a TMDL for trash in the Los Angeles River Watershed that will require the county, over a 10-year period, to eliminate trash in runoff. The county is testing a variety of devices that remove trash from runoff and specialized catch-basin devices that are designed to prevent trash from ever reaching the storm sewers.
- **Milwaukee, Wisconsin**, changed its monitoring and public education activities in its recent permit to test the effectiveness of a BMP targeting public education efforts to a specific community. The new permit also requires a monitoring program aimed at the community, its associated watershed, and city employees who work in the area.
- **Worcester, Massachusetts**, had a significant problem with illicit connections to its storm sewers and with flow in these sewers during dry weather. Worcester's Department of Public Works (DPW) screened 71 of its storm water outfalls and determined that 32 of them had drainage areas that carried both sanitary sewage and storm drainage in separate conduits through common manholes. DPW has retrofitted over 65 percent of the manholes to prevent sewage from mixing with storm water.

[32]The Chesapeake Bay Program Office, U.S. EPA Region III, was founded in 1983 with the formation of the Chesapeake Bay Program. The program is a voluntary regional partnership that leads and directs restoration of the Chesapeake Bay. Members of the Chesapeake Bay Program include Maryland, Pennsylvania, Virginia, the District of Columbia, the Chesapeake Bay Commission (a tristate legislative body), EPA, and participating citizen advisory groups.

R0012696

Third, local governments participating in the Phase I program are required to report annually to EPA or the state regulatory agency on their storm water programs. These reports are to include a status report on the program; a summary of data, including monitoring results collected during the reporting year; information on annual expenditures on the program and a budget for the coming year; and a description of any water quality improvements or degradation.

Information on the Costs of Addressing Storm Water Runoff Is Limited

Good information about the cost of implementing federal storm water requirements is limited. EPA conducted a survey to estimate the nation's future water infrastructure needs over a 20-year period—from 1996 to 2016. In its 1996 report,[33] EPA estimated that states would require over $50 billion to meet their current (as of 1996) water infrastructure needs. The estimate consists of storm water management needs (at $7.4 billion) and CSO needs (at $44.7 billion).[34] EPA noted, however, that estimated storm water management needs are likely too low and could increase following an analysis of data collected to prepare the agency's 2000 clean water needs survey—to be released in 2002. According to EPA, many cities have implemented the Phase I program since EPA reported to the Congress in 1996, and municipalities should now be better able to provide documented cost data. As a result, EPA will need to rely less on modeled storm water needs than it did in the 1996 needs survey. EPA did not project the costs and benefits of the program when it was initiated; therefore, no initial cost estimates are available. When EPA promulgated the Phase I program regulations in 1990, the agency decided that the storm water program did not meet the requirements for preparing a benefit/cost analysis.

[33] *1996 Clean Water Needs Survey Report to Congress*, U.S. Environmental Protection Agency (Sept. 1997). EPA's estimate represents the estimated capital costs for water quality projects eligible for state revolving fund support.

[34] EPA also estimates that $81.9 billion of its 20-year water infrastructure needs cost can be attributed to sanitary sewer overflows. These overflows may occur when rainwater or snowmelt leaks into sanitary sewage pipes, exceeding the pipes' capacity and causing them to overflow. This overflow can release untreated sewage from municipal sanitary sewer systems into streams, basements, and streets.

R0012697

The costs to local governments of complying with the Phase I program have generally been portrayed as high. However, because of inconsistencies in cost accounting and reporting practices, we could not determine the cost of the program to several of the cities we visited. Although municipalities are required to provide information on the expenditures that they anticipate will be needed to implement their storm water management programs for each fiscal year covered by the permit, EPA has not issued any cost reporting guidelines. Consequently, while the reported fiscal year 1999 total cost to manage and treat storm water runoff across the five municipalities in our review ranged from less than $1 million (Milwaukee) to $135 million (Los Angeles County),[35] these numbers are not comparable because the municipalities did not have consistent cost accounting and reporting practices and did not fully express storm water management costs.[36] For example, some cities reported only the costs of activities that were funded by the city department that held the permit. Significant activities funded by other city departments were not reported, even if they were important components of the storm water program. Officials in the Milwaukee Department of Infrastructure Services and the Boston Water and Sewer Commission told us that other city departments perform and fund activities such as street sweeping and flood control. The costs of these activities are not reported as storm water program costs because the activities serve other purposes besides preventing storm water pollution.

In addition, according to some city officials, these activities were in place before the permit was issued and, therefore, cannot be characterized solely as storm water costs. The cost of street sweeping can be significant—for fiscal year 1999, Baltimore City and Worcester, which did include street-sweeping costs in their storm water program's cost estimate, stated that their street-sweeping expenses totaled about $9.5 million and $1.2 million, respectively. Similarly, Milwaukee did not report the cost of a significant project related to storm water runoff because it was mostly funded by the state of Wisconsin.

[35]Los Angeles County's cost was projected by the municipal permit holder and represents the cost of the 85 cities covered by the permit.

[36]We were unable to obtain comprehensive information on the total cost to the Boston Water and Sewer Commission of managing storm water, so their fiscal year 1999 costs could not be included in this range.

R0012698

An EPA official told us that the agency had not yet made a national effort to analyze the information that Phase I permittees submitted on the costs of their storm water programs. This official cited the inconsistent formats of the annual reports as a reason that the information was not readily available at the national level and also indicated that adequate staff are not available to analyze the data. In addition, other EPA officials informed us that the Office of Wastewater Management must divide its resources among a number of issues that will challenge the agency's water program over the next decade.

Several officials in the cities we visited said that their annual costs are likely to increase. A number of factors could affect the costs. For example, a Baltimore City official explained that the anticipated, future program costs depend on several factors, including (1) requirements in watershed-management plans currently being developed, (2) pollution-reduction goals the city will be required to achieve, (3) requirements of the state regulatory agency in future permits, and (4) requirements the city may have to meet if TMDLs or numeric effluent limits are incorporated into NPDES storm water permits. Other city officials also expressed concern about the extent to which TMDLs could affect their future costs. These city officials are concerned that when and if TMDLs are established, their future storm water permits may require that storm water runoff meet specific water quality standards. For example, Los Angeles County's trash TMDL could potentially drive the county's storm water management costs upward, and the county expects additional TMDLs to be imposed. On the other hand, Worcester officials estimated that their future storm water costs would be about the same as they were at the time of our review—about $4.5 million per year.

In a separate analysis, EPA estimated in 1999 that it will cost Phase II municipalities about $848 million to $981 million per year (in 1998 dollars) to manage storm water runoff. Because Phase II permits have not been issued as of May 2001, we did not gather any cost information on them from these cities.

Funding for Managing Storm Water Runoff Is Available From Local and Federal Sources

The five cities we visited had not generally obtained federal funds for their storm water management efforts. They used local sources, including general revenues, bonds, revenue from specifically created storm water utilities, state grants, and inspection and permit fees.

R0012699

While several sections of the Clean Water Act provide funding that can be used for municipal storm water control, relatively few federal funds have been directed to these types of projects. The most significant source of funds is the state revolving loan funds administered by states.[37] These revolving loan funds provide loans for eligible storm water control projects. In some cases, nonpoint source projects may also qualify for funding when storm water permits are not required or issued. However, municipal storm water management is generally a low priority in these programs. Specifically, in the year 2000, revolving fund loans were made in the "storm sewers" category in the amount of $38.76 million for 44 different projects. These funds represented less than 1 percent of the amounts loaned from these revolving funds that year. Activities eligible for revolving fund loans include constructing BMPs to control runoff, but support for ongoing operations and maintenance is not eligible. Revolving fund loans can also be used for eligible CSO control projects. In 2000, Clean Water State Revolving Fund Program loans were made in the "CSO Correction" category of a national EPA database in the amount of $411.3 million for 69 different projects and could have been used for CSO or sanitary sewer overflow projects. This amount represented about 9 percent of the funds loaned in 2000.

According to EPA, the agency also issues grants to universities and other research institutions to help implement the storm water program. Some of these grants provide training and guidance to Phase I permittees on watershed protection and the proper selection of BMPs.

Other sources of funding may be available to local governments beginning in 2002. In December 2000, the Congress authorized programs for fiscal years 2002 through 2004 to provide grants to local governments for (1) pilot projects for managing municipal CSOs, sanitary sewer overflows, and storm water discharges on a watershed basis and for testing BMPs and (2) controlling pollutants from MS4s to demonstrate and determine cost-effective, innovative technologies for reducing pollutants from storm water discharge. EPA's proposed budget does not request funds for these programs. In addition, the Congress authorized programs for fiscal years 2002 and 2003 to provide grants to local governments for planning, designing, and constructing treatment works to intercept, transport,

[37]Under the Clean Water State Revolving Fund Program, the federal government provides grants to capitalize states' funds. States provide loans to local governments for wastewater projects.

R0012700

control, or treat municipal CSOs and sanitary sewer overflows. EPA's proposed budget requested $450 million for this program.

EPA, States, and Local Governments Believe the NPDES Storm Water Program Is Effective, but It Has Not Been Evaluated

EPA, state, and municipal officials generally believe that the NPDES Storm Water Program will improve water quality. These officials believe that the program will result in more bodies of water that meet water quality standards, improved aesthetic conditions, reduced risk from bacterial contamination, and improvements attributable to the discovery and management of pollutants in storm water that otherwise would have gone unnoticed. EPA attempted to put a dollar value on these benefits in its benefit/cost analysis prepared for the Phase II storm water regulations, estimating that such benefits could range from $672 million to $1.1 billion per year (in 1998 dollars).[38]

However, little information is currently available on the benefits of the storm water program or its general effectiveness. There is no doubt that it will take time for the results of the Phase I program to be demonstrated. As EPA notes in its February 2000 report to the Congress, pollution control efforts under water quality management programs produce long-term changes, and the agency expects water quality improvements attributable to the Phase I program to become evident in the future, as the program matures. In this report, EPA concluded that the program has improved storm water management at the local level, improved water quality, and decreased pollutant loads in storm water. However, EPA relied on a survey of only nine Phase I cities in making these conclusions and, therefore, also reported that the agency could not provide national estimates on water quality protection and improvements generated by Phase I of the program. To evaluate the entire program, EPA would have to establish goals for the program that are based on its mission; obtain information about the program's results; compare the results with the goals; and make changes to the program, if warranted, to get closer to achieving the agency's goals.

EPA and the states also have not taken advantage of information that is available to evaluate the program. Each city we visited was regularly monitoring its storm water to establish baseline information on pollutant levels and was reporting this information to EPA or the regulatory state agency each year. Although cities with Phase I permits are required to report on their storm water monitoring results and changes in water

[38]Using another method, EPA estimated the benefits at $1.6 billion per year.

R0012701

quality, overall, EPA and the states have not successfully developed measurable goals for the program or demonstrated its effectiveness through the review of municipal reports. An EPA official said that some states had requested funding to analyze program data because they did not have the resources to do so, and that EPA had provided the funding in a few cases. EPA also has not established any guidelines for how these data should be reported. Therefore, the reports may be as variable as the cost information we obtained in our five site visits.

EPA has not yet taken any of these data-analysis steps because, according to EPA officials, other program challenges within the Office of Wastewater Management compete with storm water management efforts for priority. For example, EPA officials stressed that available resources within the office must address other significant wet-weather pollution problems, such as CSOs and sanitary sewer overflows, and nonpoint source pollution problems, such as agricultural practices, forestry, and mining. One agency official noted that the highest priority is addressing needs that the agency and local governments have identified for improving wastewater infrastructure, such as sewage treatment facilities. The program also has relatively few staff assigned—about five in the headquarters office and about 10 in the regional offices—for the municipal, industrial, and construction portions of the program. In a program plan recently prepared for the storm water program, EPA estimated that nine to 10 staff would be needed in EPA headquarters to evaluate the program and implement other program requirements.

EPA officials described two efforts that may be the first steps in developing better information about the program. First, EPA intends to issue a grant to the University of Alabama in June 2001 to evaluate monitoring data submitted by a sample of municipalities with Phase I permits. This effort will (1) determine the different types of monitoring being conducted by Phase I municipalities, (2) assess water quality in and around permitted municipalities and determine any correlation between program implementation and impacts on water quality, and (3) recommend approaches for improving the effectiveness of municipal storm water monitoring programs. EPA expects the results of this study in 2003. Second, an EPA official stated that the agency would like to establish a system for analyzing program findings, incorporating necessary changes that are based on these findings, and evaluating the program's effectiveness. The agency plans to implement a pilot project in 2001 in the agency's Atlanta Region IV office for analyzing data reported in annual

R0012702

reports and developing key indicators for the program. If this project is successful and resources are available, the project could be expanded.

Conclusions

EPA regards urban runoff as a significant threat to water quality across the nation and considers it to be one of the most significant reasons that water quality standards are not being met nationwide. Prompted by the Congress, EPA has responded with a variety of programs, including the NPDES Storm Water Program, which requires more than 1,000 local governments to implement storm water management programs. Those municipalities that are currently involved in Phase I of the program have been attempting to reduce pollutants in storm water runoff for several years. It is time to begin evaluating these efforts. However, EPA has not established measurable goals for this program. In addition, the agency has not attempted to evaluate the effectiveness of this program in reducing storm water pollution or to determine its cost. The agency attributes this problem to inconsistent data reporting from permitted municipalities, insufficient staff resources, and other competing priorities within the Office of Wastewater Management. Although Phase I municipalities report monitoring and cost data to EPA or state regulatory agencies annually, these agencies have not reviewed this information to determine whether it can be of use in determining the program's overall effectiveness or cost. Our analysis shows that the reported cost information will be difficult to analyze unless EPA and its state partners set guidelines designed to elicit more standardized reporting. Better data on costs and program effectiveness are needed—especially in light of the Phase II program that will involve thousands more municipalities in 2003. EPA's planned research grant to the University of Alabama and its pilot project in the agency's Region IV to analyze data from annual reports and develop baseline indicators is a step in the right direction and could point the way for a more comprehensive approach.

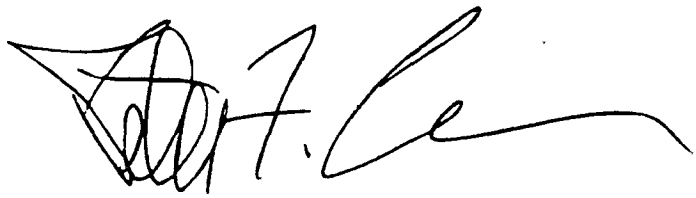
Recommendation

To determine the extent to which activities undertaken through the NPDES Storm Water Program are reducing pollutants in urban runoff and improving water quality, and the costs of this program to local governments, we recommend that the Administrator, EPA, direct the Assistant Administrator for the Office of Water to

- establish measurable goals for the program;

R0012703

- establish guidelines for obtaining consistent and reliable data from local governments with Phase I permits, including data on the effects of the program and the costs to these governments;
- review the data submitted by these permittees to determine whether program goals are being met and to identify the costs of the program; and
- assess whether the agency has allocated sufficient resources to oversee and monitor the program.



Agency Comments and Our Evaluation

We provided a draft of this report to EPA and DOT for their review and comment. EPA generally agreed with the report and with the recommendation, although it did not explicitly comment on all parts of it. (EPA's comments appear in app. VI.) In response to our recommendation that EPA set measurable goals for the storm water program, EPA stated that under the second phase of the program, local governments will establish their own goals. Although this is an important activity, EPA will have difficulty evaluating the program's effectiveness at a national level without setting goals that reflect the program's mission of improving water quality. The agency (1) agreed that it should establish guidelines for obtaining consistent and reliable data from local governments about their programs and (2) plans to award grants to two universities for reviews of monitoring data reported by local governments. EPA did not comment on whether local governments should report on the costs of their programs. EPA also agreed that it and its state partners should review data reported by local governments to determine whether the program's goals are being met. In April 2001, EPA officials told us that the agency planned to undertake a project in the Region IV (Atlanta) office to evaluate the methods local governments are using to control storm water. EPA's letter indicates that the agency now plans to implement this project in three regional offices and 10 states. EPA did not comment on the part of our recommendation that the agency review the level of resources devoted to overseeing and monitoring the program. EPA also provided technical comments that we incorporated where appropriate.

DOT generally agreed with the draft report and provided technical comments that we incorporated where appropriate. In particular, DOT suggested that we revise several references in the draft report to paved surface area and its relationship to increases in urban runoff, to emphasize that impervious surfaces, of which paved surfaces are a significant subset, cause increases in runoff. We revised the language in these places.

R0012704

As agreed with your offices, unless you publicly announce its contents earlier, we plan no further distribution of this report until 7 days after the date of this report. At that time, we will send copies of this report to the Administrator, Environmental Protection Agency, and the Secretary of Transportation. We will make copies available to others on request. If you or your staff have any questions about this report, please call me at (202) 512-2834. Key contributors to this report are listed in appendix VII.

Peter F. Guerrero
Director, Physical Infrastructure Issues

R0012705

The Storm Water Program in Baltimore City, Maryland

Baltimore City's municipal separate storm sewer system (MS4) is regulated by the Maryland Department of Environment (MDE) and, according to a city official, services the entire city. The city is currently implementing its second, 5-year National Pollutant Discharge Elimination System (NPDES) permit, issued on February 8, 1999. Before obtaining the first NPDES storm water permit in 1993, Baltimore City addressed the adverse affects of storm water runoff by implementing Maryland's Storm Water Management Program and Erosion and Sediment Control Program. According to the 2000 census, Baltimore City's population is about 651,000.

Urban Runoff Problems in Baltimore City

Baltimore City's urban runoff discharges to four major areas—Gwynns Falls, Jones Falls, Herring Run, and the Patapsco River—and then ultimately to the Chesapeake Bay. In 1990, the Environmental Protection Agency's (EPA) 319(a) report[1] implicated urban runoff as the main source of pollution in these waters. Moreover, Baltimore City was one of the areas studied in EPA's Nationwide Urban Runoff Program in the 1980s. This study reported that urban runoff contributed over 60 percent of the total nitrogen, phosphorus, and organic carbon; over 70 percent of the chemical oxygen demand; and over 80 percent of the total suspended solids, lead, and zinc in local water bodies.

An MDE official told us that nutrients, zinc, and suspended solids are among the constituents most commonly found in urban runoff, but the quantitative contribution to water quality impairment in the state's waters was not known. Also, in 1996, the Chesapeake Executive Council designated the Baltimore Harbor as one of three toxic regions of concern in the Chesapeake Bay. The harbor suffers from sediment contaminated by banned substances (such as the termiticide chlordane) and contaminants currently being released (such as metals and organics). Furthermore, according to the Chesapeake Bay Program Office, data collected from Phase I permittees indicate that storm water runoff can be a significant source of metals and organics in the harbor.

A Baltimore City official told us that some portions of Maryland's waters are impaired because of unacceptable levels of nutrients, metals,

[1]Section 319(a) of the Clean Water Act requires, among other things, that states identify and report to EPA the navigable waters that cannot reasonably be expected to maintain water quality standards (e.g., established water body uses) without additional action to control nonpoint source pollution.

R0012706

suspended sediments, and chlordane. Moreover, this official noted that the state does not consider data that municipalities collect under their NPDES storm water permits during the 303(d) listing process. Therefore, he believes that streams in Maryland are much more impaired than indicated by the listing process.

Baltimore City's Use of Best Management Practices

Like other NPDES storm water permit holders, Baltimore City uses a variety of best management practices (BMP) to reduce the amount of pollutants in runoff to the maximum extent practicable. These BMPs include detention ponds, shallow marshes (which use the biological and naturally occurring chemical processes in water and plants to remove pollutants), sand filter devices, public education programs, and the identification of illicit discharges to the MS4 system. Furthermore, Baltimore City participates in Maryland's effort to reduce nutrient levels in the Chesapeake Bay. Refer to the section of this report describing local government efforts to manage storm water for details concerning this nutrient-reduction goal. One other BMP includes the following:

- Baltimore City has incorporated the *2000 Maryland Storm Water Design Manual's* management policies, principles, methods, and practices into its current NPDES storm water discharge permit. The purpose of the design manual is to (1) protect the waters of the state from the adverse effects of urban storm water runoff; (2) provide design guidance on the most effective structural and nonstructural BMPs for development sites; and (3) improve the quality of BMPs that are constructed in the state, with particular attention to their performance, longevity, safety, ease of maintenance, community acceptance, and environmental benefit.

Costs Associated With Managing Storm Water

We were not able to obtain comprehensive information on the total cost to Baltimore City of managing storm water. Therefore, we do not present that information here.

Funding Sources

Baltimore City funds its storm water management control efforts with city water and sewer user fees and with state funds.

R0012707

The Storm Water Program in Boston, Massachusetts

The Boston Water and Sewer Commission received a NPDES storm water permit in October 1999. The commission is a separate entity from the city of Boston and, therefore, does not manage some storm water controls that are common in Phase I permits, such as street sweeping, winter deicing, and many of the urban runoff controls required for new developments. Boston has combined sewer systems as well as separate sanitary sewers and storm drains. The commission maintains 206 storm water outfalls and serves approximately 33 percent of the city through its separate MS4 system. In addition to the resident population of about 589,000, this system also almost daily serves 340,000 commuting workers; 70,000 shoppers, tourists, and business people; and 75,000 commuting students. The commission's sanitary and combined flows are transported to the Massachusetts Water Resources Authority at Deer Island. The commission is also the permittee for EPA's Combined Sewer Overflow Program.

Urban Runoff Problems in Boston

The commission considers the identification and elimination of illegal sanitary sewer connections as the most effective means of improving water quality and protecting public health. It is also concerned with the washoff of animal wastes from residential and open land, which is another major contributor to the impairment of water quality because it can cause an increase in coliform levels in the storm water discharges to the receiving waters.

The commission has contracted for various studies to determine the impact of storm water runoff. The following two studies identified sources of bacterial contamination and characterized the quality of storm water discharged from different types of land uses. The studies included metering storm water flows, collecting and analyzing the storm water and receiving water quality samples, and identifying and remediating illegal sewer connections. Observations from the studies include the following:

- A 1996 study determined that pet waste, rather than sanitary sewage, was a key contributor of bacteria to the storm drain system that had possibly led to beach closings in the area.
- A 1998 study identified several illegal connections to the storm drain system. Furthermore, the study showed that deicing and sanding efforts resulted in levels of sodium, chloride, total dissolved solids, and cyanide that exceeded EPA's acute (high dose) toxicity levels.

R0012708

Boston's Use of Best Management Practices

To meet the NPDES permit's requirements, the commission, like other permittees, continued BMPs, such as identifying illegal connections, and implemented new BMPs aimed at preventing the discharge of pollutants to storm drains and receiving waters. Refer to the section of this report describing local government efforts to manage storm water for details describing the commission's citywide catch-basin inspection cleaning and preventative maintenance program. Other efforts include the following:

- The commission has placed particle separators, which remove oil, grease, and sediments from storm water flows, throughout the city. The commission requires particle separators to be installed by developers on all newly constructed storm drains that serve outdoor parking areas. Fuel-dispensing areas not covered by a canopy or other type of roof enclosure must also have a particle separator.
- The commission requires developers to consider on-site retention of storm water for all new projects, wherever feasible. On-site retention aids in controlling the rate, volume, and quality of storm water discharged to the commission's storm drainage system.

Costs Associated With Managing Storm Water

We were not able to obtain comprehensive information on the total cost to the commission of managing storm water because the commission does not separate the cost of its storm water program from the cost of its sewer operations. Therefore, we do not present that information here.

Funding Sources

The commission funds its storm water management control efforts primarily with city water and sewer user fees and bond proceeds.

R0012709

The Storm Water Program in Los Angeles County, California

Under the NPDES Storm Water Program, the Los Angeles Regional Water Quality Control Board issues 5-year permits to Los Angeles County for its municipal storm water program. The Los Angeles County permit, issued in July 1996, is the county's second storm water permit. This permit includes Los Angeles County as the principal permittee and 85 cities as permittees. According to the 2000 census, Los Angeles County's population is about 9.5 million.

Urban Runoff Problems in Los Angeles County

The effects of urban runoff on the ocean are of particular concern in southern California. Contaminated sediments, impaired natural resources, and potential human illness could threaten the county's tourism economy, estimated to be about $2 billion a year.

The following three studies have shown that urban runoff can pose health risks to swimmers near storm drains and contribute toxic metals to receiving water sediments:

- The Santa Monica Bay Restoration Project conducted a study to assess the possible adverse health effects of swimming in waters contaminated by urban runoff.[1] This study revealed that there is an increased risk of illness associated with swimming near flowing storm drain outlets and an increased risk of illness associated with swimming in areas with high concentrations of bacteria indicators. Furthermore, illnesses were reported more frequently on days when the samples were positive for enteric viruses. Refer to the section of this report describing the effects of runoff on aquatic life and human health for more details.
- The Southern California Coastal Water Research Project coordinated a study that assessed microbiological water quality and found that the majority of shoreline waters exceeded water quality standards during wet-weather conditions. Furthermore, the ocean waters near storm water outlets demonstrated the worst water quality regardless of the weather.[2]
- The Southern California Coastal Water Research Project also compared the runoff from an urban area and a nonurban area in the Santa Monica

[1]R.W. Haile and others, "The Health Effects of Swimming in Ocean Water Contaminated by Storm Drain Runoff," *Epidemiology*, July 1999, Vol. 10, No. 4.

R0012710

Bay Watershed.[3] The results of the study indicated that storm water plumes extended up to several miles offshore and persisted for a few days. Furthermore, the runoff from the urban area proved to be toxic to sea urchin fertilization, and dissolved zinc and copper were determined to be contributors to the toxicity. The study also found that in urban areas, sediments offshore generally had higher concentrations of contaminants such as lead and zinc.

Los Angeles County's Use of Best Management Practices

As in the other sites we visited, the county is managing its runoff through the use of conventional BMPs. These BMPs include the elimination of illicit connections and discharges to the storm sewer system, construction control measures, routine inspections, staff training, pollution prevention plans for public vehicle maintenance and material storage facilities, sweeping and cleaning public parking facilities, street sweeping, catch-basin cleaning, and public education.

The Los Angeles Regional Water Quality Control Board recently adopted a Total Maximum Daily Load (TMDL) Program to reduce trash loads to the Los Angeles River. As a result, the county is exploring a number of trash reduction BMPs, which are discussed in the section of this report describing local government efforts to manage storm water.

Costs Associated With Managing Storm Water

Table 3 indicates that the county and the other permittees have allocated significant funding for storm water management activities over the years. For example, for fiscal year 1999,[4] projected funding for storm water management activities for the county and the other permittees amounted to over $134 million.[5] The largest projections for both went toward public agency activities. For example, during fiscal year 1999, the principal permittee and the permittees together projected almost 67 percent of storm water management funds to public agency activities. The activities in this

[3]Southern California Coastal Water Research Project, *Study of the Impact of Stormwater Discharge on Santa Monica Bay–Executive Summary,* Nov. 1, 1999.

[4]The county's fiscal year begins July 1 and ends June 30.

[5]According to an official with the Los Angeles Regional Water Quality Control Board, this figure may also include activities that are outside the scope of the permit.

R0012711

program include staff training, inspections of construction projects, street sweeping, and catch-basin cleaning.

Table 3: Summary of Fiscal Resources Projected for Los Angeles County and Its Co-permittees, Fiscal Years 1997-99

(Dollars in thousands)[a]

	Fiscal year 1997		Fiscal year 1998		Fiscal year 1999	
Activity	County	Others[b]	County	Others[b]	County	Others
Program Management	$2,225	$6,195	$1,856	$4,874	$1,466	$6,187
Illicit Connection, Illicit Discharge Program	1,620	3,515	1,017	3,075	764	2,901
Development planning and construction	784	6,208	1,300	3,769	1,452	5,743

[a]Totals may not add up because of rounding.

[b]Does not include 17 permittees for fiscal year 1998 and 13 permittees for fiscal year 1997 for the following reasons: The permittee operated on a different budget cycle, the final document was not available at the time of the annual report, or the information submitted by the permittee was not complete.

Source: GAO's analysis of cost data provided by the Los Angeles County Department of Public Works.

As shown in table 3, the county maintains primary responsibility for monitoring activities, having projected over $2 million for storm water monitoring activities in fiscal year 1997, almost $2 million in fiscal year 1998, and over $1.5 million in fiscal year 1999. Conversely, the permittees' projected funding levels for monitoring activities amounted to only $619,000 in fiscal year 1997, $729,000 in fiscal year 1998, and $737,000 in fiscal year 1999. According to an official with the Los Angeles Regional Water Quality Control Board, the County has consistently maintained primary responsibility for monitoring activities required under the permit.

R0012712

Funding Sources

The primary source of funds for the county's storm water program is flood control assessments collected throughout the district. Although the county has not applied for any state revolving funds, it has applied for and received approval for federal funds through the Transportation Equity Act for the 21st Century (TEA-21) for a pilot study of an engineering device that would remove trash from storm water. Additionally, the county has received partial funding through Proposition A of the Safe Neighborhood Parks of 1992 and 1996[6] for two Vortex Separation Systems—a Continuous Deflective Separation unit and a Stormceptor unit. Additionally, the county received grant money from the Metropolitan Transit Authority, which partially funded catch-basin screens, a Continuous Deflective Separation unit, and 120 catch-basin inserts.[7]

[6]The Los Angeles County Regional Park and Open Spaces District (a district within the Parks Department) received this funding from Proposition A and, in turn, made grants to the Los Angeles County Department of Public Works for the BMP devices.

[7]The Metropolitan Transit Authority receives TEA-21 funds from the California Department of Transportation.

R0012713

The Storm Water Program in Milwaukee, Wisconsin

The Wisconsin Department of Natural Resources (WDNR) has the authority to regulate the discharge of storm water from municipalities, construction sites, and industries under Natural Resources Code 216. This rule identifies Wisconsin municipalities that are required to obtain a storm water discharge permit under the Wisconsin Pollutant Discharge Elimination System (WPDES). Milwaukee completed its application process in 1994, and WDNR issued a WPDES permit to the city in October 1994. This was the first municipal storm water permit issued to a municipality in EPA's Region 5 covering the midwest. In July 2000, WDNR reissued Milwaukee's storm water permit. According to the 2000 census, Milwaukee's population is about 597,000.

Urban Runoff Problems in Milwaukee

Milwaukee has a combined sewer system as well as a separate sanitary sewer system. The Milwaukee Metropolitan Sewerage District implemented a rehabilitation program that cost over $2 billion to reduce the number of combined sewer overflow (CSO) events each year. The rehabilitation program involved the construction of deep tunnels to store untreated wastewater and rainwater for later treatment at a wastewater treatment plant. Since 1996, the deep tunnels have significantly reduced the number of overflow events from an average of 50 to 60 per year before the construction to an average of two per year afterwards.

Urban runoff has been identified as a leading source of pollution to the Milwaukee River basin's streams, lakes, and wetlands and the Milwaukee River estuary. To address pollution from urban runoff, WDNR issues storm water permits to municipalities with MS4s serving areas with populations of 100,000 or more, municipalities in Great Lakes "areas of concern" where water quality has been identified as a serious problem, municipalities with populations of 50,000 or more that are located in priority watershed planning areas, and designated municipalities that contribute to the violation of a water-quality standard or are significant contributors of pollutants to state waters.

Milwaukee's Use of Best Management Practices

In addition to BMPs such as the elimination of illicit connections and discharges to the storm sewer system, the reduction of pollutants in storm water runoff from construction sites, public education, catch-basin cleaning, street sweeping, and the use of detention basins, Milwaukee has explored the use of innovative BMPs. Refer to the section of this report describing local government efforts to manage storm water for more

R0012714

details about an educational campaign directed at a specific watershed. Additional BMPs include the following:

- An innovative storm water control device was installed in a parking lot at a heavily used municipal public works yard that was found to discharge significant amounts of storm water pollutants. Termed the Multi-Chambered Treatment Tank (MCTT), this device is suitable for areas with limited space, cleans up polluted runoff close to its source, removes pollutants that are not susceptible to other treatment methods, and is hidden from view. The MCTT consists of a catch basin, a settling chamber, and a filter. Although the results of the monitoring studies have revealed that the device has a positive effect on water quality, officials with the Department of Public Works explained that it is cost-prohibitive and suitable only for sites with limited space.
- The permittee has also been working with WDNR, the Department of Transportation, the U.S. Geological Survey, and a neighborhood association in a joint effort to develop a storm water monitoring assessment program consisting of two innovative storm water treatment devices. One device removes grit, contaminated sediments, heavy metals, and oily floating pollutants from surface runoff. The other device removes a broad range of pollutants from runoff, such as bacteria, heavy metals, nutrients, petroleum hydrocarbons, and suspended solids. The devices are to be installed along a new reach of the Milwaukee Riverwalk through the third ward of Milwaukee.

Costs Associated With Managing Storm Water

Reliable data on the total cost to manage storm water in Milwaukee were not available and cannot be presented here because certain activities are not reported as program costs in the city's annual report. These activities include street sweeping; leaf collection; catch-basin and inlet cleaning; maintenance of public boulevards, parks, and public green spaces; and the recycling of waste oil and antifreeze. Therefore, the program costs reflected in the annual report do not take into account many of the nonstructural BMPs employed by the city nor do the totals include activities funded through grants. The storm water management activities that were included in the city's 2000 budget request were estimated to cost $460,000.

Funding Sources

Milwaukee's storm water program is primarily funded through the city's sewer maintenance fund. Unlike the general revenue account, which is

R0012715

based on property taxes, the sewer maintenance fund is based on water consumption. The city has also received supplemental funding from the Wisconsin Nonpoint Source Water Pollution Abatement Program in the form of WDNR grants. The city has received over $1 million since 1991 for a wide variety of storm water management activities.

R0012716

The Storm Water Program in Worcester, Massachusetts

Worcester's Department of Public Works (DPW) received a NPDES permit on November 1, 1998. The Sewer Operations Division, within the DPW, is directly responsible for operating and maintaining the city's separate storm sewer system, along with the sanitary and combined sewer system. Since 1993, the Sewer Operations Division has had a full-time storm water coordinator, reflecting Worcester's increased emphasis on meeting NPDES program requirements. Worcester has a population of about 173,000. Its water system covers an extensive area, including 371 miles of sanitary sewers, 340 miles of storm sewers, 56 miles of combined sewers, 27,000 manholes, over 14,000 catch basins, and 263 outfalls. Worcester's separate storm drain systems consist of 93 main drainage areas covering approximately 6,680 acres.

Urban Runoff Problems in Worcester

The constituents that are typically found in urban runoff in Worcester are the same as those normally found in urban runoff in older cities. Because virtually all of the paved surfaces in the Worcester area are devoted to the city's transportation infrastructure, the constituents generated include automobile-related petroleum products, such as total petroleum hydrocarbons, oil and grease, along with total suspended solids. Also, coliform, silt, and sediment have been identified in the city's runoff.

Worcester's Use of Best Management Practices

Like other permittees, the DPW has implemented BMPs under the major areas of education outreach, pollution prevention and source controls, storm-drainage system maintenance, regulatory efforts, and storm-drainage system infrastructure. Additionally, to reduce storm water pollution, the DPW has retrofitted a number of twin manholes in the city as discussed below. BMPs that are specific to Worcester include the following:

- The DPW implemented a demonstration project to determine the effectiveness of an oil and grit separator installed on a street drain. The drain is a major surface sewer main that services approximately 226 acres of heavily urbanized area with a typical mix of residential, commercial, and industrial use. The drain discharges into Lake Quinsigamond, which is a large lake used for recreational purposes such as swimming and boating. In its April 2000 annual plan submitted to EPA, the DPW noted that because of drought conditions, it currently did not have sufficient sampling data to determine the effectiveness of the project.

R0012717

- The DPW has embarked on a comprehensive program to minimize the possibility that sewage and storm water will be mixed in its twin invert manholes. Since the program began, the DPW has installed hold-down devices on over 1,680 of the approximately 2,580 twin invert manholes in the city. The DPW expects to continue the program until all of the manholes have been retrofitted.
- The DPW is also working closely with the Massachusetts Department of Environmental Protection in its ongoing tracking efforts to ensure that industries in Worcester are doing their part to reduce storm water pollution.
- To improve its storm-drainage infrastructure, the city has established a voluntary plan to reduce the number of unpaved private roads. The dirt from these roads, especially after rain storms, causes sediment to build up in the drainage system. The DPW has developed a plan to pave the streets at a lower grade than would be necessary to meet the legal requirements for a public street. Under this plan, residents would not have to pay the additional betterment taxes that are now required to cover the costs of sediment removal and less sediment would be transported in runoff.

Costs Associated With Managing Storm Water

Since 1993, the DPW has allocated significant funding from the water and sewer utility fees it collects for controlling the effects of runoff, especially through catch-basin cleaning, street sweeping, and correcting illegal connections. For example, its fiscal year 1993 budget for storm water programs included about $1.6 million for specific programs and another $1 million for capital improvement programs, such as inflow/infiltration and flood control. The DPW also spent $500,000 to develop and submit its permit application. Furthermore, as shown in table 4, Worcester made extensive capital expenditures during fiscal years 1994 through 1999 on pertinent storm water projects to improve the quality of storm water runoff emanating from the city's storm water sewer system.

R0012718

Table 4: City of Worcester's Capital Expenditures for Storm Water Management

(Dollars in thousands)

	Fiscal year					
Activity	**1994**	**1995**	**1996**	**1997**	**1998**	**1999**
Sewer construction	$0	$500	$500	$300	$300	$300
Infiltration control	0	400	400	100	100	100
Pump station rehabilitation	200	200	200	200	200	200
Sewer rehabilitation	300	750	300	750	750	1,500
Landfill closeout	150	1,200	200	500	0	0
Belmont Drainage project	0	100	600	100	0	0
Beaver Brook Culvert project	0	500	100	100	300	100
Surface drain control	40	150	200	200	200	200
Geographic Information System	0	0	0	125	125	125
Other	0	70	10	0	0	0
Total	**$690**	**$3,870**	**$2,510**	**$2,375**	**$1,975**	**$2,525**

Note: The Belmont Drainage project involved enlarging the drain to eliminate surcharging and siltation and moving the outfall to eliminate stagnation. The Beaver Brook Culvert project involved repairing the culvert and conducting a study that included a detailed hydraulic analysis of the drainage basin.

Source: Worcester Department of Public Works.

Furthermore, during fiscal year 1999, the DPW spent approximately another $2.1 million to operate and maintain storm water activities. Key expenditures included about $1.2 million for street sweeping, about $617,000 for catch-basin maintenance, $52,000 for root control, and another $48,000 for street paving. Also included was $40,000 per year for sampling five outfalls around the city three times per year as required by the permit. According to a DPW official, in previous fiscal years, the DPW funded the same or similar operation and maintenance activities to help control storm water runoff. As a result, the costs since 1994 were similar to those for 1999, except for annual adjustments for inflation. Therefore, the annual operation and maintenance expenditures ranged from about $1.7 million for 1994 to about $2.1 million for 1999.

According to a DPW official, the department expects to spend from $3 million to $4.5 million annually over the next several years on storm water-

R0012719

related activities. The amount of the cost increase will depend on whether EPA asks the city to increase its spending.

Funding Sources

The DPW funds its storm water management controls effort from the water and sewer user fees it assesses to homes and businesses.

R0012720

Comments From the Environmental Protection Agency

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D C 20460

JUN 14 2001

OFFICE OF WATER

Mr. Peter F. Guerrero
Director, Physical Infrastructure Issues
United States General Accounting Office
Washington, DC 20548

Dear Mr. Guerrero:

Thank you for the opportunity to review your draft report entitled "Better Data and Evaluation of Urban Runoff Needed to Assess Effectiveness." We appreciate the difficulty that assimilating and interpreting such information on an extremely complex subject must have presented. Your report provides a fair and balanced depiction of the Agency's efforts, with the assistance of our State and local partners, to implement a national urban storm water runoff control program.

As the report correctly acknowledges, the Environmental Protection Agency (EPA) believes that urban runoff is a significant threat to water quality and is actively working to control the discharge of pollutants in storm water runoff. EPA's urban storm water control program has been a very successful undertaking to date and we are taking steps to address several of the recommendations identified in the report.

One of the challenges of controlling urban storm water runoff is to be able to address a wide array of complex environmental issues, even within the boundaries of one municipality. EPA's urban storm water program is developed with the understanding that a "one size fits all" approach will not work. For example, existing municipal separate storm sewer system (MS4) permits are tailored to suit the needs of each individual municipality. In fact, the municipalities select the majority of the measures that will be implemented to control storm water runoff. Similarly, EPA's Phase II regulatory framework for small MS4s requires the municipality to identify appropriate BMPs to control runoff and establish measurable goals against which program effectiveness will be measured. These BMPs and measurable goals then become the enforceable permit conditions for that municipality. EPA expects that approximately 5,000 small MS4s will each have a unique set of measurable goals that will define expectations of a successful storm water control program.

While EPA has developed a sound regulatory basis for urban storm water control, competing initiatives have limited our ability to invest sufficient resources to fully evaluate the effectiveness of the program and the associated implementation costs. We believe that the flexibility afforded MS4 permittees provides some assurance that permit requirements do not become onerous or unjustified. Additionally, with the MS4 permits reissued every five years,

Internet Address (URL) • http://www.epa.gov
Recycled/Recyclable • Printed with Vegetable Oil Based Inks on Recycled Paper (Minimum 30% Postconsumer)

R0012721

EPA expects that dialogue between MS4s and permitting authorities will better focus on those activities found to be most beneficial.

Over the next year, we will address challenges relating to evaluating the effectiveness of municipal storm water programs. Consistent with the first recommendation, EPA will evaluate storm water monitoring data that has been collected since program inception. Two grantees (UCLA and the University of Alabama) will review monitoring data that has been submitted as part of routine discharge monitoring reports and annual reports. EPA expects these efforts will evaluate the correlation between storm water discharges and trends in water quality impairment. Another anticipated finding from these grants is a compilation of the range of monitoring activities required of municipalities in storm water permits and the identification of the monitoring that appears to be most effective in demonstrating program results.

To meet another challenge, we are evaluating MS4 permit requirements and annual reports to identify the types of storm water control activities in place and the environmental and programmatic results of these activities. Initially, this effort will evaluate MS4s in at least three EPA Regions and 10 states to gather information on the range of methods employed by permitted MS4s to control storm water discharges. Through this effort, EPA expects to determine whether program goals are being met and establish meaningful indicators of program performance. Should this effort prove useful, EPA will expand the evaluation to a national effort that will evaluate MS4 permits and annual reports in all affected EPA Regions and states. In either case, results of this effort will be disseminated nationally to ensure that findings are incorporated into other MS4 programs, as appropriate.

Enclosed are additional comments on terminology and regulatory citations provided in the report. Again, we appreciate the opportunity to review and comment on the draft report. If you have any questions about these comments or would like to discuss urban storm water runoff issues, please contact me or call Jeff Lape, Acting Director of the Water Permits Division, at (202) 564-9545.

Sincerely,

Michael B. Cook
Director
Office of Wastewater Management

Enclosure

R0012722

Enclosure

Below are several additional comments for your consideration that address terminology and regulatory citations provided in the report:

- The term "nonpoint source" throughout the report, when referring to storm water runoff, is somewhat misleading in that the federal definition of "point source" includes many of the types of storm water discharges discussed in the draft report as "nonpoint source pollution." We recommend clarifying that EPA's NPDES storm water permits regulate point source discharges that includes storm water runoff from small, medium, and large municipal separate storm sewer systems. In fact, to avoid confusion between point sources and nonpoint sources in an NPDES context, we recommend that you consider using the term "wet weather discharges" when referring to storm water runoff.

- The third sentence in the first full paragraph on page 3 states that "EPA requires cities to use 'best management practices' to reduce contamination in storm water runoff." We recommend that you change the word "requires" to "recommends." While best management practices are common for reducing storm water contamination, EPA regulations allow MS4s to reduce the discharge of pollutants to the maximum extent practicable using management practices, control techniques, and system, design, and engineering methods, and such other provisions which are appropriate.

- The last sentence in the second full paragraph on page 3 states that "managing storm water runoff will reduce runoff and improve water quality." We recommend changing this sentence to indicate that "managing storm water runoff will reduce the volume and concentration of pollutants in runoff and improve water quality.

- The last sentence of the same paragraph indicates that "Neither EPA nor states have developed measurable program goals or reviewed municipal reports on the results of storm water programs to determined whether the reports provide information that could demonstrate the program's effectiveness." A similar statement is made in the first full paragraph on page 31. We recommend that these two sentences be revised to indicate that "EPA and states have generally been unsuccessful in developing measurable program goals and in demonstrating program effectiveness through the review of municipal reports." EPA and some states have attempted to determine program effectiveness through the review of municipal reports but, to date, these efforts have been unsuccessful in making this determination.

PRINTED ON RECYCLED PAPER

USGS science for a changing world

U.S. Department of the Interior
U.S. Geological Survey

Comparison of NPDES Program Findings for Selected Cities in the United States

The U.S. Environmental Protection Agency, under section 402(p) of the Water Quality Act of 1987, has required municipalities with populations of more than 100,000 to obtain National Pollutant Discharge Elimination System (NPDES) permits for urban stormwater discharge. This regulation is intended to minimize pollutant loadings from urbanized areas and preserve the quality of streams that receive stormwater. To apply for a NPDES permit, a municipality must monitor the chemistry of stormwater from basins having residential, commercial, and industrial land uses, and estimate storm- and annual-pollutant loads and event-mean concentrations of 12 selected properties and constituents. The properties and constituents include biochemical oxygen demand (BOD), chemical oxygen demand (COD), suspended solids, dissolved solids, total nitrogen, total ammonia plus organic nitrogen, total phosphorus, dissolved phosphorus, total recoverable cadmium, total recoverable copper, total recoverable lead, and total recoverable zinc. These estimates will be used by the municipalities to evaluate the magnitude of pollutant loadings and the efficiency of management strategies that are intended to reduce pollutant loads.

As part of a national synthesis of the study units in the U.S. Geological Survey (USGS) NPDES program, data were compiled on concentrations of the 12 properties and constituents required for load calculations. This report presents a comparison of these data.

Data Collection

The USGS, in cooperation with local agencies, sampled stormwater from 1991 through 1996 in 13 cities and metropolitan areas that are required to obtain NPDES permits (fig. 1). For this comparison, Birmingham and Montgomery, Alabama, were considered one study unit and designated as Birmingham/Montgomery, Alabama. Samples were collected from various conveyances, such as culverts, concrete pipes, lined ditches, and unlined channels. The drainage area of sampling sites typically was small and ranged from 4.0 to 2,564 acres. Each site had a predominant land use—residential, commercial, or industrial (fig. 2). Flow and rainfall data either were collected on site or were estimated from nearby gages. Flow data are used to calculate loads from the concentration data. Samples were collected either by manually collecting discrete samples at timed intervals and flow-weighting volumes of these discrete samples or by collecting flow-weighted composite samples using an automatic sampler. Flow-weighted samples were collected during the first 3 hours of the storm or until the stream returned to pre-storm levels. Samples were collected at a particular site about 30 or more days apart and after approximately 72 hours of less than 0.1 inch of rain.

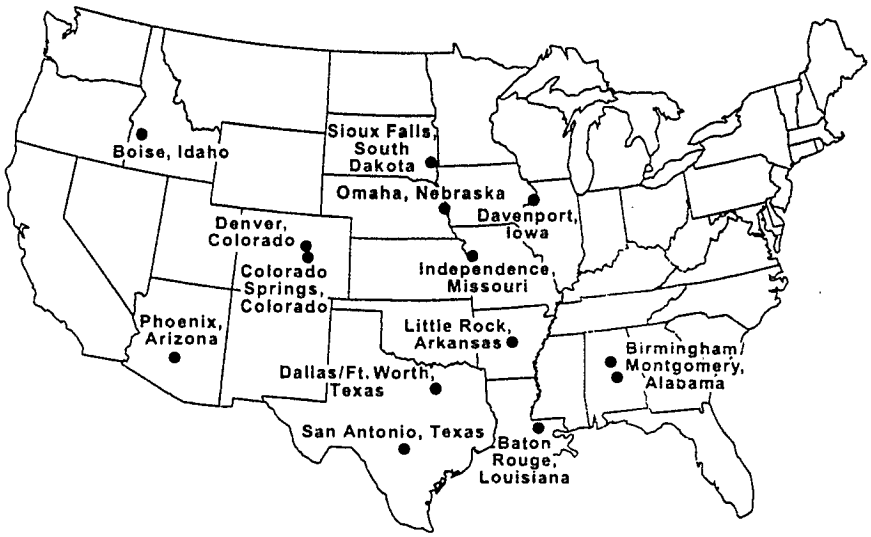

Figure 1. Cities and metropolitan areas where NPDES constituents were sampled in urban stormwater, 1991–96.

Data Analysis

Analyses of the flow-weighted composite samples were done at the USGS National Water-Quality Laboratory with the exception of the Sioux Falls, South Dakota, and BOD analyses. These analyses were done at the individual USGS offices or at contract laboratories.

Nationwide Data Comparison

In an effort to compare storm loads for different land uses, concentration and flow data were compiled from study units in the USGS NPDES data bases. Concentration data and flow volumes were combined along with a unit-conversion factor to obtain storm loads in pounds for each storm. The storm loads then were divided by the area of the individual basins to obtain storm load per unit area, in pounds per acre. Mean storm loads for all constituents then were calculated for the three land uses in each city or metropolitan area (table 1). This manipulation allows direct comparison of the storm loads for each land use.

R0012726

R0012727

Physical Properties

BOD, COD, suspended solids, and dissolved solids were compared for all the cities with the exception of Davenport, Iowa; Boise, Idaho; and Birmingham/Montgomery, Alabama. Samples from Davenport, Iowa, were not analyzed for these properties and constituents. An industrial land-use basin was not sampled in Boise, Idaho. Samples from Birmingham/Montgomery, Alabama, were not analyzed for BOD.

BOD and COD are determined by measurement of the quantity of oxygen utilized by organic matter and chemicals in stormwater samples and are used to indicate pollution (Hem, 1992). Mean storm loads of BOD varied by two orders of magnitude, from 0.05 to 10 pounds per acre. The largest mean storm loads of BOD were associated with industrial land-use basins, except for the maximum that occurred in commercial land-use basins in Denver, Colorado. Mean storm loads of COD varied by two orders of magnitude, from 0.17 to 37 pounds per acre. The largest mean storm loads of COD were associated with commercial land-use sites, except for the maximum that occurred in industrial land-use basins in Baton Rouge, Louisiana.

Concentrations of suspended solids and dissolved solids are measures of solids loads in stormwater and also may be used as indicators of pollution. Mean storm loads of suspended solids varied by more than two orders of magnitude, from 0.28 to 66 pounds per acre. The largest mean storm loads of suspended solids were associated with the industrial land-use basins; the maximum occurred in Omaha, Nebraska. Mean storm loads of dissolved solids varied by more than three orders of magnitude, from 0.17 to 250 pounds per acre. The largest mean storm loads of dissolved solids were associated with industrial land-use basins; the maximum occurred in Independence, Missouri.

Nutrients

Four nutrient constituents—total nitrogen, total ammonia plus organic nitrogen, total phosphorus, and dissolved phosphorus—are being analyzed by the USGS NPDES program. These constituents were compared for all land uses in selected cities, with the exception of industrial land-use basins in Boise, Idaho. An industrial land-use basin was not part of the sampling program in Boise.

Nutrients are essential components in plant growth; however, an overabundance of these constituents will cause undesirable algal blooms in bodies of water that are used for urban drinking-water supplies (Hem, 1992). These algal blooms cause adverse effects on the taste and odor of drinking water and have the potential to cause more serious health problems.

Mean storm loads of total nitrogen varied by more than two orders of magnitude, from 0.0013 to 0.54 pounds per acre. The largest mean storm loads of total nitrogen are associated with industrial land-use basins; the maximum occurred in Baton Rouge, Louisiana.

Mean storm loads of total ammonia plus organic nitrogen varied by almost two orders of magnitude, from 0.0064 to 0.43 pounds per acre. The largest mean storm loads of total ammonia plus organic nitrogen were associated with industrial and commercial land-use basins; the maximum occurred in Baton Rouge, Louisiana.

Mean storm loads of total phosphorus varied by almost two orders of magnitude, from 0.0009 to 0.074 pounds per acre. The largest mean storm loads of total phosphorus were associated with industrial land-use basins; the maximum occurred in Baton Rouge, Louisiana.

Mean storm loads of dissolved phosphorus varied by more than three orders of magnitude, from 0.0001 to 0.044 pounds per acre. The largest mean storm loads of dissolved phosphorus were associated with industrial land-use basins; the maximum occurred in Baton Rouge, Louisiana.

Figure 2. National Pollutant Discharge Elimination System (NPDES) residential land-use site at Glendale, Arizona.

R0012728

Trace Metals

Concentrations of four trace-metal constituents—total recoverable copper, total recoverable zinc, total recoverable cadmium, and total recoverable lead are being analyzed by the USGS NPDES program. These constituents were compared for all land uses in the selected cities with the exception of Davenport, Iowa, and Boise, Idaho. Concentrations of these constituents were not determined in Davenport, Iowa, and an industrial land-use basin was not sampled in Boise, Idaho.

Copper and zinc are essential to plant and animal metabolism and are needed in small amounts by all plants and animals. Large amounts of these metals in drinking water, however, can cause adverse effects on the taste and odor of drinking water.

Mean storm loads of total recoverable copper varied by more than three orders of magnitude, from 3.1×10^{-5} to 5.1×10^{2} pounds per acre. The largest mean storm loads of total recoverable copper were associated with commercial and industrial land-use basins. The exception was the maximum that occurred in a residential land-use basin in Birmingham/Montgomery, Alabama.

Mean storm loads of total recoverable zinc varied by almost three orders of magnitude, from 4.4×10^{-4} to 1.1×10^{-1} pounds per acre (fig. 3). The largest mean storm loads of total recoverable zinc were associated with industrial land-use basins, the maximum occurred in Independence, Missouri.

Cadmium and lead tend to bioaccumulate in plants and animals. Large concentrations of these metals lead to toxicity and health problems in plants and humans (Hem, 1992).

Concentrations of total recoverable cadmium were considered in this analysis of data, but more than 70 percent of the analyses were below detection limits. No mean storm loads of cadmium were included in the data tables.

Mean storm loads of total recoverable lead varied by almost three orders of magnitude, from 8.3×10^{-5} to 3.9×10^{-2} pounds per acre. The largest mean storm loads of total recoverable lead were associated with industrial land-use basins; the maximum occurred in Baton Rouge, Louisiana.

The majority of minimum mean storm loads occurred in residential land-use basins and the majority of maximum mean storm loads occurred in industrial land-use basins. The information contained in this fact sheet is part of ongoing studies and may be updated upon completion of the NPDES program.

—Kenneth D. Fossum and Dawn S. McDoniel

Nonpoint source pollution—that is, pollution from contaminants picked up and carried into surface water by water running over land—is known to be one of the leading causes of water quality problems in the United States. Water that runs over developed areas, including paved surfaces such as roads and parking lots, before reaching a water body is known as urban runoff and is an increasingly important category of water pollution. As urban areas have expanded over the past several decades, the amount of urban runoff has also increased. Although the overall quality of the nation's waters has improved since the passage of the Clean Water Act in 1972, a significant number of water bodies still suffer from poor water quality. Because the act brought discharges from "point sources," such as industrial plants and municipal treatment plants, under control, the continuing pollution of these waters suggests that other sources, including urban runoff, are contributing to water quality problems. As a result, the Environmental Protection Agency (EPA) now classifies urban runoff as a significant cause of impairment to water quality. The Water Quality Act of 1987, which amended the Clean Water Act, required EPA, among other things, to regulate as a point source urban runoff that reaches municipal sewer systems. EPA's National Pollutant Discharge Elimination System Program for storm water requires that certain local governments take measures to control storm water runoff.

R0012737

Concerned about the degradation of water quality in urban areas, you asked us to report on (1) the amount of runoff from urban areas, particularly from roads, highways, and other impervious surfaces,[1] and its effects on water quality and (2) the programs that federal regulations require local governments to develop to address urban runoff, and the costs and effectiveness of those programs. To address these issues, we reviewed federal and other studies and interviewed experts on the relationship between the amount of paved and other impervious surfaces and the amount of runoff, and on the types of materials typically contained in urban runoff. We also reviewed studies and interviewed experts on the sources of these materials and any actual or potential effects on water quality from urban runoff. We visited five urban areas and organizations that are affiliated with their watersheds[2] to obtain site-specific information about urban runoff problems, programs these areas have implemented in response to federal requirements, and the costs and effectiveness of these programs. Finally, we reviewed studies and estimates of the costs and investment requirements associated with implementing storm water management programs. Because this report focuses on local governments' actions, we did not review the portions of the National Pollutant Discharge Elimination System Storm Water Program that address industrial facilities and construction sites.

We performed our review from August 2000 through May 2001 in accordance with generally accepted government auditing standards.

Results in Brief

The volume of urban storm water runoff increased throughout the United States in the last half of the 20th century because of the growth in impervious surfaces that resulted from the development of urban and suburban areas. According to the U.S. Department of Agriculture, between 1945 and 1997, land devoted to urban areas in the United States has increased by about 327 percent; according to EPA, paved road mileage has increased by 278 percent. Because paved surfaces are almost impervious, they allow little storm water to infiltrate the ground; therefore, the storm water runs off into creeks, rivers, and lakes. As storm water runs across these impervious surfaces and land, it picks up pollutants from these surfaces and carries them to receiving bodies of water—either directly or

[1]An impervious surface keeps water from soaking into soils.

[2]A watershed is an area of land in which all surface water drains to a common point.

R0012738

through conveyances such as gutters, storm sewers, and culverts. EPA's 1998 *National Water Quality Inventory Report to Congress* showed that certain rivers, streams, lakes, and estuaries are impaired in terms of their ability to support such uses as aquatic life, swimming, and fish consumption, and concluded that urban runoff was a major source of this impairment. Studies have shown that urban runoff and the pollutants it carries can cause increases in sedimentation, water temperature, and pathogen levels and decreases in dissolved oxygen levels in bodies of water. These changes can lead to the degradation of habitat in these water bodies and a decline in diversity of aquatic life and can endanger public health. For example, metals, a pollutant typically found in urban runoff, can be toxic to aquatic organisms. Pathogens, such as bacteria from animal waste, another pollutant commonly found in urban runoff, can pose public health problems when present in waters used for recreational purposes. The magnitude and nature of these effects vary by region, depending on the type and concentration of pollutants in storm water, rainfall characteristics, land use, and other factors.

Local governments are required to address urban runoff through EPA's National Pollutant Discharge Elimination System Storm Water Program. Under permits that EPA and states issue through this program, over 1,000 local governments must meet EPA's requirements to implement storm water management programs to reduce contaminants in storm water to the "maximum extent practicable." EPA recommends that these cities use "best management practices" to reduce contaminants in storm water runoff. The most typical practices included controlling runoff through a combination of structural means, such as detention ponds, and nonstructural means, such as increasing the frequency of street sweeping and educating the public about how to prevent pollutants from reaching storm sewers. Cities also used specialized practices to address specific local runoff problems. For example, Baltimore, Maryland, has focused on reducing the level of nutrients, such as fertilizers, in its runoff because of its proximity to the Chesapeake Bay, which suffers from high nutrient levels.

Neither the overall costs of implementing the storm water program nor the program's effectiveness has been determined. EPA estimated in a 1996 report to congress that the potential need for spending on storm water runoff and overflows of sewage resulting from runoff was over $50 billion over 20 years, but the agency also believes this estimate will increase when it issues its next report in 2002. EPA's regulations require that permitted cities annually report the costs of implementing their storm water

R0012739

programs, along with the results of their monitoring of storm water runoff and water quality. However, in part because EPA has not established guidelines for reporting costs, these data have not been calculated or reported consistently and, therefore, are not currently useful in characterizing the program's overall cost. EPA, state, and city officials generally believe that managing storm water runoff will reduce the volume of runoff and concentrations of pollutants in the runoff, as well as improve water quality, but no systematic effort to evaluate the program's results has been started. EPA and the states have generally been unsuccessful in developing measurable program goals and in demonstrating program effectiveness through the review of water quality data reported by local governments.

We believe it is time for EPA to begin evaluating this program, which is directed at one of the nation's most significant water quality problems. Therefore, this report includes a recommendation to EPA to work with states to develop program goals, establish standards for reporting on program costs and effectiveness, and review reported water quality data to determine whether the current storm water management programs are having the intended effect of improving the quality of the nation's waters and how much the programs cost. We provided a draft of this report to EPA and the Department of Transportation (DOT). EPA generally agreed with the report and plans to take action to implement several parts of the recommendation; the agency did not comment on the other parts of the recommendation. DOT generally agreed with the report. (See the Agency Comments and Our Evaluation section of this report.)

Background

Nonpoint source pollution can result when water, such as precipitation, runs over land surfaces and into bodies of water. Significant nonpoint sources of pollution can include paved urban areas, agricultural practices, forestry, and mining. However, in urban and suburban areas, this runoff generally enters a sewer system that can be regulated as a point source of water pollution. For example, precipitation from rain or snowmelt may run into a municipal separate storm sewer system (MS4 or storm sewer) that eventually discharges into a body of water. The precipitation may also run into a combined sewer system, which carries a combination of storm water runoff, industrial waste, and raw sewage in a single pipe to a sewage treatment facility for discharge after treatment. Lastly, the precipitation may run off of land or paved surfaces directly into nearby receiving waters.

R0012740

EPA's Office of Wastewater Management, which is within the Office of Water, implements the National Pollutant Discharge Elimination System (NPDES) Program. The program was created in 1972 with the passage of the Clean Water Act. Created to control water pollution from point sources—those sources, such as a factory or wastewater treatment plant, that contribute pollutants directly into a body of water from a pipe or other conveyance—the NPDES Program did not specifically address storm water discharges. In 1987, the Congress amended the Clean Water Act with the Water Quality Act, which directed EPA to also control storm water discharges that enter MS4s—essentially requiring EPA to treat such storm water as a point source.[3] MS4s are defined as those sewers that collect and convey storm water; are owned or operated by the federal, state, or local government; and are not part of a publicly owned treatment (sewage) facility.

To regulate urban storm water runoff, EPA published regulations in 1990 that established the NPDES Storm Water Program and described permit application requirements. According to EPA, the program's objective, in part, is to preserve, protect, and improve water quality by, among other things, controlling the volume of runoff from paved surfaces and by reducing the level of runoff pollutants to the maximum extent practicable using best management practices (BMP).[4] The 1987 act also authorized EPA to implement a program that provides federal funds and technical assistance to states to develop their own nonpoint source pollution management programs. States can use the federal funds they receive for nonpoint source programs to address nonpoint sources of pollution as well as urban runoff.

Currently, EPA manages NPDES Storm Water programs in six states (Alaska, Arizona, Idaho, Massachusetts, New Hampshire, and New Mexico) and has delegated authority to the remaining 44 states to manage these programs. The storm water program is being implemented in two phases. Local governments meeting the following criteria must comply with EPA's storm water program regulations. First, Phase I of the program requires that municipalities with a population of 100,000 or more obtain a permit for their MS4 system; second, the program requires that entities obtain a

[3]Section 402(p) of the Clean Water Act.

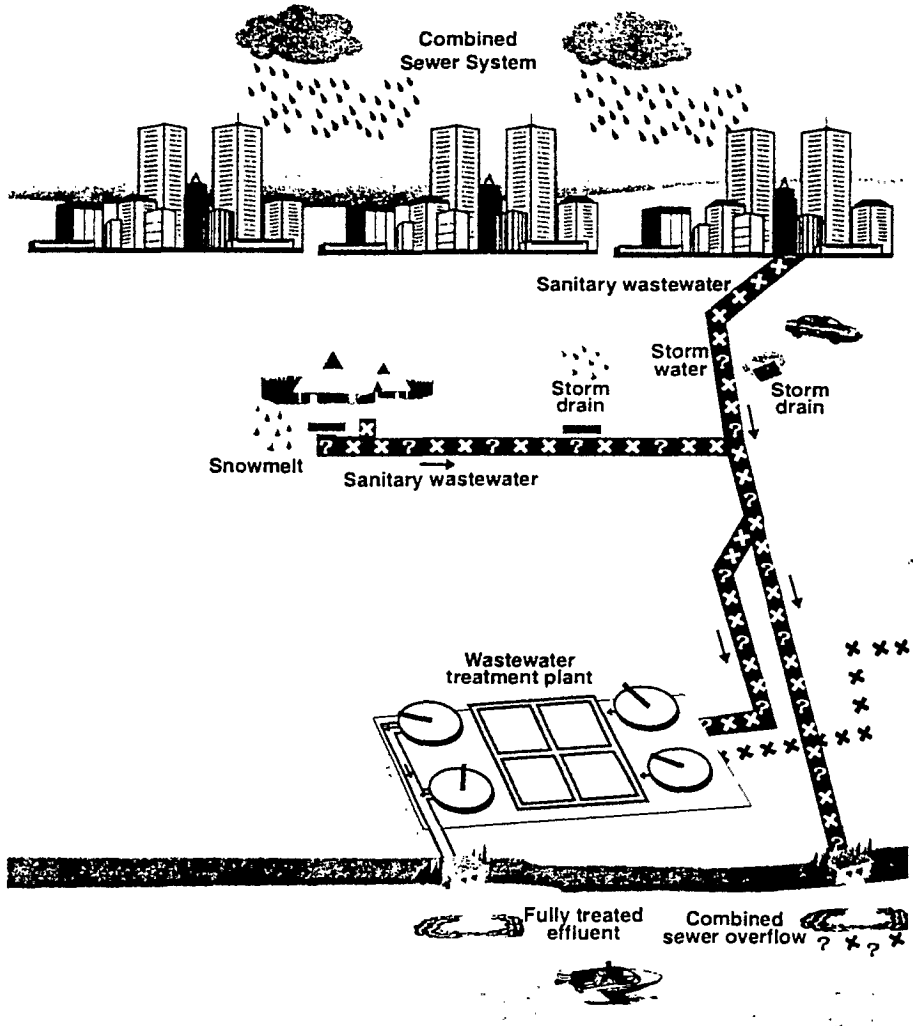
[4]According to EPA, a best management practice is a device, practice, or method for removing, reducing, retarding, or preventing targeted storm water runoff constituents, pollutants, and contaminants from reaching receiving waters.

R0012741

permit if they discharge storm water from sites with industrial activities, including construction activities that disturb 5 acres or more of land. In addition, NPDES permitting authorities may also bring other municipalities and industrial entities into the program if they deem it necessary. Municipalities that meet these conditions must submit a permit application to EPA or the governing regulatory state agency. In 1990, the regulations specifically identified 220 municipalities throughout the United States that were required to apply for a Phase I permit. According to EPA, as of April 2001, about 256 Phase 1 MS4 permits had been issued and about 17 more still needed to be issued. Because some permits cover more than one municipality, these permits cover about 1,000 medium and large municipalities nationwide.

The final rule for Phase II of the program was issued in December 1999. Phase II extends Phase I efforts by requiring that a storm water discharge permit be obtained by (1) operators of all MS4s not already covered by Phase I of the program in urbanized areas[5] and (2) construction sites that disturb areas equal to or greater than 1 acre and less than 5 acres of land. As with Phase I of the program, permitting authorities may require additional small MS4s and construction sites to obtain a permit if they are a significant contributor of pollutants. Currently, EPA anticipates that about 5,000 municipalities may be subject to permitting requirements under Phase II of the storm water program. These municipalities are required to obtain permits no later than March 10, 2003.

[5]The Bureau of the Census generally defines an urbanized area as a land area comprising one or more places—central place(s)—and the adjacent densely settled surrounding area—urban fringe—that together have a residential population of at least 50,000 and an overall population density of at least 1,000 per square mile.



R0012742

EPA also regulates combined sewer overflows (CSO) that can be caused by urban storm water runoff. Combined sewer systems, in which storm water enters pipes already carrying sewage, may overflow when rain or snowmelt entering the system exceeds the system's flow capacity. In the CSO that results, the mixture of untreated sewage and runoff bypasses the water treatment facility and is diverted directly into receiving waters. (See fig. 1 for an illustration of combined and separate sewer systems.) These combined systems generally serve the older parts of approximately 900 cities in the United States. Pipes carrying sewage and storm water separately generally serve newer parts of cities. EPA's 1994 CSO policy requires communities with combined sewer systems to take immediate and long-term actions to address CSO problems. The policy contains provisions for developing appropriate, site-specific NPDES permit requirements for all combined sewer systems that overflow because of wet-weather events. The Wet Weather Water Quality Act of 2000 requires that any permit, order, or decree issued for a CSO conform to the 1994 policy. Under this act, EPA is also required to submit a report to the Congress by September 2001 on the status of the program.[6]

[6]Sanitary sewer overflows, which are illegal under the Clean Water Act, can also result from rainfall. A sanitary sewer overflow may occur when rainwater or snowmelt leaks into sanitary sewage pipes, thereby exceeding the pipes' capacity and causing them to overflow. This discharge of raw sewage from municipal sanitary sewer systems can release untreated sewage into places such as streams, basements, and streets. EPA proposed regulations to require municipalities to reduce the number of overflows. However, these regulations have been withdrawn for further review.

R0012745

The Total Maximum Daily Load (TMDL) Program, established under the Clean Water Act, is intended to address water bodies that do not meet water quality standards because of pollutant loadings from point and nonpoint sources. Currently, it is unclear how and when this program will affect EPA's and states' issuance of storm water permits. A TMDL is a calculation of the maximum amount of a pollutant that a body of water can receive and still meet the water quality standard set by the state. Under EPA's regulations, the state is to allocate this "pollutant load" among the point and nonpoint pollutant sources that flow into the water body and then take steps to ensure that no source exceeds its assigned load. In 1996, EPA issued a policy that outlined an interim approach to including water quality standards in storm water permits. The policy promoted the use of BMPs in the first 5-year term permits, followed by a tailoring of BMPs in the second round of permits as necessary to comply with water quality standards. Until recently, few TMDLs had been established, and citizen organizations sued EPA for its lack of action. EPA issued a new set of regulations for the TMDL Program in 2000, but the Congress prevented EPA from spending money to implement the rule in 2000 and 2001. It is possible that establishing a TMDL for a body of water could result in the application of a numeric effluent limit to outfalls[7] that release storm water into that body of water. Some city officials we spoke with generally felt that numeric effluent limits would significantly increase the cost of managing storm water.

Volume of Urban Runoff Increases With the Expansion of Urban Development and Can Affect Water Quality

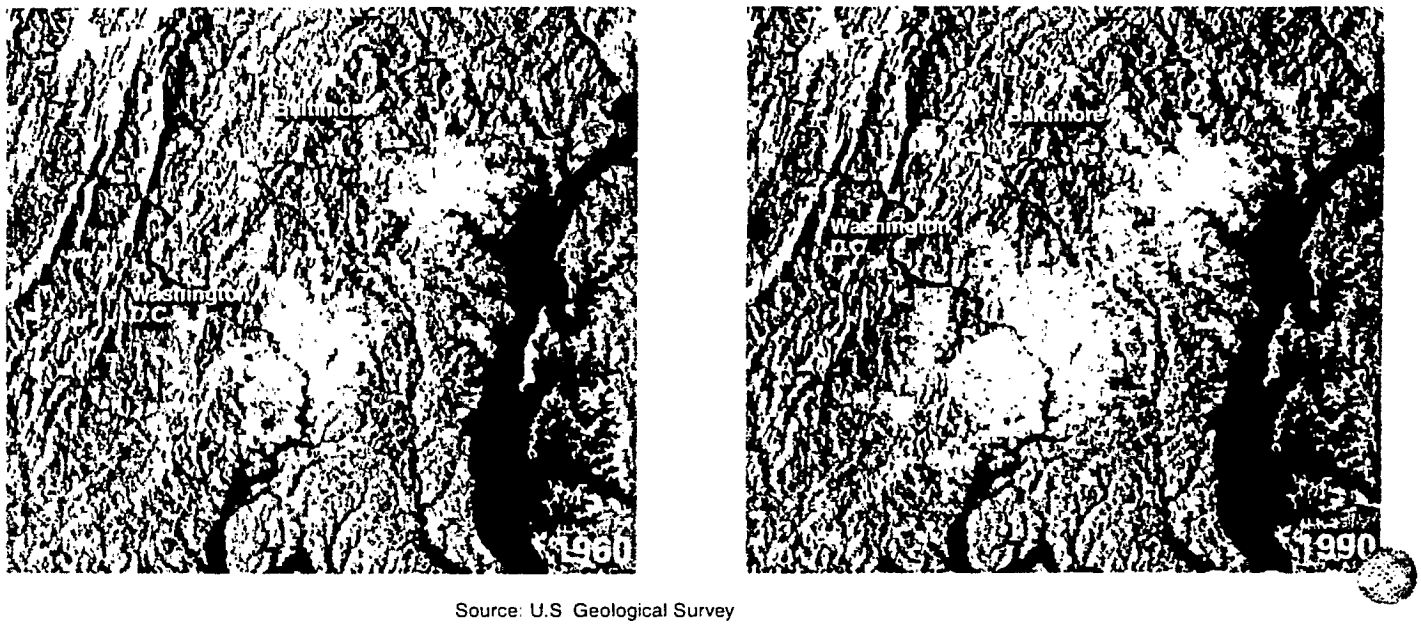
Since World War II, urban runoff has increased throughout the United States. This increase is directly related to growth in the amount of impervious surfaces due to urban and suburban development and the construction of roads, highways, and other impervious surfaces. Coinciding with this growth in impervious surfaces has been a reduction in wetlands and in the amount of storm water that infiltrates the ground to recharge aquifers. Moreover, the loss of vegetation due to development and related runoff can cause major erosion. Ultimately, much of this runoff is channeled into gutters, storm drains, and paved channels, and vegetation and sediment removed with the runoff may end up in receiving waters. EPA has identified urban storm water runoff as one of the leading sources of pollution to the nation's rivers, streams, lakes, and estuaries. Runoff from impervious surfaces picks up potentially harmful pollutants and

[7]An outfall is an outlet, such as a pipe, that allows storm water to flow into a river, lake, or other body of water

R0012746

carries them into receiving waters. Studies have shown that urban runoff and the pollutants it carries can negatively affect water quality, aquatic life, and public health.

Paved Surfaces Have Increased With Urban and Suburban Expansion and Growth in Automobile Use



According to the U.S. Department of Agriculture, between 1945 and 1997, urban land area increased by almost 327 percent, from 15 million acres to about 64 million acres in the contiguous 48 states. From 1992 through 1997, the annual rate of development averaged about 1 million acres per year. The land developed between 1945 and 1997 came primarily from forestland and pasture and range.[8] For example, according to the Bureau of the Census, between 1960 and 1990, the amount of land used for urban purposes in Baltimore, Maryland, and Washington, D.C., grew by about 170 percent and 177 percent, respectively. As a result, urbanization, with its accompanying expansion of impervious surfaces like sidewalks, roofs, parking lots, and roads, has significantly increased the nation's total developed land and paved surface area.[9] Figure 2 demonstrates the growth in the urbanized areas of Baltimore and Washington, D.C., over the last half of the 20th century.

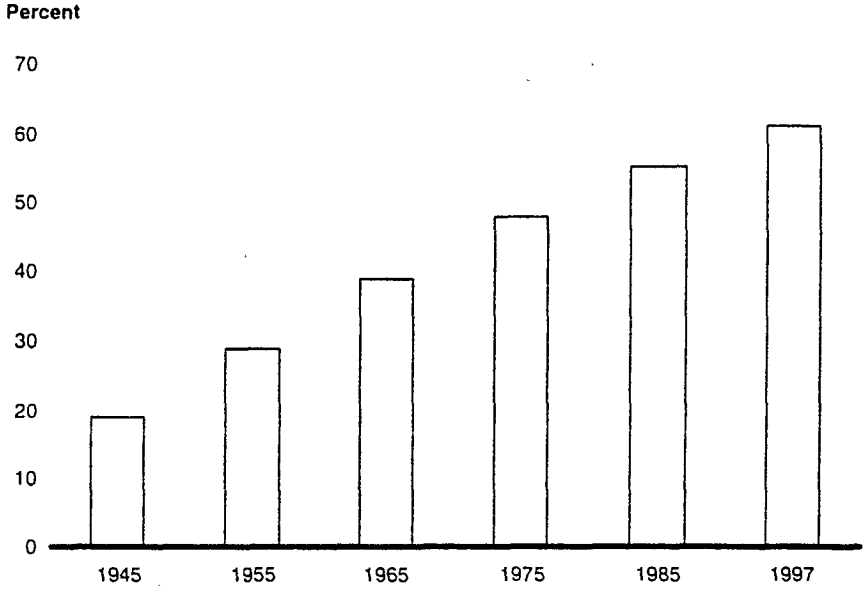
R0012747

Figure 2: Increase in Urbanized Land in Selected Cities, 1960-90



Source: U.S Geological Survey

The increase in paved surfaces has been spurred not only by urban and suburban development, but also by a steady increase in the use of automobiles, the primary mode of daily transportation for most Americans. Roads also play an important role in the economy of the United States, since trucks carry about 75 percent of the value of all goods shipped. According to EPA, paved road mileage in the United States increased by 278 percent from 1945 to 1997. In 1945, 19 percent of the public roads in the country were paved; by 1997, that percentage had increased to 61. (See fig. 3.) According to a 1999 study, motor-vehicle infrastructure, such as roads and parking lots, accounts for close to half of the land area in U.S. urban cities.[10]

R0012748

Figure 3: Percentage of Paved Public Road Miles, 1945-97

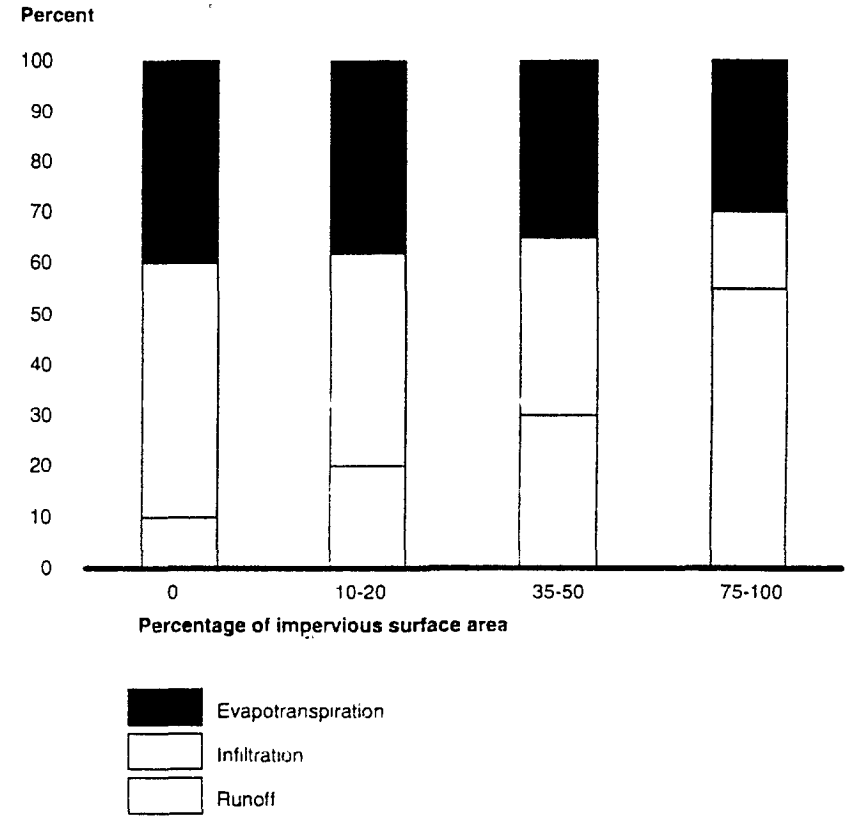
Source: EPA.

Increase in Impervious Surfaces Leads to Increased Runoff

The increase in impervious surfaces over the past several decades has led to an increase in storm water runoff. In part, this has occurred because highways and other developments have reduced the amount of wetlands and other undeveloped land. Wetlands mitigate the effects of storm water runoff by acting as a natural form of flood control, facilitating sediment replenishment, and improving water quality by removing excess nutrients and other chemical contaminants before the contaminants can affect receiving waters. According to a 2000 EPA report,[11] of the 12 states that listed wetland losses, six reported that they had significant losses due to highway construction, and 10 reported that they had significant losses due to residential growth and development. However, the effect of road building on wetland loss has been reduced in recent years. According to a Federal Highway Administration (FHWA) official, since 1996, wetlands have been replaced and restored under the Federal-Aid Highway Program

[11]See footnote 9.

R0012749



at an average rate of 2.7 acres for every acre lost to highway building. Other undeveloped land with vegetation also performs some of the roles that wetlands play in managing runoff, although to a lesser extent.

Furthermore, as impervious surfaces increase, less storm water is able to infiltrate through the soil to groundwater. Impervious areas allow only a very small amount of initial infiltration compared with unpaved areas whose infiltration capacity varies, depending on the soil type. Figure 4 demonstrates EPA's estimates of the impact of impervious surfaces on the percentages of storm water that runs off, infiltrates the ground, and is lost through evapotranspiration.[12] When natural ground cover is present over an entire site, normally 10 percent of precipitation runs off the land into nearby creeks, rivers, and lakes. In contrast, when a site is 75- to 100-percent impervious, 55 percent of the precipitation runs off into these receiving waters. However, according to an FHWA official, the runoff rates can be reduced if developers take mitigating actions to develop and implement BMPs to control flooding or runoff.

[12]Evapotranspiration represents water loss from evaporation and the absorption and eventual release into the atmosphere of water that plants and trees have collected. The extent to which evapotranspiration occurs is dependent primarily on the solar energy available to vaporize the water. As a result, the effect of evapotranspiration varies greatly across the country

R0012750

Figure 4: Impact of Impervious Surfaces on the Amount of Storm Water That Runs Off, Infiltrates, and Evapotranspires

Source. EPA

R0012751

The decrease in storm water infiltration that accompanies urbanization also reduces the amount of water that is available to recharge groundwater supplies. For this reason, reduced infiltration may lead to problems with the water table in certain urban areas. For example, a Massachusetts Department of Environmental Protection official noted that a low recharge rate affects water quality because it can result in a loss of wetlands and adversely affect aquatic habitat as water-table levels fall during dry weather.[13] In addition, officials from the Charles River Watershed Association in Massachusetts are concerned that the lack of infiltration might cause some communities to run short of drinking water in the next 20 years.

Urban Runoff Has the Potential to Impair Water Quality and Disrupt Biological Integrity

Urban runoff can adversely affect the quality of the nation's waters, and urban storm water runoff has been identified as one of the leading sources of pollution to rivers, streams, lakes, and estuaries.[14] Section 305(b) of the Clean Water Act requires states and other jurisdictions to report on the quality of their waters to EPA every 2 years. The 1998 *National Water Quality Inventory Report to Congress* showed that 35 percent of assessed river and stream miles, 45 percent of assessed lake acres, and 44 percent of assessed estuarine square miles were impaired in terms of their ability to support uses such as aquatic life, swimming, and fish consumption.[15] The report identified urban storm water runoff as one of the leading sources of impairment to the assessed waters.

[13]Dry weather is defined as a period when rainfall measuring at least 0.10 of an inch has not occurred for 72 hours.

[14]Other leading sources of pollution include agricultural runoff, municipal point sources, hydrologic modifications, and atmospheric deposition.

[15]Information contained in the 1998 report reflects only those waters assessed by states and other jurisdictions and cannot be used to characterize nationwide water quality. Furthermore, water quality standards among states are not identical, and the monitoring design used to collect data differed among states.

R0012752

Studies have shown that as the percentage of impervious cover increases within a watershed, biodiversity also declines. Research conducted by the Center for Watershed Protection found that, generally speaking, when a watershed has 10 percent or less impervious cover, the associated stream can be categorized as sensitive.[16] Sensitive streams are characterized as having high fish diversity and good water quality. Once the percentage of impervious cover exceeds 25 to 30 percent of the watershed, however, streams tend to become nonsupporting. Nonsupporting streams are highly unstable, have poor diversity of fish and aquatic life, and have poor water quality. For example, one study evaluated the relationship between the extent of impervious cover in watersheds to the number and diversity of fish populations in 47 small streams in southeastern Wisconsin between the 1970s and 1990s.[17] The results revealed that the number of fish species per site was highly variable for drainage areas that had less than 10-percent imperviousness. In contrast, sites that had greater than 10-percent imperviousness had consistently low numbers of fish species.

Other studies have associated urban runoff with basic changes in the receiving body of water. Runoff can carry sediment into surface water, and this sediment can carry contaminants, harm aquatic plants, and smother organisms. Runoff can also be warmed by the impervious surfaces it flows across. When sufficient amounts of warmed runoff enter a water body, the water temperature can rise. Less oxygen is then available for aquatic organisms because water holds less oxygen as it becomes warmer. These combined factors lead to the degradation of aquatic habitat. According to EPA, the common effects of these types of pollution on aquatic life include a decline in biodiversity and an increase in invasive species.

An increase in the volume of storm water runoff also increases the likelihood of erosion, which allows for transport of eroded sediment downstream into receiving waters. For example, during a site visit, we observed extensive erosion along the Gingerville Creek Subbasin in Anne Arundel County, Maryland, that was caused by urban runoff channeled into the creek. Figure 5 depicts the eroded banks and channel of this creek.

Contaminants in Urban Runoff Can Affect Aquatic Life and Human Health

There have been several efforts to characterize the chemicals and other constituents in urban runoff. The Nationwide Urban Runoff Program, conducted by EPA between 1978 and 1983, examined the characteristics of urban runoff. Another federal effort to characterize urban runoff is an ongoing joint project of the U.S. Geological Survey (USGS) and the FHWA to evaluate guidelines for highway runoff. As table 1 indicates, these studies and others have shown that the principal contaminants found in

R0012754

urban runoff include nutrients, solids, pathogens, metals, hydrocarbons, organics, salt, and trash. Water flowing over various surfaces, such as streets, parking lots, construction sites, industrial facilities, rooftops, and lawns, carries these pollutants to receiving waters. The contaminants have the potential to impair water quality, degrade aquatic ecosystems, and pose health risks to swimmers.

Table 1: Storm Water Pollutants in Urban Runoff, Including Sources and Potential Impacts

Contaminant	Source	Potential impact
Nutrients		
Nitrogen, phosphorous	Animal waste, fertilizers, failing septic systems, atmospheric deposition,[a] CSOs	Nutrient enrichment can cause an excessive growth of algae. Nuisance levels of algae are associated with dissolved oxygen deficiencies leading to fish kills, loss of submerged aquatic vegetation that serves as a habitat for aquatic organisms, and loss of natural biodiversity.
Solids		
Sediment	Construction sites, other disturbed and/or nonvegetated lands, eroding banks, road sanding	Sediment can cause infection and disease among fish, scour submerged aquatic vegetation, prevent sunlight from reaching aquatic plants, and bury bottom-dwelling aquatic organisms.
Pathogens		
Bacteria, viruses	Animal waste, failing septic systems, illicit connections and discharges to storm sewer system, CSOs	Pathogens entering waters used for recreational purposes can pose human health risks.
Metals		
Lead, cadmium, copper, zinc, mercury, chromium, aluminum, and others	Industrial processes, normal wear of automobile brake linings and tires, automobile emissions, automobile fluid leaks, metal roofs	Metals can cause acute or chronic toxicity for aquatic organisms.
Hydrocarbons		
Oil and grease, polycyclic aromatic hydrocarbons	Industrial processes, automobile wear, automobile emissions, automobile fluid leaks, waste oil	Hydrocarbons have the potential to be acutely toxic for aquatic organisms and several are suspected carcinogens.
Organics		
Pesticides, polychlorinated biphenyls (PCB), synthetic chemicals	Pesticides (herbicides, insecticides, fungicides, rodenticides, etc.), industrial processes	Low concentrations of some organics have the potential to bioaccumulate in the food chain.

R0012755

(Continued From Previous Page)

Contaminant	Source	Potential impact
Salt		
Sodium Chlorides	Road salting and uncovered salt storage	Salt can damage roadside vegetation, transport high levels of chlorides to receiving waters, and degrade aquatic ecosystems. Chloride can be harmful to some species of fish.
Trash		
	Street refuse and improperly discarded waste material	Trash impairs water quality by inhibiting the growth of aquatic vegetation and conveys nutrients, toxic substances, and other pollutants to aquatic ecosystems.

[a]Atmospheric deposition occurs when pollutants in the air fall on land or water.

R0012756

In our visits to cities with Phase I permits and their watersheds, we identified specific instances in which these contaminants had affected water quality. The Chesapeake Bay, for example, has been polluted with the nutrients nitrogen and phosphorus and with excess sediment caused, in part, by urban runoff. The excess nutrients cause algae blooms that block sunlight from reaching bay grasses—which are a source of food, shelter, and nursery grounds for many aquatic species. In an effort to control nutrient pollution in the Chesapeake Bay, the Executive Council of the Chesapeake Bay Program[19] established a goal to reduce the nitrogen and phosphorus entering the Chesapeake Bay by 40 percent, including through control of runoff from urban areas. In addition, an assessment of the status of chemical contaminant effects on living resources in the bay's tidal rivers found "hot spots" of contaminated sediment. As a result, the Baltimore Harbor and the Patapsco River in Maryland; the Anacostia River in Washington, D.C.; and the Elizabeth River in Virginia were designated as "regions of concern." Urban storm water runoff is a significant source of contaminants in the three regions. The Chesapeake Executive Council has committed to reduce by 30 percent the chemicals of concern in the regions of concern by 2010 through pollution prevention measures and other voluntary means.[20]

Pathogens such as bacteria and viruses, which are often present in urban runoff, can pose public health problems. For example, the Santa Monica Bay Restoration Project conducted a study to identify adverse health effects of untreated urban runoff by surveying over 13,000 swimmers at three bay beaches. [21] The study established a positive association between an increased risk of illness and swimming near flowing storm-drain outlets. Table 2 explains health outcome measures at various distances from storm drains. For example, the study found a 1-in-14 chance of fever for swimmers in front of the drain versus a 1-in-22 chance at 400 or more yards away.

[19]The Chesapeake Executive Council includes the governors of Maryland, Pennsylvania, and Virginia; the Administrator of the U.S. Environmental Protection Agency; the mayor of the District of Columbia, and the chair of the Chesapeake Bay Commission.

Metals and polycyclic aromatic hydrocarbons (PAH) in urban runoff can present a threat to aquatic life. Studies have found the following:

- Storm water runoff from an urban area proved to be toxic to sea urchin fertilization in the Santa Monica Bay, and dissolved zinc and copper were determined to be contributors to this toxicity. [22]
- Brown bullheads (a bottom-dwelling catfish) in the Anacostia River developed tumors that were believed to be caused by PAHs associated in part with urban runoff.[23]
- High PAH and heavy metal concentrations were found in crayfish tissue samples from several urban streams in Milwaukee. The study associated these contaminants with storm water runoff.[24]

[24]J.P. Masterson and R.T. Bannerman, "Impacts of Stormwater Runoff on Urban Streams in Milwaukee County, Wisconsin," *National Symposium on Water Quality, American Water Resources Association*, Nov. 1994.

R0012758

In addition, USGS tracked trends in the concentrations of PAHs found in sediment in 10 lakes and reservoirs in six metropolitan areas over the last several decades. This study found that PAH concentrations in developed watersheds are increasing and that these increases may be linked to the amount of urban development and vehicle traffic in urban and suburban areas.[25] For example, from 1982 to 1996, PAH concentrations in the sediment core in Town Lake (Austin, Texas) and total miles driven in greater Austin both increased by about 2.5 times. Figure 6 illustrates this correlation.

Figure 6: Comparison of Town Lake PAHs and Traffic Trends

Note: According to USGS, irregularities in the date pattern are due to intervals at which sediment samples were collected.

R0012759

Although the studies we reviewed show that certain contaminants are likely to be present in urban runoff, factors such as land development practices, climate conditions, atmospheric deposition, and traffic characteristics all can affect the characteristics of runoff from a particular area. Therefore, given the diffuse nature of many storm water discharges and the variability of other contributing factors, characterizing the concentrations of pollutants contained in storm water runoff has been challenging. Recent USGS reports also suggest that improvements are needed in the methods used to analyze sediment and metals in runoff.[26]

Local Governments Take Actions to Manage Urban Storm Water Runoff, but Information Is Limited on the Cost and Effectiveness of These Actions

To comply with federal and state storm water management for Phase I permitting requirements, permitted municipalities must create and implement storm water management programs. The three primary activities used in these programs include efforts to characterize storm water runoff; BMPs aimed at reducing pollutants in storm water runoff to the maximum extent practicable; and reporting program activities, monitoring results, and costs of implementing the program. Some BMPs are structural—meaning that they are designed to trap and detain runoff until constituents settle or are filtered out. Other BMPs are nonstructural—meaning that they are designed to prevent contaminants from entering storm water through actions like street sweeping and inspections. Many permitted municipalities use specialized BMPs tailored to address particular runoff problems in their locations. Over 1,000 cities are undertaking these efforts under the NPDES Storm Water Program, but information on the overall costs of managing urban runoff and the effectiveness of the actions taken is limited. EPA's attempts to forecast costs have not encompassed the entire program or are out of date. In addition, the permitted municipal agencies we visited estimated their annual storm water management costs and reported them to state agencies or EPA, but the approaches they used to calculate these estimates varied considerably, making it difficult to draw any conclusions. Although EPA and state agencies believe that the program will be effective in improving water quality, EPA has not made a systematic effort to evaluate the program. Without such an effort, EPA cannot tell what effect the program is having on water quality nationally.

[26]The USGS reports indicate that certain methods used to analyze sediment and metals samples can be unreliable. For example, sample collection and processing methods can have an effect on measured concentrations of metals.

R0012760

Municipalities Comply With Federal and State Requirements Through Monitoring, Best Management Practices, and Reporting

The NPDES Storm Water Program requires municipalities operating under a Phase I MS4 permit to characterize and monitor storm water runoff, implement BMPs to reduce pollutants to the maximum extent practicable, and report costs and monitoring results to the permitting authorities. Because of these requirements, local governments have generally shifted the focus of their storm water management from water quantity control or flood management to water quality concerns.

Besides following the basic federal requirements, municipalities must follow any additional regulations developed by states that have been delegated the authority to manage the NPDES Storm Water Program. For example, Wisconsin's Department of Natural Resources broadened the requirements for determining which municipalities must get permits. The state requires local governments with storm sewer systems in priority watersheds (based on the significance of storm water runoff as a pollutant source) that serve a populace of 50,000 or more[27] to obtain a permit with requirements similar to those for a Phase I permit. Wisconsin's Department of Natural Resources also requires municipalities that are located in one of the state's five Great Lakes Areas of Concern[28] to obtain a state permit. Furthermore, in line with specific criteria in Wisconsin's Administrative Code, the state requires other municipalities to obtain a permit if the municipality is found to significantly contribute storm water pollutants to waters of the state. These various requirements increased the number of municipalities that must get permits from the two under federal requirements to over 70 under the states' requirements.

The local governments we reviewed were undertaking three primary activities when applying for permits and implementing their storm water management programs. Specifically, these activities were (1) characterizing storm water runoff; (2) developing BMPs to reduce discharges of pollutants to the maximum extent practicable; and (3) reporting program activities, monitoring results, and reporting program costs.

First, to characterize runoff, applicants are to provide quantitative data that describe the volume and quality of discharges from municipal storm

[27]For example, we visited West Allis, Wisconsin, which has a permit even though its population is under 100,000.

[28]Areas of concern have persistent water quality problems, which impair beneficial uses.

R0012761

sewers. For example, cities must map all storm sewer outfalls—an undertaking that one group representing cities described as significant. After the permit application is approved, additional monitoring is required throughout the life of the permit to facilitate the design of effective storm water management programs and to document the nature of the storm water. The local governments we visited were all monitoring for a variety of purposes, including characterizing runoff from different types of land use in order to target their BMPs, testing the effectiveness of a particular BMP, or establishing a baseline for their storm water quality evaluations.

Second, the storm water management programs that local governments develop focus on implementing BMPs. While active treatment, such as sending storm water through a treatment facility, is a possible BMP, the cities we visited were generally not using active treatment. EPA's February 2000 report[29] on the Phase I program described the program as based on the "use of low-cost, common-sense solutions." The five cities we visited were generally using similar types of structural and nonstructural BMPs, as follows:

- Structural BMPs are designed to separate contaminants from storm water. For example, detention ponds temporarily hold storm water runoff to allow solids and other constituents in the runoff to settle before the water is released at a predetermined rate into receiving waters. In addition, catch-basin inserts, placed in a storm drain, catch trash and other debris, and particle separators, placed beneath the surface of an impervious area such as a parking lot, separate oils from runoff and allow sediment and debris to settle. Structural devices such as these require regular maintenance to function properly and remain effective.
- Nonstructural BMPs are primarily designed to minimize the contaminants that enter storm water. These nonstructural BMPs include
  - "good housekeeping" practices by the local government, such as oil collection and recycling, spill response, household and hazardous waste collection, pesticide controls, flood control management, and street sweeping;

[29] *Report to Congress on the Phase I Storm Water Regulations*, U.S. Environmental Protection Agency, February 2000. This report includes information on the program for local governments, industries, and construction sites.

R0012762

- public education programs, such as storm-drain stenciling, to remind the public that trash, motor oil, and other pollutants thrown into storm drains end up in nearby receiving waters;[30]
- new ordinances to control pollution sources, such as prohibiting the disposal of lawn clippings in storm drains and requiring pet owners to clean up after their pets;[31]
- requirements that developers comply with storm water regulations and incorporate erosion and sediment controls at all new development sites;
- requirements that runoff from properties owned or activities sponsored by the municipality be properly controlled; and
- efforts to identify and eliminate illicit connections and illegal discharges to the storm sewer systems, such as those from pipes carrying sewage.

We found that the NPDES Program's requirements allowed local governments to tailor their storm water management efforts to prioritize local concerns, such as a particular type of contaminant, a particular climatic condition, or a particular body of water. Some cities also developed specialized BMPs to address these concerns. The following information highlights specific storm water-related concerns in the five cities we visited and the specialized BMPs these municipalities have developed to address these particular concerns. (See apps. I to V for additional information on these cities' storm water management programs.)

[30]Other public education programs we observed included in-school education programs, partnerships with grassroots organizations concerned with water quality issues, and the identification of commercial businesses and industries to educate owners on methods to control storm water runoff.

[31]According to Worcester, Massachusetts' April 2000 *City of Worcester DPW Stormwater Management Program Annual Report*, the city has proposed ordinances that prohibit the disposal of lawn clippings and other yard waste in catch basins and that require pet owners to clean up after their pets. As of April 2001, neither ordinance had been implemented.

R0012763

- In **Baltimore, Maryland**, excessive levels of nutrients, particularly phosphorus and nitrogen, are among the city's major water quality concerns because of the city's participation in the Chesapeake Bay Program. Baltimore City agreed to assist the state in reaching the Chesapeake Bay Program's goal to reduce nutrients discharged to the bay by 40 percent by the year 2000. According to a Chesapeake Bay Program Office representative,[32] as of March 2001, the program has not met this goal but expects to reach it within the next several years.
- In **Boston, Massachusetts**, the Boston Water and Sewer Commission, which holds the permit for Boston's storm sewer system, is concerned about runoff from roadways, especially runoff containing salt and sand used in the winter months and dissolved metals (copper and zinc) from automobiles. In September 2000, the commission began a 3-year program to develop and implement a citywide catch-basin inspection, cleaning, and preventive maintenance program. The program will also include the development of a database and map that can be linked to the commission's Geographic Information System.
- **Los Angeles County, California**, is responding to a TMDL for trash in the Los Angeles River Watershed that will require the county, over a 10-year period, to eliminate trash in runoff. The county is testing a variety of devices that remove trash from runoff and specialized catch-basin devices that are designed to prevent trash from ever reaching the storm sewers.
- **Milwaukee, Wisconsin**, changed its monitoring and public education activities in its recent permit to test the effectiveness of a BMP targeting public education efforts to a specific community. The new permit also requires a monitoring program aimed at the community, its associated watershed, and city employees who work in the area.
- **Worcester, Massachusetts**, had a significant problem with illicit connections to its storm sewers and with flow in these sewers during dry weather. Worcester's Department of Public Works (DPW) screened 71 of its storm water outfalls and determined that 32 of them had drainage areas that carried both sanitary sewage and storm drainage in separate conduits through common manholes. DPW has retrofitted over 65 percent of the manholes to prevent sewage from mixing with storm water.

[32]The Chesapeake Bay Program Office, U.S. EPA Region III, was founded in 1983 with the formation of the Chesapeake Bay Program. The program is a voluntary regional partnership that leads and directs restoration of the Chesapeake Bay. Members of the Chesapeake Bay Program include Maryland, Pennsylvania, Virginia, the District of Columbia, the Chesapeake Bay Commission (a tristate legislative body), EPA, and participating citizen advisory groups.

R0012764

Third, local governments participating in the Phase I program are required to report annually to EPA or the state regulatory agency on their storm water programs. These reports are to include a status report on the program; a summary of data, including monitoring results collected during the reporting year; information on annual expenditures on the program and a budget for the coming year; and a description of any water quality improvements or degradation.

Information on the Costs of Addressing Storm Water Runoff Is Limited

Good information about the cost of implementing federal storm water requirements is limited. EPA conducted a survey to estimate the nation's future water infrastructure needs over a 20-year period—from 1996 to 2016. In its 1996 report,[33] EPA estimated that states would require over $50 billion to meet their current (as of 1996) water infrastructure needs. The estimate consists of storm water management needs (at $7.4 billion) and CSO needs (at $44.7 billion).[34] EPA noted, however, that estimated storm water management needs are likely too low and could increase following an analysis of data collected to prepare the agency's 2000 clean water needs survey—to be released in 2002. According to EPA, many cities have implemented the Phase I program since EPA reported to the Congress in 1996, and municipalities should now be better able to provide documented cost data. As a result, EPA will need to rely less on modeled storm water needs than it did in the 1996 needs survey. EPA did not project the costs and benefits of the program when it was initiated; therefore, no initial cost estimates are available. When EPA promulgated the Phase I program regulations in 1990, the agency decided that the storm water program did not meet the requirements for preparing a benefit/cost analysis.

[33] *1996 Clean Water Needs Survey Report to Congress*, U.S. Environmental Protection Agency (Sept. 1997). EPA's estimate represents the estimated capital costs for water quality projects eligible for state revolving fund support.

[34] EPA also estimates that $81.9 billion of its 20-year water infrastructure needs cost can be attributed to sanitary sewer overflows. These overflows may occur when rainwater or snowmelt leaks into sanitary sewage pipes, exceeding the pipes' capacity and causing them to overflow. This overflow can release untreated sewage from municipal sanitary sewer systems into streams, basements, and streets.

R0012765

The costs to local governments of complying with the Phase I program have generally been portrayed as high. However, because of inconsistencies in cost accounting and reporting practices, we could not determine the cost of the program to several of the cities we visited. Although municipalities are required to provide information on the expenditures that they anticipate will be needed to implement their storm water management programs for each fiscal year covered by the permit, EPA has not issued any cost reporting guidelines. Consequently, while the reported fiscal year 1999 total cost to manage and treat storm water runoff across the five municipalities in our review ranged from less than $1 million (Milwaukee) to $135 million (Los Angeles County),[35] these numbers are not comparable because the municipalities did not have consistent cost accounting and reporting practices and did not fully express storm water management costs.[36] For example, some cities reported only the costs of activities that were funded by the city department that held the permit. Significant activities funded by other city departments were not reported, even if they were important components of the storm water program. Officials in the Milwaukee Department of Infrastructure Services and the Boston Water and Sewer Commission told us that other city departments perform and fund activities such as street sweeping and flood control. The costs of these activities are not reported as storm water program costs because the activities serve other purposes besides preventing storm water pollution.

In addition, according to some city officials, these activities were in place before the permit was issued and, therefore, cannot be characterized solely as storm water costs. The cost of street sweeping can be significant—for fiscal year 1999, Baltimore City and Worcester, which did include street-sweeping costs in their storm water program's cost estimate, stated that their street-sweeping expenses totaled about $9.5 million and $1.2 million, respectively. Similarly, Milwaukee did not report the cost of a significant project related to storm water runoff because it was mostly funded by the state of Wisconsin.

[35]Los Angeles County's cost was projected by the municipal permit holder and represents the cost of the 84 cities covered by the permit.

[36]We were unable to obtain comprehensive information on the total cost to the Boston Water and Sewer Commission of managing storm water, so their fiscal year 1999 costs could not be included in this range.

R0012766

An EPA official told us that the agency had not yet made a national effort to analyze the information that Phase I permittees submitted on the costs of their storm water programs. This official cited the inconsistent formats of the annual reports as a reason that the information was not readily available at the national level and also indicated that adequate staff are not available to analyze the data. In addition, other EPA officials informed us that the Office of Wastewater Management must divide its resources among a number of issues that will challenge the agency's water program over the next decade.

Several officials in the cities we visited said that their annual costs are likely to increase. A number of factors could affect the costs. For example, a Baltimore City official explained that the anticipated, future program costs depend on several factors, including (1) requirements in watershed-management plans currently being developed, (2) pollution-reduction goals the city will be required to achieve, (3) requirements of the state regulatory agency in future permits, and (4) requirements the city may have to meet if TMDLs or numeric effluent limits are incorporated into NPDES storm water permits. Other city officials also expressed concern about the extent to which TMDLs could affect their future costs. These city officials are concerned that when and if TMDLs are established, their future storm water permits may require that storm water runoff meet specific water quality standards. For example, Los Angeles County's trash TMDL could potentially drive the county's storm water management costs upward, and the county expects additional TMDLs to be imposed. On the other hand, Worcester officials estimated that their future storm water costs would be about the same as they were at the time of our review—about $4.5 million per year.

In a separate analysis, EPA estimated in 1999 that it will cost Phase II municipalities about $848 million to $981 million per year (in 1998 dollars) to manage storm water runoff. Because Phase II permits have not been issued as of May 2001, we did not gather any cost information on them from these cities.

Funding for Managing Storm Water Runoff Is Available From Local and Federal Sources

The five cities we visited had not generally obtained federal funds for their storm water management efforts. They used local sources, including general revenues, bonds, revenue from specifically created storm water utilities, state grants, and inspection and permit fees.

R0012767

While several sections of the Clean Water Act provide funding that can be used for municipal storm water control, relatively few federal funds have been directed to these types of projects. The most significant source of funds is the state revolving loan funds administered by states.[37] These revolving loan funds provide loans for eligible storm water control projects. In some cases, nonpoint source projects may also qualify for funding when storm water permits are not required or issued. However, municipal storm water management is generally a low priority in these programs. Specifically, in the year 2000, revolving fund loans were made in the "storm sewers" category in the amount of $38.76 million for 44 different projects. These funds represented less than 1 percent of the amounts loaned from these revolving funds that year. Activities eligible for revolving fund loans include constructing BMPs to control runoff, but support for ongoing operations and maintenance is not eligible. Revolving fund loans can also be used for eligible CSO control projects. In 2000, Clean Water State Revolving Fund Program loans were made in the "CSO Correction" category of a national EPA database in the amount of $411.3 million for 69 different projects and could have been used for CSO or sanitary sewer overflow projects. This amount represented about 9 percent of the funds loaned in 2000.

According to EPA, the agency also issues grants to universities and other research institutions to help implement the storm water program. Some of these grants provide training and guidance to Phase I permittees on watershed protection and the proper selection of BMPs.

Other sources of funding may be available to local governments beginning in 2002. In December 2000, the Congress authorized programs for fiscal years 2002 through 2004 to provide grants to local governments for (1) pilot projects for managing municipal CSOs, sanitary sewer overflows, and storm water discharges on a watershed basis and for testing BMPs and (2) controlling pollutants from MS4s to demonstrate and determine cost-effective, innovative technologies for reducing pollutants from storm water discharge. EPA's proposed budget does not request funds for these programs. In addition, the Congress authorized programs for fiscal years 2002 and 2003 to provide grants to local governments for planning, designing, and constructing treatment works to intercept, transport,

[37]Under the Clean Water State Revolving Fund Program, the federal government provides grants to capitalize states' funds. States provide loans to local governments for wastewater projects.

R0012768

control, or treat municipal CSOs and sanitary sewer overflows. EPA's proposed budget requested $450 million for this program.

EPA, States, and Local Governments Believe the NPDES Storm Water Program Is Effective, but It Has Not Been Evaluated

EPA, state, and municipal officials generally believe that the NPDES Storm Water Program will improve water quality. These officials believe that the program will result in more bodies of water that meet water quality standards, improved aesthetic conditions, reduced risk from bacterial contamination, and improvements attributable to the discovery and management of pollutants in storm water that otherwise would have gone unnoticed. EPA attempted to put a dollar value on these benefits in its benefit/cost analysis prepared for the Phase II storm water regulations, estimating that such benefits could range from $672 million to $1.1 billion per year (in 1998 dollars).[38]

However, little information is currently available on the benefits of the storm water program or its general effectiveness. There is no doubt that it will take time for the results of the Phase I program to be demonstrated. As EPA notes in its February 2000 report to the Congress, pollution control efforts under water quality management programs produce long-term changes, and the agency expects water quality improvements attributable to the Phase I program to become evident in the future, as the program matures. In this report, EPA concluded that the program has improved storm water management at the local level, improved water quality, and decreased pollutant loads in storm water. However, EPA relied on a survey of only nine Phase I cities in making these conclusions and, therefore, also reported that the agency could not provide national estimates on water quality protection and improvements generated by Phase I of the program. To evaluate the entire program, EPA would have to establish goals for the program that are based on its mission; obtain information about the program's results; compare the results with the goals; and make changes to the program, if warranted, to get closer to achieving the agency's goals.

EPA and the states also have not taken advantage of information that is available to evaluate the program. Each city we visited was regularly monitoring its storm water to establish baseline information on pollutant levels and was reporting this information to EPA or the regulatory state agency each year. Although cities with Phase I permits are required to report on their storm water monitoring results and changes in water

[38]Using another method, EPA estimated the benefits at $1.6 billion per year.

R0012769

quality, overall, EPA and the states have not successfully developed measurable goals for the program or demonstrated its effectiveness through the review of municipal reports. An EPA official said that some states had requested funding to analyze program data because they did not have the resources to do so, and that EPA had provided the funding in a few cases. EPA also has not established any guidelines for how these data should be reported. Therefore, the reports may be as variable as the cost information we obtained in our five site visits.

EPA has not yet taken any of these data-analysis steps because, according to EPA officials, other program challenges within the Office of Wastewater Management compete with storm water management efforts for priority. For example, EPA officials stressed that available resources within the office must address other significant wet-weather pollution problems, such as CSOs and sanitary sewer overflows, and nonpoint source pollution problems, such as agricultural practices, forestry, and mining. One agency official noted that the highest priority is addressing needs that the agency and local governments have identified for improving wastewater infrastructure, such as sewage treatment facilities. The program also has relatively few staff assigned—about five in the headquarters office and about 10 in the regional offices—for the municipal, industrial, and construction portions of the program. In a program plan recently prepared for the storm water program, EPA estimated that nine to 10 staff would be needed in EPA headquarters to evaluate the program and implement other program requirements.

EPA officials described two efforts that may be the first steps in developing better information about the program. First, EPA intends to issue a grant to the University of Alabama in June 2001 to evaluate monitoring data submitted by a sample of municipalities with Phase I permits. This effort will (1) determine the different types of monitoring being conducted by Phase I municipalities, (2) assess water quality in and around permitted municipalities and determine any correlation between program implementation and impacts on water quality, and (3) recommend approaches for improving the effectiveness of municipal storm water monitoring programs. EPA expects the results of this study in 2003. Second, an EPA official stated that the agency would like to establish a system for analyzing program findings, incorporating necessary changes that are based on these findings, and evaluating the program's effectiveness. The agency plans to implement a pilot project in 2001 in the agency's Atlanta Region IV office for analyzing data reported in annual

R0012770

reports and developing key indicators for the program. If this project is successful and resources are available, the project could be expanded.

Conclusions

EPA regards urban runoff as a significant threat to water quality across the nation and considers it to be one of the most significant reasons that water quality standards are not being met nationwide. Prompted by the Congress, EPA has responded with a variety of programs, including the NPDES Storm Water Program, which requires more than 1,000 local governments to implement storm water management programs. Those municipalities that are currently involved in Phase I of the program have been attempting to reduce pollutants in storm water runoff for several years. It is time to begin evaluating these efforts. However, EPA has not established measurable goals for this program. In addition, the agency has not attempted to evaluate the effectiveness of this program in reducing storm water pollution or to determine its cost. The agency attributes this problem to inconsistent data reporting from permitted municipalities, insufficient staff resources, and other competing priorities within the Office of Wastewater Management. Although Phase I municipalities report monitoring and cost data to EPA or state regulatory agencies annually, these agencies have not reviewed this information to determine whether it can be of use in determining the program's overall effectiveness or cost. Our analysis shows that the reported cost information will be difficult to analyze unless EPA and its state partners set guidelines designed to elicit more standardized reporting. Better data on costs and program effectiveness are needed—especially in light of the Phase II program that will involve thousands more municipalities in 2003. EPA's planned research grant to the University of Alabama and its pilot project in the agency's Region IV to analyze data from annual reports and develop baseline indicators is a step in the right direction and could point the way for a more comprehensive approach.

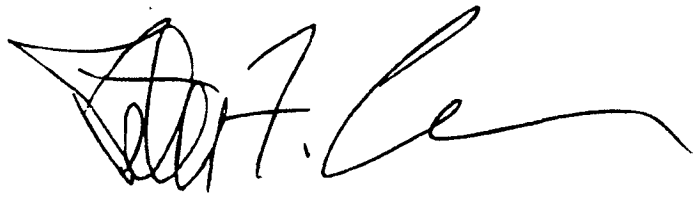
Recommendation

To determine the extent to which activities undertaken through the NPDES Storm Water Program are reducing pollutants in urban runoff and improving water quality, and the costs of this program to local governments, we recommend that the Administrator, EPA, direct the Assistant Administrator for the Office of Water to

- establish measurable goals for the program;

R0012771

- establish guidelines for obtaining consistent and reliable data from local governments with Phase I permits, including data on the effects of the program and the costs to these governments;
- review the data submitted by these permittees to determine whether program goals are being met and to identify the costs of the program; and
- assess whether the agency has allocated sufficient resources to oversee and monitor the program.



Agency Comments and Our Evaluation

We provided a draft of this report to EPA and DOT for their review and comment. EPA generally agreed with the report and with the recommendation, although it did not explicitly comment on all parts of it. (EPA's comments appear in app. VI.) In response to our recommendation that EPA set measurable goals for the storm water program, EPA stated that under the second phase of the program, local governments will establish their own goals. Although this is an important activity, EPA will have difficulty evaluating the program's effectiveness at a national level without setting goals that reflect the program's mission of improving water quality. The agency (1) agreed that it should establish guidelines for obtaining consistent and reliable data from local governments about their programs and (2) plans to award grants to two universities for reviews of monitoring data reported by local governments. EPA did not comment on whether local governments should report on the costs of their programs. EPA also agreed that it and its state partners should review data reported by local governments to determine whether the program's goals are being met. In April 2001, EPA officials told us that the agency planned to undertake a project in the Region IV (Atlanta) office to evaluate the methods local governments are using to control storm water. EPA's letter indicates that the agency now plans to implement this project in three regional offices and 10 states. EPA did not comment on the part of our recommendation that the agency review the level of resources devoted to overseeing and monitoring the program. EPA also provided technical comments that we incorporated where appropriate.

DOT generally agreed with the draft report and provided technical comments that we incorporated where appropriate. In particular, DOT suggested that we revise several references in the draft report to paved surface area and its relationship to increases in urban runoff, to emphasize that impervious surfaces, of which paved surfaces are a significant subset, cause increases in runoff. We revised the language in these places.

R0012772

As agreed with your offices, unless you publicly announce its contents earlier, we plan no further distribution of this report until 7 days after the date of this report. At that time, we will send copies of this report to the Administrator, Environmental Protection Agency, and the Secretary of Transportation. We will make copies available to others on request. If you or your staff have any questions about this report, please call me at (202) 512-2834. Key contributors to this report are listed in appendix VII.

Director, Physical Infrastructure Issues

R0012773

The Storm Water Program in Baltimore City, Maryland

Baltimore City's municipal separate storm sewer system (MS4) is regulated by the Maryland Department of Environment (MDE) and, according to a city official, services the entire city. The city is currently implementing its second, 5-year National Pollutant Discharge Elimination System (NPDES) permit, issued on February 8, 1999. Before obtaining the first NPDES storm water permit in 1993, Baltimore City addressed the adverse affects of storm water runoff by implementing Maryland's Storm Water Management Program and Erosion and Sediment Control Program. According to the 2000 census, Baltimore City's population is about 651,000.

Urban Runoff Problems in Baltimore City

Baltimore City's urban runoff discharges to four major areas—Gwynns Falls, Jones Falls, Herring Run, and the Patapsco River—and then ultimately to the Chesapeake Bay. In 1990, the Environmental Protection Agency's (EPA) 319(a) report[1] implicated urban runoff as the main source of pollution in these waters. Moreover, Baltimore City was one of the areas studied in EPA's Nationwide Urban Runoff Program in the 1980s. This study reported that urban runoff contributed over 60 percent of the total nitrogen, phosphorus, and organic carbon; over 70 percent of the chemical oxygen demand; and over 80 percent of the total suspended solids, lead, and zinc in local water bodies.

An MDE official told us that nutrients, zinc, and suspended solids are among the constituents most commonly found in urban runoff, but the quantitative contribution to water quality impairment in the state's waters was not known. Also, in 1996, the Chesapeake Executive Council designated the Baltimore Harbor as one of three toxic regions of concern in the Chesapeake Bay. The harbor suffers from sediment contaminated by banned substances (such as the termiticide chlordane) and contaminants currently being released (such as metals and organics). Furthermore, according to the Chesapeake Bay Program Office, data collected from Phase I permittees indicate that storm water runoff can be a significant source of metals and organics in the harbor.

A Baltimore City official told us that some portions of Maryland's waters are impaired because of unacceptable levels of nutrients, metals,

[1]Section 319(a) of the Clean Water Act requires, among other things, that states identify and report to EPA the navigable waters that cannot reasonably be expected to maintain water quality standards (e.g., established water body uses) without additional action to control nonpoint source pollution.

R0012774

suspended sediments, and chlordane. Moreover, this official noted that the state does not consider data that municipalities collect under their NPDES storm water permits during the 303(d) listing process. Therefore, he believes that streams in Maryland are much more impaired than indicated by the listing process.

Baltimore City's Use of Best Management Practices

Like other NPDES storm water permit holders, Baltimore City uses a variety of best management practices (BMP) to reduce the amount of pollutants in runoff to the maximum extent practicable. These BMPs include detention ponds, shallow marshes (which use the biological and naturally occurring chemical processes in water and plants to remove pollutants), sand filter devices, public education programs, and the identification of illicit discharges to the MS4 system. Furthermore, Baltimore City participates in Maryland's effort to reduce nutrient levels in the Chesapeake Bay. Refer to the section of this report describing local government efforts to manage storm water for details concerning this nutrient-reduction goal. One other BMP includes the following:

- Baltimore City has incorporated the *2000 Maryland Storm Water Design Manual's* management policies, principles, methods, and practices into its current NPDES storm water discharge permit. The purpose of the design manual is to (1) protect the waters of the state from the adverse effects of urban storm water runoff; (2) provide design guidance on the most effective structural and nonstructural BMPs for development sites; and (3) improve the quality of BMPs that are constructed in the state, with particular attention to their performance, longevity, safety, ease of maintenance, community acceptance, and environmental benefit.

Costs Associated With Managing Storm Water

We were not able to obtain comprehensive information on the total cost to Baltimore City of managing storm water. Therefore, we do not present that information here.

Funding Sources

Baltimore City funds its storm water management control efforts with city water and sewer user fees and with state funds.

R0012775

The Storm Water Program in Boston, Massachusetts

The Boston Water and Sewer Commission received a NPDES storm water permit in October 1999. The commission is a separate entity from the city of Boston and, therefore, does not manage some storm water controls that are common in Phase I permits, such as street sweeping, winter deicing, and many of the urban runoff controls required for new developments. Boston has combined sewer systems as well as separate sanitary sewers and storm drains. The commission maintains 206 storm water outfalls and serves approximately 33 percent of the city through its separate MS4 system. In addition to the resident population of about 589,000, this system also almost daily serves 340,000 commuting workers; 70,000 shoppers, tourists, and business people; and 75,000 commuting students. The commission's sanitary and combined flows are transported to the Massachusetts Water Resources Authority at Deer Island. The commission is also the permittee for EPA's Combined Sewer Overflow Program.

Urban Runoff Problems in Boston

The commission considers the identification and elimination of illegal sanitary sewer connections as the most effective means of improving water quality and protecting public health. It is also concerned with the washoff of animal wastes from residential and open land, which is another major contributor to the impairment of water quality because it can cause an increase in coliform levels in the storm water discharges to the receiving waters.

The commission has contracted for various studies to determine the impact of storm water runoff. The following two studies identified sources of bacterial contamination and characterized the quality of storm water discharged from different types of land uses. The studies included metering storm water flows, collecting and analyzing the storm water and receiving water quality samples, and identifying and remediating illegal sewer connections. Observations from the studies include the following:

- A 1996 study determined that pet waste, rather than sanitary sewage, was a key contributor of bacteria to the storm drain system that had possibly led to beach closings in the area.
- A 1998 study identified several illegal connections to the storm drain system. Furthermore, the study showed that deicing and sanding efforts resulted in levels of sodium, chloride, total dissolved solids, and cyanide that exceeded EPA's acute (high dose) toxicity levels.

R0012776

Boston's Use of Best Management Practices

To meet the NPDES permit's requirements, the commission, like other permittees, continued BMPs, such as identifying illegal connections, and implemented new BMPs aimed at preventing the discharge of pollutants to storm drains and receiving waters. Refer to the section of this report describing local government efforts to manage storm water for details describing the commission's citywide catch-basin inspection cleaning and preventative maintenance program. Other efforts include the following:

- The commission has placed particle separators, which remove oil, grease, and sediments from storm water flows, throughout the city. The commission requires particle separators to be installed by developers on all newly constructed storm drains that serve outdoor parking areas. Fuel-dispensing areas not covered by a canopy or other type of roof enclosure must also have a particle separator.
- The commission requires developers to consider on-site retention of storm water for all new projects, wherever feasible. On-site retention aids in controlling the rate, volume, and quality of storm water discharged to the commission's storm drainage system.

Costs Associated With Managing Storm Water

We were not able to obtain comprehensive information on the total cost to the commission of managing storm water because the commission does not separate the cost of its storm water program from the cost of its sewer operations. Therefore, we do not present that information here.

Funding Sources

The commission funds its storm water management control efforts primarily with city water and sewer user fees and bond proceeds.

R0012777

The Storm Water Program in Los Angeles County, California

Under the NPDES Storm Water Program, the Los Angeles Regional Water Quality Control Board issues 5-year permits to Los Angeles County for its municipal storm water program. The Los Angeles County permit, issued in July 1996, is the county's second storm water permit. This permit includes Los Angeles County as the principal permittee and 85 cities as permittees. According to the 2000 census, Los Angeles County's population is about 9.5 million.

Urban Runoff Problems in Los Angeles County

The effects of urban runoff on the ocean are of particular concern in southern California. Contaminated sediments, impaired natural resources, and potential human illness could threaten the county's tourism economy, estimated to be about $2 billion a year.

The following three studies have shown that urban runoff can pose health risks to swimmers near storm drains and contribute toxic metals to receiving water sediments:

- The Santa Monica Bay Restoration Project conducted a study to assess the possible adverse health effects of swimming in waters contaminated by urban runoff.[1] This study revealed that there is an increased risk of illness associated with swimming near flowing storm drain outlets and an increased risk of illness associated with swimming in areas with high concentrations of bacteria indicators. Furthermore, illnesses were reported more frequently on days when the samples were positive for enteric viruses. Refer to the section of this report describing the effects of runoff on aquatic life and human health for more details.
- The Southern California Coastal Water Research Project coordinated a study that assessed microbiological water quality and found that the majority of shoreline waters exceeded water quality standards during wet-weather conditions. Furthermore, the ocean waters near storm water outlets demonstrated the worst water quality regardless of the weather.[2]
- The Southern California Coastal Water Research Project also compared the runoff from an urban area and a nonurban area in the Santa Monica

[1]R.W. Haile and others, "The Health Effects of Swimming in Ocean Water Contaminated by Storm Drain Runoff," *Epidemiology*, July 1999, Vol. 10, No. 4.

[2]Southern California Coastal Water Research Project, *Southern California Bight 1998 Regional Monitoring Program, Volume 3: Storm Event Shoreline Microbiology*, 2000.

R0012778

Bay Watershed.[3] The results of the study indicated that storm water plumes extended up to several miles offshore and persisted for a few days. Furthermore, the runoff from the urban area proved to be toxic to sea urchin fertilization, and dissolved zinc and copper were determined to be contributors to the toxicity. The study also found that in urban areas, sediments offshore generally had higher concentrations of contaminants such as lead and zinc.

Los Angeles County's Use of Best Management Practices

As in the other sites we visited, the county is managing its runoff through the use of conventional BMPs. These BMPs include the elimination of illicit connections and discharges to the storm sewer system, construction control measures, routine inspections, staff training, pollution prevention plans for public vehicle maintenance and material storage facilities, sweeping and cleaning public parking facilities, street sweeping, catch-basin cleaning, and public education.

The Los Angeles Regional Water Quality Control Board recently adopted a Total Maximum Daily Load (TMDL) Program to reduce trash loads to the Los Angeles River. As a result, the county is exploring a number of trash reduction BMPs, which are discussed in the section of this report describing local government efforts to manage storm water.

Costs Associated With Managing Storm Water

Table 3 indicates that the county and the other permittees have allocated significant funding for storm water management activities over the years. For example, for fiscal year 1999,[4] projected funding for storm water management activities for the county and the other permittees amounted to over $134 million.[5] The largest projections for both went toward public agency activities. For example, during fiscal year 1999, the principal permittee and the permittees together projected almost 67 percent of storm water management funds to public agency activities. The activities in this

[3]Southern California Coastal Water Research Project, *Study of the Impact of Stormwater Discharge on Santa Monica Bay–Executive Summary,* Nov. 1, 1999.

[4]The county's fiscal year begins July 1 and ends June 30.

[5]According to an official with the Los Angeles Regional Water Quality Control Board, this figure may also include activities that are outside the scope of the permit.

R0012779

program include staff training, inspections of construction projects, street sweeping, and catch-basin cleaning.

[a]Totals may not add up because of rounding.

[b]Does not include 17 permittees for fiscal year 1998 and 13 permittees for fiscal year 1997 for the following reasons: The permittee operated on a different budget cycle, the final document was not available at the time of the annual report, or the information submitted by the permittee was not complete.

Source: GAO's analysis of cost data provided by the Los Angeles County Department of Public Works.

As shown in table 3, the county maintains primary responsibility for monitoring activities, having projected over $2 million for storm water monitoring activities in fiscal year 1997, almost $2 million in fiscal year 1998, and over $1.5 million in fiscal year 1999. Conversely, the permittees' projected funding levels for monitoring activities amounted to only $619,000 in fiscal year 1997, $729,000 in fiscal year 1998, and $737,000 in fiscal year 1999. According to an official with the Los Angeles Regional Water Quality Control Board, the County has consistently maintained primary responsibility for monitoring activities required under the permit.

R0012780

Funding Sources

The primary source of funds for the county's storm water program is flood control assessments collected throughout the district. Although the county has not applied for any state revolving funds, it has applied for and received approval for federal funds through the Transportation Equity Act for the 21st Century (TEA-21) for a pilot study of an engineering device that would remove trash from storm water. Additionally, the county has received partial funding through Proposition A of the Safe Neighborhood Parks of 1992 and 1996[6] for two Vortex Separation Systems—a Continuous Deflective Separation unit and a Stormceptor unit. Additionally, the county received grant money from the Metropolitan Transit Authority, which partially funded catch-basin screens, a Continuous Deflective Separation unit, and 120 catch-basin inserts.[7]

[6]The Los Angeles County Regional Park and Open Spaces District (a district within the Parks Department) received this funding from Proposition A and, in turn, made grants to the Los Angeles County Department of Public Works for the BMP devices.

[7]The Metropolitan Transit Authority receives TEA-21 funds from the California Department of Transportation.

R0012781

The Storm Water Program in Milwaukee, Wisconsin

The Wisconsin Department of Natural Resources (WDNR) has the authority to regulate the discharge of storm water from municipalities, construction sites, and industries under Natural Resources Code 216. This rule identifies Wisconsin municipalities that are required to obtain a storm water discharge permit under the Wisconsin Pollutant Discharge Elimination System (WPDES). Milwaukee completed its application process in 1994, and WDNR issued a WPDES permit to the city in October 1994. This was the first municipal storm water permit issued to a municipality in EPA's Region 5 covering the midwest. In July 2000, WDNR reissued Milwaukee's storm water permit. According to the 2000 census, Milwaukee's population is about 597,000.

Urban Runoff Problems in Milwaukee

Milwaukee has a combined sewer system as well as a separate sanitary sewer system. The Milwaukee Metropolitan Sewerage District implemented a rehabilitation program that cost over $2 billion to reduce the number of combined sewer overflow (CSO) events each year. The rehabilitation program involved the construction of deep tunnels to store untreated wastewater and rainwater for later treatment at a wastewater treatment plant. Since 1996, the deep tunnels have significantly reduced the number of overflow events from an average of 50 to 60 per year before the construction to an average of two per year afterwards.

Urban runoff has been identified as a leading source of pollution to the Milwaukee River basin's streams, lakes, and wetlands and the Milwaukee River estuary. To address pollution from urban runoff, WDNR issues storm water permits to municipalities with MS4s serving areas with populations of 100,000 or more, municipalities in Great Lakes "areas of concern" where water quality has been identified as a serious problem, municipalities with populations of 50,000 or more that are located in priority watershed planning areas, and designated municipalities that contribute to the violation of a water-quality standard or are significant contributors of pollutants to state waters.

Milwaukee's Use of Best Management Practices

In addition to BMPs such as the elimination of illicit connections and discharges to the storm sewer system, the reduction of pollutants in storm water runoff from construction sites, public education, catch-basin cleaning, street sweeping, and the use of detention basins, Milwaukee has explored the use of innovative BMPs. Refer to the section of this report describing local government efforts to manage storm water for more

R0012782

details about an educational campaign directed at a specific watershed. Additional BMPs include the following:

- An innovative storm water control device was installed in a parking lot at a heavily used municipal public works yard that was found to discharge significant amounts of storm water pollutants. Termed the Multi-Chambered Treatment Tank (MCTT), this device is suitable for areas with limited space, cleans up polluted runoff close to its source, removes pollutants that are not susceptible to other treatment methods, and is hidden from view. The MCTT consists of a catch basin, a settling chamber, and a filter. Although the results of the monitoring studies have revealed that the device has a positive effect on water quality, officials with the Department of Public Works explained that it is cost-prohibitive and suitable only for sites with limited space.
- The permittee has also been working with WDNR, the Department of Transportation, the U.S. Geological Survey, and a neighborhood association in a joint effort to develop a storm water monitoring assessment program consisting of two innovative storm water treatment devices. One device removes grit, contaminated sediments, heavy metals, and oily floating pollutants from surface runoff. The other device removes a broad range of pollutants from runoff, such as bacteria, heavy metals, nutrients, petroleum hydrocarbons, and suspended solids. The devices are to be installed along a new reach of the Milwaukee Riverwalk through the third ward of Milwaukee.

Costs Associated With Managing Storm Water

Reliable data on the total cost to manage storm water in Milwaukee were not available and cannot be presented here because certain activities are not reported as program costs in the city's annual report. These activities include street sweeping; leaf collection; catch-basin and inlet cleaning; maintenance of public boulevards, parks, and public green spaces; and the recycling of waste oil and antifreeze. Therefore, the program costs reflected in the annual report do not take into account many of the nonstructural BMPs employed by the city nor do the totals include activities funded through grants. The storm water management activities that were included in the city's 2000 budget request were estimated to cost $460,000.

Funding Sources

Milwaukee's storm water program is primarily funded through the city's sewer maintenance fund. Unlike the general revenue account, which is

R0012783

based on property taxes, the sewer maintenance fund is based on water consumption. The city has also received supplemental funding from the Wisconsin Nonpoint Source Water Pollution Abatement Program in the form of WDNR grants. The city has received over $1 million since 1991 for a wide variety of storm water management activities.

R0012784

The Storm Water Program in Worcester, Massachusetts

Worcester's Department of Public Works (DPW) received a NPDES permit on November 1, 1998. The Sewer Operations Division, within the DPW, is directly responsible for operating and maintaining the city's separate storm sewer system, along with the sanitary and combined sewer system. Since 1993, the Sewer Operations Division has had a full-time storm water coordinator, reflecting Worcester's increased emphasis on meeting NPDES program requirements. Worcester has a population of about 173,000. Its water system covers an extensive area, including 371 miles of sanitary sewers, 340 miles of storm sewers, 56 miles of combined sewers, 27,000 manholes, over 14,000 catch basins, and 263 outfalls. Worcester's separate storm drain systems consist of 93 main drainage areas covering approximately 6,680 acres.

Urban Runoff Problems in Worcester

The constituents that are typically found in urban runoff in Worcester are the same as those normally found in urban runoff in older cities. Because virtually all of the paved surfaces in the Worcester area are devoted to the city's transportation infrastructure, the constituents generated include automobile-related petroleum products, such as total petroleum hydrocarbons, oil and grease, along with total suspended solids. Also, coliform, silt, and sediment have been identified in the city's runoff.

Worcester's Use of Best Management Practices

Like other permittees, the DPW has implemented BMPs under the major areas of education outreach, pollution prevention and source controls, storm-drainage system maintenance, regulatory efforts, and storm-drainage system infrastructure. Additionally, to reduce storm water pollution, the DPW has retrofitted a number of twin manholes in the city as discussed below. BMPs that are specific to Worcester include the following:

- The DPW implemented a demonstration project to determine the effectiveness of an oil and grit separator installed on a street drain. The drain is a major surface sewer main that services approximately 226 acres of heavily urbanized area with a typical mix of residential, commercial, and industrial use. The drain discharges into Lake Quinsigamond, which is a large lake used for recreational purposes such as swimming and boating. In its April 2000 annual plan submitted to EPA, the DPW noted that because of drought conditions, it currently did not have sufficient sampling data to determine the effectiveness of the project.

R0012785

- The DPW has embarked on a comprehensive program to minimize the possibility that sewage and storm water will be mixed in its twin invert manholes. Since the program began, the DPW has installed hold-down devices on over 1,680 of the approximately 2,580 twin invert manholes in the city. The DPW expects to continue the program until all of the manholes have been retrofitted.
- The DPW is also working closely with the Massachusetts Department of Environmental Protection in its ongoing tracking efforts to ensure that industries in Worcester are doing their part to reduce storm water pollution.
- To improve its storm-drainage infrastructure, the city has established a voluntary plan to reduce the number of unpaved private roads. The dirt from these roads, especially after rain storms, causes sediment to build up in the drainage system. The DPW has developed a plan to pave the streets at a lower grade than would be necessary to meet the legal requirements for a public street. Under this plan, residents would not have to pay the additional betterment taxes that are now required to cover the costs of sediment removal and less sediment would be transported in runoff.

Costs Associated With Managing Storm Water

Since 1993, the DPW has allocated significant funding from the water and sewer utility fees it collects for controlling the effects of runoff, especially through catch-basin cleaning, street sweeping, and correcting illegal connections. For example, its fiscal year 1993 budget for storm water programs included about $1.6 million for specific programs and another $1 million for capital improvement programs, such as inflow/infiltration and flood control. The DPW also spent $500,000 to develop and submit its permit application. Furthermore, as shown in table 4, Worcester made extensive capital expenditures during fiscal years 1994 through 1999 on pertinent storm water projects to improve the quality of storm water runoff emanating from the city's storm water sewer system.

R0012786

Table 4: City of Worcester's Capital Expenditures for Storm Water Management

(Dollars in thousands)

	Fiscal year					
Activity	**1994**	**1995**	**1996**	**1997**	**1998**	**1999**
Sewer construction	$0	$500	$500	$300	$300	$300
Infiltration control	0	400	400	100	100	100
Pump station rehabilitation	200	200	200	200	200	200
Sewer rehabilitation	300	750	300	750	750	1,500
Landfill closeout	150	1,200	200	500	0	0
Belmont Drainage project	0	100	600	100	0	0
Beaver Brook Culvert project	0	500	100	100	300	100
Surface drain control	40	150	200	200	200	200
Geographic Information System	0	0	0	125	125	125
Other	0	70	10	0	0	0
Total	**$690**	**$3,870**	**$2,510**	**$2,375**	**$1,975**	**$2,525**

Note. The Belmont Drainage project involved enlarging the drain to eliminate surcharging and siltation and moving the outfall to eliminate stagnation. The Beaver Brook Culvert project involved repairing the culvert and conducting a study that included a detailed hydraulic analysis of the drainage basin.

Source: Worcester Department of Public Works.

Furthermore, during fiscal year 1999, the DPW spent approximately another $2.1 million to operate and maintain storm water activities. Key expenditures included about $1.2 million for street sweeping, about $617,000 for catch-basin maintenance, $52,000 for root control, and another $48,000 for street paving. Also included was $40,000 per year for sampling five outfalls around the city three times per year as required by the permit. According to a DPW official, in previous fiscal years, the DPW funded the same or similar operation and maintenance activities to help control storm water runoff. As a result, the costs since 1994 were similar to those for 1999, except for annual adjustments for inflation. Therefore, the annual operation and maintenance expenditures ranged from about $1.7 million for 1994 to about $2.1 million for 1999.

According to a DPW official, the department expects to spend from $3 million to $4.5 million annually over the next several years on storm water-

R0012787

related activities. The amount of the cost increase will depend on whether EPA asks the city to increase its spending.

Funding Sources

The DPW funds its storm water management controls effort from the water and sewer user fees it assesses to homes and businesses.

Comments From the Environmental Protection Agency

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D C 20460

JUN 14 2001

OFFICE OF WATER

Mr. Peter F. Guerrero
Director, Physical Infrastructure Issues
United States General Accounting Office
Washington, DC 20548

Dear Mr. Guerrero:

Thank you for the opportunity to review your draft report entitled "Better Data and Evaluation of Urban Runoff Needed to Assess Effectiveness." We appreciate the difficulty that assimilating and interpreting such information on an extremely complex subject must have presented. Your report provides a fair and balanced depiction of the Agency's efforts, with the assistance of our State and local partners, to implement a national urban storm water runoff control program.

As the report correctly acknowledges, the Environmental Protection Agency (EPA) believes that urban runoff is a significant threat to water quality and is actively working to control the discharge of pollutants in storm water runoff. EPA's urban storm water control program has been a very successful undertaking to date and we are taking steps to address several of the recommendations identified in the report.

One of the challenges of controlling urban storm water runoff is to be able to address a wide array of complex environmental issues, even within the boundaries of one municipality. EPA's urban storm water program is developed with the understanding that a "one size fits all" approach will not work. For example, existing municipal separate storm sewer system (MS4) permits are tailored to suit the needs of each individual municipality. In fact, the municipalities select the majority of the measures that will be implemented to control storm water runoff. Similarly, EPA's Phase II regulatory framework for small MS4s requires the municipality to identify appropriate BMPs to control runoff and establish measurable goals against which program effectiveness will be measured. These BMPs and measurable goals then become the enforceable permit conditions for that municipality. EPA expects that approximately 5,000 small MS4s will each have a unique set of measurable goals that will define expectations of a successful storm water control program.

While EPA has developed a sound regulatory basis for urban storm water control, competing initiatives have limited our ability to invest sufficient resources to fully evaluate the effectiveness of the program and the associated implementation costs. We believe that the flexibility afforded MS4 permittees provides some assurance that permit requirements do not become onerous or unjustified. Additionally, with the MS4 permits reissued every five years,

Internet Address (URL) • http://www.epa.gov
Recycled/Recyclable • Printed with Vegetable Oil Based Inks on Recycled Paper (Minimum 30% Postconsumer)

R0012789

EPA expects that dialogue between MS4s and permitting authorities will better focus on those activities found to be most beneficial.

Over the next year, we will address challenges relating to evaluating the effectiveness of municipal storm water programs. Consistent with the first recommendation, EPA will evaluate storm water monitoring data that has been collected since program inception. Two grantees (UCLA and the University of Alabama) will review monitoring data that has been submitted as part of routine discharge monitoring reports and annual reports. EPA expects these efforts will evaluate the correlation between storm water discharges and trends in water quality impairment. Another anticipated finding from these grants is a compilation of the range of monitoring activities required of municipalities in storm water permits and the identification of the monitoring that appears to be most effective in demonstrating program results.

To meet another challenge, we are evaluating MS4 permit requirements and annual reports to identify the types of storm water control activities in place and the environmental and programmatic results of these activities. Initially, this effort will evaluate MS4s in at least three EPA Regions and 10 states to gather information on the range of methods employed by permitted MS4s to control storm water discharges. Through this effort, EPA expects to determine whether program goals are being met and establish meaningful indicators of program performance. Should this effort prove useful, EPA will expand the evaluation to a national effort that will evaluate MS4 permits and annual reports in all affected EPA Regions and states. In either case, results of this effort will be disseminated nationally to ensure that findings are incorporated into other MS4 programs, as appropriate.

Enclosed are additional comments on terminology and regulatory citations provided in the report. Again, we appreciate the opportunity to review and comment on the draft report. If you have any questions about these comments or would like to discuss urban storm water runoff issues, please contact me or call Jeff Lape, Acting Director of the Water Permits Division, at (202) 564-9545.

Sincerely,

Michael B. Cook
Director
Office of Wastewater Management

Enclosure

R0012790

Enclosure

Below are several additional comments for your consideration that address terminology and regulatory citations provided in the report:

- The term "nonpoint source" throughout the report, when referring to storm water runoff, is somewhat misleading in that the federal definition of "point source" includes many of the types of storm water discharges discussed in the draft report as "nonpoint source pollution." We recommend clarifying that EPA's NPDES storm water permits regulate point source discharges that includes storm water runoff from small, medium, and large municipal separate storm sewer systems. In fact, to avoid confusion between point sources and nonpoint sources in an NPDES context, we recommend that you consider using the term "wet weather discharges" when referring to storm water runoff.

- The third sentence in the first full paragraph on page 3 states that "EPA requires cities to use 'best management practices' to reduce contamination in storm water runoff." We recommend that you change the word "requires" to "recommends." While best management practices are common for reducing storm water contamination, EPA regulations allow MS4s to reduce the discharge of pollutants to the maximum extent practicable using management practices, control techniques, and system, design, and engineering methods, and such other provisions which are appropriate.

- The last sentence in the second full paragraph on page 3 states that "managing storm water runoff will reduce runoff and improve water quality." We recommend changing this sentence to indicate that "managing storm water runoff will reduce the volume and concentration of pollutants in runoff and improve water quality.

- The last sentence of the same paragraph indicates that "Neither EPA nor states have developed measurable program goals or reviewed municipal reports on the results of storm water programs to determined whether the reports provide information that could demonstrate the program's effectiveness." A similar statement is made in the first full paragraph on page 31. We recommend that these two sentences be revised to indicate that "EPA and states have generally been unsuccessful in developing measurable program goals and in demonstrating program effectiveness through the review of municipal reports." EPA and some states have attempted to determine program effectiveness through the review of municipal reports but, to date, these efforts have been unsuccessful in making this determination.

PRINTED ON RECYCLED PAPER

USGS science for a changing world

U.S. Department of the Interior
U.S. Geological Survey

Comparison of NPDES Program Findings for Selected Cities in the United States

The U.S. Environmental Protection Agency, under section 402(p) of the Water Quality Act of 1987, has required municipalities with populations of more than 100,000 to obtain National Pollutant Discharge Elimination System (NPDES) permits for urban stormwater discharge. This regulation is intended to minimize pollutant loadings from urbanized areas and preserve the quality of streams that receive stormwater. To apply for a NPDES permit, a municipality must monitor the chemistry of stormwater from basins having residential, commercial, and industrial land uses, and estimate storm- and annual-pollutant loads and event-mean concentrations of 12 selected properties and constituents. The properties and constituents include biochemical oxygen demand (BOD), chemical oxygen demand (COD), suspended solids, dissolved solids, total nitrogen, total ammonia plus organic nitrogen, total phosphorus, dissolved phosphorus, total recoverable cadmium, total recoverable copper, total recoverable lead, and total recoverable zinc. These estimates will be used by the municipalities to evaluate the magnitude of pollutant loadings and the efficiency of management strategies that are intended to reduce pollutant loads.

As part of a national synthesis of the study units in the U.S. Geological Survey (USGS) NPDES program, data were compiled on concentrations of the 12 properties and constituents required for load calculations. This report presents a comparison of these data.

Data Collection

The USGS, in cooperation with local agencies, sampled stormwater from 1991 through 1996 in 13 cities and metropolitan areas that are required to obtain NPDES permits (fig. 1). For this comparison, Birmingham and Montgomery, Alabama, were considered one study unit and designated as Birmingham/Montgomery, Alabama. Samples were collected from various conveyances, such as culverts, concrete pipes, lined ditches, and unlined channels. The drainage area of sampling sites typically was small and ranged from 4.0 to 2,564 acres. Each site had a predominant land use—residential, commercial, or industrial (fig. 2). Flow and rainfall data either were collected on site or were estimated from nearby gages. Flow data are used to calculate loads from the concentration data. Samples were collected either by manually collecting discrete samples at timed intervals and flow-weighting volumes of these discrete samples or by collecting flow-weighted composite samples using an automatic sampler. Flow-weighted samples were collected during the first 3 hours of the storm or until the stream returned to pre-storm levels. Samples were collected at a particular site about 30 or more days apart and after approximately 72 hours of less than 0.1 inch of rain.

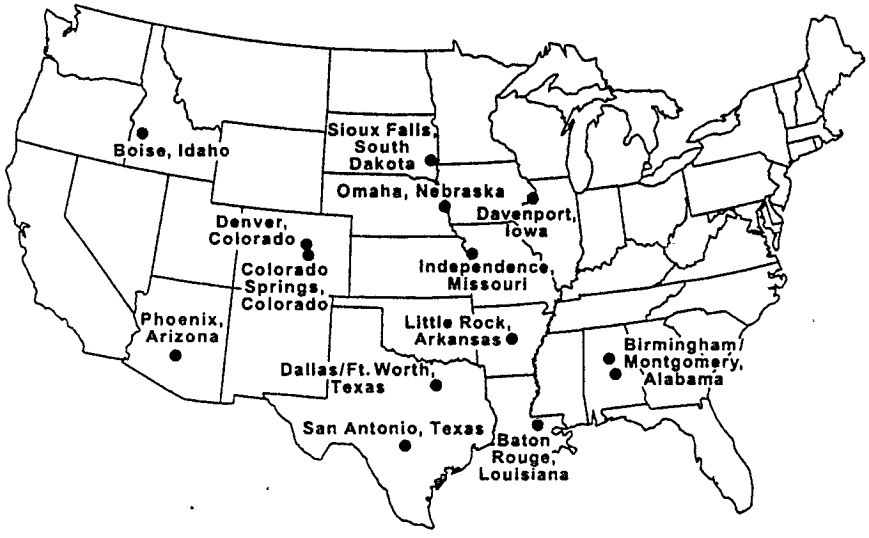

Figure 1. Cities and metropolitan areas where NPDES constituents were sampled in urban stormwater, 1991–96.

Data Analysis

Analyses of the flow-weighted composite samples were done at the USGS National Water-Quality Laboratory with the exception of the Sioux Falls, South Dakota, and BOD analyses. These analyses were done at the individual USGS offices or at contract laboratories.

Nationwide Data Comparison

In an effort to compare storm loads for different land uses, concentration and flow data were compiled from study units in the USGS NPDES data bases. Concentration data and flow volumes were combined along with a unit-conversion factor to obtain storm loads in pounds for each storm. The storm loads then were divided by the area of the individual basins to obtain storm load per unit area, in pounds per acre. Mean storm loads for all constituents then were calculated for the three land uses in each city or metropolitan area (table 1). This manipulation allows direct comparison of the storm loads for each land use.

R0012794

R0012795

Physical Properties

BOD, COD, suspended solids, and dissolved solids were compared for all the cities with the exception of Davenport, Iowa; Boise, Idaho; and Birmingham/Montgomery, Alabama. Samples from Davenport, Iowa, were not analyzed for these properties and constituents. An industrial land-use basin was not sampled in Boise, Idaho. Samples from Birmingham/Montgomery, Alabama, were not analyzed for BOD.

BOD and COD are determined by measurement of the quantity of oxygen utilized by organic matter and chemicals in stormwater samples and are used to indicate pollution (Hem, 1992). Mean storm loads of BOD varied by two orders of magnitude, from 0.05 to 10 pounds per acre. The largest mean storm loads of BOD were associated with industrial land-use basins, except for the maximum that occurred in commercial land-use basins in Denver, Colorado. Mean storm loads of COD varied by two orders of magnitude, from 0.17 to 37 pounds per acre. The largest mean storm loads of COD were associated with commercial land-use sites, except for the maximum that occurred in industrial land-use basins in Baton Rouge, Louisiana.

Concentrations of suspended solids and dissolved solids are measures of solids loads in stormwater and also may be used as indicators of pollution. Mean storm loads of suspended solids varied by more than two orders of magnitude, from 0.28 to 66 pounds per acre. The largest mean storm loads of suspended solids were associated with the industrial land-use basins; the maximum occurred in Omaha, Nebraska. Mean storm loads of dissolved solids varied by more than three orders of magnitude, from 0.17 to 250 pounds per acre. The largest mean storm loads of dissolved solids were associated with industrial land-use basins; the maximum occurred in Independence, Missouri.

Nutrients

Four nutrient constituents—total nitrogen, total ammonia plus organic nitrogen, total phosphorus, and dissolved phosphorus—are being analyzed by the USGS NPDES program. These constituents were compared for all land uses in selected cities, with the exception of industrial land-use basins in Boise, Idaho. An industrial land-use basin was not part of the sampling program in Boise.

Nutrients are essential components in plant growth; however, an overabundance of these constituents will cause undesirable algal blooms in bodies of water that are used for urban drinking-water supplies (Hem, 1992). These algal blooms cause adverse effects on the taste and odor of drinking water and have the potential to cause more serious health problems.

Mean storm loads of total nitrogen varied by more than two orders of magnitude, from 0.0013 to 0.54 pounds per acre. The largest mean storm loads of total nitrogen are associated with industrial land-use basins; the maximum occurred in Baton Rouge, Louisiana.

Mean storm loads of total ammonia plus organic nitrogen varied by almost two orders of magnitude, from 0.0064 to 0.43 pounds per acre. The largest mean storm loads of total ammonia plus organic nitrogen were associated with industrial and commercial land-use basins; the maximum occurred in Baton Rouge, Louisiana.

Mean storm loads of total phosphorus varied by almost two orders of magnitude, from 0.0009 to 0.074 pounds per acre. The largest mean storm loads of total phosphorus were associated with industrial land-use basins; the maximum occurred in Baton Rouge, Louisiana.

Mean storm loads of dissolved phosphorus varied by more than three orders of magnitude, from 0.0001 to 0.044 pounds per acre. The largest mean storm loads of dissolved phosphorus were associated with industrial land-use basins; the maximum occurred in Baton Rouge, Louisiana.

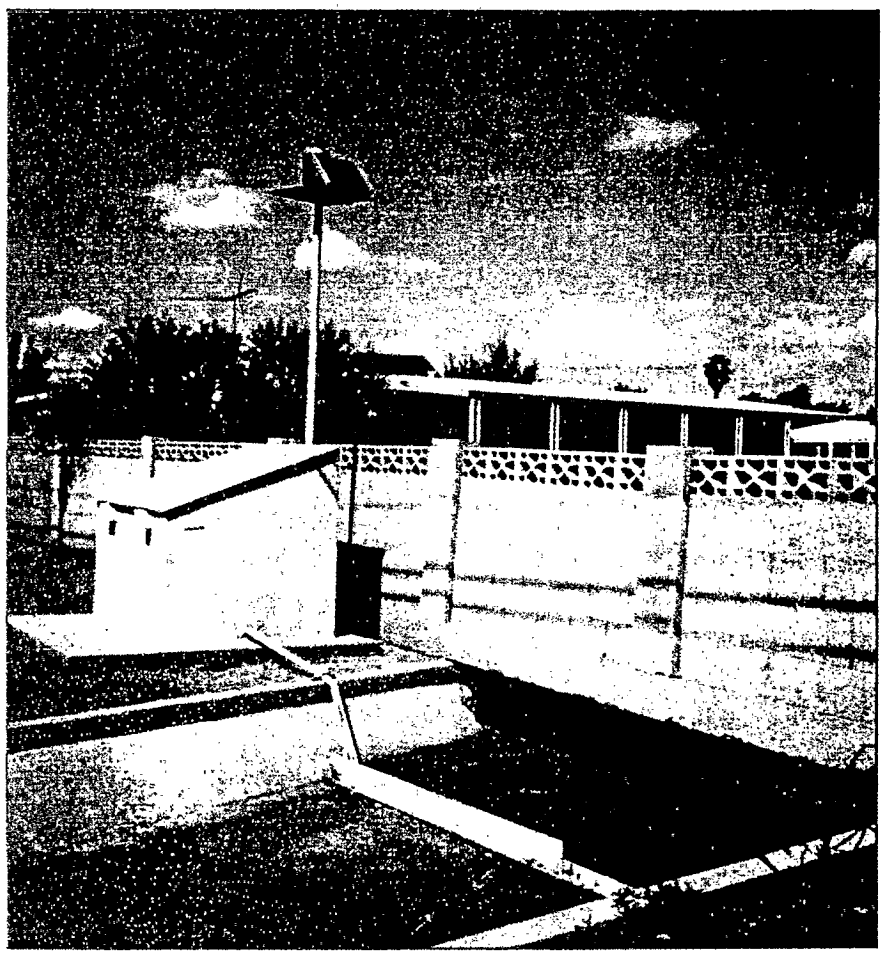

Figure 2. National Pollutant Discharge Elimination System (NPDES) residential land-use site at Glendale, Arizona.

R0012796

Trace Metals

Concentrations of four trace-metal constituents—total recoverable copper, total recoverable zinc, total recoverable cadmium, and total recoverable lead are being analyzed by the USGS NPDES program. These constituents were compared for all land uses in the selected cities with the exception of Davenport, Iowa, and Boise, Idaho. Concentrations of these constituents were not determined in Davenport, Iowa, and an industrial land-use basin was not sampled in Boise, Idaho.

Copper and zinc are essential to plant and animal metabolism and are needed in small amounts by all plants and animals. Large amounts of these metals in drinking water, however, can cause adverse effects on the taste and odor of drinking water.

Mean storm loads of total recoverable copper varied by more than three orders of magnitude, from 3.1×10^{-5} to 5.1×10^{2} pounds per acre. The largest mean storm loads of total recoverable copper were associated with commercial and industrial land-use basins. The exception was the maximum that occurred in a residential land-use basin in Birmingham/Montgomery, Alabama.

Mean storm loads of total recoverable zinc varied by almost three orders of magnitude, from 4.4×10^{-4} to 1.1×10^{-1} pounds per acre (fig. 3). The largest mean storm loads of total recoverable zinc were associated with industrial land-use basins; the maximum occurred in Independence, Missouri.

Cadmium and lead tend to bioaccumulate in plants and animals. Large concentrations of these metals lead to toxicity and health problems in plants and humans (Hem, 1992).

Concentrations of total recoverable cadmium were considered in this analysis of data, but more than 70 percent of the analyses were below detection limits. No mean storm loads of cadmium were included in the data tables.

Mean storm loads of total recoverable lead varied by almost three orders of magnitude, from 8.3×10^{-5} to 3.9×10^{-2} pounds per acre. The largest mean storm loads of total recoverable lead were associated with industrial land-use basins; the maximum occurred in Baton Rouge, Louisiana.

The majority of minimum mean storm loads occurred in residential land-use basins and the majority of maximum mean storm loads occurred in industrial land-use basins. The information contained in this fact sheet is part of ongoing studies and may be updated upon completion of the NPDES program.

—Kenneth D. Fossum and Dawn S. McDoniel

Quantity and Quality of Urban Stormwater Runoff from Selected Drainage Basins

By Abraham H. Chen and Francis J. Jelinek

U.S. Geological Survey
Water-Resources Investigations Report 98-4168
Lincoln, Nebraska
1998

ABSTRACT

The U.S. Geological Survey, in cooperation with the City of Omaha and the Papio-Missouri River Natural Resources District, Nebraska, conducted a study to describe stormwater-runoff quantity and quality from selected basins in Omaha. The study was done to meet technical data requirements for the City of Omaha to obtain a National Pollutant Discharge Elimination System Permit from the U.S. Environmental Protection Agency.

Stormwater-runoff quantity and quality from five sites located in residential, commercial, and industrial land-use basins were monitored from May to November 1992 and April through August 1993. Sites 1 and 4 were representative of residential land use; sites 2 and 5 were representative of commercial land use; and site 3 was representative of industrial land use.

Total rainfall, runoff volume, runoff-rainfall ratio, peak discharge, rainfall and runoff duration, and number of dry hours between storms were calculated and compiled. Mean rainfall during the study was slightly greater in the residential basins (0.60 inch) than in the commercial (0.45 inch) and industrial (0.46 inch) basins. However, mean runoff-rainfall ratio for the industrial (0.32) and commercial (0.38) basins was more than twice the runoff-rainfall ratio of the residential basins (0.15).

Grab samples and flow-weighted composite samples were collected at each of the five sites during six storms and were analyzed for 147 chemical, physical, and biological characteristics. Grab samples, collected within the first 30 minutes of each storm, represented the storm's first-flush effects, and were analyzed for pH, water temperature, residual chlorine, volatile organic compounds, cyanide, total phenols, biological oxygen demand, fecal coliform and fecal streptococcus bacteria, and oil and grease. Flow-weighted samples were composited during the first 3 hours of a storm and were analyzed for acid and base/neutral organic compounds, pesticides and polychlorinated biphenyls, trace elements, chemical oxygen demand, suspended solids, dissolved solids, nutrients, major ions, alkalinity, pH, specific conductance, and total organic carbon.

The volatile organic compounds-chloro-form, dichlorobromomethane, methyl chloride, and toluene-were detected in concentrations ranging from 0.4 to 7.0 micrograms per liter. Toluene was detected only in the residential basins. Eleven base/neutral compounds with concentrations ranging from 9 to 150

micrograms per liter were detected in a commercial basin (site 5) during a storm-runoff event May 22, 1993. Eleven of 12 base/neutral compounds sampled for were detected at five sites. Concentrations of six of the compounds exceeded U.S. Environmental Protection Agency (USEPA) Maximum Contaminant Levels (MCLs) for drinking water.

No pesticide or polychlorinated biphenyl concentrations exceeded MCLs. The trace elements-total beryllium and total lead-exceeded MCLs for drinking water. Total lead also exceeded treatment action levels established by the USEPA for drinking water. Median concentrations of lead from the industrial basin were about 6 times greater than in the residential and commercial basins. Median concentrations of total copper, total nickel, and total zinc were about 3 times greater in samples collected from the industrial basin than from the residential and commercial basins.

Stormwater-runoff constituent loads for 12 constituents were estimated using three methods. The 12 constituents were biochemical oxygen demand, chemical oxygen demand, suspended solids, dissolved solids, total nitrogen as nitrogen (N), total ammonia plus organic nitrogen as N, total phosphorus, dissolved phosphorus, total cadmium, total copper, total lead, and total zinc. The first method used was direct computation of observed data. The second method used was the USEPA simple method for calculating annual pollutant loads. The third method used was a statistical regression method, adjusting the regional models by using local monitoring data. The regression models estimated stormwater-runoff constituent loads.

Business Inspection Program

Seattle's waterways are vulnerable to pollution from a wide variety of human activities. Some businesses within Seattle drain to a creek, lake or bay. Spills or debris may be washed from properties into a public storm system and flow to these aquatic habitats.

Seattle Public Utilities is inspecting commercial and industrial properties to improve stormwater pollution prevention practices in the City of Seattle. The intent of this program is to work with local businesses to improve stormwater quality in Seattle's creeks, lakes and Puget Sound.

Business inspections are part of the City's stormwater pollution prevention program, a requirement of the Washington State Department of Ecology administered through the City's National Pollutant Discharge Elimination System (NPDES) permit for municipal stormwater discharges.

Stormwater Pollution Prevention Requirements

Under the Seattle Stormwater, Grading, and Drainage Control Code (SMC 22.800), all businesses are required to implement certain operational and structural source controls to reduce stormwater pollution.

- **Operational stormwater source controls consist of management practices that prevent or reduce the amount of pollutants in stormwater runoff.** Best Management practices include simple housekeeping activities such as regularly sweeping parking lots and sidewalks, maintaining existing drainage systems, training employees about stormwater pollution prevention practices, and maintaining spill control supplies onsite to prevent and cleanup accidental spills.
- **Structural stormwater source controls are physical, structural, or mechanical devices or facilities that are constructed to prevent pollutants from entering stormwater.** Examples of structural source controls include: enclosing and/or containing the pollutant source; constructing berms, curbs, or dikes to prevent unpolluted stormwater from entering an area where pollution-generating activities take place; and containing and/or treating runoff from contaminated areas.

Check the Director's Rules to see what the new requirements are for public property. If your property drains are connected to the city stormwater system, then you are responsible for maintaining your drainage structures:

- conveyance systems, detention systems and treatment systems
- maintaining streets, driveways, parking lots and sidewalks
- identifying and eliminating illicit connections to the drainage control system.

Business Inspection Program FAQs

More Information for business owners
Four Director's Rules describe City requirements for stormwater flow control, treatment, and construction-related drainage requirements for new and redevelopment projects. They also cover stormwater pollution source control

requirements for existing and new or redevelopment projects.

- DR 16-2000 (5.7MB PDF), Volume 2, Construction Stormwater Control Technical Requirements Manual
  Describes requirements for construction projects (temporary erosion and sedimentation control and control of other pollutants).
- DR 17-2000 (1.6MB PDF), Volume 1, Source Control Technical Requirements Manual
  Describes the operational and structural source controls that are required to reduce stormwater pollution.
- DR 26-2000 (1.9MB PDF), Volume 3, Flow Control Technical Requirements Manual
  Describes requirements for controlling peak flow rates for new and redevelopment projects.
- DR 27-2000 (3.7MB PDF), Volume 4, Stormwater Treatment Technical Requirements Manual
  Describes requirements for treating stormwater from new and redevelopment projects.

Paper copies of these rules are also available at the DCLU Applicant Services Center, Key Tower, 700 5th Avenue, 20th Floor. However, due to their considerable length, a fee is being charged to cover production costs.

If you have questions or concerns regarding the business inspection process, please contact:

Ellen Stewart at 206-615-0023 or ellen.stewart@seattle.gov

Frequently Asked Questions about Business Inspection

Why are we inspecting businesses at this time?
The intent of this program is to work with local businesses to improve stormwater quality. However not all businesses in the City of Seattle will be inspected. If your business is selected to be inspected, you will receive a letter of notification. Business inspections will be conducted to ensure that local businesses understand and implement the requirements of the new code. The goal of this program is to reduce the amount of pollutants entering private and public storm drains, because these systems eventually discharge untreated water to nearby streams, lakes, and Puget Sound. To protect water quality and promote a healthy aquatic ecosystem, we must all make an effort to prevent pollutants such as sediment, oil, soap, and other chemicals from reaching local waters.

When will an inspection take place?
If your business had been selected for an inspection, you will receive a letter of notification within one month of the inspection date. You are welcome to set up an appointment with the inspector prior to the inspection. The inspector will make every effort to contact the responsible party on-site and then commence the inspection. (see contact information)

What will happen on the day of an inspection?
Business inspections are conducted to ensure that local businesses understand and implement the requirements of the new stormwater code. An SPU surface water quality inspector will visit your business to identify potential sources of pollutants to the drainage system and will also observe your general housekeeping practices to make sure that you are using appropriate controls to prevent pollutants from entering any storm drains.

Where will the inspector be looking?
The inspector will mainly need to check the outdoor areas on your property where chemicals, waste, or equipment are stored and where manufacturing or other possible pollution-generating activities take place. In addition, the inspector will look at the drainage system on your property to make sure that it is in good shape. In some cases, the inspector may need to check indoor areas to confirm whether or not they are connected to the drainage system. Inspectors will provide you with information on best management practices that are effective in reducing stormwater pollution.

What if there are corrective actions?
As the property owner, you are responsible for making any corrections needed to comply with the City Code. If any corrective actions are needed, they will be described in the letter sent to you within two weeks after the inspection. The letter will include a brief description of the problem(s), recommendations for correcting the problem(s), information about how to minimize the amount of pollutants discharged from your property, and will also specify a date when the inspector will return to re-inspect your property. Re-inspections will be scheduled as needed to ensure those necessary improvements or corrective actions are completed. The re-inspection date will be determined based on the severity of the problem(s) found during the inspection. Corrective actions should be completed before the re-inspection.

What happens if corrective action is not taken?
As the property owner, you are responsible for any corrections needed to comply with the City Code. If compliance is not achieved within a timely manner, a Notice of Violation may be issued that could result in a fine of up to $500 for each day the violation continues.

If I have other questions about business inspections not covered here, who can I contact?

CITY OF FORT WORTH, TEXAS
STORM DRAIN MONITORING PROGRAM

Fort Worth's Industrial Inspection Program

The City's Industrial Inspection Program was created as a requirement of the City's NPDES Storm Water Permit with the EPA. For the purposes of compliance with the permit, the City must inspect (1) SARA Title III Section 313 industrial facilities, (2) hazardous waste treatment, disposal or recovery facilities, (3) municipal facilities under NPDES regulations and (4) industries that discharge, or have the potential to discharge, substantial pollutant loadings to the storm drain system. Each of these facilities must be inspected once every five years, at a minimum. These inspections are based upon EPA criteria and primarily include a review of the facility's Storm Water Pollution Prevention Plan (SWPPP) and a physical inspection of the facility to identify any potential sources of storm water pollution.

The City of Fort Worth Department of Environmental Management (DEM) has taken a unique approach in performing these inspections. As a regulatory agency, the City has the authority to impose fines and initiate state and federal investigations upon non-compliant industries. However, the federal storm water regulations are not only complicated, they are new to many industries.

DEM is cognizant of this and has taken an approach of education and cooperation with the industries, as opposed to enforcement. When our inspectors visit an industry for the first time, they will perform a comprehensive review of the industry's SWPPP. Any deficiencies in the SWPPP are noted and the industry is given 30 days to make appropriate corrections. During this initial phase, the inspector is willing to assist the industry gain compliance with its permit. This assistance may be in the form of supplying EPA paperwork, answering questions, performing plan reviews, interpreting data, or anything else needed by the industry.

At the end of the 30 day period, the inspector reviews the SW3P again and notes whether the facility is in compliance. In some cases, the industry may not be in compliance at the end of the 30 day period. DEM recognizes that in some special cases, 30 days may not be enough time to make major changes. In such cases, DEM will continue to work with the industry until the industry is in compliance. Industries that do not obtain permits or make reasonable efforts to implement SWPPPs are referred to the EPA for possible federal enforcement action.

For additional information on the inspection process, please call 817-871-5451 and ask for an Industrial Inspector.

Return to Storm Water Discharges Associated With Industrial Activity

FORT WORTH

This page was last modified on February 22, 2001.

In cooperation with the San Antonio Water System

The Edwards aquifer is one of the most productive carbonate aquifers in the Nation. The dissolution-modified, faulted limestone aquifer is the sole source of public water supply for San Antonio, Texas (fig. 1) and is the major source of water for Bexar County. In addition to providing public water supply to more than 1 million people, the Edwards aquifer supplies large quantities of water for agriculture, industry, and military installations. Major springs discharging from the aquifer support recreational activities and businesses, provide water to downstream users, and provide habitat for several threatened or endangered species.

The Edwards aquifer recharge zone is approximately coincident with the stratigraphic units that constitute the Edwards aquifer outcrop; however, the recharge zone includes outcrops of other stratigraphic units in proximity to the units of the Edwards aquifer outcrop where caves, sinkholes, faults, fractures, or other permeable features create a potential for recharge. For this report, areas that are immediately adjacent to the Edwards aquifer outcrop and that drain to the outcrop are considered to be in the recharge zone.

In Bexar County, the area of the Edwards aquifer outcrop is about 119 square miles (mi^2). Most of the land (about 72 percent) on the outcrop is undeveloped (fig. 2). Residential use is about 10 percent of the outcrop land use.

Residential and commercial development on the Edwards aquifer recharge zone in Bexar County is increasing. Urban development can have an appreciable influence on water quality. Impervious cover in developed areas can result in increased stormwater runoff, conveying contaminants from nonpoint sources to local streams or geologic features such as

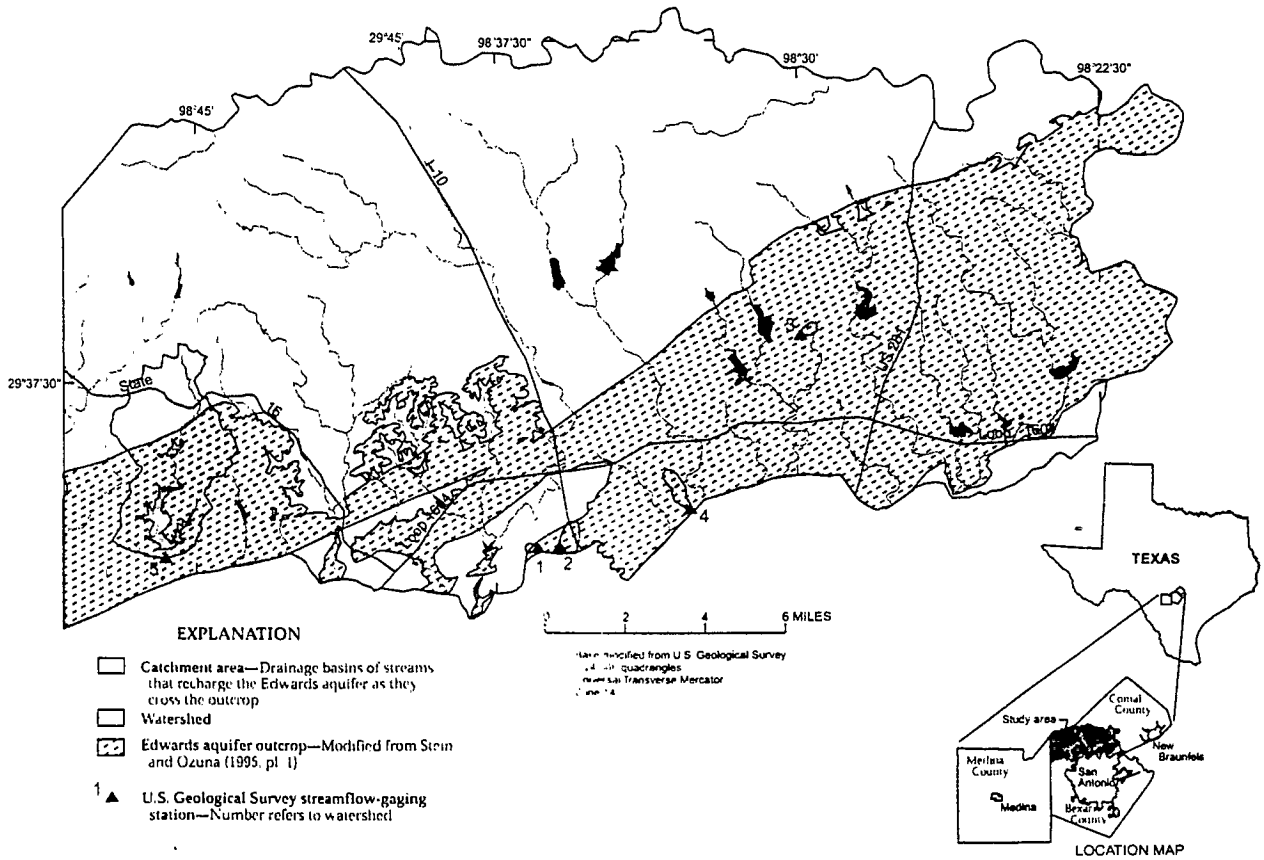

Figure 1. Location of selected watersheds and streamflow-gaging stations in the Edwards aquifer recharge zone, Bexar County, Texas.

R0012805

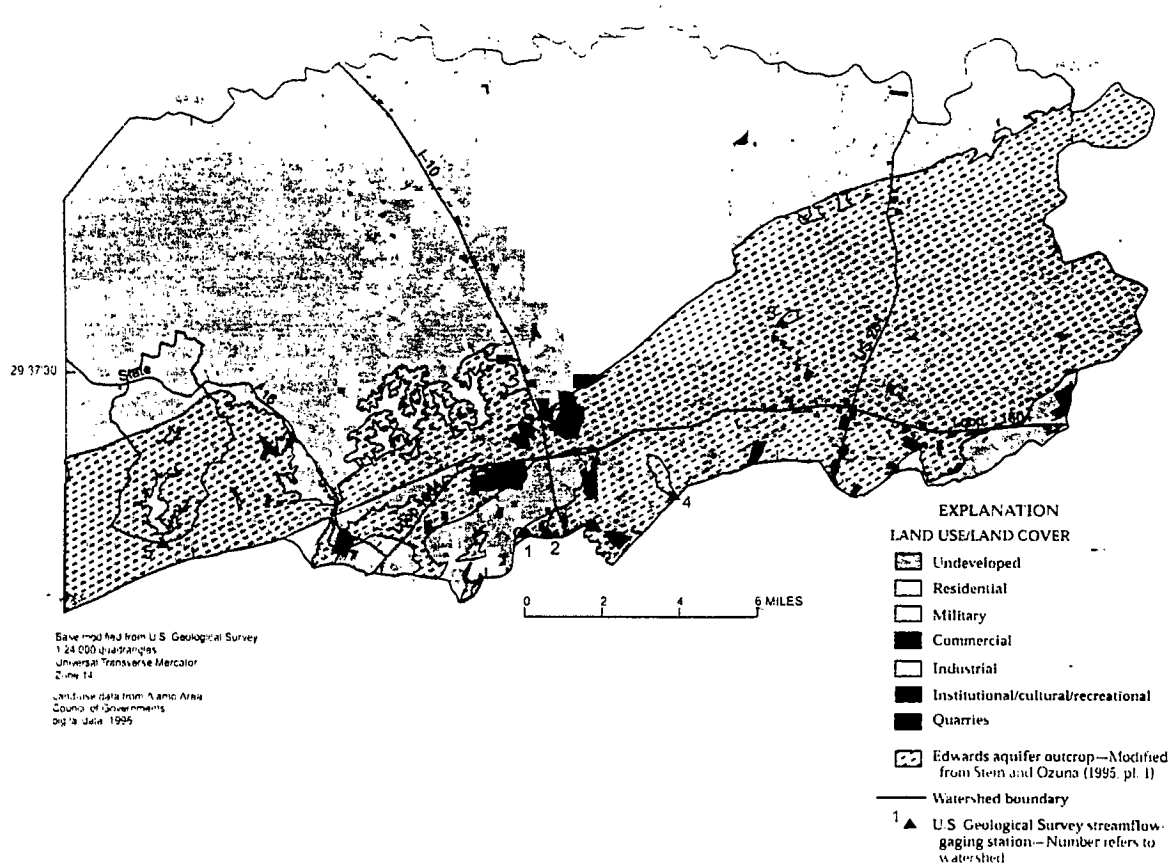

Figure 2. Land use/land cover in the Edwards aquifer recharge zone, Bexar County, Texas, 1996.

caves and fractures where infiltration into the aquifer can occur.

In 1996, the U.S. Geological Survey (USGS), in cooperation with the San Antonio Water System, began a study to monitor the quality and quantity of stormwater runoff of five selected watersheds in the Edwards aquifer recharge zone. The purpose of the study is to further the understanding of relations between stormwater and land use and to help resource managers assess the effects of development on the Edwards aquifer recharge zone. Land use is relatively commercial in two of the watersheds and predominantly residential in two of the watersheds; one watershed is largely undeveloped (table 1). This fact sheet provides an overview of the data-collection methods and selected results of analysis.

Data Collection and Analysis

Rainfall and runoff data and stormwater samples were collected during June 1996–October 1998 from streamflow-gaging stations at the outlets of the five selected watersheds in the Edwards aquifer recharge zone. At each station, rainfall and gage height (stream water level) were measured during storm-runoff events. A computer recorded instrument readings, calculated stream discharges (and runoff), and activated automatic water samplers on the basis of calculated runoff. During each storm-runoff event, the autosamplers were programmed to collect numerous

Table 1. Characteristics of selected watersheds in the Edwards aquifer recharge zone, Bexar County, Texas, 1996–98

[<, less than]

Watershed (fig. 1)	Drainage area (acres)	Impervious cover (percent)	Land use/ land cover	Remarks
1	19	50	Commercial	No stormwater-control structures.
2	315	45–65	Commercial	Watershed includes section of I–10; stormwater-control structures required for businesses; ongoing construction during study period.
3	75	40–50	Residential	Medium density, single-family homes.
4	250	<5	Residential	3- to 5-acre lots; septic tanks.
5	6,880	<2	Undeveloped	Upper 2,450 acres of watershed is upstream of recharge zone; runoff events are rare.

R0012806

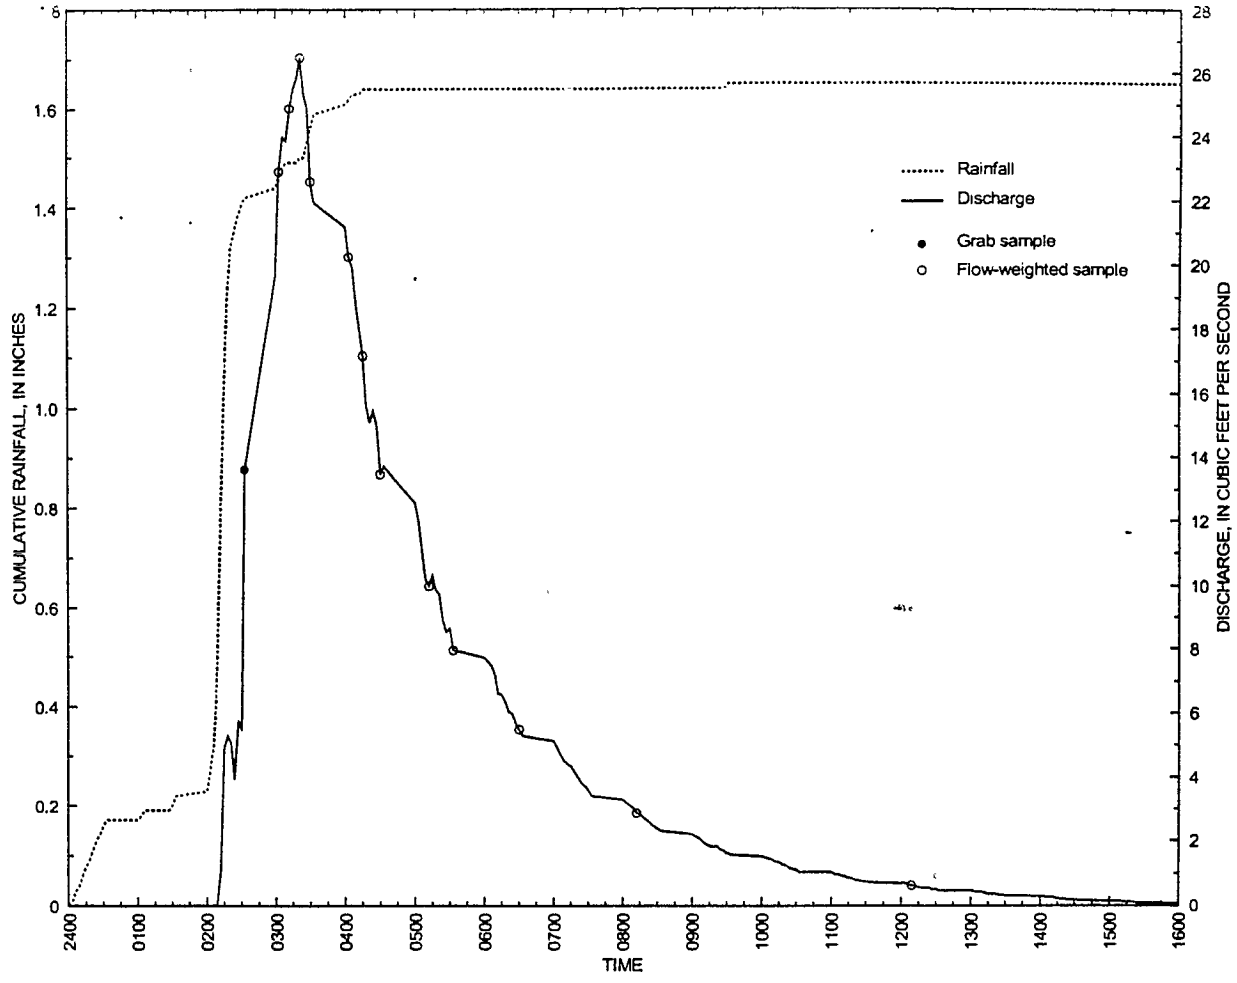

Figure 3. Rainfall, discharge, and times of flow-weighted and grab sample collection during a storm-runoff event at watershed 4, Bexar County, Texas, March 16, 1998.

flow-weighted samples. At the end of a storm-runoff event, the samples were composited, packaged, and shipped to the USGS National Water Quality Laboratory in Arvada, Colo., for analysis. The composite samples were analyzed for common inorganic constituents, chemical oxygen demand (COD), biochemical oxygen demand (BOD), nutrients, trace elements, selected organic compounds, and pesticides.

Analyses of the composite samples yielded event-mean concentrations (EMC), which represent average water-quality conditions during a runoff event. EMCs are useful for comparing concentrations from different sites or from different runoff events at the same site, and for estimating the mass of a chemical constituent exiting the watershed during an event. The mass of a constituent exiting the watershed in runoff can be estimated by multiplying the EMC by the runoff (and appropriate conversion factor).

Discrete grab samples also were collected during each storm-runoff event and analyzed for specific conductance, pH, fecal coliform and fecal streptococcus bacteria, cyanide, phenols, oil and grease, and volatile organic compounds (VOC). Generally, grab samples are collected during the early stages of a runoff event and indicate the presence of constituents in the "first flush" of a runoff. As the constituent concentrations might not represent the average concentrations during a runoff event, estimates of mass of these constituents are uncertain. Rainfall, discharge, and times of flow-weighted and grab sample collection for an example storm-runoff event at watershed 4 on March 16, 1998, are graphed in figure 3.

Selected Water-Quality Property and Constituent Concentrations

Thirty-two composite storm-runoff samples (representing 32 storm-runoff events) were collected at the five selected watersheds during June 1996–October 1998. The watersheds with the larger percentages of impervious cover (1 and 2, table 1) yielded more runoff per acre than the less developed watersheds (4 and 5, table 1). More samples were collected from the watersheds with more impervious cover (1 and 2) because runoff occurred with as little as 0.05 inch (in.) of rainfall in the watershed, whereas runoff in watersheds 4 and 5 occurred only during intense rainfall with totals of at least 1.5 in. The median EMCs of selected constituents for each watershed are listed in table 2.

Boxplots were constructed to show example comparisons of concentrations

R0012807

Table 2. Median event-mean concentrations of selected properties and constituents by watershed, Bexar County, Texas, 1994–95

[µS/cm, microsiemens per centimeter at 25 degrees Celsius; mg/L, milligrams per liter; cols./100 mL, colonies per 100 milliliters; $CaCO_3$, calcium carbonate; <, less than; µg/L, micrograms per liter; --, insufficient data]

Property or constituent	Watershed (fig. 1)				
	1	2	3	4	5
Number of composite storm-runoff samples collected	10	2	12	4	4
Specific conductance (µS/cm)	91	106	88	114	200
Chemical oxygen demand (mg/L)	38	39	31	27	30
Fecal coliforms (cols./100 mL)	10,000	27,000	13,000	4,900	4,300
Fecal streptococci (cols./100 mL)	5,600	64,000	38,000	67,000	5,180
Calcium, dissolved (mg/L)	12	13	11	16	35
Magnesium, dissolved (mg/L)	.4	4.0	.4	.8	2.1
Sodium, dissolved (mg/L)	2.2	1.3	1.3	1.2	1.7
Potassium, dissolved (mg/L)	1.6	2.6	1.6	3.0	2.4
Alkalinity (mg/L as $CaCO_3$)	45	54	48	57	102
Sulfate, dissolved (mg/L)	4.9	4.0	2.3	2.2	4.0
Chloride, dissolved (mg/L)	1.5	1.0	1.8	1.6	2.5
Dissolved solids, sum of constituents (mg/L)	52	60	52	98	119
Suspended solids (mg/L)	114	111	54	42	48
Nitrogen, nitrite plus nitrate, dissolved (mg/L)	.41	.20	.28	.20	.44
Nitrogen, ammonia, dissolved (mg/L)	.10	.10	.08	.03	<.02

Nitrogen, ammonia plus organic, dissolved (mg/L)	.30	.30	.40	.40	.39
Phosphorus, total (mg/L)	.20	.18	.19	.14	.07
Arsenic, total (µg/L)	2	2	12	3	--
Cadmium, total (µg/L)	<1	<1	<1	<1	<1
Chromium, total (µg/L)	4	6	1	2	<1
Copper, total (µg/L)	7	6	6	3	2.1
Lead, total (µg/L)	9	10	3	10	2.2
Mercury, total (µg/L)	<.1	<.1	<.1	<.1	<.1
Nickel, total (µg/L)	3	4	2	2	--
Zinc, total (µg/L)	100	45	37	16	<10
Organic carbon, total (mg/L)	14	13	10	12	10
Cyanide, total (mg/L)	<.01	<.01	<.01	<.01	<.01
Phenols, total (µg/L)	4	--	<1	4	<1
Oil and grease, total (mg/L)	3	--	2	<1	<1
DDD, total (µg/L)	<.1	<.1	<.1	<.1	<.1
DDE, total (µg/L)	<.04	<.04	<.04	<.04	<.04
DDT, total (µg/L)	<.1	<.1	<.1	<.1	<.1
Diazinon, total (µg/L)	<.05	<.05	.5	<.05	<.05

of selected trace elements (chromium, copper, lead, and zinc) by land use (fig. 4). Water-quality data from watersheds with similar land uses (1 and 2; 3 and 4) (table 1) were grouped together. Boxplots with data less than the laboratory minimum reporting levels were truncated at the reporting level. The numbers of samples with concentrations less than the reporting levels are shown in brackets in figure 4. In most cases, less than 25 percent of the data were below the reporting levels and the interquartile range is plotted. Boxplots for the undeveloped land-use category were not constructed because only four samples were collected

Total chromium, lead, and zinc concentrations were significantly larger, at the 95-percent confidence level, for commercial land use than for residential land use on the basis of one-sided Mann-Whitney tests (Helsel and Hirsch, 1992). The statistical test for total copper concentrations did not show significant difference between commercial and residential land use. Statistical comparisons of concentrations in samples from the undeveloped watershed were not included because of the small data set (four samples).

Example of Mass Yields

The effect of land use and percent impervious cover of a watershed in generating stormwater-runoff pollutants is evident when examining the annual mass

R0012808

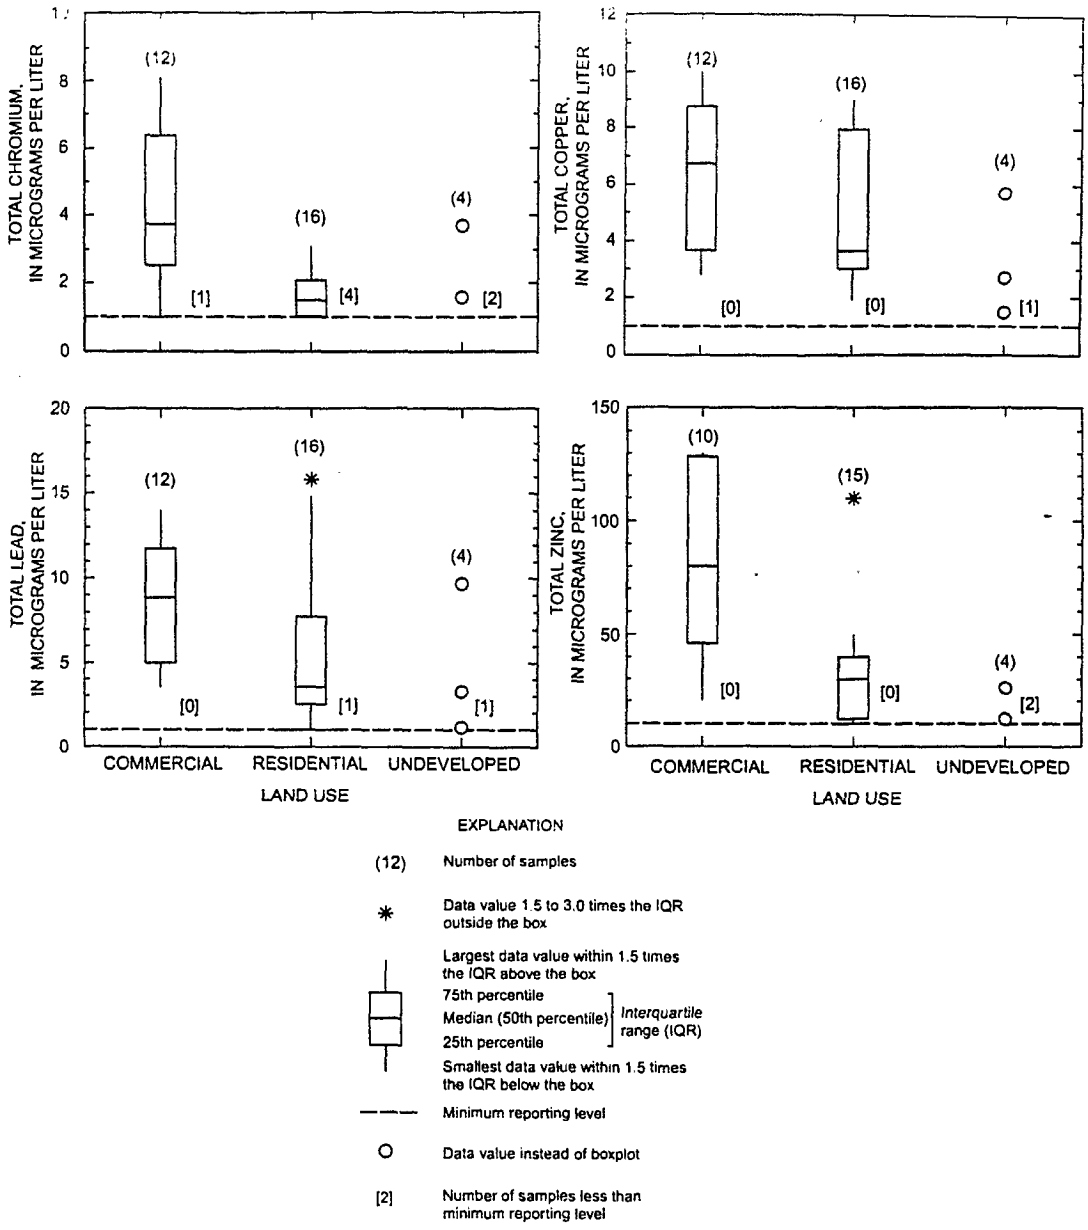

Figure 4. Distributions of total chromium, copper, lead, and zinc concentrations by land use, Bexar County, Texas, 1996–98.

yield of total lead, for example, for the watersheds. Annual mass yields for 1997 were computed for total lead for each watershed using the equation:

$$Y = \frac{QC}{A} \cdot cf,$$

where

Y = annual mass yield in pounds per year per acre;

Q = annual runoff in acre-feet per year;

C = flow-weighted average of EMCs in micrograms per liter;

A = watershed area in acres; and

cf = conversion factor (0.00272).

Annual runoff, flow-weighted averages of EMCs, and mass yields of total lead for the five watersheds are listed in table 3. All samples collected from June 1996 through October 1998 (some watersheds had limited runoff during 1997) were used to compute the flow-weighted average of total lead EMCs, except for watershed 5. In 1997, all of the runoff for watershed 5 occurred during a single event. Samples collected for watershed 5 during the event yielded total lead concentrations that were less than the laboratory minimum reporting level, so a value equal to the reporting level was used as the average EMC to calculate a maximum for the annual yield. The magnitude of differences in annual mass yields among the watersheds is illustrated in figure 5.

R0012809

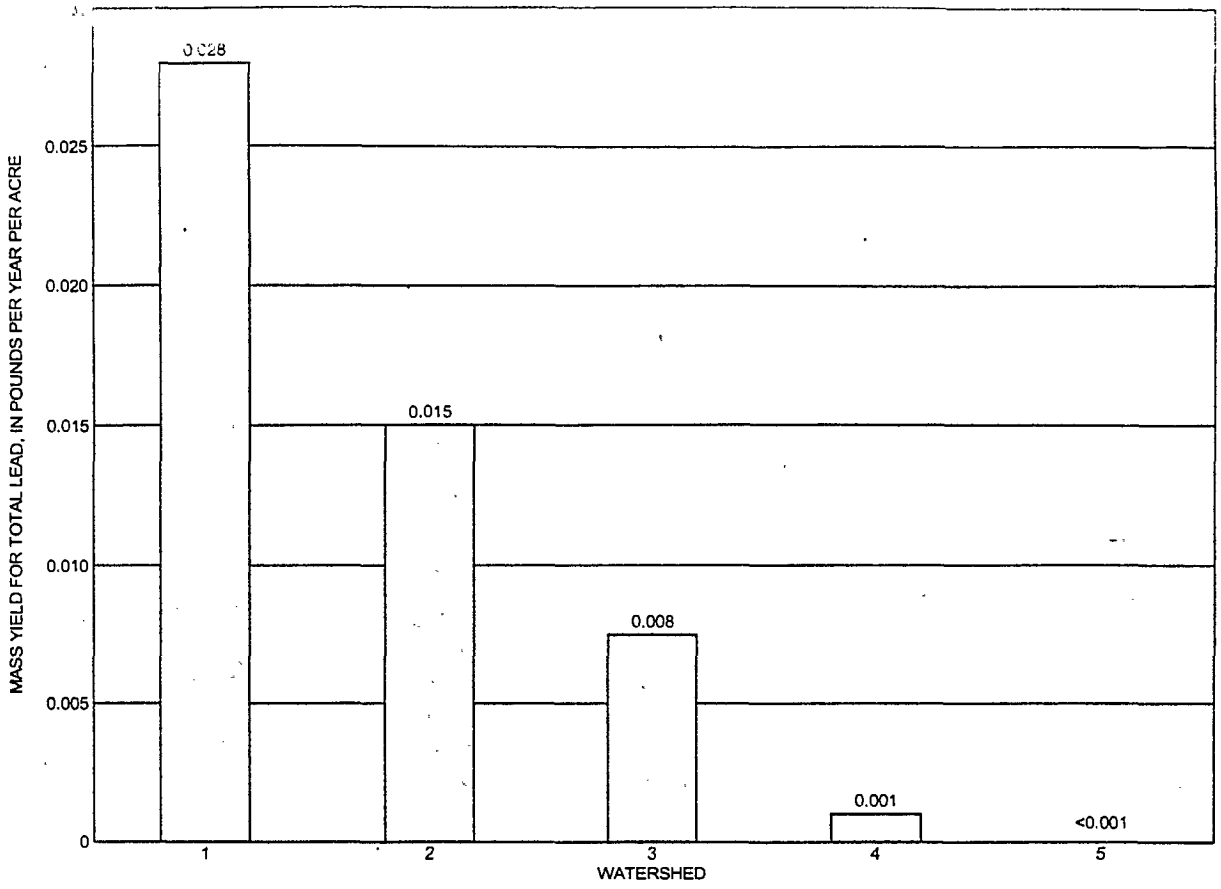

Figure 5. Annual mass yields for total lead by watershed, Bexar County, Texas, 1997.

PERMIT NO. FLS000004
Major MS4

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION IV

AUTHORIZATION TO DISCHARGE UNDER THE NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM

In compliance with the provisions of the Clean Water Act, 33 U.S.C. 1251 et seq., as amended by the Water Quality Act of 1987, P.L. 100-4, the "Act",

Sarasota County - Municipal Separate Storm Sewer System Permittees:

Sarasota County
Engineering Department
Sarasota, Florida

Town of Longboat Key
Department of Public Works
Longboat Key, Florida

City of North Port
Roads and Drainage Department
North Port, Florida

City of Sarasota
Department of Public Works
Sarasota, Florida

City of Venice
Department of Public Works
Venice, Florida

Florida Department of Transportion
District One
Bartow, Florida

are authorized to discharge, in accordance with the approved Storm Water Management Program(s), effluent limitations, monitoring requirements, and other provisions as set forth in Parts I, II, III, IV, V, VI, VII, and VIII herein, from all portions of the

Municipal Separate Storm Sewer System owned or operated by any Permittee listed above,

to waters of the United States and all tributaries thereto.

This permit shall become effective on January 1, 1995.

This permit and the authorization to discharge under the National Pollutant Discharge Elimination System shall expire at midnight, on December 31, 1999.

DEC 21 1994
Date Issued

Robert F. McGhee, Acting Director
Water Management Division

Part VIII. DEFINITIONS

PART I.

DISCHARGES AUTHORIZED UNDER THIS PERMIT

A. **Permit Area.** This permit covers all areas located within the political boundary of Sarasota County and the portion of the Town of Longboat Key within Manatee County served by municipal separate storm sewer systems owned or operated by the permittees identified in Part I.C.

B. **Authorized Discharges.** Except for discharges prohibited under Part I.D., this permit authorizes all existing or new storm water point source discharges to waters of the United States from those portions of the Municipal Separate Storm Sewer System (MS4) owned or operated by the permittees.

C. **Permittees.**

The following entities are permittees subject to the conditions of this permit:

- **Sarasota County**
- **Town of Longboat Key***
- **City of North Port**
- **City of Sarasota**
- **City of Venice**
- **Florida Department of Transportation, District One**

* ***Permit coverage includes the entire Town of Longboat Key which is located in both Sarasota and Manatee Counties***

References to "permittee" in this permit includes each of the entities above.

1. Each permittee is individually responsible for:

   a. Compliance with permit conditions relating to discharges from portions of the MS4 where they are the operator;

   b. Storm water management program implementation on portions of the MS4 where they are the operator;

   c. Where permit conditions are established for specific portions of the MS4, the permittee need only comply with the permit conditions relating to those portions of the MS4 for which they are the operator; and

   d. A plan of action to assume responsibility for implementation of storm water management and monitoring programs on their portions of the MS4 should inter-jurisdictional agreements allocating responsibility between permittees be dissolved or in default. (See Part II.G.3., page 20 of this permit also.)

2. Each permittee is jointly responsible for:

   a. Submission of annual reporting requirements as specified in Part V.C. (ANNUAL REPORT), page 49;

   b. Collection of monitoring data as required by Part V.B., page 47, according to such agreements as may be established between permittees;

   c. Insuring implementation of system-wide management program elements, including any system-wide public education efforts.

3. Specific permittees are jointly liable for permit compliance on portions of the MS4:

   a. Where operational or storm water management program implementation authority over portions of the MS4 has been transferred from one permittee to another in accordance with legally binding interagency or inter-jurisdictional agreements, both the owner and operator are jointly responsible for permit compliance on those portions of the MS4, unless specific responsibility provisions have been otherwise outlined in said agreements.

D. **Limitations on Coverage.** Section 402(p)(3)(B)(ii) of the Clean Water Act specifically requires EPA to include within this permit an effective prohibition on non-storm water entering the MS4. The following discharges are not authorized by this permit:

1. *Non-storm Water:* discharges of non-storm water, except where such discharges are:

   a. in compliance with a separate NPDES permit (or the discharger has applied for such permit); or

   b. identified by and in compliance with Part II.A.7.a., page 9 of this permit.

2. *Spills*: discharges of material resulting from a spill, except where such discharges are:

   a. the result of an Act of God where reasonable and prudent measures have been taken to minimize the impact of the discharge; or

   b. an emergency discharge required to prevent imminent threat to human health or prevent severe property damage, provided reasonable and prudent measures have been taken to minimize the impact of the discharge.

PART II.

STORM WATER POLLUTION PREVENTION & MANAGEMENT PROGRAMS

Each permittee covered by this permit shall contribute to the development, revision, and implementation of a comprehensive Storm Water Management Program (SWMP) including pollution prevention measures, treatment or removal techniques, storm water monitoring, use of legal authority, and other appropriate means to control the quality of storm water discharged from the Municipal Separate Storm Sewer System (MS4). The SWMP shall be implemented in accordance with Section 402(p)(3)(B) of the Clean Water Act and 40 CFR Part 122.26.

Controls and activities in the SWMP shall identify areas of permittee jurisdiction, applicability, or specific area basis. The SWMP shall include controls necessary to effectively prohibit the discharge of non-storm water into municipal separate storm sewers and reduce the discharge of pollutants from the MS4 to the MEP and shall not cause or contribute to violations of State water quality standards of the receiving stream. Compliance with this SWMP shall be reported annually in the ANNUAL REPORT discussed in Part V.C. on page 49 of this permit.

The SWMP shall cover the term of the permit and shall be updated as necessary, or as required by the Director, to ensure compliance with this statutory requirement of Clean Water Act Section 402(p)(3)(B). Modifications to the SWMP shall be made in accordance with Part II.G. of this permit. Compliance with the SWMP and the compliance schedules in Part III shall be deemed in compliance with Parts II.A. and II.B. of the permit. **The Storm Water Management Program submitted by the permittees in the July 23, 1993, Part 2 Application, and all approved updates, are hereby incorporated into this permit by reference and thus are conditions of this permit. FDOT's *Statewide Storm Water Management Program for Part 2 EPA NPDES-MS4 Permit Application* dated June 1993 and all approved updates, are hereby incorporated into this permit by reference and thus are conditions of this permit.** Specific components from these Storm Water Management Programs are identified in Parts II and III to serve as measurable enforcement permit conditions. Compliance dates specified in Part III of the permit shall take precedence over compliance dates which may have been proposed in Part 1 or Part 2 of the municipal applications from the permittees.

Implementation of the SWMP may be achieved through participation with other permittees, public agencies, or private entities in cooperative efforts to satisfy the requirements of Part II and Part III of the permit in lieu of creating duplicate program elements for each individual permittee. The SWMP, taken as a whole, shall achieve the "effective prohibition" and "MEP" standards from Section 402(p)(3)(B) of the Clean Water Act, and shall not cause or contribute to violations of State water quality standards of the receiving stream pursuant to the Florida Administrative Code (FAC)§62-40.420(1)-(4).

A. Storm Water Management Program (SWMP) Requirements.

1. *Structural Controls and Storm Water Collection System Operation:* The MS4 and any storm water structural control shall be operated in a manner to reduce the discharge of pollutants to the MEP and shall not cause or contribute to violations of State water quality standards of the receiving stream.

   a. The permittees listed in Table II.A.1.a. on pages 4 and 5 own and/or operate the structural controls identified. The maintenance activities identified for the structural controls in Table II.A.1.b. on page 6 of this permit represent suggested maintenance practices that can be implemented on an as needed basis. In addition, each shall maintain an internal record keeping system to track inspections and maintenance activities performed during the permit term. If these activities are performed by others under a contractual agreement, then the permittee shall retain copies of the contractual agreement which specifies the maintenance activities to be performed and the schedule of frequency. Inspection and maintenance records shall be retained by the permittees in accordance with Part V.G. on page 58 of this permit. Annual evaluations shall be made to assess the appropriateness of the inspection and maintenance schedule and to ensure the optimization of equipment use. A summary of the annual evaluation shall be included within each ANNUAL REPORT required under Part V.C. on page 49 of this permit.

PERMITTEE / LABOR SOURCE(S)	STRUCTURAL CONTROL	TOTAL NO. MAINTAINED
SARASOTA COUNTY / Prison Labor and Contract Staff	Wet Retention Areas (Maintained Lakes)	85
	Storm Water Treatment Ponds	62
	Channel Control Structures	51
	Channels	500 miles
CITY OF SARASOTA / Interlocal agreement with Sarasota County	Wet Retention Areas (Maintained Lakes)	4
	Storm Water Treatment Ponds	11
	Channels	30 miles

PERMITTEE / LABOR SOURCE(S)	**STRUCTURAL CONTROL**	**TOTAL NO. MAINTAINED**
CITY OF VENICE / City of Venice Parks Dept. and Maintenance Dept.	Storm Water Treatment Ponds	7
	Channels	5 miles
CITY OF NORTH PORT / Maintenance Dept.	Wet Retention Areas (Maintained Lakes)	1
	Storm Water Treatment Ponds	190
	Channel Control Structures	10
	Channels	76 miles
FDOT / Maintenance Management System	Storm Water Treatment Ponds	2

TABLE II.A.1.b.
MAINTENANCE SCHEDULE FOR STRUCTURAL CONTROLS

STRUCTURAL CONTROL	FREQUENCY OF INSPECTION	FREQUENCY OF MAINTENANCE	MAINTENANCE ACTIVITY
Dry Retention Areas	Semi-Annually	As Needed	oMowing and invasive plant species removal oSediment and grass clippings removal, including proper sediment disposal oAeration of bottom (dry/infiltration-type ponds) oStabilization of eroded bank areas oLitter and debris removal oBack flush underdrains (where applicable)
Wet Retention Areas (Mantained Lakes) ~~Treatment Ponds~~	Semi-Annually	As Needed	oMowing and invasive plant species removal oStabilization of eroded bank areas oLitter and debris removal
		As necessary to ensure that the depth of sediments does not exceed 1/3 of the design storage volume	oSediment and grass clippings removal, including proper sediment disposal oMonitor sediment accumulations and remove when 1/3 of the storage volume is filled
	Every 18 Months	As Needed	oBack flush underdrains (where applicable)
Channel Control Structures	Quarterly	As Needed	oLitter and debris removal oSediment removal with proper sediment disposal
Channels	Annually - to determine priority	As Needed	oLitter and debris removal oMowing and invasive plant species removal oStabilization of eroded bank areas
		5 Year Revolving Schedule	oSediment removal with proper sediment disposal provided the original cross-section is not exceeded

R0012819

1. *Structural Controls and Storm Water Collection System Operation:* (continued)

   b. Additionally, to satisfy the requirements of this section, the permittees shall develop and implement the Storm Water Management Programs identified in Part III.A.1. on pages 21 and 22 of this permit.

2. *Areas of New Development and Significant Redevelopment:* A comprehensive master planning process (or equivalent) shall be implemented to reduce, to the MEP, the discharge of pollutants from MS4s, which receive discharges from areas of new development and significant redevelopment, after construction is completed. The master planning process shall limit the increases in the discharge of pollutants in storm water as a result of new development, and shall reduce the discharge of pollutants in storm water from redeveloped areas, and shall not cause or contribute to violations of State water quality standards of the receiving stream.

   a. To satisfy the requirements of this section, the permittees shall implement the Storm Water Management Programs identified in Part III.A.2. on page 23 of this permit.

3. *Roadways:* Public streets, roads, and highways shall be operated and maintained in a manner to reduce to the MEP the discharge of pollutants and shall not cause or contribute to violations of State water quality standards of the receiving stream.

   a. As per the schedule identified in Part III.A.3. on page 24 of this permit, the permittees shall develop and implement standard road repair practices to reduce the pollutants in storm water runoff from areas associated with road repair and maintenance. The program developed shall include practices such as limiting the amount of soil disturbance to the immediate area under repair and scheduling potential pollutant-causing routine repair work during dry seasons, when possible. The program shall establish procedures that address spill prevention, material management practices, and good housekeeping measures at all municipal equipment yards & maintenance shops that support road maintenance activities.

   b. Additionally, to satisfy the requirements of this section, the permittees shall implement the Storm Water Management Programs identified in Part III.A.3. on pages 24 and 25 of this permit.

4. *Flood Control Projects:* Water quality impacts on receiving water shall be assessed for all flood management projects identified in the basin master planning process (or comparable planning process). The feasibility of retrofitting existing structural flood control devices to provide additional pollutant removal from storm water shall be evaluated.

   a. To satisfy the requirements of this section, the permittees shall implement the Storm Water Management Programs identified in Part III.A.4. on page 26 of this permit.

5. *Municipal waste treatment, storage, or disposal facilities not covered by an NPDES storm water permit:* The permittees shall implement a program to identify measures to monitor and reduce pollutants in storm water discharges from facilities that handle municipal waste, including sewage sludge.

   a. To satisfy the requirements of this section, the permittees shall develop and implement a program to reduce pollutants in the storm water discharges from municipally-operated solid waste transfer stations, maintenance and storage yards for waste transportation fleets and equipment, publicly owned treatment works (POTWs), and sludge application and/or disposal sites which are not covered by NPDES storm water permits. This program shall be developed and implemented in accordance with the schedule identified in Part III.A.5. on page 27 of this permit. The initial phase of the program developed shall contain procedures to evaluate, inspect, and monitor these sites. Based upon the evaluations, inspections and monitoring performed, priorities and procedures for implementing control measures for pollutant reduction at these sites shall be developed. Monitoring methodology used during the initial investigative period may be relaxed from standard protocol and may be based on experience gained during actual field activities. The goal of this investigative portion is to actively identify areas within these sites with poorer quality discharges during storm events, so that those areas will be given priority when implementing control measures.

6. *Pesticide, Herbicide, and Fertilizer Application:* Each permittee shall implement controls to reduce, to the MEP and shall not cause or contribute to violations of State water quality standards of the receiving stream, the discharge of pollutants related to the storage and application of pesticides, herbicides, and fertilizers applied, by employees or contractors, to public right of ways, parks, and other municipal property. Permittees with jurisdiction over lands shall implement programs to encourage the reduction of the discharge of pollutants related to application and distribution of pesticides, herbicides, and fertilizers.

   a. To satisfy the requirements of this section, the permittees shall implement the Storm Water Management Programs identified in Part III.A.6. on pages 28 and 29 of this permit.

7. *Illicit Discharges and Improper Disposal:* The permittees shall implement an ongoing program to detect and eliminate (or require the discharger to the MS4 to eliminate) illicit discharges and improper disposal into the storm sewer system.

a. *Inspection, Ordinances, and Enforcement Measures:* Non-storm water discharges to the MS4 shall be effectively prohibited by the permittees through the use of inspections, ordinances, and enforcement. The permittees, however, may allow the following non-storm water discharges to the MS4 where they are not identified as a source of pollutants to waters of the United States:

- water line flushing;
- landscape irrigation;
- diverted stream flows;
- rising ground waters;
- uncontaminated ground water infiltration (as defined at 40 CFR 35.2005(20)) to separate storm sewers;
- uncontaminated pumped ground water;
- discharges from potable water sources;
- foundation drains;
- air conditioning condensate;
- irrigation water;
- springs;
- water from crawl space pumps;
- footing drains;
- lawn watering;
- individual residential car washing;
- flows from riparian habitats and wetlands;
- dechlorinated swimming pool discharges;
- street wash waters; and
- discharges or flows from emergency fire fighting activities.

To satisfy the requirements of this section, the permittee(s) identified in Part III.A.7.a. on pages 30 and 31 of the permit shall:

(1) Identify those of the non-storm water discharges listed under Part II.A.7.a. (above), as well as any other non-storm water discharges, which will be allowed to be discharged to the MS4. Describe any conditions to be placed on these allowable discharges.

(2) Enforce ordinances which prohibit illicit connections and illegal dumping into the MS4. As per the schedule in Part III.A.7.a. on page 30 of this permit (page 31 for FDOT), the permittees shall develop a random inspection program to uncover illicit connections. The program shall include a schedule for inspections and an allocation of staff and resources. A description of the enforcement procedures shall be detailed within the program developed. Because the potential for illicit discharges and improper disposal is generally higher for areas of older development, areas with many automobile-related industries, and areas with significant numbers of heavy industrial facilities, the permittees shall consider the specific land use and age of development when determining inspection priorities and inspection schedules for this program component. Facility inspections may be carried out in conjunction with other municipal programs (e.g. pretreatment inspections of industrial users, health inspections, fire inspections, etc.). The permittees shall maintain an internal log documenting the inspections performed.

(3) Provide in the first ANNUAL REPORT, a photocopy of the signed adopted ordinance(s) identified in Table II.A.7.a.(3) below.

Table II.A.7.a.(3)

PERMITTEE	ORDINANCE
Sarasota County	93-038
Town of Longboat Key	Chapters 33, 52, and 158.102 of the Ordinances of the Town of Longboat Key
City of Sarasota	93-3699 and Section 2-314 of the City of Sarasota Code

(4) As per the schedule in Part III.A.7.a. on page 31 of this permit, the permittees in Table II.A.7.a.(4) shall amend the identified ordinances to change the citation for the definition of *"industrial activity,"* contained within these ordinances, to 40 CFR 122.26(b)(14) from the incorrect citation of 40 CFR 122.26(a)(14).

Table II.A.7.a.(4)	
PERMITTEE	ORDINANCE
City of Sarasota	93-3699
City of North Port	93-15, Section 180-21
City of Venice	93-14, Section 9-74

b. *Dry Weather Field Screening Program:* The permittees shall continue ongoing efforts to detect the presence of illicit connections and improper discharges to the MS4.

(1) To satisfy the requirements of this section, the permittees shall implement a dry weather field screening program to locate and eliminate illicit discharges and improper disposal into the MS4 in accordance with the schedule provided in Part III.A.7.b. on page 32 of this permit. This program shall include the dry weather screening activities identified in Table II.A.7.b. The minimum level of effort for the field screening program shall be based upon a 0.50-mile grid system, with each grid area containing at least one field screening location. In industrial and heavy commercial areas, the minimum level of effort shall be based upon a 0.25-mile grid system, with each grid area containing at least one field screening location. Under this program, all grid areas of the MS4 must be screened once during the permit term. Some grid areas may require more than one field screening location or a more frequent inspection schedule. In lieu of the grid system, the permittees may choose to field screen at all outfalls. Follow-up activities to eliminate illicit discharges and improper disposal may be prioritized on the basis of magnitude and nature of the suspected discharge; sensitivity of the receiving water; and/or other relevant factors. Screening methodology may be modified based on experience gained during actual field screening activities. While performing field screening activities, the permittees shall collect information on outfalls and portions of the MS4 which are not mapped, and this updated information shall be entered into the database system on an ongoing basis. An internal log documenting the results of all field screening performed shall be maintained.

Table II.A.7.b.	
GRID MAP COVERING AREA SERVED BY MS4 or ALL OUTFALLS	**FREQUENCY OF FIELD SCREENING**
Industrial Land Use	0.25-mile Grid or All Outfalls Once / 3 years
Heavy Commercial Land Use	0.25-mile Grid or All Outfalls Once / 3 years
All Other Land Uses	0.50-mile Grid or All Outfalls Once / 5 years
Entire MS4 System	⅓ of the Outfalls or ⅓ of the Grid Areas Screened During Permit Years Three, Four, & Five with the Entire MS4 Screened Once / 5 years

c. *Investigation of Suspected Illicits and/or Improper Disposal:* The permittees shall develop and implement standard procedures to be followed to investigate portions of the MS4 that, based on the results of the field screen or other appropriate information, indicate a reasonable potential of containing illicit discharges or other sources of non-storm water. Notification to EPA of any illicit connection shall be an element of the investigative standard procedures.

(1) To satisfy the requirements of this section, the permittees identified in Part III.A.7.c. on page 32 shall develop and implement standard investigative procedures to identify and terminate the source of the illicit connection or discharge in accordance with the schedule provided. The procedures developed shall require proper training for the field personnel involved in identifying conditions that may indicate the presence of illicit discharges. Upon the verification of responsible parties, the standard procedures developed shall require the immediate cessation of improper disposal practices and the elimination of the illicit connection as expeditiously as possible. Where the elimination of an illicit connection or the submittal of an NPDES application to EPA is not possible within a specified time frame determined by the permittee, the standard procedures developed shall require that the responsible parties submit for approval a written compliance schedule for the removal of the discharge. In the interim, the permittees shall require the operator of the illicit discharge to take all reasonable and prudent measures to minimize the discharge of pollutants to the MS4.

(2) To satisfy the requirements of this section, FDOT shall develop and implement standard investigative procedures to identify the source of the illicit connection or discharge to the FDOT MS4, in accordance with the schedule provided in Part III.A.7.c. on page 33 of this permit. Upon the identification of responsible parties, the standard procedures developed shall require the timely reporting of water quality violations to Florida Department of Environmental Protection (FDEP) and EPA. Until such time that the illicit connection has been eliminated or the responsible parties have submitted an NPDES application for the discharge to EPA, FDOT shall require the operator of the illicit discharge to take all reasonable and prudent measures to minimize the discharge of pollutants to the MS4. Where measures to minimize the discharge are not taken, the developed procedures shall consider the termination of the connecting entity's FDOT drainage connection permit.

d. *Spill Prevention and Response:* The permittees shall implement procedures to prevent, contain, and respond to spills that may discharge into the MS4.

(1) To satisfy the requirements of this section, the permittees shall adopt Sarasota County's *Hazardous Materials Emergency Plan*, FDOT's *Emergency Operations Procedures*, or a comparable plan and procedures which effectively mitigate potential pollutant discharges to surface waters. These documents shall be adopted in accordance with the schedule provided in Part III.A.7.d. on page 33 of this permit.

e. *Public Notification:* The permittees shall develop and implement a program to promote, publicize, and facilitate public reporting of illicit discharges of water quality impacts associated with discharges from the MS4.

(1) To satisfy the requirements of this section, the permittees shall develop and implement programs to facilitate public reporting of illicit discharges and improper disposal of materials into the MS4 in accordance with the schedule provided in Part III.A.7.e. on page 34 of this permit. The program shall inform the public about what to look for and how to report incidents. The program shall also enhance public awareness of the problems associated with illicit discharges and may include programs such as educating school students, using inserts in utility bills, and public service announcements in newspaper, on television, or on radio.

f. *Oils, Toxics, and Household Hazardous Waste Control:* The permittees shall effectively prohibit the discharge or disposal of used motor vehicle fluids, household hazardous wastes, grass clippings, leaf litter, and animal wastes into the MS4.

(1) To satisfy the requirements of this section, the permittees shall implement the Storm Water Management Programs identified in Part III.A.7.f. on page 35 of this permit.

g. *Limitation of Sanitary Sewer Seepage:* The permittees shall prevent (or require the operator of the sanitary sewer to eliminate) unpermitted discharges of dry and wet weather overflows from sanitary sewers into the MS4. Each permittee shall eliminate the infiltration of seepage from sanitary sewers into the MS4.

(1) To satisfy the requirements of this section, the permittees shall implement the Storm Water Management Programs identified in Part III.A.7.g. on page 36 of this permit.

8. *Industrial and High Risk Runoff:* The permittees shall develop and implement a program to identify and control pollutants, to the MEP and shall not cause or contribute to violations of State water quality standards of the receiving stream, in storm water discharges to the MS4 from the municipal landfill(s); hazardous waste treatment, storage, disposal and recovery facilities; facilities that are subject to EPCRA Title III, Section 313; and any other industrial or commercial discharge in which the permittees determine is contributing a substantial pollutant loading to the MS4.

To satisfy the two (2) requirements of this section, the permittees shall:

a. *Identify priorities and procedures for inspections:* Identify all targeted facilities and determine priority sites in accordance with the schedule provided in Part III.A.8.a. on pages 37 and 38 of this permit. Inspection schedules and procedures for the identified facilities shall be developed and implemented. Also, the permittees shall provide a listing in each ANNUAL REPORT of additionally identified industrial facilities which discharge storm water into the MS4 which have not been previously reported. The industrial storm water discharges that must be included in this inventory fall into the eleven (11) classes of industrial activities as defined in the November 1990 regulations under 40 CFR 122.26(b)(14).

b. *Monitoring for High Risk Industries:* Develop and implement a monitoring (or self monitoring) program for facilities identified under this section in accordance with the schedule provided in Part III.A.8.b. on page 38 of this permit. The monitoring program shall include the collection of quantitative data on the following constituents:

- any pollutants limited in an existing NPDES permit for an identified facility;
- oil and grease;
- chemical oxygen demand (COD);
- pH;
- biochemical oxygen demand, five-day (BOD_5);
- total suspended solids (TSS);
- total phosphorous;
- total Kjeldahl nitrogen (TKN);
- nitrate plus nitrite nitrogen; and
- any information on discharges required under 40 CFR 122.21(g)(7)(iii) and (iv).

Data collected by the industrial facility to satisfy the monitoring requirements of an NPDES or State discharge permit may be used to satisfy this requirement. Permittees may require the industrial facility to conduct self-monitoring to satisfy this requirement.

9. *Construction Site Runoff:* The permittees shall develop and implement a program to reduce the discharge of pollutants from construction sites to the MEP, and to shall not cause or contribute to violations of State water quality standards of the receiving stream.

a. *Site Planning and Non-structural & Structural Best Management Practices:* The permittees shall require the use and maintenance of appropriate structural and non-structural best management practices to reduce pollutants discharged to the MS4 during the time of construction.

(1) To satisfy the requirements of this section, the permittees shall implement the Storm Water Management Programs identified in Part III.A.9.a. on page 39 of this permit.

b. *Inspection and Enforcement:* The permittees shall develop and implement a program for inspecting construction sites and for enforcing the requirement for control measures.

(1) To satisfy the requirements of this section, the permittees shall implement the Storm Water Management Programs identified in Part III.A.9.b. on pages 40 and 41 of this permit.

c. *Site Operator Training:* The permittees shall conduct appropriate education and training measures for construction site operators and those associated with the implementation of proper sediment & erosion control measures at construction sites.

(1) To satisfy the requirements of this section, the permittees shall implement the Storm Water Management Program(s) identified in Part III.A.9.c. on pages 41 and 42 of this permit.

B. Area-specific Storm Water Management Program Requirements.

Reserved pending additional requirements which may be included as a result of State Certification of the permit. (See Section 401 of the CWA.)

C. Deadlines for Program Compliance. Except as provided in Part III, compliance with the storm water management program shall be required 90 days from the effective date of the permit.

D. Roles and Responsibilities of Permittees. The Storm Water Management Program, together with any attached interagency agreements or interagency agreements developed subsequent to the effective date of the permit, shall clearly identify the roles and responsibilities of each permittee. Following the effective date of the permit, interagency agreements developed and implemented must be included in the ANNUAL REPORT covering the permit year in which the agreement became effective.

E. Legal Authority. To the extent allowed by law, each permittee shall ensure legal authority to control discharges to and from those portions the MS4 over which it has jurisdiction. This legal authority may be a combination of statute, ordinance, permit, contract, order or inter-jurisdictional agreements between permittees with adequate existing legal authority to accomplish Items 1 - 6 below. This legal authority for FDOT may be a combination of State statutes administered and enforced by sister agencies within the State of Florida government system which have adequate existing legal authority to accomplish Items 1 - 6 below.

1. Control the contribution of pollutants to the MS4 by Storm Water Discharges Associated with Industrial Activity and the quality of storm water discharged from sites of industrial activity;

2. Prohibit illicit discharges to the MS4;

3. Control the discharge of spills and the dumping or disposal of materials other than storm water (e.g. industrial and commercial wastes, trash, used motor vehicle fluids, leaf litter, grass clippings, animal wastes, etc.) into the MS4;

4. Control through interagency or inter-jurisdictional agreements among permittees the contribution of pollutants from one portion of the MS4 to another;

5. Require compliance with conditions in ordinances, permits, contracts or orders; and

6. Carry out all inspection, surveillance and monitoring procedures necessary to determine compliance with permit conditions.

F. Storm Water Management Program Resources. Each permittee shall provide adequate finances to implement their activities under the Storm Water Management Program. Each permittee shall also have a source of funding for implementing all other requirements included within this NPDES storm water permit.

G. Storm Water Management Program Review and Modification.

1. *Program Review:* Each permittee shall participate in an annual review of the current Storm Water Management Program (SWMP) in conjunction with preparation of the ANNUAL REPORT required under Part V.C. of the permit.

2. *Program Modification:* The permittee(s) may modify the SWMP during the life of the permit in accordance with the following procedures:

   a. Modifications adding (but not subtracting nor replacing) components, controls, or requirements to the approved SWMP may be made by the permittee(s) at any time. A description of the modification shall be included within the subsequent ANNUAL REPORT.

   b. Modifications replacing an ineffective or unfeasible BMP specifically identified in the SWMP with an alternate BMP may be made by the permittee(s) at any time. A description of the replacement BMP shall be included in the subsequent ANNUAL REPORT along with the following information:

      (1) an analysis of why the former BMP was ineffective or infeasible (including cost prohibitive);

      (2) expectations on the effectiveness of the replacement BMP; and

      (3) an analysis of why the replacement BMP is expected to achieve the goals of the BMP which was replaced.

   c. Modifications to adjust the schedule for maintenance activities or the frequency of inspections or monitoring identified in the SWMP may be made by the permittee(s) on an annual basis. The permittees must include in the subsequent ANNUAL REPORT a description of the schedule adjustment along with the following information:

      (1) an analysis of why the former schedule was ineffective or infeasible;

      (2) expectations on the effectiveness of the replacement schedule; and

      (3) an analysis, if applicable, of why the replacement schedule will ensure the optimization of equipment use.

d. Modifications subtracting components, controls, or requirements of the SWMP may not be made by the permittee(s) UNLESS it can be clearly demonstrated that with the elimination of this component, the SWMP will continue to achieve a reduction in pollutants to the MEP and shall not cause or contribute to violations of State water quality standards of the receiving stream. In the case where this type of modification is appropriate, the permittee(s) may make the required modification and shall include in the subsequent ANNUAL REPORT a description of the component which has been eliminated along with the following information:

(1) an analysis of why the component was ineffective or infeasible, and

(2) a detailed explanation of why, with the elimination of this component, the SWMP will continue to achieve a reduction in pollutants to the MEP and shall not cause or contribute to violations of State water quality standards of the receiving stream.

e. Modifications included within the ANNUAL REPORT shall be signed in accordance with Part VI.H. by all directly affected permittees, and shall include a certification that all affected permittees were given an opportunity to comment on proposed changes.

3. *Transfer of Ownership, Operational Authority, or Responsibility for Storm Water Management Program Implementation:* The permittee(s) shall implement the SWMP on all new areas added to their portion of the municipal separate storm sewer system (or for which they become responsible for implementation of storm water quality controls) as expeditiously as practicable. Implementation of the program in any new area shall consider the plans in the SWMP of the previous MS4 ownership.

Prior to land annexation, the permittee shall include a schedule for extending the SWMP to the annexed areas. At least 30 days prior to transfer of operational authority or responsibility for SWMP implementation, all parties shall prepare a schedule for transfer of responsibility for SWMP implementation on the affected portions of the MS4. This schedule shall be included in the ANNUAL REPORT.

PART III. SCHEDULES FOR IMPLEMENTATION AND COMPLIANCE

The permittee(s) shall comply with the following schedules for Storm Water Management Program implementation and augmentation, and for permit compliance.

A. IMPLEMENTATION AND AUGMENTATION OF STORM WATER MANAGEMENT PROGRAMS

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
1. *Operation and Maintenance of Structural Controls and Storm Water Collection System*	Sarasota County City of Sarasota City of Venice City of North Port FDOT	Perform inspections and maintenance of structural controls. Maintain an internal record keeping system to track inspections and maintenance activities performed during the permit. Conduct an annual assessment of the effectiveness of inspection & maintenance schedule and provide a summary of the assessment in each ANNUAL REPORT.	Annual Requirement
	ALL	Identify and inventory each privately-owned and maintained storm water management facility which discharges into the MS4.	Within 12 Months of the Effective Date of the Permit
		Develop a revolving inspection program for privately-owned and maintained storm water treatment systems which discharge into the MS4 to determine compliance with local permit conditions and/or local ordinances. Program developed shall include a description of the enforcement provisions for non-compliance. Following development, include a summary of the inspection program & schedule in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 12 Months of the Effective Date of the Permit
		Implement revolving inspection program for privately-owned and maintained storm water treatment systems which discharge into the MS4.	Within 24 Months of the Effective Date of the Permit.

R0012834

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
1. *Operation and Maintenance of Structural Controls and Storm Water Collection System* (continued)	Sarasota County	Complete Florida Water & Pollution Control Operators Association (FW&PCOA) course or equivalent.	5 employees / year
	ALL OTHERS **except for** FDOT		1 employee / permit

R0012835

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
2. *Control of Discharges from Areas of New Development and Significant Redevelopment*	ALL **except for** City of North Port and FDOT	Adopt as local ordinances storm water quality treatment criteria consistent, but not necessarily similar to the State of Florida Storm Water Treatment Regulations (F.A.C. 40D-4, 40D-40, 62-25).	Prior to the end of the Permit Term
	FDOT	Employ new FDOT Drainage Connection Permit requirements which include a "certification of water quality" to be provided by the connecting entity.	Effective Date of Permit
	ALL **except for** FDOT	Continue on the current schedule to perform master basin studies on the major watersheds identified in Table 1 on page 4A-34 of Appendix A. Develop a course of action for each as they are completed. Include in each ANNUAL REPORT a brief summary of each basin study completed during the permit year and the resulting course of action.	Effective Date of the Permit
	ALL **except for** City of North Port and FDOT	Evaluate land development practices to reduce the amount of impervious surfaces in future development. After completing the evaluation, include a summary of the resulting course of action in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 36 Months of the Effective Date of Permit
		Implement appropriate land development practices & incentives for the reduction of impervious surfaces.	As Determined by the Evaluation - Prior to the end of the Permit Term

R0012836

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
3. *Operation and Maintenance of Public Streets, Roads, and Highways*	Sarasota County City of Sarasota City of Venice	Provide a description of the municipally-operated Litter Control Program(s) for highways and streets within jurisdictional area for incorporation into the permit.	Provide in First ANNUAL REPORT
	ALL **except for** City of North Port and FDOT	Implement Litter Control Program(s) for highways and streets within jurisdictional area and properly dispose of collected material.	Effective Date of the Permit
	FDOT	Implement Litter Control Program for highways and streets within jurisdictional area and properly dispose of collected material. Report in each ANNUAL REPORT the approximate frequency of litter collection services performed under contractual agreements during the permit year.	Effective Date of the Permit
	ALL **except for** North Port WCD City of North Port & FDOT	Implement street sweeping program within jurisdictional area and properly dispose of collected material.	Effective Date of the Permit
	FDOT	Implement street sweeping program within jurisdictional area and properly dispose of collected material. Report in each ANNUAL REPORT the approximate frequency of street sweeping services performed under contractual agreements during the permit year.	
	Sarasota County	Provide the maintenance schedule for storm water structures (i.e., catch basins) and roadside ditches.	Provide in First ANNUAL REPORT

R0012837

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
3. *Operation and Maintenance of Public Streets, Roads, and Highways* (continued)	ALL	Perform scheduled maintenance on catch basins, grates, and other storm water structures and roadside ditches and properly dispose of accumulated sediments. Maintain an internal log documenting maintenance activities.	Effective Date of the Permit
	ALL **except for** City of North Port	As described in Part II.3.a. on page 7 of the permit, develop practices to reduce to the MEP and shall not cause or contribute to violations of State water quality standards of the receiving stream regarding the pollutants from road repair and from all municipal equipment yards & maintenance shops. After development, include a summary of the practices in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 12 months of the Effective Date of the Permit
		Implement developed practices to reduce to the MEP pollutants from road repair and municipal yards.	Within 24 months of the Effective Date of the Permit
	FDOT	Coordinate the "Adopt A Highway" program for local organizations to be identified with specific highway cleanup and beautification projects.	Within 24 months of the Effective Date of the Permit
		Conduct annual routine inspections of each FDOT maintenance facility to ensure that BMPs are operational. The FDOT NPDES Coordinator or his/her representative shall perform this activity.	

R0012838

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
4. *Ensure Flood Control Projects Comply With State Storm Water Quality Requirements*	ALL **except for** FDOT	Develop a priority list and construction schedule for the retrofit projects recommended by the master basin studies completed to date.	Within 12 Months of the Effective Date of the Permit
		Include a copy of the prioritized project list and construction schedule in the ANNUAL REPORT for incorporation into the permit. Provide updates to this list in future ANNUAL REPORTS as additional master basin studies are completed.	
	FDOT	Present a retrofitting program to the local Metropolitan Planning Organizations (MPO) for consideration which focuses on water quality improvement.	Within 12 Months of the Effective Date of the Permit
		Submit within the ANNUAL REPORT the list of approved retrofit projects in the MPO's work program for District One. Also provide the construction schedule for these approved projects. Provide updates to this list in future ANNUAL REPORTS as additional projects are approved.	Within 24 Months of the Effective Date of the Permit
		Begin retrofit priority projects as per the construction schedule in the approved work program for District One.	

RC012839

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
5. *Identification, Monitoring, and Control of Discharges from Municipal Waste Treatment, Storage, or Disposal Facilities not covered by an NPDES Storm Water Permit*	Sarasota County City of Sarasota City of North Port	Develop program to evaluate, through inspections and monitoring, the municipally-operated solid waste transfer station(s), maintenance and storage yards for waste transportation fleets, POTWs, and sludge application and/or disposal sites. The goals of the evaluation program shall be to identify these facilities, determine the necessary control measures & procedures to be employed at each, and administer an appropriate implementation schedule. After developing the evaluation program, submit a program summary in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 30 Months of the Effective Date of the Permit
		Implement developed program to reduce pollutants in storm water discharges to the MEP and shall not cause or contribute to violations of State water quality standards of the receiving stream from these facilities.	Within 36 Months of the Effective Date of the Permit

R0012840

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
6. *Control of Pollutants Related to Application of Pesticides, Herbicides, and Fertilizers*	ALL	Provide the details, for incorporation into the permit, of the specific public education program(s) designed to encourage the public to reduce their use of pesticides, herbicides and fertilizers.	Provide in First ANNUAL REPORT
		Implement public education program(s).	Effective Date of the Permit
	ALL **except for** FDOT	Evaluate current training requirements & certification procedures for employees who handle pesticides, herbicides and fertilizers. After completing the evaluation, include a summary of the results in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 24 Months of the Effective Date of the Permit
		Implement any revised procedures for the training & certification of these employees.	As Necessary - Within 36 Months of the Effective Date of the Permit
	ALL	Require evidence of proper certification and licensing for all applicators contracted to apply pesticides, herbicides, and fertilizers on municipal and FDOT property.	Effective Date of the Permit

R0012841

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
6. *Control of Pollutants Related to Application of Pesticides, Herbicides, and Fertilizers* (continued)	ALL **except for** FDOT	Develop a program with procedures to minimize the use of pesticides, herbicides, and fertilizers and to properly store and mix these products. The program developed should also consider including components such as providing xeriscape planning assistance and promoting voluntary use of native Florida plantings and slow-release fertilizers. After development, include a summary of the procedures in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 24 Months of the Effective Date of the Permit
	ALL **except for** FDOT	Employ program procedures to minimize the use of pesticides, herbicides, and fertilizers and to properly store and mix these products.	Within 36 Months of the Effective Date of the Permit
	FDOT		Effective Date of the Permit

R0012842

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
7. *Illicit Discharges and Improper Disposal*			
a.) *Inspections, ordinances, and enforcement measures*	ALL **except for** City of North Port and FDOT	Complete the assessment of non-storm water discharges allowed to be discharged to the MS4 as detailed on page 9 of the permit. After completing the assessment, include a summary of the results in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 18 Months of the Effective Date of the Permit
	ALL **except for** City of North Port and FDOT	Develop an inspection program to enforce ordinances which prohibit illicit connections and illegal dumping into the MS4. After development, include a summary of the inspection program in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 30 Months of the Effective Date of the Permit
	Sarasota County	Implement inspection program to enforce ordinances which prohibit illicit connections and illegal dumping into the MS4. Maintain an internal log documenting inspections and enforcement actions performed and provide a summary of these reports in each ANNUAL REPORT.	Within 36 Months of the Effective Date of the Permit
	ALL OTHERS **except for** City of North Port and FDOT		Within 36 Months of the Effective Date of the Permit

R0012843

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
7. *Illicit Discharges and Improper Disposal*			
a.) Inspections, ordinances, and enforcement measures (continued)	FDOT	Develop a program to inspect drainage connections after project completion to ensure continued compliance with drainage connection permit requirements and to ensure that no illicit or non-permitted connections have been made. In cases where another regulatory agency requires a periodic certification of compliance, the program developed may allow FDOT to accept this certification of compliance in lieu of further inspections by FDOT. After development, include a summary of the inspection program in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 21 Months of the Effective Date of the Permit
		Implement developed program to inspect drainage connections after project completion. Maintain an internal log documenting inspections and enforcement actions performed and provide a summary of these records in each ANNUAL REPORT.	Within 30 Months of the Effective Date of the Permit
	Sarasota County Longboat Key City of Sarasota	Provide photocopies of signed adopted storm water ordinances as identified in Table II.A.7.a.(3) on page 10 of the permit.	Provide in First ANNUAL REPORT
	City of North Port City of Sarasota City of Venice	Amend ordinances as identified in Table II.A.7.a.(4) on page 11 of the permit to reflect correct citation for *"industrial activity"* {40 CFR 122.26(b)(14)} Include a copy of the amended ordinances in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 12 Months of the Effective Date of the Permit

R0012844

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
7. *Illicit Discharges and Improper Disposal* (continued)			
b.) Field Screening	ALL	Conduct field screening of the MS4 for illicit discharges and improper disposal as shown in Table II.A.7.b. on page 12 of this permit. Collect inventory information on outfalls and on portions of MS4 not mapped and update database system on an ongoing basis. Maintain an internal log documenting the results of all field screening performed.	At least ⅕ of Grid Areas Screened in Permit Years Three, Four and Five with Entire MS4 Screened Once / 5 years
c.) Investigation of Suspected Illicits and/or Improper Disposal	ALL **except for** FDOT	Develop standard investigative procedures to identify and terminate the source(s) of illicit connections or discharges to the MS4. After development, include a summary of the investigative procedures in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 24 Months of the Effective Date of the Permit
		Implement standard investigative procedures to identify and terminate the source(s) of illicit connections or discharges to the MS4.	Within 30 Months of the Effective Date of the Permit

R0012845

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
7. *Illicit Discharges and Improper Disposal* (continued)			
c.) *Investigation of Suspected Illicits and/or Improper Disposal* (continued)	FDOT	Develop standard investigative procedures to identify and report the source(s) of illicit connections or discharges. These procedures shall include notification to FDEP and EPA of illicit connections. After development, include a summary of the investigative procedures in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 24 Months of the Effective Date of the Permit
		Implement standard investigative procedures to identify the sources(s) of illicit connections or discharges to the MS4.	Within 30 Months of the Effective Date of the Permit
d.) *Spill Prevention and Response*	Sarasota County FDOT	Provide a copy of the applicable portions of Sarasota County's *Hazardous Materials Emergency Plan* and FDOT's *Emergency Operations Procedures* which effectively mitigate potential pollutant discharges to surface waters.	Provide in First Annual Report
	ALL **except for** Sarasota County and FDOT	Adopt Sarasota County's *Hazardous Materials Emergency Plan*, FDOT's *Emergency Operations Procedures*, or a comparable plan and procedures which effectively mitigate potential pollutant discharges to surface waters.	Within 12 Months of the Effective Date of the Permit

R0012846

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
7. *Illicit Discharges and Improper Disposal* (continued)			
e.) Public Notification	ALL	Develop a program to promote, publicize, and facilitate public reporting of the presence of illicit discharges and improper disposal of materials into the MS4. After development, include a summary of the public program in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 30 Months of the Effective Date of the Permit
		Implement public reporting program.	Within 36 Months of the Effective Date of the Permit
		Maintain a citizen complaint log documenting all reports of illicit discharges and what actions were taken to investigate and resolve the problem. Include a summary of this log in each ANNUAL REPORT.	Within 36 Months of the Effective Date of the Permit
	FDOT	Establish a direct dial local telephone number at the District Office to be used for the reporting of illicit connections, accidental spills, illegal dumping, or other water quality violations and action as needed. This requirement may be satisfied through cooperative efforts with other permittees.	Within 36 Months of the Effective Date of the Permit

R0012847

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
7. *Illicit Discharges and Improper Disposal* (continued)			
f.) Oils, Toxics, and Household Hazardous Waste Control	ALL **except for** FDOT	Support and promote on a regular basis the six (6) oil recycling site locations within Sarasota County and the two (2) permanent collection centers for household hazardous waste materials. Continue Amnesty Days program. Document the total annual amount of household hazardous waste materials collected.	Effective date of Permit
		Actively promote and support a voluntary stenciling program for all storm sewer inlets which discharge directly or indirectly into surface waters.	Within 12 Months of the Effective Date of the Permit
	FDOT	With each FDOT Drainage Connection Permit, include information on used oil recycling, proper hazardous waste disposal, storm water regulations, and spill reporting.	Within 12 Months of the Effective Date of the Permit

R0012848

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
7. *Illicit Discharges and Improper Disposal* (continued)			
g.) *Limitation of Sanitary Sewer Seepage*	ALL **except for** City of North Port and FDOT	Develop procedures to limit the infiltration of sanitary seepage into the MS4, in areas where wastewater infiltration is suspected. After development, include a summary of the procedures in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 30 Months of the Effective Date of the Permit
		Implement developed procedures to limit the infiltration of sanitary seepage into the MS4.	Within 36 Months of the Effective Date of the Permit
	ALL	Advise appropriate utility owner of violation if constituents common to wastewater contamination are discovered in the MS4 during dry weather field screening.	Effective Date of the Permit
		Identify areas served by septic tanks. Advise appropriate State Agency of violation if constituents common to wastewater contamination due to malfunctioning septic tank systems are discovered in the MS4 during dry weather field screening.	Within 12 Months of the Effective Date of the Permit

R0012849

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
8. *Industrial and High Risk Runoff*			
a.) Identification of Priorities and Procedures for Inspections	ALL	Develop an inventory of all existing high risk facilities discharging into the MS4. This inventory shall identify the outfall and surface waterbody into which each high risk facility drains.	Within 24 Months of the Effective Date of the Permit
		Based upon historical information and available monitoring & screening data, prioritize the identified high risk facilities.	Within 24 Months of the Effective Date of the Permit
	ALL **except for** FDOT	Develop procedures for inspecting high risk facilities and establish an inspection schedule. After development, include a summary of the procedures & inspection schedule in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 24 Months of the Effective Date of the Permit
	FDOT	Develop procedures for the inspection of high risk facilities which hold FDOT drainage connection permits to ensure compliance with permit requirements. In cases where another regulatory agency requires a periodic certification of compliance, the program developed may allow FDOT to accept this certification of compliance in lieu of further inspections by FDOT. After development, include a summary of the procedures & inspection schedule in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 24 Months of the Effective Date of the Permit
	ALL	Begin inspections of identified high risk facilities. Maintain an internal log documenting the results of the inspections performed.	Within 36 Months of the Effective Date of the Permit

R0012850

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
8. *Industrial and High Risk Runoff* (continued)			
a.) *Identification of Priorities and Procedures for Inspections* (continued)	ALL	Maintain a list of all industrial storm water sources discharging to MS4 & update in ANNUAL REPORTS.	Effective Date of the Permit
b.) *Monitoring for High Risk Industries*	ALL **except for** FDOT	Develop a monitoring (or self monitoring) program for high risk industrial facilities. Include a description of the specific enforcement steps to be taken to require compliance with local storm water ordinances if violations are identified. After development, include a summary of the monitoring program in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 24 Months of the Effective Date of the Permit
	FDOT	Develop a monitoring (or self monitoring) program for high risk industrial facilities which hold FDOT drainage connection permits. Include a description of the specific enforcement steps to be taken to require compliance with permit conditions if violations are identified. After development, include a summary of the monitoring program in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 24 Months of the Effective Date of the Permit
	ALL	Implement the monitoring program for high risk industrial facilities.	Within 36 Months of the Effective Date of the Permit

R0012851

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
9. *Construction Site Runoff*			
a.) Site Planning & Structural and Non-structural Controls	ALL **except for** City of North Port and FDOT	Review erosion and sediment control requirements to determine modifications necessary to correlate with SWFWMD's requirements and EPA's NPDES Construction Activity General Permit. Summarize the necessary modifications in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 12 Months of the Effective Date of the Permit
		Incorporate necessary modifications to the erosion and sediment control requirements.	Within 36 Months of the Effective Date of the Permit
		In land development regulations, incorporate guidelines and recommendations for reducing the amount of sediment leaving construction sites.	Within 36 Months of the Effective Date of the Permit
		Track construction projects required to install erosion and sediment controls. Document the installation, maintenance, and effectiveness of the controls. Integrate these records with the education program for training the site contractors.	Within 18 Months of the Effective Date of the Permit
	FDOT	Employ new FDOT Drainage Connection Permit requirements which direct connecting entities subject to the NPDES storm water regulations to submit a copy of their NPDES Storm Water Pollution Prevention Plan to FDOT.	Effective Date of the Permit

R0012852

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
9. *Construction Site Runoff* (continued)			
b.) *Inspection and Enforcement*	ALL **except for** City of North Port and FDOT	Review existing inspection policies and code enforcement programs to first identify all agencies conducting site inspections and then to determine which agency is responsible for issuing enforcement actions for which code violations. Summarize results and include in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 24 Months of the Effective Date of the Permit
		Train inspectors (regardless of specialty) who are likely to be on-site during earth moving activities in erosion control techniques.	1 Inspector / Year
		Implement the use of an erosion & sediment control checklist for all inspectors. Include verification that construction sites subject to the NPDES Storm Water Regulations have NPDES permit coverage and a Storm Water Pollution Prevention Plan on site. Include developed checklist in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 24 Months of the Effective Date of the Permit
	ALL **except for** City of North Port	Develop a program to inspect construction projects for compliance with local storm water ordinances and/or local permits.	Within 24 Months of the Effective Date of the Permit
	ALL **except for** City of North Port and FDOT	Implement program developed to inspect construction projects for compliance with local storm water ordinances and/or local permits.	Within 36 Months of the Effective Date of the Permit

R0012853

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
9. *Construction Site Runoff* (continued)			
b.) Inspection and Enforcement (continued)	FDOT	Implement program developed to inspect construction projects that propose to directly discharge storm water to the FDOT MS4 and have been granted an FDOT drainage connection permit for compliance with FDOT permit conditions. Require connection entities, who are found or suspected of discharging storm water of unacceptable quality during or following construction, to sample and test the discharge to prove compliance with FDOT permit conditions.	Within 36 Months of the Effective Date of the Permit
c.) Site Operator Training	ALL **except for** City of North Port and FDOT	Implement an annual NPDES workshop for design professionals, land developers, inspectors and contractors, including earth moving contractors. Topics to include are measures to reduce pollutants from sites, awareness of the NPDES program requirements for construction activities, and solutions to erosion and sediment problems commonly found by the inspectors during construction.	Within 24 Months of the Effective Date of the Permit
		Evaluate the feasibility of an erosion & sediment control certification program for construction site operators (contractors and developers), plan reviewers, and inspectors that work on sites that discharge to the MS4. Upon conclusion of the evaluation, include a summary of the findings in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 30 Months of the Effective Date of the Permit
		If certification program is deemed feasible, implement program for construction site operators, plan reviewers, and inspectors.	If Deemed Feasible - Within 36 Months of the Effective Date of the Permit

R0012854

STORM WATER MANAGEMENT PROGRAM	PERMITTEE(S)	ACTIVITY	DATE DUE / FREQUENCY
c.) *Site Operator Training* (continued)	ALL **except for** City of North Port and FDOT	Develop a procedure to notify building permit applicants in developments which, because of the amount of land area disturbed, are subject to the NPDES storm water regulations of their application responsibilities under the NPDES permitting program for construction site runoff. After development, include a summary of procedures in the subsequent ANNUAL REPORT for incorporation into the permit.	Within 24 Months of the Effective Date of the Permit
		Implement developed procedures to notify building permit applicants in developments which, because of amount of land area disturbed, are subject to the NPDES storm water regulations of their application responsibilities under the NPDES permitting program for construction site runoff.	Within 30 Months of the Effective Date of the Permit
		Conduct presentations to local professional organizations which are associated with the construction industry to discuss proper construction site management for water quality.	Ongoing

R0012855

B. COMPLIANCE WITH EFFLUENT LIMITATIONS.

NONE

PART IV. NUMERIC EFFLUENT LIMITATIONS

NONE

A. Seasonal Loadings and Event Mean Concentrations.

1. As per 40 CFR 122.26(d)(2)(iii)(C), the permittees shall provide estimates of the seasonal pollutant load and of the event mean concentration of a representative storm for the parameters listed in Table V.A.1. for each "major outfall" within the MS4. These constituents were detected in the sampling data reported in the Part 2 application. The location of all known major outfalls shall be inventoried in the ANNUAL REPORT for Year One of the permit, with updates describing any additionally identified major outfalls in each sequent ANNUAL REPORT. The seasonal pollutant load and event mean concentration for each major outfall may be estimated from the representative monitoring locations, from regional NURP or State data, or from pooling results from other nearby Florida MS4 monitoring activities and shall take into consideration land uses and drainage areas for the outfall. The estimates of seasonal loadings and event mean concentrations shall be included in the ANNUAL REPORT for Year Four of the permit. For the purposes of this permit, a "major outfall"is defined as follows:

   - a pipe (or closed conveyance) system with a cross-sectional area equal to or greater than 7.07 square feet (e.g., if a single circular pipe system, an inside diameter of 36 inches or greater);
   - a single conveyance other than a pipe, such as an open channel ditch, which is associated with a drainage area of more than 50 acres;
   - a pipe (or closed conveyance) system, draining *"industrial land use,"* with a cross-sectional area equal to or greater than 0.79 square feet (e.g., if a single circular pipe system, an inside diameter of 12 inches or greater); or
   - a single conveyance other than a pipe, such as an open channel ditch, which is associated with an *"industrial land use"* drainage area of more than 2 acres;

TABLE V.A.1.	
PARAMETERS	
Biochemical Oxygen Demand (BOD_5) (mg/l)	Oil & Grease (mg/l)
Chemical Oxygen Demand (COD) (mg/l)	Total Recoverable Cadmium (mg/l)
Total Suspended Solids (TSS) (mg/l)	Total Recoverable Chromium (mg/l)
Total Dissolved Solids (TDS) (mg/l)	Total Recoverable Copper (mg/l)
Total Kjeldahl Nitrogen (as N) (mg/l)	Total Recoverable Lead (mg/l)
Nitrate plus Nitrite (as N) (mg/l)	Total Recoverable Zinc (mg/l)
Total Phosphorus (mg/l)	Dissolved Phosphorus (mg/l)

2. The permittees listed in Table V.A.2. below shall conduct an investigation of the identified drainage basins to determine the sources of the following organic pollutants detected in the Part 2 application sampling data. A report summarizing the conclusions of this investigation shall be included in the ANNUAL REPORT for Year Three of the permit.

TABLE V.A.2.		
PARAMETERS	BASIN	PERMITTEE(S)
Benezo(a)anthracene	Indian Ave. - Site #5	City of Venice
Benezo(k)fluoranthene	Indian Ave. - Site #5	City of Venice
3,4-Benzofluoranthene	East Ave. - Site #2	City of Sarasota
	Indian Ave. - Site #5	City of Venice
Bis(2-ethylhexyl)phthalate	Longboat Key - Site #1	Longboat Key
	East Ave. - Site #2	City of Sarasota
	Indian Ave. - Site #5	City of Venice
	Richardson Rd. - Site #3	Sarasota County
Chrysene	East Ave. - Site #2	City of Sarasota
	Indian Ave. - Site #5	City of Venice
4,4'-DDE	East Ave. - Site #2	City of Sarasota
	Indian Ave. - Site #5	City of Venice

B. Monitoring Data Collection. According to the agreements established between permittees, the following monitoring program shall be developed and implemented:

1. *Monitoring:* Establish local monitoring stations in conjunction with the State of Florida's *Surface Water Ambient Monitoring Program.* (See definition of the *Surface Water Ambient Monitoring Program* in Part VIII for description of program goals and monitoring strategies.) The selection of the monitoring stations shall be the result of a cooperative effort between the permittees, EPA, and the Bureau of Surface Water Management, Florida Department of Environmental Protection (FDEP). Acceptance of the monitoring program components proposed by the permittees in the July 23, 1993, Part 2 application submittal shall be explored before any alternative monitoring programs are introduced. The number of monitoring stations as well as the type of sampling performed shall be established in accordance with the following:

   a.) The costs associated with the monitoring program developed shall not exceed the projected costs for the monitoring program proposed by the permittees in the July 23, 1993, Part 2 application submittal.

   b.) The monitoring program developed shall assist in determining the impact of storm water discharges on receiving waters located in the geographical area covered by this permit.

   c.) The monitoring program developed shall assist in determining the effectiveness of the storm water management programs being implemented under this permit and shall assist in identifying and prioritizing portions of the MS4 requiring additional controls.

   d.) The monitoring program developed shall be designed to help identify local sources and impacts of specific pollutants considered a problem in the geographic area covered by this permit. Once the source and the impacts are identified, these pollutants may be more effectively reduced or eliminated.

   e.) The selection of the monitoring stations and sampling program schedule shall be agreed upon by the permittees and the Bureau of Surface Water Management, FDEP and EPA. The monitoring program developed shall be implemented by the permittees within 24 months of the effective date of this permit or within 12 months of the date of program development, whichever is later. The details of the monitoring program shall be submitted to EPA in the subsequent ANNUAL REPORT; status reports shall be given in any Annual Reports prior to this one.

It is the intent of EPA to use the monitoring information collected to evaluate any trends in the reduction in pollutant loads discharged to waters of the U.S during the term of the permit. The pollutant loading trends will be used to evaluate the effectiveness of the permittees' Storm Water Management Program to reduce the discharge of pollutants to the MEP and to shall not cause or contribute to violations of State water quality standards of the receiving stream.

2. *Monitoring Data:* For Part V.B.1., records shall be maintained of all analytical results. Additionally, for the monitoring program developed under Part V.B.1. which involves storm event sampling, the records maintained shall include: the date and duration (in hours) of the storm event(s) sampled; rainfall measurements or estimates (in inches or centimeters) of the storm event which generated the sampled runoff; the duration (in hours) between the storm event sampled and the end of the previous measurable (greater than 0.1 inch or 0.25 centimeter rainfall) storm event; and an estimate of the total volume (in gallons or liters) of the discharge sampled.

3. *Sample Analysis:* All samples collected for Part V.B.1. shall be analyzed in accordance with the methods specified at 40 CFR Part 136.

4. *Sampling Waiver.* When a discharger is unable to collect samples required by Part V.B.1. due to adverse climatic conditions, the discharger must submit in lieu of sampling data, a description of why samples could not be collected, including available documentation of the event. Adverse climatic conditions which may prohibit the collection of samples include weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, etc.).

C. Annual Report. Each permittee shall contribute to the preparation of an annual system-wide report to be submitted by no later than six months following the period covered by the report. The ANNUAL REPORT shall cover the 12 month period beginning on the effective date of this permit and annually thereafter.

The preparation and submittal of a system-wide ANNUAL REPORT shall be coordinated by a *"committee."* The *"committee"* shall include a member or designated representative from each municipal entity covered by this permit. Each permittee shall be individually responsible for providing information on the portions of the MS4 for which they are the operator and for providing information for the system-wide report in a timely manner. Joint responsibility for the ANNUAL REPORT submission shall be limited to the following: (1) participation in preparation of the overview for the entire system; and (2) inclusion of the identity of any permittee who failed to provide input to the report. Each permittee shall sign and certify the ANNUAL REPORT in accordance with Part VI.H. & VI.I. of this permit, and shall include a statement or resolution that the permittee's governing body or agency (or delegated representative) has reviewed or has been appraised of the content of the ANNUAL REPORT.

The ANNUAL REPORT shall include the following sections:

- Contacts List
- SWMP Evaluation
- Summary Table
- Narrative Report
- Monitoring Section
- Summary of SWMP and Monitoring Modifications
- Fiscal Analysis
- FDOT District Report
- Appendices

The following items describe in more detail the specific requirements for the ANNUAL REPORT.

1. Provide a list of contacts and responsible parties (e.g.: agency, name, phone number) who had input to and are responsible for the preparation of the ANNUAL REPORT.

2. Provide an overall evaluation of the Storm Water Management Program including: Objective of Program; Major Findings (e.g.: water quality improvements or degradation); Major Accomplishments; Overall Program Strengths / Weaknesses; and Future Direction of Program.

3. Provide a Summary Table of Storm Water Management Program Elements.

a. A Summary Table of appropriate SWMP annual activities for each permittee shall be provided. The purpose of the Summary Table is to document in a concise form the program activities and permittees' compliance status with quantifiable permit requirements. Program elements that are administrative (e.g.: planning procedures, program development and pilot studies) are inappropriate for the summary table and shall be discussed in the narrative section of the ANNUAL REPORT. The following are examples of SWMP activities to be included in the Summary Table:

(1) Structural Controls - maintenance and/or inspection activities of existing structural controls

(2) Roadway Maintenance - street sweeping, litter control activities, and maintenance on storm water structures & roadside ditches

(3) Municipal Waste TSD Facilities - inspections, monitoring, and implementation of control measures

(4) Pesticide, Herbicide, and Fertilizer Application - certification training and public education

(5) Illicits - facility inspections, investigations, enforcement actions, illicit (dry weather) screening, illicit public reporting, oil/household hazardous waste collection, and storm sewer inlet stencilling

(6) High Risk Industrial Facilities - inspection activities and monitoring

(7) Construction - training of inspectors, certification of construction site operators, inspections, and enforcement actions

(8) Storm Water Treatment Projects - description of municipal storm water treatment projects that have been completed, including a brief description of the affected drainage basin

b. The Summary Table shall indicate each permittee's SWMP activities and accomplishments. The format for this information shall adhere to the example shown in Table V.C.1. on page 55. Items to be reported include:

(1) Activity description;

(2) Number of activities (with frequency) that were scheduled for implementation and/or accomplishment in program element discussion (i.e., once/6 months, 100%/5 years, 6 sites monitored once/year, all sites inspected/permit term). Enter "Not Applicable" (N/A) if no specific schedule was specified;

(3) Status of schedule for year ("yes" for schedule was adhered to, or "no" for schedule was not adhered to);

(4) Number of activities which were accomplished; and

(5) The availability of documentation (i.e., inspection reports) for those activities which were accomplished and comments describing the reason(s) for any non-compliance.

4. The ANNUAL REPORT shall contain a Narrative Report to succinctly discuss the SWMP Elements which were not included within the SWMP Summary Table. Those SWMP Elements required to be developed under Parts II and III of the permit shall be discussed within this section of the ANNUAL REPORT following development.

a. The permittees shall include a brief discussion of the following applicable SWMP Elements:

(1) Structural Controls Maintenance
(2) Development Planning Procedures
(3) Roadway Maintenance
(4) Flood Management
(5) Municipal Facilities
(6) Pesticides, Herbicides, and Fertilizers
(7) Illicits Inspection/Investigation/Enforcement
(8) Field Screening
(9) Spill Response

(10) Public Reporting of Illicit Discharges
(11) Oil and Household Hazardous Waste
(12) Sanitary Sewer Seepage
(13) High Risk Industrial Facility Inspection
(14) Construction Planing Procedures
(15) Construction Inspections
(14) Education Activities
(15) Monitoring Activities
(16) Any additional elements of Storm Water Management Program

b. The format for the Narrative Report section of the ANNUAL REPORT shall be a brief discussion of the SWMP Element. The aspects of each permittee's activities concerning a SWMP Element shall be succinctly discussed in the section of the Narrative Report dedicated to that Element. The discussion shall include the following:

(1) Objective of SWMP Element,

(2) SWMP Element activities completed and those in progress,

(3) General discussion of Element. Explanation of all Element activity deficiencies (e.g.: activities described in the program that have not been fully implemented or completed). Results of activities shall be summarized and discussed (e.g.: maintenance caused by inspection, pollutants detected by monitoring, investigations as a result of dry and wet weather screening, number and nature of enforcement items, education activities participation),

(4) Status of SWMP Element with compliance, implementation, and augmentation schedules in Part III of the permit,

(5) SWMP Element strengths and weaknesses,

(6) Assessment of controls, and

(7) Discussion of Element revisions that are summarized elsewhere in the ANNUAL REPORT.

5. The ANNUAL REPORT shall contain a Monitoring Section which discusses the progress and results of the monitoring programs required under Part V of the permit.

   a. The Monitoring Section of the ANNUAL REPORT shall include a summary of the monitoring program developed and implemented under Part V.B.1. of the permit. The details to be discussed include:

      (1) Brief summary statement of the objective of each monitoring project included under the program,

      (2) Summary chart of the data from the monitoring completed,

      (3) Discussion of any results or conclusions derived from the monitoring completed,

      (4) Status of monitoring with respect to the compliance schedule in Part V.B.1. of the permit, and

      (5) Discussion of monitoring program revisions that are summarized elsewhere in the ANNUAL REPORT.

   b. The Monitoring Section of the ANNUAL REPORT shall include the following information as required in Part V.A. of the permit:

      (1) The ANNUAL REPORT for Year One of the permit shall contain an inventory of all known major outfalls, with updates describing additionally identified major outfall in each sequent ANNUAL REPORT.

      (2) The ANNUAL REPORT for Year Three of the permit shall include the investigation of the sources of the organic pollutants detected in the Part 2 application sampling data as required in Part V.A.2. of the permit.

      (3) The ANNUAL REPORT for Year Four of the permit shall include estimates of seasonal pollutant loadings and event mean concentrations (EMC) for each major outfall required by Part V.A.1.

6. Provide a summary of SWMP and Monitoring Modifications made during the permit year.

7. Provide a complete fiscal analysis for each permittee's program implementation, both for the past calendar year and the next. The analysis shall indicate budgets and funding sources.

8. FDOT shall report on the status of the FDOT statewide Storm Water Management Program elements as shown in Table V.C.8.a. on page 56 and shall indicate whether the resulting program modifications have been implemented at the District Office. In addition, FDOT shall also indicate the number of District employees included in the training courses described in Table V.C.8.b. on page 57.

9. The following information shall be included as Appendices within the ANNUAL REPORT for Year Five of the permit:

   a. Analytical data collected from the monitoring program.

   b. Results of illicit connections screening or dry weather screening.

   c. Any other data specifically requested by EPA to substantiate statements and conclusions reached in the ANNUAL REPORTS.

Table V.C.1. - EXAMPLE Summary Table for Storm Water Management Program Element Status/Compliance (EXAMPLE ONLY)

PROGRAM ELEMENT	PERMITTEE	REQUIREMENT	ACTIVITY SCHEDULE			COMMENTS
			Activities Required by SWMP	Complied with	Activities Accomplished during calendar year	
Structural Controls	Permittee 1	Major Channels Inspected	15 Channels, once/6 mos.	YES	15 Channels, once/6 mos	Copies of Inspection Report Forms - Available Upon Request
		Major Channels Maintained	As needed	N/A	7 Channels maintained	
		Grate Inlets Inspected	1500 Inlets, once/year	NO	1000 Inlets	Ambitious projection. Reducing to 1000 next year due to resources.
	Permittee 2	Detention Ponds Maintained	1 Pond, once/month	YES	1 Pond once/month	Sediment removed after spring rains
		Storm Drain Inlets Inspected	35 Inlets, once/6 mos.	YES	35 Inlets once/6 mos.	Copies of Inspection Report Forms Available Upon Request
Monitoring	Permittee 1	Municipal - Landfills	2 Facilities, once/6 mos.	YES	2 Facilities once/6 mos.	Copies of Monitoring Data - Available Upon Request
		POTW	3 Facilities, once/year	NO	2 Facilities	Copies of Monitoring Data - Available Upon Request
		Industrial - Hazardous	5 Facilities, once/6 mos.	YES	5 Facilities, once/6 mos.	Copies of Monitoring Data - Available Upon Request
		Title III	3 Facilities, once/6 mos.	YES	3 Facilities, once/6 mos.	Copies of Monitoring Data - Available Upon Request
		Others	2 Facilities, once/year	YES	2 Facilities	Copies of Monitoring Data - Available Upon Request
		Dry Weather Screening	100% system, once/5 yrs.	YES	20% system	Copies of Screening Field Reports - Appendix B.
		Floatable Assessment	100 sections surveyed/yr.	YES	140 sections surveyed	Copies of Field Survey - Available Upon Request

R0012868

Table V.C.8.a. - Table for FDOT Statewide Storm Water Management Program Element Status

FDOT STATEWIDE STORM WATER MANAGEMENT PROGRAM ELEMENT (To Be Conducted at State Office)	ACTIVITY ACCOMPLISHED DURING THE PERMIT YEAR?	DESCRIPTION OF RESULTING PROGRAM MODIFICATIONS	PROGRAM POLICY INCORPORATED AT DISTRICT OFFICE?
Evaluate the feasibility of the FDOT drainage connection permit becoming an operating permit requiring long-term storm water facility management by the connecting entity.	YES / NO (If no, list anticipated completion date)		YES / NO (If no, list reason and/or anticipated implementation date.)
Add information specific to storm water runoff protection and reduction of chemical usage to the FDOT's *Turf Management Manual* and *Chemical Weed and Grass Control Manual.*	YES / NO (If no, list anticipated completion date)		YES / NO (If no, list reason and/or anticipated implementation date.)
Evaluate, on an ongoing basis, innovative structural and non-structural BMPs and new technologies as they evolve to determine their efficiency and cost effectiveness in the field. Comment on those which are found suitable & adopted for use in FDOT projects in the District.	ONGOING ACTIVITY		Describe new BMPs adopted for use in the District.
Identify those of the non-storm water discharges listed under Part II.A.7.a. on page 9 of the permit, as well as any other non-storm water discharges, which will be allowed to be discharged into the FDOT MS4.	YES / NO (If no, list anticipated completion date)		YES / NO (If no, list reason and/or anticipated implementation date.)

R0012869

Table **V.C.8.b.** - Table for FDOT Statewide Storm Water Management Program Training Status

FDOT STATEWIDE STORM WATER MANAGEMENT PROGRAM TRAINING (Conducted through State Office)	TRAINING CONDUCTED DURING THE PERMIT YEAR?	DESCRIPTION OF TRAINING COURSE	NO. OF DISTRICT EMPLOYEES COMPLETING TRAINING COURSE?
Conduct training for FDOT maintenance and construction inspectors in the identification and detection of potential storm water related problems, signs of illegal dumping and illicit connections, proper containment methods, and reporting procedures.	YES / NO (If no, give anticipated schedule.)		
Conduct training for the FDOT Emergency Coordinator assigned to each FDOT maintenance facility. Training shall not only educate the FDOT Emergency Coordinator in the proper containment of spills and spill reporting procedures, but shall include storm water remediation activities, storm water regulations, and storm water retrofitting necessary to eliminate polluted storm water discharges from FDOT maintenance facilities.	YES / NO (If no, give anticipated schedule.)		
Conduct training for all FDOT personnel involved in the chemical weed and grass control program to ensure a safe and effective program. Incorporate into the training of these applicators an emphasis on storm water implications of the use of pesticides, herbicides, and fertilizers.	YES / NO (If no, give anticipated schedule.)		
Conduct training for all FDOT personnel involved in hazardous waste handling. Incorporate into the training a segment on the identification, detection, and reporting of illicit storm water connections and potential storm water related problems such as visible water quality degradation and signs of illegal dumping.	YES / NO (If no, give anticipated schedule.)		

R0012870

D. Certification and Signature of Reports.

All reports required by the permit and other information requested by the Director shall be signed and certified in accordance with Parts VI.H. & VI.I. of the permit.

E. Reporting: Where and When to Submit.

1. As required by Part V.C., monitoring results obtained during the reporting period running from the 12 month term beginning on the effective date of this permit and annually thereafter shall be submitted on Discharge Monitoring Report Form(s) in the ANNUAL REPORT for Year Five of the permit. A separate Discharge Monitoring Report Form is required for each event monitored.

2. Signed copies of the ANNUAL REPORT required by Part V.C. and all other reports required herein, shall be submitted to:

U.S. EPA, Region IV
Water Management Division
Water Permits and Enforcement Branch (WPEB-7)
345 Courtland Street, N.E.
Atlanta, Georgia 30365

F. Additional Notification.

In addition, the permittees shall provide a copy of each ANNUAL REPORT to:

Florida Department of Environmental Protection
Bureau of Surface Water Management
Storm Water Section
Twin Towers Office Building
2600 Blair Stone Road
Tallahassee, Florida 32399-2400

G. Retention of Records.

The permittees shall retain the latest version of the Storm Water Management Program developed in accordance with Part II of this permit for at least three years after the expiration date of this permit. The permittees shall retain all records of all monitoring information, copies of all reports required by this permit, and records of all other data required by or used to demonstrate compliance with this permit, until at least three years after the expiration date of this permit. This period may be explicitly modified by alternative provisions of this permit or extended by request of the Director at any time.

PART VI. STANDARD PERMIT CONDITIONS

A. Duty to Comply. The permittees must comply with all conditions of this permit insofar as those conditions are applicable to each permittee, either individually or jointly. Any permit noncompliance by a permittee constitutes a violation of the CWA and is grounds for enforcement action, for permit termination, revocation and reissuance, or modification, or for denial of a permit renewal application for the non-complying permittee.

B. **Penalties for Violations of Permit Conditions.**

1. Criminal

a. Negligent Violations The CWA provides that any person who negligently violates permit conditions implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a fine of not less than $2,500 nor more than $25,000 per day of violation, or by imprisonment for not more than 1 year, or both.

b. Knowing Violations The CWA provides that any person who knowingly violates permit conditions implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a fine of not less than $5,000 nor more than $50,000 per day of violation, or by imprisonment for not more than 3 years, or both.

c. Knowing Endangerment The CWA provides that any person who knowingly violates permit conditions implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act and who knows at that time that he is placing another person in imminent danger of death or serious bodily injury is subject to a fine of not more than $250,000, or by imprisonment for not more than 15 year, or both.

d. False Statement The CWA provides that any person who knowingly makes any false material statement, representation, or certification in any application, record, report, plan, or other document filed or required to be maintained under the Act or who knowingly falsifies, tampers with, or renders inaccurate, any monitoring device or method required to be maintained under the Act, shall upon conviction, be punished by a fine of not more than $10,000 or by imprisonment for not more than 2 years, or by both. If a conviction is for a violation committed after a first conviction of such person under this paragraph, punishment shall be by a fine of not more than $20,000 per day of violation, or by imprisonment of not more than 4 years, or by both. (See Section 309(c)(4) of the Clean Water Act).

2. Civil Penalties - The CWA provides that any person who violates a permit condition implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a civil penalty not to exceed $25,000 per day for each violation.

3. Administrative Penalties - The CWA provides that any person who violates a permit condition implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to an administrative penalty, as follows:

   a. Class I penalty Not to exceed $10,000 per violation nor shall the maximum amount exceed $25,000.

   b. Class II penalty Not to exceed $10,000 per day for each day during which the violation continues nor shall the maximum amount exceed $125,000.

C. **Duty to Reapply.** If a permittee(s) wishes to continue an activity regulated by this permit after the permit expiration date, the permittee(s) must apply for and obtain a new permit. The application shall be submitted at least 180 days prior to expiration of this permit. The Director may grant permission to submit an application less than 180 days in advance but no later than the permit expiration date. Continuation of expiring permits shall be governed by regulations promulgated at 40 CFR 122.6 and any subsequent amendments.

D. **Need to Halt or Reduce Activity Not a Defense.** It shall not be a defense for a permittee in an enforcement action that it would have been necessary to halt or reduce the permitted activity in order to maintain compliance with the conditions of this permit.

E. **Duty to Mitigate.** Each permittee shall take all reasonable steps to minimize or prevent any discharge in violation of this permit which has a reasonable likelihood of adversely affecting human health or the environment.

F. **Duty to Provide Information.** Each permittee shall furnish to the Director, within a time specified by the Director, any information which the Director may request to determine compliance with this permit. The permittees shall also furnish to the Director upon request copies of records required to be kept by this permit.

G. **Other Information.** When a permittee becomes aware that he or she failed to submit any relevant facts or submitted incorrect information in any report to the Director, he or she shall promptly submit such facts or information.

H. Signatory Requirements. All Discharge Monitoring Reports, storm water management programs, reports, certifications or information either submitted to the Director or that this permit requires be maintained by the permittees, shall be signed by:

1. Either a principal executive officer or ranking elected official; or

2. A duly authorized representative of that person. A person is a duly authorized representative only if:

   a. The authorization is made in writing by a person described above and submitted to the Director, and

   b. The authorization specifies either an individual or a position having responsibility for the overall operation of the regulated facility or activity, such as the position of manager, operator, superintendent, or position of equivalent responsibility or an individual or position having overall responsibility for environmental matters for the company. (A duly authorized representative may thus be either a named individual or any individual occupying a named position.)

   If an authorization is no longer accurate because a different individual or position has responsibility for the overall operation of the facility, a new written authorization satisfying the requirements of this paragraph must be submitted to the Director prior to or together with any reports, information, or applications to be signed by an authorized representative.

I. Certification. Any person signing documents under this section shall make the following certification:

   "I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gathered and evaluated the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations."

J. Penalties for Falsification of Reports. Section 309(c)(4) of the Clean Water Act provides that any person who knowingly makes any false material statement, representation, or certification in any record or other document submitted or required to be maintained under this permit, including reports of compliance or noncompliance shall, upon conviction, be punished by a fine of not more than $10,000, or by imprisonment for not more than 2 years, or by both.

K. Penalties for Falsification of Monitoring Systems. The CWA provides that any person who falsifies, tampers with, or knowingly renders inaccurate any monitoring device or method required to be maintained under this permit shall, upon conviction, be punished by fines and imprisonment described in Section 309 of the CWA.

L. Oil and Hazardous Substance Liability. Nothing in this permit shall be construed to preclude the institution of any legal action or relieve the permittees from any responsibilities, liabilities, or penalties to which the permittee is or may be subject under section 311 of the CWA or section 106 of CERCLA.

M. Property Rights. The issuance of this permit does not convey any property rights of any sort, nor any exclusive privileges, nor does it authorize any injury to private property nor any invasion of personal rights, nor any infringement of Federal, State or local laws or regulations.

N. Severability. The provisions of this permit are severable, and if any provision of this permit, or the application of any provision of this permit to any circumstance, is held invalid, the application of such provision to other circumstances, and the remainder of this permit shall not be affected thereby.

O. Requiring an Individual Permit.

1. The Director may require any permittee authorized by this permit to obtain an individual NPDES permit. Any interested person may petition the Director to take action under this paragraph. The Director may require any owner or operator authorized to discharge under this permit to apply for an individual NPDES permit only if the owner or operator has been notified in writing that a permit application is required. This notice shall include a brief statement of the reasons for this decision, an application form (as necessary), a statement setting a deadline for the owner or operator to file the application, and a statement that on the effective date of the individual NPDES permit, coverage under this permit shall automatically terminate. Individual permit applications shall be submitted to the address of the appropriate Regional Office shown in Part V.E.2. of this permit. The Director may grant additional time to submit the application upon request of the applicant. If an owner or operator fails to submit in a timely manner an individual NPDES permit application as required by the Director, then the applicability of this permit to the individual NPDES permittee is automatically terminated at the end of the day specified for application submittal.

2. Any owner or operator authorized by this permit may request to be excluded from the coverage of this permit by applying for an individual permit. The owner or operator shall submit an individual application as specified by 40 CFR 122.26(d) with reasons supporting the request to the Director. Individual permit applications shall be submitted to the address of the appropriate Regional Office shown in Part V.E.2. of this permit. The request may be granted by the issuance of a individual permit if the reasons cited by the owner or operator are adequate to support the request.

P. **State/Environmental Laws.**

1. Nothing in this permit shall be construed to preclude the institution of any legal action or relieve the permittee from any responsibilities, liabilities, or penalties established pursuant to any applicable State law or regulation under authority preserved by Section 510 of the Act.

2. No condition of this permit shall release the permittee from any responsibility or requirements under other environmental statutes or regulations.

Q. **Proper Operation and Maintenance**. Each permittee shall at all times properly operate and maintain all facilities and systems of treatment and control (and related appurtenances) which are installed or used by the permittee to achieve compliance with the conditions of this permit and with the requirements of storm water management programs. Proper operation and maintenance also includes adequate laboratory controls and appropriate quality assurance procedures. Proper operation and maintenance requires the operation of backup or auxiliary facilities or similar systems, installed by a permittee only when necessary to achieve compliance with the conditions of the permit.

R. **Monitoring and Records.**

1. Samples and measurements taken for the purpose of monitoring shall be representative of the monitored activity.

2. The permittees shall retain records of all monitoring information including all calibration and maintenance records and all original strip chart recordings for continuous monitoring instrumentation, copies of the reports required by this permit, and records of all data used to complete the application for this permit, for a period of at least 3 years from the date of the sample, measurement, report or application. This period may be extended by request of the Director at any time.

3. Records of monitoring information shall include:

a. The date, exact place, and time of sampling or measurements;

b. The initials or name(s) of the individual(s) who performed the sampling or measurements;

c. The date(s) analyses were performed;

d. The time(s) analyses were initiated;

e. The initials or name(s) of the individual(s) who performed the analyses;

f. References and written procedures, when available, for the analytical techniques or methods used; and

g. The results of such analyses, including the bench sheets, instrument readouts, computer disks or tapes, etc., used to determine these results.

S. Monitoring Methods. Monitoring must be conducted according to test procedures approved under 40 CFR Part 136, unless other test procedures have been specified in this permit.

T. Inspection and Entry. The permittee shall allow the Director or an authorized representative of EPA, or the State, upon the presentation of credentials and other documents as may be required by law, to:

1. Enter the permittee's premises where a regulated facility or activity is located or conducted or where records must be kept under the conditions of this permit;

2. Have access to and copy at reasonable times, any records that must be kept under the conditions of this permit; and

3. Inspect at reasonable times any facilities or equipment (including monitoring and control equipment).

U. Permit Actions. This permit may be modified, revoked and reissued, or terminated for cause. The filing of a request by the permittee for a permit modification, revocation and reissuance, or termination, or a notification of planned changes or anticipated noncompliance does not stay any permit condition.

V. Additional Monitoring by the Permittee(s). If the permittees monitor more frequently than required by this permit, using test procedures approved under 40 CFR Part 136 or as specified in this permit, the results of this monitoring shall be included in the calculation and reporting of the data submitted in the Discharge Monitoring Report (DMR). Such increased monitoring frequency shall also be indicated on the DMR.

PART VII. PERMIT MODIFICATION

A. **Modification of the Permit:** The permit may be reopened and modified during the life of the permit to:

1. Incorporate into the permit the finalized pollutant load reduction goals agreed to by the permittees and the National Estuary Program (NEP) in the National Estuary Program Comprehensive Conservation and Management Plan for the geographical area covered by this NPDES permit;

2. Address impacts on receiving water quality caused, or contributed to, by discharges from the MS4;

3. Address changes in State or Federal statutory or regulatory requirements;

4 Include the addition of a new permittee who is the owner or operator of a portion of the Municipal Separate Storm Sewer System; or

5. Include other modifications deemed necessary by the Director to comply with the goals and requirements of the Clean Water Act.

All modification to the permit will be made in accordance with 40 CFR 122.62, 122.63, and 124.5.

B. **Termination of Coverage for a Single Permittee**

Permit coverage may be terminated, in accordance with the provisions of 40 CFR 122.64 and 124.5, for a single permittee without terminating coverage for other permittees.

C. **Modification of Storm Water Management Program(s)**

Only those portions of the Storm Water Management Programs specifically required as permit conditions shall be subject to the modification requirements of 40 CFR 124.5. Replacement of an ineffective or infeasible BMP implementing a required component of the Storm Water Management Program with an alternate BMP expected to achieve the goals of the ineffective or infeasible BMP shall be considered minor modifications to the Storm Water Management Program and not modifications to the permit. (See also Part II.G.)

D. Changes in Monitored Outfalls

This permit is issued on a system-wide basis in accordance with CWA §402(p)(3)(i) and authorizes discharges from all portions of the Municipal Separate Storm Sewer System. Since all outfalls are authorized, changes in monitoring outfalls, other than those with specific numeric effluent limitations, if any, shall be considered minor modifications to the monitoring program and not modifications to the permit. (See also Part V.B.1. and V.C.6.) Changes in monitoring outfalls with specific numeric effluent limitations shall be considered modifications to the permit and will be made in accordance with the procedures at 40 CFR 122.62.

PART VIII. DEFINITIONS

All definitions contained in Section 502 of the CWA shall apply to this permit and are incorporated herein by reference. Unless otherwise specified in this permit, additional definitions of words or phrases used in this permit are as follows:

A. "Best Management Practices" ("BMPs") means schedules of activities, prohibitions of practices, maintenance procedures, and other management practices to prevent or reduce the pollution of waters of the United States. BMPs also include treatment requirements, operating procedures, and practices to control facility site runoff, spillage or leaks, sludge or waste disposal, or drainage from raw material storage.

B. "Bypass" means the intentional diversion of waste streams from any portion of a treatment facility, which is not a designed or established operating mode for the facility.

C. "CWA" means Clean Water Act, also referred to as "the Act" (formerly referred to as the Federal Water Pollution Control Act or Federal Water Pollution Control Act Amendments of 1972) Pub.L. 92-500, as amended Pub. L. 95-217, Pub. L. 95-576, Pub. L. 6-483 and Pub. L. 97-117, 33 U.S.C. 1251 et.seq., as amended by the WQA of 1987, P.L. 100-4, the "Act."

D. "Director" means the EPA Regional Administrator or an authorized representative.

E. "Discharge" for the purpose of this permit, unless indicated otherwise, refers to discharges from the Municipal Separate Storm Sewer System (MS4).

F. "Flow-weighted composite sample" means a composite sample consisting of a mixture of aliquots collected at a constant time interval, where the volume of each aliquot is proportional to the flow rate of the discharge at the time of sampling.

G. "Illicit connection" means any man-made conveyance connecting a non-storm water discharge directly to a municipal separate storm sewer system.

H. "Illicit discharge" means any discharge to a municipal separate storm sewer that is not composed entirely of storm water except discharges pursuant to a NPDES permit (other than the NPDES permit for discharges from the municipal separate storm sewer) and other discharges listed in Part II. A.7.a. of this permit.

I. "Industrial Land Use" means land utilized in connection with manufacturing, processing, or raw materials storage at facilities identified under 40 CFR 122.26(b)(14).

J. "Landfill" means an area of land or an excavation in which wastes are placed for permanent disposal, and which is not a land application unit, surface impoundment, injection well, or waste pile.

K. "Large Municipal Separate Storm Sewer System" means all municipal separate storm sewers that are either:

(i) located in an incorporated place (city) with a population of 250,000 or more as determined by the latest Decennial Census by the Bureau of Census (these cities are listed in Appendices F and G of 40 CFR Part 122); or

(ii) located in the counties with unincorporated urbanized populations of 250,000 or more, except municipal separate storm sewers that are located in the incorporated places, townships or towns within such counties (these counties are listed in Appendices H and I of 40 CFR Part 122); or

(iii) owned or operated by a municipality other than those described in paragraph (i) or (ii) and that are designated by the Director as part of the large municipal separate storm sewer system.

L. "Medium Municipal Separate Storm Sewer System" means all municipal separate storm sewers that are either:

(i) located in an incorporated place (city) with a population of 100,000 or more as determined by the latest Decennial Census by the Bureau of Census (these cities are listed in Appendices F and G of 40 CFR Part 122); or

(ii) located in the counties with unincorporated urbanized populations of 100,000 or more, except municipal separate storm sewers that are located in the incorporated places, townships or towns within such counties (these counties are listed in Appendices H and I of 40 CFR Part 122); or

(iii) owned or operated by a municipality other than those described in paragraph (i) or (ii) and that are designated by the Director as part of the medium municipal separate storm sewer system.

M. "MEP" is an acronym for "Maximum Extent Practicable," the technology-based discharge standard for Municipal Separate Storm Sewer Systems established by CWA §402(p).

N. "MS4" is an acronym for "municipal separate storm sewer system" and is used to refer to either a Large or Medium Municipal Separate Storm Sewer System (e.g. "the Atlanta MS4").

O. "Municipal Separate Storm Sewer" means a conveyance, or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, man-made channels, and storm drains):

(i) owned or operated by a State, city, town, borough, county, parish, district, association, or other public body (created by or pursuant to State Law) having jurisdiction over disposal of sewage, industrial wastes, storm water, or other wastes, including special districts under State Law such as a sewer district, flood control district or drainage district, or similar entity, or an Indian Tribe or an authorized Indian tribal organization, or a designated and approved management agency under section 208 of the CWA that discharges to waters of the United States;

(ii) designed or used for collecting or conveying storm water;

(iii) which is not a combined sewer; and

(iv) which is not part of a Publicly Owned Treatment Works (POTW) as defined at 40 CFR 122.2.

P. "Permittee" means each individual co-applicant for an NPDES permit who is only responsible for permit conditions relating to the discharge that they own or operate. (Also, See 40 CFR 122.2)

Q. "Point Source" means any discernible, confined, and discrete conveyance, including but not limited to, any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, landfill leachate collection system, vessel or other floating craft from which pollutants are or may be discharged. This term does not include return flows from irrigated agriculture or agricultural storm water runoff.

R. "Severe property damage" means substantial physical damage to property, damage to the treatment facility which causes them to become inoperable, or substantial and permanent loss of natural resources which can reasonably be expected to occur in the absence of a bypass. Severe property damage does not mean economic loss caused by delays in production.

S. "State Storm Water Quality Standards", is defined at Section 403.0891 of the Florida Statutes, and State Water Policy, Chapter 62-40, Florida Administrative Code.

T. "Storm Sewer", unless otherwise indicated, refers to a municipal separate storm sewer.

U. "Storm Water" means storm water runoff, snow melt runoff, surface runoff and drainage.

V. "Storm Water Discharge Associated with Industrial Activity" is defined at 40 CFR 122.26(b)(14). (Also, See Fact Sheet for this Permit.)

W. "Storm Water Management Program" refers to a comprehensive program to manage the quality of storm water discharged from the municipal separate storm sewer system. For the purposes of this permit, the Storm Water Management Program is considered a single document, but may actually consist of separate programs (e.g. "chapters") for each permittee.

X. "Surface Water Ambient Monitoring Program" refers to a comprehensive program implemented by the Florida Department of Environmental Protection, Bureau of Surface Water Management, which is designed to accomplish the following goals:

1. Identify and document the existing condition of the surface waters of the State,

2. Document potential problem areas,

3. Establish stream ecoregion reference sites for comparison purposes,

4. Collect biological data at ecoregion reference sites to establish preliminary biological integrity measurements techniques, and

5. Establish a Statewide ambient monitoring network which will eliminate duplication, share data, increase efficiency, and improve assessment and management capabilities.

To date, the monitoring strategies included within the State of Florida's Surface Water Ambient Monitoring Program have been based on:

- Ecoregion Subregionalization and the associated stream Community Bioassessment Protocols (CBA) developed for the nonpoint source program,

- Chemistry Trend Network to fulfill the need to evaluate the State's water quality over time,

- Chemistry Status Network with emphasis on water bodies with fair or poor water quality or areas which have not been recently sampled, and

- Lake Ecoregion and Community Bioassessment Projects.

Y. "SWMP" is an acronym for "Storm Water Management Program."

Z. "Time-weighted composite" means a composite sample consisting of a mixture of equal volume aliquots collected at a constant time interval.

AA. "Waters of the United States" is defined at 40 CFR 122.2.

Anchorage, AK 99503

Re: NPDES Permit No. AKS052426
Port of Anchorage NPDES Municipal Storm Water Permit

Dear Ms. Adair:

A National Pollutant Discharge Elimination System (NPDES) permit has been issued to the referenced facility. Enclosed is a copy of the transmittal letter, permit, and list of changes made from the draft to the final permit.

There were no significant comments received during the public notice period. The permit will be effective 30 days after the issuance unless a request for evidentiary hearing is received.

Sincerely,

Charles E. Findley
Director, Water Division

Anchorage, Alaska 99501

Re: NPDES Permit No. AKS052426
Port of Anchorage NPDES Municipal Storm Water Permit

Dear Mr. Dietz:

We are issuing the above referenced National Pollutant Discharge Elimination System (NPDES) permit. The enclosed document is your official copy of the permit and demonstrates that the referenced facility is authorized to discharge to waters of the United States subject to certain specified requirements. Stipulations of the state's water quality certification and Coastal Management Program consistency determination have been incorporated into the permit. More specifically, the stipulations revising the monitoring conditions are in Part IV of the permit.

There were no significant comments received during the public notice period. This permit will become effective 30 days after the issuance date unless a request for an evidentiary hearing which meets the requirements of 40 CFR 124.74 is received. A copy of these requirements is enclosed for your information.

Sincerely,

Charles E. Findley
Director, Water Division

CHANGES TO DRAFT PERMIT

The following changes to the draft permit have been made for this final permit:

1) The Port of Anchorage commented that the outfall previously labelled 001, Transit Area A, was discovered by its consulting engineers to no longer exist, and asked that it be deleted from the application.

   EPA has deleted this outfall and re-numbered the remaining three outfalls as 001, 002, and 003 (see Table V.A.1.b).

2) Special requirements stipulated as part of the State of Alaska water quality certification are contained in Part IV of the permit. These special requirements include changes in monitoring, analytical test methods, and reporting requirements. Specifically:

   - The monitoring parameter "Total Aqueous Hydrocarbons" has been substituted for the parameter "Oil and Grease" found in Part II.B.9.b.

   - The analytical test methods EPA 602 and EPA 610 will be used to determine the presence of "Total Aqueous Hydrocarbons".

   - Copies of all documents, reports, and requests, required in the permit will be sent to the state offices as stipulated.

   In addition, the following changes to the permit have been made pursuant to the water quality stipulations and comments from the State:

   - Part II.A.1 has been expanded to include a statement on emphasizing source reduction techniques as a means to reduce the discharge of pollutants.

   - In Part II.B.4 the permittee is now directed to operate and maintain parking and cargo storage/staging areas in a manner to reduce, to the Maximum Extent Practicable, discharge of pollutants.

   - In Part II.B.11 the following was added as paragraph (d): a program to promote, publicize and facilitate implementation of technologies and techniques to prevent pollution through source reduction and recycling.

   - In Part II.B.7.b the items numbered 8, 12, and 13 now specify that the water be uncontaminated as found in #6.

   - The term "co-permittees" in Part II.C has been deleted.

- In Part II.C.1 the term "port vehicles" has been clarified to mean those vehicles owned or operated by The Port.

- The citation in Part H.1 has been changed to correctly read Part II.I.

- The phrase "at the permittees option" in Part V.A.4.b has been deleted.

- The reference in Part V.B.1 has been changed to correctly read Part III.A.

AUTHORIZATION TO DISCHARGE UNDER THE

NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM

In compliance with the provisions of the Clean Water Act, 33 U.S.C. §1251 et seq., as amended by the Water Quality Act of 1987, P.L. 100-4, the "Act",

Port of Anchorage

is authorized to discharge from a **Municipal Separate Storm Sewer System** located at **Port of Anchorage, 2000 Anchorage Port Road, Anchorage, Alaska,**

to receiving waters named **Cook Inlet,**

in accordance with discharge point(s), an approved storm water management plan, monitoring requirements, and other conditions set forth herein.

This permit shall become effective March 3, 1995.

This permit and the authorization to discharge shall expire at midnight, March 3, 2000.

Signed this 1st day of February, 1995.

Director, Water Division, Region 10

- D. Changes in Monitored Outfalls.

Part VIII. DEFINITIONS

PART I. DISCHARGES AUTHORIZED UNDER THIS PERMIT

A. Permit Area

This permit covers all areas within the jurisdictional boundary of the Port of Anchorage within the Municipality of Anchorage, Alaska, served by, or otherwise contributing to discharges from, municipal separate storm sewers (MS4s) owned or operated by the permittee listed in Part I.C.

B. Authorized Discharges

This permit authorizes all existing or new storm water point source discharges to waters of the United States from the MS4. This permit also authorizes the discharge of storm water commingled with flows contributed by process wastewater, non-process wastewater, or storm water associated with industrial activity provided such discharges are authorized under separate NPDES permits. This permit will consider any and all activities conducted by lessees of the Port of Anchorage while within the jurisdictional boundaries of the Port, and which activity leads to a discharge either to or from the MS4s for which this permit is written, to be the activity of the Port and subject to the conditions of this permit.

C. Limitations on Coverage

The following discharges are not authorized by this permit:

1. *Non-storm Water:* storm water discharges that are mixed with non-storm water or storm water associated with industrial activity except where such discharges are:

   a. in compliance with a separate NPDES permit; or

   b. identified by and in compliance with Part II.B.7 of this permit.

2. *Endangered Species Protection:* storm water discharges whose direct, indirect, interrelated, interconnected, or interdependent impacts would jeopardize a listed endangered or threatened species or adversely modify designated critical habitat.

3. *Historic Preservation:* storm water discharges, or the permittee construction activities or implementation of storm water management controls, which adversely effect properties listed or eligible for listing in the National Register of Historic Places, unless the permittee is in compliance with requirements of the National Historic Preservation Act and has coordinated any necessary activities to avoid or minimize impacts with the appropriate State Historic Preservation Officer; and

4. *Coastal Zone Management:* storm water discharges not in compliance with any applicable requirements of a State's Coastal Zone Management Plan.

PART II. STORM WATER POLLUTION PREVENTION & MANAGEMENT PROGRAMS

The permittee is required to develop and implement a storm water pollution prevention and management program designed to limit, to the maximum extent practicable, the discharge of pollutants from the MS4. Either collectively, or separately, the permittee's storm water pollution prevention and management program shall satisfy the requirements of paragraphs A through I, below for all portions of the MS4 authorized to discharge under this permit.

A. **POLLUTION PREVENTION REQUIREMENTS**

The permittee shall develop and implement the following pollution prevention measures:

1. The permittee shall include requirements to consider water quality impacts of new and significant re-development in its comprehensive master planning process. The goal of such requirements shall be limiting, to the maximum extent practicable, the discharge of pollutants to pre-development levels.

2. The permittee shall ensure the establishment or availability of a program to collect used motor vehicle fluids (including oil and antifreeze) and batteries for recycle or reuse. Such program shall be readily available to all lessees. This program shall be publicized and promoted on a regular basis, but at least anually.

3. The permittee shall ensure the establishment or availability of a program to collect commonly-used hazardous materials (including paint, pesticides, herbicides, cleaners, solvents, and similar hazardous materials) for recycle, reuse, or safe disposal. The program shall be readily available to all lessees and include information on locations accepting such materials on a continuous basis. This program shall be publicized and promoted on a regular basis, but at least anually.

4. The permittee shall ensure the establishment of a program, including structural controls where necessary, to reduce the discharge of floatables (including solid wastes) to the maximum extent practicable.

B. **SWMP SYSTEM-WIDE REQUIREMENTS**

The permittee shall operate a Storm Water Management Program (SWMP) in accordance with Section 402(p)(3)(B) of the Clean Water Act, the storm water regulations (40 CFR Part 122.26) and the approved SWMP plan to be submitted to EPA by the permittee. SWMP controls and activities identified in the SWMP plan shall clearly identify areas of applicability on a system-wide basis, jurisdiction-wide basis, or specific-area basis. The SWMP, and all approved updates, are hereby incorporated into this permit by reference and shall be implemented in a manner consistent with the following requirements:

1. *Statutory Requirements*: SWMPs shall include controls necessary to reduce the discharge of pollutants from the MS4 to the Maximum Extent Practicable (MEP). Controls may consist of a combination of best management practices, control techniques, system design and engineering methods, and such other provisions as the permittee, Administrator or the State determines appropriate. The various components of the SWMP, taken as a whole (rather than individually), shall be sufficient to meet the statutory MEP standard. The SWMP shall be updated as necessary to ensure conformance with the statutory requirements of Clean Water Act §402(p)(3)(B)(ii) and (iii).

2. *Structural Controls:* The permittee shall operate and maintain any storm water structural controls over which it has jurisdiction, in a manner so as to reduce the discharge of pollutants (including floatables) to the MEP.

3. *Areas of New Development:* The Port of Anchorage shall utilize a comprehensive master planning process to develop, implement, and enforce controls to reduce, to the MEP, the discharge of pollutants from areas of new development and significant redevelopment after construction is completed.

4. *Roadways:* The permittee shall operate and maintain public streets, roads, highways, parking areas, and cargo storage/staging areas under its jurisdiction in a manner so as to reduce, to the MEP, discharge of pollutants (including those related to deicing or sanding activities).

5. *Flood Control Projects:* The permittee shall ensure any flood control project it undertakes assesses and minimize to the MEP the impacts on water quality of the receiving waters. The permittee shall also evaluate the feasibility of retro-fitting existing structural flood control devices to provide additional pollutant removal from storm water. If retro-fitting is found to be feasible, the permittee shall implement the retro-fitting of existing structural devices within 3 years of such determination of feasibility.

6. *Pesticide, Herbicide, and Fertilizer Application:* The permittee shall implement controls to reduce, to the MEP, the discharge of pollutants related to application of pesticides, herbicides, and fertilizers applied by Port employees, contractors, or lessees to public right of ways, parks, and all port lands and facilities.

7. *Illicit Discharges and Improper Disposal*: The permittee shall implement an ongoing program to detect and eliminate illicit discharges and improper disposal into the storm sewer. The permittee may chose to require the discharger to the MS4 to eliminate the illicit discharges or obtain a separate NPDES permit for such discharges.

a. The permittee shall effectively prohibit non-storm water discharges to the MS4.

b. Unless identified by either the permittee, the Administrator, or the State as significant sources of pollutants to waters of the United States, the following non-storm water discharges need not be prohibited from entering the MS4, provided the necessity of such discharge(s) and appropriate control measures (if needed) to minimize the impacts of such sources, are developed under the SWMP:

(1) water line flushing;
(2) landscape irrigation;
(3) diverted stream flows;
(4) rising ground waters;
(5) uncontaminated ground water infiltration (as defined at 40 CFR 35.2005(20)) to separate storm sewers;
(6) uncontaminated pumped ground water;
(7) discharges from potable water sources;
(8) uncontaminated foundation drains;
(9) air conditioning condensate;
(10) irrigation water;
(11) springs;
(12) uncontaminated water from crawl space pumps;
(13) uncontaminated footing drains;
(14) lawn watering;
(15) individual residential car washing;
(16) flows from riparian habitats and wetlands;
(17) dechlorinated swimming pool discharges;
(18) street wash waters;
(19) NPDES permitted non-contact cooling waters and remediated ground waters, provided appropriate management practices are implemented and the discharges are in accordance with the Municipality's storm water management program; and,
(20) discharges or flows from emergency fire fighting activities.

c. The permittee shall prevent discharges of dry and wet weather overflows from sanitary sewers into the MS4. The permittee shall limit, to the maximum extent practicable, the infiltration of seepage from sanitary sewers into the MS4.

d. The permittee shall prohibit the discharge or disposal of all motor vehicle fluids and chemical wastes into separate storm sewers.

e. The permittee shall require the elimination of illicit connections as expeditiously as possible and the immediate cessation of improper disposal practices upon identification of responsible parties. Where elimination of an illicit connection within seven (7) days is not possible, the Port of Anchorage shall require an expeditious

schedule for elimination of the discharge. In the interim, the Port of Anchorage shall require the operator of the illicit connection to take all reasonable and prudent measures to minimize the discharge of pollutants to the MS4. Elimination schedules should not exceed ninety (90) days, except for capital intensive projects which shall not exceed 455 days (one year ninety days).

8. *Spill Prevention and Response:* The permittee shall implement a program to prevent, contain, and respond to spills that may discharge into the MS4. The spill response program may include a combination of spill response actions by the permittee and its lessees.

9. *Industrial & High Risk Runoff:* The permittee shall implement a program to identify, monitor, and control pollutants in storm water discharges to the MS4 from: hazardous waste treatment, storage and disposal facilities that are subject to EPCRA Title III, Section 313; bulk storage facilities; **and, any other industrial or commercial discharges the permittee determines are contributing a substantial pollutant loading to the MS4.** The program shall include:

   a. **priorities and procedures for inspections** and **establishing and implementing control measures for such discharges;**

   b. a monitoring (or self-monitoring) program for facilities identified under this section, including the collection of quantitative data on the following constituents:

      (1) any pollutants limited in an existing NPDES permit for an identified facility;
      (2) oil and grease;
      (3) chemical oxygen demand (COD);
      (4) pH;
      (5) biochemical oxygen demand, five-day (BOD_5);
      (6) total suspended solids (TSS);
      (7) total phosphorous;
      (8) total Kjeldahl nitrogen (TKN);
      (9) nitrate plus nitrite nitrogen; and
      (10) any of the metals cadmium, copper, lead, and zinc which can be reasonably expected in storm water runoff from such industrial site; and,
      (11) any information on discharges required under 40 CFR 122.21(g)(7)(iii) and (iv).

10. *Construction Site Runoff:* The permittee shall implement a program to reduce, to the MEP, the discharge of pollutants from constructions sites, including:

   a. requirements for the use and maintenance of appropriate structural and nonstructural best management practices to reduce pollutants

discharged to the MS4 upon commencement of, and during, the construction activities;

b. procedures for site planning which incorporate considerations for potential short and long term water quality impacts and minimizes, to the MEP, these impacts;

c. prioritized inspection of construction sites and enforcement of SWMP-required control measures;

d. appropriate education and training measures for construction site operators; and,

e. notification of all construction permit applicants of their potential responsibilities under the NPDES permitting program for construction site runoff.

11. *Public Education:* The permittee shall implement a public education program including:

a. a program to promote, publicize, and facilitate public reporting of the presence of illicit discharges or improper disposal of materials into the MS4;

b. a program to promote, publicize, and facilitate the proper management and disposal of used oil and commonly-used hazardous materials.

c. a program to promote, publicize, and facilitate the proper use, application, and disposal of pesticides, herbicides, and fertilizers by commercial and private applicators and distributors conducting such business within the Port of Anchorage jusrisdictional area.

C. **AREA-SPECIFIC STORM WATER MANAGEMENT PROGRAM REQUIREMENTS**
The following SWMP requirements apply only to the areas or discharges specified below. Management practices must also be developed in the SWMP for the following:

1. The Port of Anchorage (The Port) will provide an area for the washing of Port vehicles (that is, vehicles owned or operated by The Port) that will not result in the discharge of wash waters. The Port will encourage the use of detergent-free methods of vehicle washing and will require regular maintenance of the area to ensure wash waters, and resulting contaminants, will not be transported by storm water to waters of the U.S. This area is not required to be within Port jurisdictional boundaries, and does not have to be operated by the Port or Port personnel.

2. The Port may provide this area to its tenants solely for the purpose of vehicle washing. In such case, The Port accepts the responsibilty of proper operation and

maintenance of this area, and will ensure proper management practices are adhered to at all times.

3. All vehicle and equipment maintenance areas will be managed so as to control discharges from these areas to the maximum extent practicable. All hydrocarbon compounds used in these areas will be handled in a manner that will eliminate or minimize potential discharges to waters of the U.S.

D. DEADLINES FOR PROGRAM COMPLIANCE

1. Except as provided in PART III, compliance with the storm water management program shall be required within 120 days of the effective date of this permit.

2. Proposed modifications and updates to the SWMP, along with proposed schedules for implementation, shall be submitted with the Annual Report required under Part II.G. to EPA.

E. ROLES AND RESPONSIBILITIES OF PERMITTEE AND LESSEES

The SWMP plan shall clearly identify the roles and responsibilities of the permittee. Activities required of the lessees by the permittee must also be clearly identified.

F. LEGAL AUTHORITY

The permittee shall ensure legal authority exists to control discharges to and from those portions of the MS4 over which it has jurisdiction. This legal authority may be a combination of statute, ordinance, permit, contract, order or inter-jurisdictional agreements with entities having existing legal authority to:

1. Control the contribution of pollutants to the MS4 by storm water discharges associated with industrial activity and the quality of storm water discharged from sites of industrial activity;

2. Prohibit illicit discharges to the municipal separate storm sewer;

3. Control the discharge of spills and the dumping or disposal of materials other than storm water into the MS4;

4. Control through interagency agreements among co-permittees the contribution of pollutants from one portion of the MS4 to another;

5. Require compliance with conditions in ordinances, permits, contracts or orders; and,

6. Carry out all inspection, surveillance and monitoring procedures necessary to determine compliance with permit conditions.

G. **SWMP RESOURCES**

The permittee shall provide adequate finances, staff, equipment, and support capabilities to fully implement the storm water management program.

H. **SWMP REVIEW AND MODIFICATION**

1. *Program Review:* The permittee shall conduct an annual review of the current SWMP in conjunction with preparation of the annual system-wide report required under Part II.I. This annual review shall include:

   a. A review of the status of program implementation and compliance (or non-compliance) with all schedules of compliance contained in this permit;

   b. An assessment of the effectiveness of controls established ~~by the SWMP~~;

   c. A review of monitoring data and any trends in estimated cumulative annual pollutant loadings; and,

   d. An assessment of any SWMP modifications needed to comply with the CWA §402(p)(3)(B)(iii) requirement to reduce the discharge of pollutants to the MEP.

2. *Program Modification:* The approved SWMP, and its plan, shall not be modified by the permittee without the prior approval of the EPA, unless in accordance with items a. through c. below:

   a. Modifications adding (but not subtracting or replacing) components, controls, or requirements to the approved SWMP may be made by the permittee at any time upon written notification to the permitting authority.

   b. Modifications replacing a failing Best Management Practice (BMP) identified in the SWMP with an alternate BMP may be requested in conjunction with the annual system-wide report required by Part II.I. below. Such requests must: 1) be made in writing; 2) provide an analysis of why the BMP is failing or ineffective (including cost prohibitive); 3) discuss the expectations of the effectiveness of the replacement BMP; and, 4) explain why the replacement BMP is expected to provide at least the same level of performance as originally expected of the BMP to be replaced.

   c. Modifications made under this paragraph shall not become enforceable permit conditions until such time as the modifications are approved by EPA.

   Modification requests and/or notifications shall be signed in accordance with Part VI.H.

3. *Modifications Required by the Permitting Authority:* The EPA may require the permittee to modify the SWMP as needed to:

   a. Address contributions by the MS4 discharges to impacts on receiving water quality;

   b. Include more stringent requirements necessary to comply with new State or Federal statutory or regulatory requirements; or,

   c. Include such other conditions deemed necessary by the Administrator to comply with the goals and requirements of the Clean Water Act.

   Modifications requested by the Administrator shall be made in writing, set forth the time schedule for the permittee to develop the modification(s), and offer the permittee the opportunity to propose alternative program modifications to meet the objective of the requested modification.

I. SYSTEM-WIDE REPORT

The permittee shall prepare and submit a system-wide report no later than one year after the anniversary of the effective date of this permit (**March 3, 1995**), and continue to submit an updated system-wide report every year thereafter. The report shall include the following separate sections and an overview for the entire MS4:

1. The status of implementing the components of the SWMPs that are established as permit conditions (status of compliance with any schedules established under this permit shall be included in this section);

2. Proposed changes to the SWMPs that are established as permit conditions, including an update on areas added to the MS4 due to annexation or other legal means;

3. Revisions, if necessary, to the assessments of controls and management practices;

4. A summary of the data, including monitoring data, that is accumulated throughout the last reporting year;

5. Annual expenditures for the reporting period (i.e., the last year), and projected budget for the one year period comprising the next system-wide report;

6. A summary describing the number and nature of compliance actions, inspections, and public education programs; and,

7. Identification of water quality improvements or degradation, with a discussion of those management practices implemented or proposed for implementation to address identified water quality degradation.

PART III. SCHEDULES FOR COMPLIANCE

A. IMPLEMENTATION OF POLLUTION PREVENTION MEASURES

POLLUTION PREVENTION MEASURE	ACTIVITY DESCRIPTION	DATE DUE
Part II.A.1 - New Development & Re-Development	Implement construction-phase storm water runoff control program.	March 4, 1996
	Modify land use planning process within Port to require controls for storm water quality.	March 3, 1998
	Implement requirements for post-construction storm water quality controls for new and significant re-development.	July 30, 1998
Part II.A.2 - Vehicle Fluids	Implement public education program.	July 30, 1995
	Develop collection/recycling/safe disposal program.	March 4, 1996
	Implement collection/recycling/safe disposal program.	March 3, 1997
Part II.A.3 - Common Hazardous Waste	Implement public education program.	July 30, 1995
	Develop collection/recycling/safe disposal program.	March 4, 1996
	Implement collection/recycling/safe disposal program.	March 3, 1997
Part II.A.4 - Floatables	Implement public education program.	July 30, 1995
	Implement litter control program.	July 30, 1995
	Install floatables monitoring location (See Part V.A.2)	July 30, 1995
	Complete study for targeting of structural controls.	July 30, 1996
	Complete installation of structural controls on 100% of targeted storm sewer.	July 30, 1997

B. IMPLEMENTATION OF STORM WATER MANAGEMENT PLANS

SWMP ACTIVITY	ACTIVITY DESCRIPTION	DATE DUE
PART II.B - Storm Water Management Program (SWMP) plan development	Complete development of SWMP plan	June 5, 1995
Part II.B.7 - Illicit Discharges and Improper Disposal	Implement public education program.	July 30, 1995
	Complete screening of the MS4.	July 30, 1996
	Complete follow up investigations based on screening results.	July 30, 1999
Part II.I - System-wide Report	Episodic system and implementation status report	Annually: March 3

PART IV. SPECIAL PERMIT REQUIREMENTS

The following requirements are included in this permit as stipulations of water quality certification from the Alaska Department of Environmental Conservation (ADEC).

A. **MONITORING**

1. In Part II.B.9.b the parameter "Total Aqueous Hydrocarbons" will be substituted for the parameter "Oil and Grease" on the list of parameters to be monitored.

   The parameter "Total Aqueous Hydrocarbons" (TAqH) means those collective dissolved and water-accomodated monoaromatic and polynuclear aromatic petroleum hydrocarbons that are persistent in the water column; TAqH does not include floating surface oils and greases. TAqH is calculated by summing the values of the parameters Total Aromatic Hydrocarbons (TAH) and Total Polynuclear Hydrocarbons (PAH). The parameters TAqH, TAH, and PAH are all defined in the Adopted Draft Water Quality Standards, 18 AAC 70.020(b) Note #8, dated 9/13/94. The test methods to be used to determine the presence of these parameters are the EPA 602 method for TAH and the EPA 610 method for PAH. Equivalent methods may be substituted for EPA 610 that meet the performance standards, Minimum Detection Limits (MDLs), precision, and standard recoveries specified in method 610. The applicable criteria are contained in Note #8 (cited above).

2. Table V.A.1.a (Monitoring Frequency) shall be modified as follows:

   a) The monitoring frequency and the parameters listed for monitoring in years 2 and 3 shall be identical to that listed for year 4, such that the full list of parameters will be sampled in years 2, 3, and 4 at the frequency listed under YEAR 4.

   b) The parameter "Total Aqueous Hydrocarbons" will be substituted in the table for the parameter "Oil and Grease" (as discussed above).

   c) Delete "Other Water Quality Parameters" from the table.

B. **MISCELLANEOUS**

1. Copies of all reports required in the permit will be sent to the following ADEC offices:

   Alaska Department of Environmental Conservation
   Southcentral Regional Office
   3601 C Street, Suite 1334
   Anchorage, AK 99503
   (907) 563-6529

   Alaska Department of Environmental Conservation
   Anchorage Western District Office
   800 E. Dimond Blvd. #3-470
   Anchorage, Alaska 99515
   (907) 349-7755

2. In Part II.A.1., add the following statement: The permittee shall emphasize source reduction techniques as a means to reduce the discharge of pollutants. The permittee shall inform the lessees of the availability, through ADEC, of pollution prevention resources, technical assistance programs and other non-regulatory initiatives that will support the overall objective of eliminating the discharge of pollutants.

3. In Part II.B.11., add the following as paragraph (d): a program to promote, publicize and facilitate implementation of technologies and techniques to prevent pollution through source reduction and recycling.

PART V. MONITORING AND REPORTING REQUIREMENTS

A. Storm Event Monitoring

The permittee shall implement a wet-weather monitoring program for the MS4 to provide data necessary to: 1) assess the effectiveness and adequacy of control measures implemented under the SWMP; 2) estimate annual cumulative pollutant loadings from the MS4; 3) estimate event mean concentrations and seasonal pollutants in discharges from major outfalls; 4) identify and prioritize portions of the MS4 requiring additional controls; and, 5) identify water quality improvements or degradation.

1. *Representative Monitoring:*
   The permittee shall monitor representative outfalls and/or instream monitoring locations to characterize the quality of storm water discharges from the MS4.

   a. Monitoring Requirements: (See Table V.A.1.a).

   b. Outfall Descriptions: (See Table V.A.1.b)

2. *Wet Weather Screening Program:*
   The permittee shall implement a program to screen all areas contibuting storm water to the MS4 for the presence of excessive pollutants in discharges from the MS4. The wet weather screening program:

   a. Shall screen the entire MS4 at least once during the permit term.

   b. Shall specify the sampling and non-sampling techniques, parameters, collection techniques, and analytical methods to be used for initial screening purposes. For screening samples only, sample collection and analysis need not conform to the requirements of 40 CFR Part 136 and are not subject to the requirements of Paragraphs 3, 4, and 5 below.

Table V.A.1.a. - Monitoring Requirements for Outfalls 001, 002, and 003[1]

PARAMETER	MONITORING FREQUENCY				
	YEAR 1	YEAR 2	YEAR 3	YEAR 4	YEAR 5
Biochemical Oxygen Demand (BOD_5) (mg/l)	Once/year	Once/year	Once/year	Once/year	Once/year
Chemical Oxygen Demand (COD) (mg/l)	Once/year	Once/year	Once/year	Once/year	Once/year
Total Suspended Solids (TSS) (mg/l)	Once/year	Once/year	Once/year	Once/year	Once/year
Total Dissolved Solids (TDS) (mg/l)	Once/year	Once/year	Once/year	Once/year	Once/year
Total Nitrogen (mg/l)	Once/year	Once/year	Once/year	Once/year	Once/year
Total Kjeldahl Nitrogen (TKN) (mg/l)	Once/year	Once/year	Once/year	Once/year	Once/year
Total Phosphorus (mg/l)	---------	---------	---------	Once/year	---------
Dissolved Phosphorus (mg/l)	---------	---------	---------	Once/year	---------
Oil & Grease (mg/l)	Twice/year	Twice/year	Twice/year	Twice/year	Twice/year
Total Cadmium (ug/l)	---------	---------	---------	Once/year	---------
Total Copper (ug/l)	---------	Once/year	---------	Once/year	---------
Total Lead (ug/l)	---------	---------	---------	Once/year	---------
Total Zinc (ug/l)	---------	Once/year	---------	Once/year	---------
Ph (S.U.)	Twice/year	Twice/year	Twice/year	Twice/year	Twice/year
Hardness (as $CaCO_3$) (mg/l)	---------	---------	---------	Once/year	---------
Temperature (°C)	Twice/year	Twice/year	Twice/year	Twice/year	Twice/year

[1] This table represents the baseline monitoring requirements for the discharges and outfalls described in this permit. Some specific parameters and monitoring frequencies have have been modified pursuant to the special requirements as discussed in Part IV of this permit.

R0012904

Table V.A.1.b - Representative Monitoring Outfall Descriptions

OUTFALL	LOCATION	DESCRIPTION
001	Transit Area B	Storm water drain for Transit Area B. This area is 52.0 total acres with 16.2 acres of impervious surface.
002	Transit Area D and Transit Area A	Storm water drain for Transit Area D and a portion of Transit Area A. Transit Area D is 43.4 total acres and has 7.8 acres of impervious surface. This portion of Transit Area A has 55 total acres with 15 acres covered by impervious surface. The total acreage of impervious surface draining to outfall 002 is 22.8 acres.
003	Transit Area 12-B	Storm water drain for Transit Area 12-B. Area 12-B is 36.7 total acres with 16.8 acres of impervious surface.

c. Shall establish three monitoring locations for removal of floatable material in discharges from the MS4. The amount of material collected shall be estimated in cubic yards. Floatable material shall be measured periodically as necessary for maintenance of the removal device.

d. Shall submit, along with the system-wide report required by Part II.I, the following information:

(1) An estimate of the amount of floatable material collected (cubic yards);

(2) A summary of results and actions taken or proposed based on the results of the wet weather screening program.

e. Any monitoring location that collects an annual average of less than 3 cubic yards of floatables over any consecutive 3 calendar-year period during the permit term will no longer be considered a mandatory monitoring location. The Port must maintain at least one monitoring location for floatables regardless of the amount of floatables collected.

3. *Storm Event Data:*
Quantitative data shall be collected to estimate pollutant loadings and event mean concentrations for each parameter sampled. In addition to the parameters listed above, The Port shall maintain records on site of the date and duration (in hours) of the storm event(s) sampled; rainfall measurements or estimates (in inches) of the storm event which generated the sampled runoff; the duration between the storm event sampled and the end of the previous measurable (greater than 0.1 inch rainfall) storm event; and an estimate of the total volume (in gallons) of the discharge sampled.

4. *Sample Type, Collection, and Analysis:*
a. For discharges from storm water holding ponds or other storm water impoundments with a retention period greater than 24 hours, (estimated by dividing the volume of the detention pond by the estimated volume of water discharged during the 24 hours previous to the time that the sample is collected) a minimum of one grab sample may be taken.

b. Grab samples taken during the first two hours of discharge shall be used for the analysis (if required) of pH, temperature, cyanide, oil & grease, fecal coliform, fecal streptococcus, total phenols, residual chlorine, and volatile organics. For all other parameters, data shall be reported

for flow weighted composite samples of the entire event or, at a minimum, the first three hours of discharge.

c. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. Composite samples may be taken with a continuous sampler or as a combination of a minimum of three sample aliquots taken in each hour of discharge for the entire discharge or for the first three hours of the discharge, with each aliquot being separated by a minimum period of fifteen minutes.

d. Analysis and collection of samples shall be done in accordance the methods specified at 40 CFR Part 136. Where an approved Part 136 method does not exist, any available method may be used.

5. *Sampling Waiver:*
When a discharger is unable to collect samples due to adverse climatic conditions, the discharger must submit in lieu of sampling data a description of why samples could not be collected, including available documentation of the event. Adverse climatic conditions which may prohibit the collection of samples includes weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, extended frozen conditions, etc.). Dischargers are precluded from exercising this waiver more than once during a two year period.

B. **Dry Weather Monitoring**

1. *Dry Weather Screening Program:*
The permittee shall continue ongoing efforts to detect the presence of illicit connections and improper discharges to the MS4. All portions (but not necessarily all outfalls) of the MS4 must be screened at least once during the permit term, in accordance with the schedule set forth in PART III.A.

2. *Screening Procedures:*
Screening methodology may be developed and/or modified based on experience gained during actual field screening activities and need not conform to the protocol at 40 CFR 122.26(d)(1)(iv)(D).

3. *Follow-up on Dry Weather Screening Results:*
The permittee shall implement a program to locate and

eliminate suspected sources of illicit connections and improper disposal identified during dry weather screening activities. Follow-up activities may be prioritized on the basis of:

a. magnitude and nature of the suspected discharge;

b. sensitivity of the receiving water; and

c. other relevant factors.

C. **Certification and Signature of Reports**

1. All reports required by the permit and other information requested by the Director shall be signed and certified in accordance with Parts VII.H. & VII.I. of the permit.

D. **Reporting: Where to Submit**

1. Monitoring results obtained during each anual reporting period shall be submitted on Discharge Monitoring Report Form(s) and included with the annual system-wide reprt. A separate Discharge Monitoring Report Form is required for each event monitored. The first report may include less than twelve months of information.

2. Signed copies of discharge monitoring reports required under Part V., the System-Wide Report required by Part II.G., SWMP modifications and modification requests, requests for changes in monitoring outfalls and all other reports required herein, shall be submitted to:

U.S. EPA, Region 10
Wastewater Management and Enforcement Branch
Municipal Storm Water Permits (WD-135)
1200 Sixth Avenue
Seattle, Washington 98101

E. **Additional Notification**

1. Copies of the discharge monitoring reports required under Part V., the System-Wide Report required by Part II.G., and other reports requested by the State shall be submitted to:

Alaska Department of Environmental Conservation
Southcentral Regional Office
3601 C Street, Suite 1334
Anchorage, AK 99503
(907) 563-6529

Alaska Department of Environmental Conservation
Anchorage Western District Office
800 E. Dimond Blvd. #3-470
Anchorage, Alaska 99515
(907) 349-7755

F. **Retention of Records**

1. The permittee shall retain at The Port the latest approved version of the storm water management program developed in accordance with Part II of this permit until at least three years after coverage under this permit terminates. The permittee shall retain at The Port all records of all monitoring information, copies of all reports required by this permit, and records of all other data required by or used to demonstrate compliance with this permit, until at least three years after coverage under this permit terminates. This period may be explicitly modified by alternative provisions of this permit or extended by request of the Director at any time.

PART VI. STANDARD PERMIT CONDITIONS

A. Duty to Comply

1. The permittee must comply with all conditions of this permit insofar as those conditions are applicable to each permittee, either individually or jointly. Any permit noncompliance constitutes a violation of CWA and is grounds for enforcement action; for permit termination, revocation and reissuance, or modification; or for denial of a permit renewal application.

B. Penalties for Violations of Permit Conditions

1. Criminal

   a. Negligent Violations The CWA provides that any person who negligently violates permit conditions implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a fine of not less than $2,500 nor more than $25,000 per day of violation, or by imprisonment for not more than 1 year, or both.

   b. Knowing Violations The CWA provides that any person who knowingly violates permit conditions implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a fine of not less than $5,000 nor more than $50,000 per day of violation, or by imprisonment for not more than 3 years, or both.

   c. Knowing Endangerment The CWA provides that any person who knowingly violates permit conditions implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act and who knows at that time that he is placing another person in imminent danger of death or serious bodily injury is subject to a fine of not more than $250,000, or by imprisonment for not more than 15 year, or both.

   d. False Statement The CWA provides that any person who knowingly makes any false material statement, representation, or certification in any application, record, report, plan, or other document filed or required to be maintained under the Act or who knowingly falsifies, tampers with, or renders inaccurate, any monitoring device or method required to be maintained under the Act, shall upon conviction, be punished by a fine of not more than $10,000 or by imprisonment for not more than 2 years, or by both. If a conviction is for a violation committed after a first conviction of such person under this paragraph, punishment shall be by a fine of not more than $20,000 per day of violation, or by imprisonment of not more than 4

years, or by both. (See Section 309(c)(4) of the Clean Water Act).

2. Civil Penalties - The CWA provides that any person who violates a permit condition implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a civil penalty not to exceed $25,000 per day for each violation.

3. Administrative Penalties - The CWA provides that any person who violates a permit condition implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to an administrative penalty, as follows:

   a. Class I penalty Not to exceed $10,000 per violation nor shall the maximum amount exceed $25,000.

   b. Class II penalty Not to exceed $10,000 per day for each day during which the violation continues nor shall the maximum amount exceed $125,000.

C. **Duty to Reapply**
If the permittee wishes to continue an activity regulated by this permit after the permit expiration date, the permittee(s) must apply for and obtain a new permit. The application shall be submitted at least 180 days prior to expiration of this permit. The Administrator may grant permission to submit an application less than 180 days in advance but no later than the permit expiration date. Continuation of expiring permits shall be governed by regulations promulgated at 40 CFR 122.6 and any subsequent amendments.

D. **Need to halt or reduce activity not a defense**
It shall not be a defense for a permittee in an enforcement action that it would have been necessary to halt or reduce the permitted activity in order to maintain compliance with the conditions of this permit.

E. **Duty to Mitigate**
The permittee shall take all reasonable steps to minimize or prevent any discharge in violation of this permit which has a reasonable likelihood of adversely affecting human health or the environment.

F. **Duty to Provide Information**
The permittee shall furnish to the Administrator, within a time specified by the Director, any information which the

Administrator may request to determine compliance with this permit. The permittee shall also furnish to the Administrator upon request copies of records required to be kept by this permit.

G. **Other Information**
When the permittee becomes aware that he or she failed to submit any relevant facts or submitted incorrect information in any report to the Director, he or she shall promptly submit such facts or information.

H. **Signatory Requirements**
All Discharge Monitoring Reports, storm water pollution prevention plans, reports, certifications or information either submitted to the Administrator or that this permit requires be maintained by the permittee, shall be signed by:

1. either a principal executive officer or ranking elected official.

2. a duly authorized representative of that person. A person is a duly authorized representative only if:

   a. The authorization is made in writing by a person described above and submitted to the Director.

   b. The authorization specifies either an individual or a position having responsibility for the overall operation of the regulated facility or activity, such as the position of manager, operator, superintendent, or position of equivalent responsibility or an individual or position having overall responsibility for environmental matters for the company. (A duly authorized representative may thus be either a named individual or any individual occupying a named position).

   c. If an authorization is no longer accurate because a different individual or position has responsibility for the overall operation of the facility, a new notice of intent satisfying the requirements of this paragraph must be submitted to the Director prior to or together with any reports, information, or applications to be signed by an authorized representative.

I. **Certification**
Any person signing documents under this section shall make the following certification:

"I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gathered and evaluated the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations."

J. **Penalties for Falsification of Reports**
Section 309(c)(4) of the Clean Water Act provides that any person who knowingly makes any false material statement, representation, or certification in any record or other document submitted or required to be maintained under this permit, including reports of compliance or noncompliance shall, upon conviction, be punished by a fine of not more than $10,000, or by imprisonment for not more than 2 years, or by both.

K. **Penalties for Falsification of Monitoring Systems**
The CWA provides that any person who falsifies, tampers with, or knowingly renders inaccurate any monitoring device or method required to be maintained under this permit shall, upon conviction, be punished by fines and imprisonment described in Section 309 of the CWA.

L. **Oil and Hazardous Substance Liability**
Nothing in this permit shall be construed to preclude the institution of any legal action or relieve the permittee from any responsibilities, liabilities, or penalties to which the permittee is or may be subject under section 311 of the CWA or section 106 of CERCLA.

M. **Property Rights**
The issuance of this permit does not convey any property rights of any sort, nor any exclusive privileges, nor does it authorize any injury to private property nor any invasion of personal rights, nor any infringement of Federal, State or local laws or regulations.

N. **Severability**
The provisions of this permit are severable, and if any provision of this permit, or the application of any provision

of this permit to any circumstance, is held invalid, the application of such provision to other circumstances, and the remainder of this permit shall not be affected thereby.

O. **Requiring an individual permit**

1. The Administrator may require the permittee authorized by this permit to obtain an individual NPDES permit. Any interested person may petition the Administrator to take action under this paragraph. The Director may require any owner or operator authorized to discharge under this permit to apply for an individual NPDES permit only if the owner or operator has been notified in writing that a permit application is required. This notice shall include a brief statement of the reasons for this decision, an application form (as necessary), a statement setting a deadline for the owner or operator to file the application, and a statement that on the effective date of the individual NPDES permit, coverage under this permit shall automatically terminate. Individual permit applications shall be submitted to the address of the appropriate Regional Office shown in Part V.D. of this permit. The Administrator may grant additional time to submit the application upon request of the applicant. If an owner or operator fails to submit in a timely manner an individual NPDES permit application as required by the Administrator, then the applicability of this permit to the individual NPDES permittee is automatically terminated at the end of the day specified for application submittal.

2. Any owner or operator authorized by this permit may request to be excluded from the coverage of this permit by applying for an individual permit. The owner or operator shall submit an individual application as specified by 40 CFR 122.26(d) with reasons supporting the request to the Administrator. Individual permit applications shall be submitted to the address of the appropriate Regional Office shown in Part V.D. of this permit. The request may be granted by the issuance of a individual permit if the reasons cited by the owner or operator are adequate to support the request.

P. **State/Environmental Laws**

1. Nothing in this permit shall be construed to preclude the institution of any legal action or relieve the permittee from any responsibilities, liabilities, or penalties established pursuant to any applicable State law or regulation under authority preserved by section 510 of the Act.

2. No condition of this permit shall release the permittee from any responsibility or requirements under other environmental statutes or regulations.

Q. **Proper Operation and Maintenance**

The permittee shall at all times properly operate and maintain all facilities and systems of treatment and control (and related appurtenances) which are installed or used by the permittee to achieve compliance with the conditions of this permit and with the requirements of storm water pollution prevention plans. Proper operation and maintenance also includes adequate laboratory controls and appropriate quality assurance procedures. Proper operation and maintenance requires the operation of backup or auxiliary facilities or similar systems, installed by a permittee only when necessary to achieve compliance with the conditions of the permit.

R. **Monitoring and records**

1. Samples and measurements taken for the purpose of monitoring shall be representative of the monitored activity.

2. The permittee shall retain records of all monitoring information including all calibration and maintenance records and all original strip chart recordings for continuous monitoring instrumentation, copies of the reports required by this permit, and records of all data used to complete the application for this permit, for a period of at least 3 years from the date of the sample, measurement, report or application. This period may be extended by request of the Administrator at any time.

3. Records of monitoring information shall include:

   a. The date, exact place, and time of sampling or measurements;

   b. The initials or name(s) of the individual(s) who performed the sampling or measurements;

   c. The date(s) analyses were performed;

   d. The time(s) analyses were initiated;

   e. The initials or name(s) of the individual(s) who performed the analyses;

   f. References and written procedures, when available, for the analytical techniques or methods used; and

g. The results of such analyses, including the bench sheets, instrument readouts, computer disks or tapes, etc., used to determine these results.

S. **Monitoring Methods**
Monitoring must be conducted according to test procedures approved under 40 CFR Part 136, unless other test procedures have been specified in this permit.

T. **Inspection and Entry**
The permittee shall allow the Administrator or an authorized representative of EPA, or the State, upon the presentation of credentials and other documents as may be required by law, to:

1. Enter upon the permittee's premises where a regulated facility or activity is located or conducted or where records must be kept under the conditions of this permit;

2. Have access to and copy at reasonable times, any records that must be kept under the conditions of this permit; and,

3. Inspect at reasonable times any facilities or equipment (including monitoring and control equipment).

U. **Permit Actions**
This permit may be modified, revoked and reissued, or terminated for cause. The filing of a request by the permittee for a permit modification, revocation and reissuance, or termination, or a notification of planned changes or anticipated noncompliance does not stay any permit condition.

PART VII. PERMIT MODIFICATION

A. **Modification of the Permit**

The permit may be reopened and modified during the life of the permit to address:

1. changes in the State's Water Quality Management Plan, including Water Quality Standards;

2. changes in State or Federal statutes or regulations;

3. add a co-permittee who is the owner or operator of a portion of the MS4;

4. changes in portions of the storm water management program that are considered permit conditions; or

5. other modifications deemed necessary by the Administrator to meet the requirements of the Clean Water Act.

All modification to the permit will be made in accordance with 40 CFR 122.62, 122.63, and 124.5.

B. **Termination of Coverage for a Single Co-permittee**

Permit coverage may be terminated, in accordance with the provisions of 40 CFR 122.64 and 124.5, for a single co-permittee without terminating coverage for other co-permittees.

C. **Modification of Storm Water Management Program(s)**

Only those portions of the SWMPs specifically required as permit conditions shall be subject to the modification requirements of 40 CFR 124.5. Replacement of a failing BMP implementing a required component of the SWMP with an alternate BMP expected to provide at least the same level of performance initially expected of the failing BMP, shall be considered minor modifications to the permit and will be made in accordance with the procedures at 40 CFR 122.63.

D. **Changes in Monitoring Outfalls**

This permit is issued on a system-wide basis in accordance with CWA § 402(p)(3)(i) and authorizes discharges from all portions of the MS4. Since all outfalls are authorized, changes in monitoring outfalls, other than those with specific numeric effluent limitations, shall be considered minor modifications to the permit and will be made in accordance with the procedures at 40 CFR 122.63.

PART VIII. DEFINITIONS

"Administrator" means the Regional Administrator.

"Best Management Practices" ("BMPs") means schedules of activities, prohibitions of practices, maintenance procedures, and other management practices to prevent or reduce the pollution of waters of the United States. BMPs also include treatment requirements, operating procedures, and practices to control facility site runoff, spillage or leaks, sludge or waste disposal, or drainage from raw material storage.

"CWA" means Clean Water Act (formerly referred to as the Federal Water Pollution Control Act or Federal Water Pollution Control Act Amendments of 1972) Pub.L. 92-500, as amended Pub. L. 95-217, Pub. L. 95-576, Pub. L. (6-483 and Pub. L. 97-117, 33 U.S.C. 1251 et.seq.

"Co-permittee" means a permittee to a NPDES permit that is only responsible for permit conditions relating to the discharge for which it is operator.

"Director" means the Regional Administrator or an authorized representative.

"Discharge" for the purpose of this permit, unless indicated otherwise, refers to discharges from the Municipal Separate Storm Sewer System (MS4).

"Flow-weighted composite sample" means a composite sample consisting of a mixture of aliquots collected at a constant time interval, where the volume of each aliquot is proportional to the flow rate of the discharge.

"Illicit connection" means any man-made conveyance connecting an illicit discharge directly to a municipal separate storm sewer.

"Illicit discharge" means any discharge to a municipal separate storm sewer that is not composed entirely of storm water except discharges pursuant to a NPDES permit (other than the NPDES permit for discharges from the municipal separate storm sewer) and discharges resulting from fire fighting activities.

"Landfill" means an area of land or an excavation in which wastes are placed for permanent disposal, and which is not a land application unit, surface impoundment, injection well, or waste pile.

"Land application unit" means an area where wastes are applied onto or incorporated into the soil surface (excluding manure spreading operations) for treatment or disposal.

"MS4" is an acronym for "municipal separate storm sewer system" and is used to refer to either a Large or Medium Municipal Separate Storm Sewer System.

"Large or Medium municipal separate storm sewer system" means all municipal separate storm sewers that are either:

(i) located in an incorporated place (city) with a population of 100,000 or more as determined by the latest Decennial Census by the Bureau of Census (these cities are listed in Appendices F and G of 40 CFR Part 122); or

(ii) located in the counties with unincorporated urbanized populations of 100,000 or more, except municipal separate storm sewers that are located in the incorporated places, townships or towns within such counties (these counties are listed in Appendices H and I of 40 CFR Part 122); or

(iii) owned or operated by a municipality other than those described in paragraph (i) or (ii) and that are designated by the Director as part of the large or medium municipal separate storm sewer system.

"Municipal Separate Storm Sewer" means a conveyance, or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, man-made channels, or storm drains): (i) owned or operated by a State, city, town, borough, county, parish, district, association, or other public body (created by or pursuant to State Law) having jurisdiction over disposal of sewage, industrial wastes, storm water, or other wastes, including special districts under State Law such as a sewer district, flood control district or drainage district, or similar entity, or an Indian Tribe or an authorized Indian tribal organization, or a designated and approved management agency under section 208 of the CWA that discharges to waters of the United States; (ii) designed or used for collecting or conveying storm water; (iii) which is not a combined sewer; and (iv) which is not part of a Publicly Owned Treatment Works (POTW) as defined at 40 CFR 122.2.

"Point Source" means any discernible, confined, and discrete conveyance, including but not limited to, any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, landfill leachate collection system, vessel or other floating craft from which pollutants are or may be discharges. This term does not include return flows from irrigated agriculture or agricultural storm water runoff.

"Storm sewer", unless otherwise indicated, refers to a municipal separate storm sewer.

"Storm Water" means storm water runoff, snow melt runoff, and surface runoff and drainage.

"SWMP" is an acronym for "Storm Water Management Program."

"Time-weighted composite" means a composite sample consisting of a mixture of equal volume aliquots collected at a constant time interval.

"Waste pile" means any noncontainerized accumulation of solid, nonflowing waste that is used for treatment or storage.

"Waters of the United States" means:

(a) All waters which are currently used, were used in the past, or may be susceptible to use in interstate or foreign commerce, including all waters which are subject to the ebb and flow of the tide;
(b) All interstate waters, including interstate "wetlands";
(c) All other waters such as interstate lakes, rivers, streams (including intermittent streams), mudflats, sandflats, wetlands, sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds the use, degradation, or destruction of which would affect or could affect interstate or foreign commerce including any such waters:
(1) Which are or could be used by interstate or foreign travelers for recreational or other purposes;
(2) From which fish or shellfish are or could be taken and sold in interstate or foreign commerce; or
(3) Which are used or could be used for industrial purposes by industries in interstate commerce;
(d) All impoundments of waters otherwise defined as waters of the United States under this definition;
(e) Tributaries of waters identified in paragraphs (a) through (d) of this definition;
(f) The territorial sea; and
(g) Wetlands adjacent to waters (other than waters that are themselves wetlands) identified in paragraphs (a) through (f) of this definition.

Waste treatment systems, including treatment ponds or lagoons designed to meet the requirements of CWA are not waters of the United States. This exclusion applies only to manmade bodies of water which neither were originally created in waters of the United States (such as disposal areas in wetlands) nor resulted from the impoundment of waters of the United States.

NPDES Permit No. OKS000201

AUTHORIZATION TO DISCHARGE UNDER THE
NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM

In compliance with the provisions of the Clean Water Act, 33 U.S.C. 1251 *et seq.*, as amended by the Water Quality Act of 1987, P.L. 100-4, the "Act",

City of Tulsa
Department of Public Works
200 Civic Center
Tulsa, Oklahoma 74103

is(are) authorized to discharge, in accordance with the Storm Water Management Program(s), effluent limitations, monitoring requirements, and other provisions set forth in Parts I, II, III, IV, V, VI, VII, and VIII herein,

from all portions of the City of Tulsa Municipal Separate Storm Sewer System (MS4) owned or operated by any permittee listed above, to waters of the United States.

This permit will become effective October 1, 1994

This permit and the authorization to discharge under the National Pollutant Discharge Elimination System shall expire at midnight, on September 30, 1999

Signed this 26 day of August, 1994

Monica L. Burrell
Environmental Engineer
Municipal Section (6W-PM)

Myron O. Knudson, P.E.
Director
Water Management Division (6W)

R0012921

PART I. DISCHARGES AUTHORIZED UNDER THIS PERMIT.

A. **Permit Area.** This permit covers all areas located within the corporate boundary of the City of Tulsa that are served by municipal separate storm sewers owned or operated by the permittee(s).

B. **Authorized Discharges.**

1. Except for discharges prohibited under Part I.B.2, this permit authorizes all existing or new storm water point source discharges to waters of the United States from those portions of the Municipal Separate Storm Sewer System owned or operated by the permittee(s).

2. The following discharges, whether discharged separately or commingled with municipal storm water, are not authorized by this permit:

a. *Non-storm Water and Industrial Storm Water:* discharges of non-storm water; any Storm Water Discharge Associated with Industrial Activity; or other storm water discharges required to obtain an NPDES permit, except where such discharges are:

(1) regulated by a separate NPDES permit (or the discharger has applied for such permit); or

(2) identified by and in compliance with Part II.A.6.a.

b. *Spills:* discharges of material resulting from a spill. Where discharge of material resulting from a spill is necessary to prevent loss of life, personal injury, or severe property damage, the permittee(s) shall take, or insure the responsible party for the spill takes, all reasonable steps to minimize or prevent any adverse effects on human health or the environment. (See also Part II.A.7 and Part VI.E.) This permit does not transfer liability for a spill itself from the party(ies) responsible for the spill to the permittee(s) nor relieve the party(ies) responsible for a spill from the reporting requirements of 40 CFR Part 117 and 40 CFR Part 302.

C. **Permittee Responsibilities.**

1. Each permittee is responsible for:

a. Compliance with permit conditions relating to discharges from portions of the Municipal Separate Storm Sewer System where the permittee is the operator;

b. Storm Water Management Program implementation on portions of the Municipal Separate Storm Sewer System where the permittee is the operator;

c. Compliance with annual reporting requirements as specified in Part V.C.;

d. Collection of representative wet weather monitoring data required by Part V.A., according to such agreements as may be established between permittees; and

e. A plan of action to assume responsibility for implementation of storm water management and monitoring programs on their portions of the Municipal Separate Storm Sewer System should interjurisdictional agreements allocating responsibility between permittees be dissolved or in default.

2. Permittees are jointly responsible for permit compliance on portions of the Municipal Separate Storm Sewer System where operational or Storm Water Management Program implementation authority over portions of the Municipal Separate Storm Sewer System is shared or has been transferred from one permittee to another in accordance with legally binding agreements.

D. **Discharge Goals.**

The following goals are established for discharges from the Municipal Separate Storm Sewer System:

1. No discharge of toxics in toxic amounts.

2. No discharge of pollutants in quantities that would cause a violation of State Water Quality Standards.

3. No discharge of floatable debris, oils, scum, foam, or grease in other than trace amounts.

4. No discharge of non-storm water from the municipal separate storm sewer system (except as provided in Part I.B.2.).

5. No degradation or loss of State-designated beneficial uses of receiving waters as a result of storm water discharges from the municipal separate storm sewer (unless authorized by the State in accordance with the State's Antidegradation Policy).

PART II. STORM WATER POLLUTION PREVENTION & MANAGEMENT PROGRAM(S).

Each permittee shall contribute to the development, revision and implementation of a comprehensive Storm Water Management Program including pollution prevention measures, treatment or removal techniques, storm water monitoring, use of legal authority, and other appropriate means to control the quality of storm water discharged from the Municipal Separate Storm Sewer System. The Storm Water Management Program shall be implemented in accordance with Section 402(p)(3)(B) of the Act, and the Storm Water Regulations (40 CFR Part 122.26).

Controls and activities in the Storm Water Management Program shall identify areas of permittee responsibility on a jurisdiction, applicability, or specific area basis. The Storm Water Management Program shall include controls necessary to effectively prohibit the discharge of non-storm water into municipal separate storm sewers and reduce the discharge of pollutants from the Municipal Separate Storm Sewer System to the Maximum Extent Practicable (MEP).

The Storm Water Management Program shall cover the term of this permit and shall be updated as necessary, or as required by the Director, to ensure compliance with the statutory requirements of Section 402(p)(3)(B) of the Act. Modifications to the Storm Water Management Program shall be made in accordance with Parts II.G., and III. Compliance with the Storm Water Management Program and any schedules in Part III. shall be deemed compliance with Parts II.A, and II.B. The Storm Water Management Program, and all updates made in accordance with Part II.G., are hereby incorporated by reference.

Implementation of the Storm Water Management Program may be achieved through participation with other permittees, public agencies, or private entities in cooperative efforts to satisfy the requirements of Part II. in lieu of creating duplicate program elements for each individual permittee. The Storm Water Management Program, taken as a whole, shall achieve the "effective prohibition on the discharge of non-storm water" and "MEP" standards from Section 402(p)(3)(B) of the Act.

A. <u>Storm Water Management Program Requirements.</u>

1. *Structural Controls and Storm Water Collection System Operation:* The Municipal Separate Storm Sewer System and any storm water structural controls shall be operated in manner to reduce the discharge of pollutants to the Maximum Extent Practicable.

2. *Areas of New Development and Significant Redevelopment:* A comprehensive master planning process (or equivalent) to develop, implement, and enforce controls to minimize the discharge of pollutants from areas of new development and significant re-development after construction is completed shall be implemented. The goals of such controls shall be:

   a. New development - limiting increases in the discharge of pollutants in storm water as a result of development, and

   b. Re-development - reducing the discharge of pollutants in storm water.

3. *Roadways:* Public streets, roads, and highways shall be operated and maintained in a manner to minimize discharge of pollutants, including those pollutants related to deicing or sanding activities.

4. *Flood Control Projects:* Impacts on receiving water quality shall be assessed for all flood management projects. The feasibility of retro-fitting existing structural flood control devices to provide additional pollutant removal from storm water shall be evaluated.

5. *Pesticide, Herbicide, and Fertilizer Application:* Each permittee shall implement controls to reduce the discharge of pollutants related to the permittee's storage and application of pesticides, herbicides, and fertilizers. Permittees with jurisdiction over lands not directly owned by that entity (e.g. incorporated city with authority over activities occurring anywhere within their city limits) shall also implement programs to reduce the discharge of pollutants related to commercial application and distribution of pesticides, herbicides, and fertilizers.

6. *Illicit Discharges and Improper Disposal:* Non-storm water discharges to the municipal separate storm sewer system shall be effectively prohibited.

   a. In accordance with 40 CFR 122.26(d)(2)(iv)(B)(1), certain non-storm water discharges to the municipal separate storm sewer system need not be addressed as illicit discharges or improper disposal. The Storm Water Management Program shall identify any non-storm water discharges that the permittee(s) does not prohibit, along with any conditions placed on such non-storm water discharges to the municipal separate storm sewer system. The permittee(s) shall prohibit, on a case-by-case basis, any individual non-storm water discharge (or class of non-storm water discharges) otherwise allowed under this paragraph that is determined to be contributing significant amounts of pollutants to the municipal separate storm sewer system.

   b. Each permittee shall prevent (or require the operator of the sanitary sewer to eliminate) unpermitted discharges of dry and wet weather overflows from sanitary sewers into the Municipal Separate Storm Sewer System. Each permittee shall limit the infiltration of seepage from sanitary sewers into the Municipal Separate Storm Sewer System.

   c. The permittee(s) shall ensure the implementation of a program to reduce the discharge of floatables (e.g. litter and other human-generated solid refuse). The floatables control program shall include source controls and, where necessary, structural controls.

   d. The discharge or disposal of used motor vehicle fluids, household hazardous wastes, grass clippings, leaf litter, and animal wastes into separate storm sewers shall be prohibited. The permittee(s) shall ensure the implementation of programs to collect used motor vehicle fluids (at a minimum, oil and antifreeze) for recycle, reuse, or proper disposal and to collect household hazardous waste materials (including paint, solvents, pesticides, herbicides, and other hazardous materials) for recycle, reuse, or proper disposal. Such programs shall be readily available to all private residents and shall be publicized and promoted on a regular basis.

   e. A program to locate and eliminate illicit discharges and improper disposal into the Municipal Separate Storm Sewer System shall be implemented. This program shall include dry

weather screening activities to locate portions of the Municipal Separate Storm Sewer System with suspected illicit discharges and improper disposal. Follow-up activities to eliminate illicit discharges and improper disposal may be prioritized on the basis of magnitude and nature of the suspected discharge; sensitivity of the receiving water; and/or other relevant factors. This program shall establish priorities and schedules for screening the entire Municipal Separate Storm Sewer System at least once per five years. The permittee(s) shall utilize a consistent method (e.g. by land area, by outfall, etc.) for determining the percentage of the municipal separate storm sewer system that has been screened. Facility inspections may be carried out in conjunction with other municipal programs (e.g. pretreatment inspections of industrial users, health inspections, fire inspections, etc.), but must include random inspections for facilities not normally visited by the municipality.

f. Each permittee shall require the elimination of illicit discharges and improper disposal practices as expeditiously as reasonably possible. Where elimination of an illicit discharge within thirty (30) days is not possible, the permittee shall require an expeditious schedule for removal of the discharge. In the interim, the permittee shall require the operator of the illicit discharge to take all reasonable and prudent measures to minimize the discharge of pollutants to the Municipal Separate Storm Sewer System.

g. The permittee(s) shall maintain, and update as necessary, a list of discharges to municipal separate storm sewers that has been issued a NPDES permit. The list shall include the name, location and NPDES permit number of the discharger.

7. *Spill Prevention and Response:* A program to prevent, contain, and respond to spills that may discharge into the Municipal Separate Storm Sewer System shall be implemented. The spill response program may include a combination of spill response actions by the permittee(s) (and/or another public or private entity), and legal requirements for private entities within the permittee's municipal jurisdiction.

8. *Industrial & High Risk Runoff:* A program to identify and control pollutants in storm water discharges to the Municipal Separate Storm Sewer System from municipal landfills; other treatment, storage, or disposal facilities for municipal waste (e.g. transfer stations, incinerators, etc.); hazardous waste treatment, storage, disposal and recovery facilities; facilities that are subject to EPCRA Title III, Section 313; and any other industrial or commercial discharge the permittee(s) determines are contributing a substantial pollutant loading to the Municipal Separate Storm Sewer System shall be implemented. The program shall include:

a. priorities and procedures for inspections and establishing and implementing control measures for such discharges;

b. a monitoring program (Part II.A.11.c.); and

c. a list of industrial storm water sources discharging to the Municipal Separate Storm Sewer System shall be maintained and update as necessary.

9. *Construction Site Runoff:* A program to reduce the discharge of pollutants from constructions sites shall be implemented. This program shall include:

   a. requirements for the use and maintenance of appropriate structural and nonstructural best management practices to reduce pollutants discharged to the Municipal Separate Storm Sewer System during the time construction is underway;

   b. inspection of construction sites and enforcement of control measures (in accordance with priorities and procedures established in the Storm Water Management Program);

   c. appropriate education and training measures for construction site operators; and

   d. notification of appropriate building permit applicants of their potential responsibilities under the NPDES permitting program for construction site runoff.

10. *Public Education:* A public education program with the following elements shall be implemented:

   a. a program to promote, publicize, and facilitate public reporting of the presence of illicit discharges or improper disposal of materials, including floatables, into the Municipal Separate Storm Sewer System;

   b. a program to promote, publicize, and facilitate the proper management and disposal of used motor vehicle fluids and household hazardous wastes.

   c. a program to promote, publicize, and facilitate the proper use, application, and disposal of pesticides, herbicides, and fertilizers by the public and commercial and private applicators and distributors.

11. *Monitoring Programs:* The following monitoring programs shall be implemented in addition to the monitoring required by Part V.:

   a. The *Dry Weather Screening Program* shall continue ongoing efforts to detect the presence of illicit connections and improper discharges to the Municipal Separate Storm Sewer System. All areas of the Municipal Separate Storm Sewer System must be screened at least once during the permit term. Screening methodology may be modified based on experience gained during actual field screening activities and need not conform to the protocol at 40 CFR 122.26(d)(1)(iv)(D). Sample collection and analysis need not conform to the requirements of 40 CFR Part 136. However, samples taken to <u>confirm</u> (e.g. in support of possible legal action) a particular illicit connection or improper disposal practice should conform to the requirements of 40 CFR Part 136.

b. *Wet Weather Screening Program:* The permittee(s) shall identify, investigate, and address areas within their jurisdiction that may be contributing excessive levels of pollutants to the Municipal Separate Storm Sewer System. The wet weather screening program:

(1) shall screen the Municipal Separate Storm Sewer System, in accordance with the procedures specified in the Storm Water Management Program.

(2) shall specify the sampling and non-sampling techniques to be used for initial screening and follow-up purposes. Sample collection and analysis need not conform to the requirements of 40 CFR Part 136. However, samples taken to confirm (e.g. in support of possible legal action) a particular discharger is a source of significant quantities of pollutants should conform to the requirements of 40 CFR Part 136.

c. The *Industrial and High Risk Runoff Monitoring Program* shall include monitoring for pollutants in storm water discharges to the Municipal Separate Storm Sewer System from municipal landfills; other treatment, storage, or disposal facilities for municipal waste (e.g. transfer stations, incinerators, etc.); hazardous waste treatment, storage, disposal and recovery facilities; facilities that are subject to EPCRA Title III, Section 313; and any other industrial or commercial discharge the permittee(s) determines are contributing a substantial pollutant loading to the Municipal Separate Storm Sewer System.

(1) Except as provided in (2) below, the monitoring program shall including the collection of quantitative data on the following constituents:

(a) any pollutants limited in an existing NPDES permit for a subject facility;
(b) oil and grease;
(c) chemical oxygen demand (COD);
(d) pH;
(e) biochemical oxygen demand, five-day (BOD_5);
(f) total suspended solids (TSS);
(g) total phosphorous;
(h) total Kjeldahl nitrogen (TKN);
(i) nitrate plus nitrite nitrogen; and
(j) any information on discharges required under 40 CFR 122.21(g)(7)(iii) and (iv).

Data collected by the industrial facility to satisfy the monitoring requirements of an NPDES or State discharge permit may be used to satisfy this requirement. Permittee(s) may require the industrial facility to conduct self-monitoring to satisfy this requirement.

(2) **Alternative Certification:** In lieu of monitoring, the permittee may accept a certification from a facility that raw and waste materials, final and intermediate products, by-products, material handling equipment or activities, industrial machinery or operations, or significant materials from past industrial activity are not presently exposed to storm water and are not expected to be exposed to storm water for the certification period. Where the permittee(s)

accept a "no exposure" certification, the permittee(s) shall conduct at least one site inspection of the facility every five years to verify the "no exposure" exemption.

B. Area-specific Storm Water Management Program Requirements. Reserved.

C. Deadlines for Program Implementation. Except as provided in Part III., full implementation of the Storm Water Management Program shall begin within 90 days from the effective date of the permit.

D. Roles and Responsibilities of Permittee(s). The Storm Water Management Program, together with any attached interagency agreements, shall clearly identify the roles and responsibilities of each permittee.

E. Legal Authority. Each permittee shall ensure legal authority to control discharges to and from those portions the Municipal Separate Storm Sewer System over which it has jurisdiction. This legal authority may be a combination of statute, ordinance, permit, contract, order or inter-jurisdictional agreements with permittees with existing legal authority to:

1. Control the contribution of pollutants to the Municipal Separate Storm Sewer System by Storm Water Discharges Associated with Industrial Activity and the quality of storm water discharged from sites of industrial activity;

2. Prohibit illicit discharges to the Municipal Separate Storm Sewer System;

3. Control the discharge of spills and the dumping or disposal of materials other than storm water (e.g. industrial and commercial wastes, trash, used motor vehicle fluids, leaf litter, grass clippings, animal wastes, etc.) into the Municipal Separate Storm Sewer System;

4. Control through interagency or interjurisdictional agreements among permittees the contribution of pollutants from one portion of the Municipal Separate Storm Sewer System to another;

5. Require compliance with conditions in ordinances, permits, contracts or orders; and

6. Carry out all inspection, surveillance and monitoring procedures necessary to determine compliance with permit conditions.

F. Storm Water Management Program Resources. Each permittee shall provide adequate finances, staff, equipment, and support capabilities to implement their activities under the Storm Water Management Program.

G. Storm Water Management Program Review and Update.

1. *Storm Water Management Program Review:* Each permittee shall participate in an annual review of the current Storm Water Management Program in conjunction with preparation of the annual report required under Part V.C.

2. *Storm Water Management Program Update:* The permittee(s) may change the Storm Water Management Program during the life of the permit in accordance with the following procedures:

   a. The approved Storm Water Management Program shall not be changed by the permittee(s) without the approval of the Director, unless in accordance with Parts II.G.2.b. and 2.c.

b. Changes adding (but not subtracting or replacing) components, controls, or requirements to the Storm Water Management Program may be made by the permittee(s) at any time upon written notification to the Director.

c. Changes replacing an ineffective or unfeasible BMP specifically identified in the Storm Water Management Program with an alternate BMP may be requested at any time. Unless denied by the Director, changes proposed in accordance with the criteria below shall be deemed approved and may be implemented by the permittee(s) 60 days from submittal of the request. Such requests shall include the following:

(1) an analysis of why the BMP is ineffective or infeasible (including cost prohibitive),

(2) expectations on the effectiveness of the replacement BMP, and

(3) an analysis of why the replacement BMP is expected to achieve the goals of the BMP to be replaced.

d. Changes resulting from schedules contained in Part III. may be requested following completion of an interim task or final deadline. Unless denied by the Director, proposed changes meeting the criteria contained in the applicable Part III schedule shall be deemed approved and may be implemented by the permittee(s) 60 days from submittal date.

e. Change requests and/or notifications shall be made in writing, signed in accordance with Part VI.H. by all directly affected permittees, and include a certification that all permittees were given an opportunity to comment on proposed changes.

3. *Updates Required by the Permitting Authority:* The permitting authority may require changes to the Storm Water Management Program as needed to:

a. address impacts on receiving water quality caused, or contributed to, by discharges from the Municipal Separate Storm Sewer System;

b. include more stringent requirements necessary to comply with new State or Federal statutory or regulatory requirements; or

c. include such other conditions deemed necessary by the Director to comply with the goals and requirements of the Act.

Changes requested by the Director shall be made in writing, set forth the time schedule for the permittee(s) to develop the changes, and offer the permittee(s) the opportunity to propose alternative program changes to meet the objective of the requested modification. All changes required by the Director shall be made in accordance with 40 CFR 124.5, 40 CFR 122.62, or as appropriate 40 CFR 122.63.

4. *Transfer of Ownership, Operational Authority, or Responsibility for Storm Water Management Program Implementation:* The permittee(s) shall implement the Storm Water Management Program on all new areas added to their portion of the municipal separate storm sewer system (or for which they become responsible for implementation of storm water quality controls) as expeditiously as practicable, but not later than three years from addition of the new areas. Implementation may be accomplished in a phased manner to allow additional time for controls that cannot be implemented immediately.

   Prior to land annexation, the permittee(s) shall include a schedule for extending the Storm Water Management Program to the annexed areas in the Storm Water Management Program. At least 30 days prior to transfer of operational authority or responsibility for Storm Water Management Program implementation, all parties shall prepare a schedule for transfer of responsibility for Storm Water Management Program implementation on the affected portions of the Municipal Separate Storm Sewer System.

H. **Retention of Storm Water Management Program Records.** The permittee shall retain the Storm Water Management Program developed in accordance with Parts II. and III. for at least 3 years after coverage under this permit terminates.

PART III. SCHEDULES FOR IMPLEMENTATION AND COMPLIANCE

The Permittee(s) shall comply with the following schedules for Storm Water Management Program implementation and augmentation, and permit compliance.

A. Implementation and Augmentation of Storm Water Management Program(s)

STORM WATER MANAGEMENT PROGRAM COMPONENT	ACTIVITY	DATE DUE/FREQUENCY
1. New & Re-Development	a. Adoption of the Storm water Management Criteria Manual or another construction storm water runoff control program.	January 1, 1995
	b. Implementation of the Stormwater Management Criteria or another construction storm water runoff control program.	February 1, 1995
2. Household Hazardous Waste	a. Provide summary of evaluation and assessment of results from various collection/recycling/safe disposal program options, including those currently underway, to determine the most applicable program for long term use which meets criteria specified in b. below.	July 1, 1996
	b. Develop collection/recycling/safe disposal program which includes periodic collection events and should ensure a publicly available drop off location(s) that provides for occasional long weekday hours, or weekend operations.	August 1, 1996
	c. Implement collection/recycling/safe disposal program.	August 1, 1997

R0012932

STORM WATER MANAGEMENT PROGRAM COMPONENT	ACTIVITY	DATE DUE/FREQUENCY
3. Floatables	a. Implement public education program.	January 1, 1995
	b. Install two floatables monitoring locations.	May 1, 1995
	c. Complete study for targeting of structural controls and develop schedule for implementation.	May 1, 1996
4. Illicit Discharges and Improper Disposal	a. Implement public education program.	January 1, 1995
	b. Complete dry weather screening of 20% of MS4.	June 1, 1995
	c. Complete dry weather screening of 40% (cumulative) of MS4	June 1, 1996
	d. Complete dry weather screening of 60% (cumulative) of MS4	June 1, 1997
	e. Complete dry weather screening of 80% (cumulative) of MS4	June 1, 1998
	f. Complete dry weather screening of 100% (cumulative) of MS4	June 1, 1999
5. Legal Authority	a. Adopt comprehensive Storm Water Ordinance	July 1, 1996
6. Wet Weather Screening Program	a. Update SWMP to include wet weather screening program.	July 1, 1995
	b. Complete wet weather screening of 50% of MS4.	July 1, 1997
	c. Complete wet weather screening of 100% (cumulative) of MS4.	July 1, 1999

R0012933

STORM WATER MANAGEMENT PROGRAM COMPONENT	ACTIVITY	DATE DUE/FREQUENCY
7. Flood Control Projects	a. Complete evaluation of existing flood control structures for feasible water quality retrofit projects.	October 1, 1998
	b. Complete schedule for proposed water quality retrofits to existing flood control structures.	November 1, 1998
8. Industrial and High Risk	a. Develop program to identify, monitor, and control pollutants from targeted facilities	July 1, 1995
	b. Implement program	July 1, 1996
9. Pesticide, Herbicide, and Fertilizer Application	a. Implement annual training/education on pesticide and fertilizer management techniques.	January 1, 1995
	b. Establish requirement for commercial pesticide applicators to be licensed under the Oklahoma Pesticide Applicators Law.	April 1, 1995

R0012934

B. **Compliance with effluent limitations.** Reserved.

C. **Reporting compliance with schedules.** No later than 14 days following a date for a specific action (interim milestone or final deadline) identified in the above schedule(s), the permittee(s) shall submit a written notice of compliance or noncompliance to the Director in accordance with Parts V.E.

D. **Updating Storm Water Management Program.** The permittee(s) shall update the Storm Water Management Program(s), as appropriate, in response to changes required by Part III.A. Such updates shall be made in accordance with Part II.G.2.

PART IV. DISCHARGE LIMITATIONS.

...RESERVED...

PART V. MONITORING AND REPORTING REQUIREMENTS.

A. Storm Event Discharges.

1. *Representative Monitoring:* Monitoring shall be conducted on representative outfalls, internal sampling stations, and/or instream monitoring locations to characterize the quality of storm water discharges from the Municipal Separate Storm Sewer System.

   a. Monitoring Requirements: Refer to Table(s) V.A.1.a(1).

   b. Outfall Descriptions: Refer to Table V.A.1.b.

   c. Alternate representative monitoring locations may be substituted for just cause during the term of the permit. Requests for approval of alternate monitoring locations shall be made to the Director in writing and include the rationale for the requested monitoring station relocation. Unless disapproved by the Director, use of an alternate monitoring location (except for outfalls with numeric effluent limitations) may commence 30 days from the date of the request. For outfalls where numeric effluent limitations have been established, the permit must be modified prior to substitution of alternate monitoring locations. Six samples shall be collected during the first year of monitoring at substitute outfalls.

Table V.A.1.a.(1) - Representative Monitoring Requirements: Outfalls 001, 002, 003, 003, 004, & 005

PARAMETERS	REPORT FOR EACH MONITORING PERIOD (each sample type)			SAMPLE TYPE(S)		MONITORING FREQUENCY[1]
	Minimum	Average	Maximum	Grab	Composite	
Biochemical Oxygen Demand (BOD_5) (mg/l)		Yes	Yes		Yes	1/season[2]
Chemical Oxygen Demand (COD) (mg/l)		Yes	Yes		Yes	1/season
Oil and Grease (mg/l)		Yes	Yes	Yes		1/season
Total Suspended Solids (TSS) (mg/l)		Yes	Yes		Yes	1/season
Total Dissolved Solids (TDS) (mg/l)		Yes	Yes		Yes	1/season
Total Nitrogen (mg/l)		Yes	Yes		Yes	1/season
Total Kjeldahl Nitrogen (TKN) (mg/l)		Yes	Yes		Yes	1/season
Total Phosphorus (mg/l)		Yes	Yes		Yes	1/season
Dissolved Phosphorus (mg/l)		Yes	Yes		Yes	1/season
Total Cadmium (ug/l)		Yes	Yes		Yes	1/season
Total Copper (ug/l)		Yes	Yes		Yes	1/season
Total Lead (ug/l)		Yes	Yes		Yes	1/season
Total Zinc (ug/l)		Yes	Yes		Yes	1/season
Fecal Coliform (colonies/100 ml)		Yes	Yes	Yes		1/season
pH (S.U.)	Yes		Yes	Yes		1/season
Hardness (as $CaCO_3$) (mg/l)	Yes	Yes	Yes	Yes		1/season
Temperature (°C)	Yes	Yes	Yes	Yes		1/season

R0012938

PARAMETERS	REPORT FOR EACH MONITORING PERIOD (each sample type)			SAMPLE TYPE(S)		MONITORING FREQUENCY[1]
	Minimum	Average	Maximum	Grab	Composite	
Diazinon (ug/l)		Yes	Yes	Yes	Yes	1/season
Total Phenol (mg/l)[3]		Yes	Yes	Yes		1/season

[1] Monitoring frequency for each year unless monitoring under Alternative Bioassessment Option (See Part V.A.2.)
[2] Seasonal monitoring periods are: **July - October, November - February, and March - June.**
[3] Total Phenol shall be monitored only at outfall 002.

R0012939

Table V.A.1.b - Representative Monitoring Outfall Descriptions

OUTFALL	LOCATION	DESCRIPTION	RESPONSIBLE PERMITTEE
001	2400 26th Street East, 200 feet west of Lewis Avenue and 5 ft south of 26th Street	100% old residential, drains 39.3 acres	City of Tulsa
002	11th Street (Southwest Blvd.), on the east bank of the Arkansas River, 50 ft north of the old 11th St. Bridge	Old commercial area, drains approximately 14.7 acres	City of Tulsa
003	71st Street East @ Joe Creek, 50 ft. south of 71st Street on the west bank of Joe Creek	100% New Commercial, drains 15.1 acres	City of Tulsa
004	54th Street East @ Mingo Creek, on the west bank of Mingo Creek at the end of 54th Street	100% Industrial, drains 25.0 acres	City of Tulsa
005	9717 58th Street East, directly north of 9717 E. 58th Street on the south bank of Mingo Creek	100% Industrial, drains 23.0 acres	City of Tulsa

R0012940

2. *Representative Monitoring - Rapid Bioassessment Option:* The permittee(s) has the option of developing and implementing a rapid bioassessment monitoring program.

   a. The permittee(s) shall obtain all necessary aquatic wildlife collection permits from appropriate State and/or Federal agencies (e.g. State Fish and Game Commission).

   b. Permittee(s) utilizing the rapid bioassessment monitoring option shall conduct monitoring of the separate storm sewer system as described in Part V.A.1., except the monitoring for years 2, 3, and 5 are no longer required. All other requirements of Part V.A.1., A.3., and A.4. (e.g.: samples types, parameters,...) remain unchanged.

   c. If the permittee(s) elects to develop and implement a rapid bioassessment monitoring program, the permittee(s) shall submit an approvable monitoring program to EPA no later than one year from the effective date of this permit. An approvable program must include:

      (1) monitoring of at least two waterbodies receiving storm water discharges from the municipal separate storm sewer system plus a reference site located within the same ecological region as the municipal separate storm sewer system;

      (2) monitoring of each station at least twice per year, with monitoring conducted at essentially the same time periods each year; and

      (3) concurrent (e.g. within a day or two) monitoring of the reference site each time a station located in the receiving waters of the municipal separate storm sewer system is monitored.

      Unless disapproved by the Director within 60 days, a proposed rapid bioassessment monitoring plan meeting the criteria herein shall be deemed approved and the permittee(s) may implement the alternate rapid bioassessment program.

   d. The permittee(s) shall notify the Director and State (addresses provided in Part V.E.), in writing, at least 14 days prior to commencing an alternate rapid bioassessment monitoring program.

3. *Storm Event Data:* For Part V.A.1. and any additional sampling conducted for Part V.A.6., quantitative data shall be collected to estimate pollutant loadings and event mean concentrations for each parameter sampled. Records shall be maintained of all analytical results, the date and duration (in hours) of the storm event(s) sampled; rainfall measurements or estimates (in inches) of the storm event which generated the sampled runoff; the duration (in hours) between the storm event sampled and the end of the previous measurable (greater than 0.1 inch rainfall) storm event; and an estimate of the total volume (in gallons) of the discharge sampled.

4. *Sample Type, Collection, and Analysis:* The following requirements apply only to samples collected for Part V.A.1 and any additional sampling conducted for Part V.A.6.

a. For discharges from holding ponds or other impoundments with a retention period greater than 24 hours, (estimated by dividing the volume of the detention pond by the estimated volume of water discharged during the 24 hours previous to the time that the sample is collected) a minimum of one grab sample may be taken.

b. Grab samples taken within the first two hours of discharge shall be used for the analysis (if required) of pH, temperature, cyanide, oil & grease, fecal coliform, fecal streptococcus, total phenols,residual chlorine, and (at the permittee's option) volatile organics. For all other parameters, data shall be reported for flow weighted composite samples of the entire event or, at a minimum, the first three hours of discharge.

c. Samples shall be collected from the discharge resulting from a representative storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. Composite samples may be taken with a continuous sampler or as a combination of a minimum of three sample aliquots taken in each hour of discharge for the entire discharge or for the first three hours of the discharge, with each aliquot being separated by a minimum period of fifteen minutes.

The required 72 hour storm event interval is waived where the preceding measurable storm event did not result in a measurable discharge. The required 72 hour storm event interval may also be waived where the permittee(s) documents that less than a 72 hour interval is representative for local storm events during the season when sampling is being conducted.

d. Analysis and collection of samples shall be done in accordance the methods specified at 40 CFR Part 136. Where an approved Part 136 method does not exist, any available method may be used unless a particular method or criteria for method selection (such as sensitivity) has been specified in the permit.

5. *Seasonal Loadings and Event Mean Concentrations.* All necessary sampling data shall be collected to provide estimates for each major outfall of seasonal pollutant loadings and event mean concentrations for a representative storm event for the parameters listed in Table V.A.1.a.(1) - Representative Monitoring Requirements. This information may be estimated from the representative monitoring locations and shall take into consideration land uses and drainage areas for the outfall. The estimates of seasonal loadings and event mean concentrations shall be included in the Annual Report for year four of the permit.

B. Floatables Monitoring.

Shall establish two monitoring locations for removal of floatable material in discharges to or from the Municipal Separate Storm Sewer System. Floatable material shall be collected at the frequency necessary for maintenance of the removal devices, but not less that twice per year. The amount of material collected shall be estimated in cubic yards.

C. **Annual Report.** Each permittee shall contribute to the preparation of an annual system-wide report to be submitted by no later than October 15, 1995, and annually thereafter by October 15th in accordance with this permit. The report shall cover the previous year from July 1 to June 30 (with first annual report period beginning on the effective date of the permit) and include the following separate sections, with an overview for the entire Municipal Separate Storm Sewer System and subsections for each permittee:

1. The status of implementing the storm water management program(s) (status of compliance with any schedules established under this permit shall be included in this section);

2. Proposed changes to the storm water management program(s) ;

3. Revisions, if necessary, to the assessments of controls and the fiscal analysis reported in the permit application under 40 CFR 122.26(d)(2)(iv) and (d)(2)(v);

4. A summary of the data, including monitoring data, that is accumulated throughout the reporting year;

5. Annual expenditures for the reporting period, with a breakdown for the major elements of the storm water management program, and the budget for the year following each annual report;

6. A summary describing the number and nature of enforcement actions, inspections, and public education programs; and

7. Identification of water quality improvements or degradation.

Preparation and submittal of a system-wide annual report shall be coordinated by the city of Tulsa. The report shall indicate which, if any, permittees have failed to provide required information on the portions of the Municipal Separate Storm Sewer System for which they are responsible to the core municipality by 45 days prior to the report due date. Joint responsibility for report submission shall be limited to participation in preparation of the overview for the entire system and inclusion of the identity of any permittee who failed to provide input to the annual report. Each individual permittee shall be individually responsible for content of the report relating to the portions of the Municipal Separate Storm Sewer System for which they are responsible and for failure to provide information for the system-wide annual report in a timely manner. Each permittee shall sign and certify the annual report in accordance with Part VI.H. and include a statement or resolution that the permittee's governing body or agency (or delegated representative) has reviewed or been appraised of the content of the Annual Report.

D. **Certification and Signature of Reports.** All reports required by the permit and other information requested by the Director shall be signed and certified in accordance with Part VI.H.

E. **Reporting: Where and When to Submit.**

1. Representative monitoring results (Part V.A.1) obtained during the reporting period running from July 1 to June 30 shall be submitted on Discharge Monitoring Report Form(s) no later than the due date for the annual report required by Part V.C.. The Discharge Monitoring Reports should be submitted along with the Annual Report. A separate Discharge Monitoring Report Form is required for each monitoring period (e.g. season) specified in Part V.A.1.

2. Signed copies of discharge monitoring reports required under Part V., the Annual Report required by Part V.C., and all other reports required herein, shall be submitted to:

U.S. EPA, Region 6
Water Management Division
Enforcement Branch (6W-EA)
1445 Ross Avenue
Dallas, Texas 75202-2733

3. Requests for Storm Water Management Program updates, changes in monitoring locations, or application for an individual permit shall be submitted to:

U.S. EPA, Region 6
Water Management Division (6W-PM)
1445 Ross Avenue
Dallas, Texas 75202-2733

4. Additional Notification. In addition, the permittee(s) shall provide copies of discharge monitoring reports, annual reports, requests for Storm Water Management Program updates or changes in monitoring locations, and all other reports required herein, to:

Program Manager
Oklahoma Department of Environmental Quality
Water Quality Program
1000 N.E. 10th Street, WQS 0207
Oklahoma City, OK 73117-1212

PART VI. STANDARD PERMIT CONDITIONS.

A. **Duty to Comply.** The permittee(s) must comply with all conditions of this permit insofar as those conditions are applicable to each permittee, either individually or jointly. Any permit noncompliance constitutes a violation of the Act and is grounds for enforcement action; for permit termination, revocation and reissuance, or modification; or for denial of a permit renewal application.

B. **Penalties for Violations of Permit Conditions.**

1. *Criminal Penalties.*

a. Negligent Violations: The Act provides that any person who negligently violates permit conditions implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a fine of not less than $2,500 nor more than $25,000 per day of violation, or by imprisonment for not more than 1 year, or both.

b. Knowing Violations: The Act provides that any person who knowingly violates permit conditions implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a fine of not less than $5,000 nor more than $50,000 per day of violation, or by imprisonment for not more than 3 years, or both.

c. Knowing Endangerment: The Act provides that any person who knowingly violates permit conditions implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act and who knows at that time that he is placing another person in imminent danger of death or serious bodily injury is subject to a fine of not more than $250,000, or by imprisonment for not more than 15 years, or both.

d. False Statement: The Act provides that any person who knowingly makes any false material statement, representation, or certification in any application, record, report, plan, or other document filed or required to be maintained under the Act or who knowingly falsifies, tampers with, or renders inaccurate, any monitoring device or method required to be maintained under the Act, shall upon conviction, be punished by a fine of not more than $10,000 or by imprisonment for not more than 2 years, or by both. If a conviction is for a violation committed after a first conviction of such person under this paragraph, punishment shall be by a fine of not more than $20,000 per day of violation, or by imprisonment of not more than 4 years, or by both. (See Section 309(c)(4) of the Act).

2. *Civil Penalties.* The Act provides that any person who violates a permit condition implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a civil penalty not to exceed $25,000 per day for each violation.

3. *Administrative Penalties.* The Act provides that any person who violates a permit condition implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to an administrative penalty, as follows:

a. Class I penalty: Not to exceed $10,000 per violation nor shall the maximum amount exceed $25,000.

b. Class II penalty: Not to exceed $10,000 per day for each day during which the violation continues nor shall the maximum amount exceed $125,000.

C. **Duty to Reapply.** If the permittee wishes to continue an activity regulated by this permit after the permit expiration date, the permittee must apply for and obtain a new permit. The application shall be submitted at least 180 days prior to expiration of this permit. The Director may grant permission to submit an application less than 180 days in advance but no later than the permit expiration date. Continuation of expiring permits shall be governed by regulations promulgated at 40 CFR 122.6 and any subsequent amendments.

D. **Need to Halt or Reduce Activity Not a Defense.** It shall not be a defense for a permittee in an enforcement action that it would have been necessary to halt or reduce the permitted activity in order to maintain compliance with the conditions of this permit.

E. **Duty to Mitigate.** The permittee(s) shall take all reasonable steps to minimize or prevent any discharge in violation of this permit which has a reasonable likelihood of adversely affecting human health or the environment.

F. **Duty to Provide Information.** The permittee(s) shall furnish to the Director, within a time specified by the Director, any information which the Director may request to determine compliance with this permit. The permittee(s) shall also furnish to the Director upon request copies of records required to be kept by this permit.

G. **Other Information.** When the permittee becomes aware that he or she failed to submit any relevant facts or submitted incorrect information in any report to the Director, he or she shall promptly submit such facts or information.

H. **Signatory Requirements.** All Discharge Monitoring Reports, storm water management programs, reports, certifications or information either submitted to the Director or that this permit requires be maintained by the permittee(s), shall be signed by:

1. for a municipality, State, or other public agency: by either a principal executive officer or ranking elected official; or

2. a duly authorized representative of that person. A person is a duly authorized representative only if:

   a. The authorization is made in writing by a person described above and submitted to the Director.

   b. The authorization specifies either an individual or a position having responsibility for the overall operation of the regulated facility or activity, such as the position of manager, operator, superintendent, or position of equivalent responsibility or an individual or position having overall responsibility for environmental matters for the company. A duly authorized representative may thus be either a named individual or any individual occupying a named position.

   c. If an authorization is no longer accurate because a different individual or position has responsibility for the overall operation of the facility, a new written authorization satisfying the requirements of this paragraph must be submitted to the Director prior to or together with

any reports, information, or applications to be signed by an authorized representative.

3. Certification: Any person signing documents under this section shall make the following certification: "I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations."

I. Penalties for Falsification of Monitoring Systems. The Act provides that any person who falsifies, tampers with, or knowingly renders inaccurate any monitoring device or method required to be maintained under this permit shall, upon conviction, be punished by fines and imprisonment described in Section 309 of the Act.

J. Oil and Hazardous Substance Liability. Nothing in this permit shall be construed to preclude the institution of any legal action or relieve the permittee from any responsibilities, liabilities, or penalties to which the permittee is or may be subject under section 311 of the Act or section 106 of CERCLA.

K. Property Rights. The issuance of this permit does not convey any property rights of any sort, nor any exclusive privileges, nor does it authorize any injury to private property nor any invasion of personal rights, nor any infringement of Federal, State or local laws or regulations.

L. Severability. The provisions of this permit are severable, and if any provision of this permit, or the application of any provision of this permit to any circumstance, is held invalid, the application of such provision to other circumstances, and the remainder of this permit shall not be affected thereby.

M. Requiring a Separate Permit.

1. The Director may require any co-permittee authorized by this permit to obtain a separate NPDES permit. Any interested person may petition the Director to take action under this paragraph. The Director may require any co-permittee authorized to discharge under this permit to apply for a separate NPDES permit only if the co-permittee has been notified in writing that a permit application is required. This notice shall include a brief statement of the reasons for this decision, an application form (as necessary), a statement setting a deadline for the co-permittee to file the application, and a statement that on the effective date of the separate NPDES permit, coverage under this permit shall automatically terminate. Separate permit applications shall be submitted to the address shown in Part V.E. The Director may grant additional time to submit the application upon request of the applicant. If an owner or operator fails to submit in a timely manner a separate NPDES permit application as required by the Director, then the applicability of this permit to the co-permittee is automatically terminated at the end of the day specified for application submittal.

2. Any co-permittee authorized by this permit may request to be excluded from the coverage of this permit by applying for an separate permit. The co-permittee shall submit a separate application as specified by 40 CFR 122.26(d) with reasons supporting the request to the Director. Separate permit applications shall be submitted to the address shown in Part V.E. The request may be granted by the issuance of a separate permit if the reasons cited by the co-permittee are adequate to support the request.

N. State/Environmental Laws.

1. Nothing in this permit shall be construed to preclude the institution of any legal action or relieve the permittee from any responsibilities, liabilities, or penalties established pursuant to any applicable State law or regulation under authority preserved by section 510 of the Act.

2. No condition of this permit shall release the permittee from any responsibility or requirements under other environmental statutes or regulations.

O. Proper Operation and Maintenance. The permittee shall at all times properly operate and maintain all facilities and systems of treatment and control (and related appurtenances) which are installed or used by the permittee to achieve compliance with the conditions of this permit and with the requirements of storm water management programs. Proper operation and maintenance also includes adequate laboratory controls and appropriate quality assurance procedures. Proper operation and maintenance requires the operation of backup or auxiliary facilities or similar systems, installed by a permittee only when necessary to achieve compliance with the conditions of the permit.

P. Monitoring and Records.

1. Samples and measurements taken for the purpose of monitoring shall be representative of the monitored activity.

2. The permittee shall retain records of all monitoring information including all calibration and maintenance records and all original strip chart recordings for continuous monitoring instrumentation, copies of the reports required by this permit, and records of all data used to complete the application for this permit, for a period of at least 3 years from the date of the sample, measurement, report or application. This period may be extended by request of the Director at any time.

3. Records of monitoring information shall include:

a. The date, exact place, and time of sampling or measurements;

b. The initials or name(s) of the individual(s) who performed the sampling or measurements;

c. The date(s) analyses were performed;

d. The time(s) analyses were initiated;

e. The initials or name(s) of the individual(s) who performed the analyses;

f. References and written procedures, when available, for the

analytical techniques or methods used; and

g. The results of such analyses, including the bench sheets, instrument readouts, computer disks or tapes, etc., used to determine these results.

Q. Monitoring Methods. Monitoring must be conducted according to test procedures approved under 40 CFR Part 136, unless other test procedures have been specified in this permit.

R. Inspection and Entry. The permittee shall allow the Director or an authorized representative of EPA, or the State, upon the presentation of credentials and other documents as may be required by law, to:

1. Enter the permittee's premises where a regulated facility or activity is located or conducted or where records must be kept under the conditions of this permit;

2. Have access to and copy at reasonable times, any records that must be kept under the conditions of this permit;

3. Inspect at reasonable times any facilities, equipment (including monitoring and control equipment), practices, or operations regulated or required under this permit; and

4. Sample or monitor at reasonable times, for the purposes of assuring permit compliance or as otherwise authorized by the Act, any substance or parameters at any location.

S. Permit Actions. This permit may be modified, revoked and reissued, or terminated for cause. The filing of a request by the permittee for a permit modification, revocation and reissuance, or termination, or a notification of planned changes or anticipated noncompliance does not stay any permit condition.

T. Additional Monitoring by the permittee. If the permittee monitor more frequently than required by this permit, using test procedures approved under 40 CFR Part 136 or as specified in this permit, the results of this monitoring shall be included in the calculation and reporting of the data submitted in the Discharge Monitoring Report (DMR). Such increased monitoring frequency shall also be indicated on the DMR.

PART VII. PERMIT MODIFICATION.

A. **Modification of the Permit.** The permit may be reopened and modified during the life of the permit to address:

1. changes in the State's Water Quality Management Plan, including Water Quality Standards;

2. changes in State or Federal statutes or regulations;

3. add a new permittee who is the owner or operator of a portion of the Municipal Separate Storm Sewer System;

4. changes in portions of the Storm Water Management Program that are considered permit conditions; or

5. other modifications deemed necessary by the Director to meet the requirements of the Clean Water Act.

All modification to the permit will be made in accordance with 40 CFR 122.62, 122.63, and 124.5.

B. **Termination of Coverage for a Single Permittee.** Permit coverage may be terminated, in accordance with the provisions of 40 CFR 122.64 and 124.5, for a single permittee without terminating coverage for other permittees.

C. **Modification of Storm Water Management Program(s).** Only those portions of the Storm Water Management Programs specifically required as permit conditions shall be subject to the modification requirements of 40 CFR 124.5. Replacement of an ineffective or infeasible BMP implementing a required component of the Storm Water Management Program with an alternate BMP expected to achieve the goals of the original BMP shall be considered minor changes to the Storm Water Management Program (as described in Part II.G.2.b. and 2.c.) and not modifications to the permit.

D. **Changes in Monitoring Outfalls.** Changes in monitoring outfalls, other than those with specific numeric effluent limitations (as described in Part V.A.1.c.), shall be considered minor modifications to the permit and will be made in accordance with the procedures at 40 CFR 122.63.

PART VIII. DEFINITIONS.

All definition contained in Section 502 of the Act shall apply to this permit and are incorporated herein by reference. Unless otherwise specified, additional definitions of words or phrases used in this permit are as follows:

A. "Best Management Practices" ("BMPs") means schedules of activities, prohibitions of practices, maintenance procedures, and other management practices to prevent or reduce the pollution of waters of the United States. BMPs also include treatment requirements, operating procedures, and practices to control facility site runoff, spillage or leaks, sludge or waste disposal, or drainage from raw material storage.

B. "CWA" or "The Act" means Clean Water Act (formerly referred to as the Federal Water Pollution Control Act or Federal Water Pollution Control Act Amendments of 1972) Pub.L. 92-500, as amended Pub. L. 95-217, Pub. L. 95-576, Pub. L. 96-483 and Pub. L. 97-117, 33 U.S.C. 1251 et.seq.

C. "Co-permittee" is defined at 40 CFR 122.26(b)(1).

D. "Core Municipality" means, for the purpose of this permit, the municipality whose corporate boundary (unincorporated area for counties and parishes) defines the municipal separate storm sewer system. (ex. City of Dallas for the Dallas Municipal Separate Storm Sewer System, Harris County for unincorporated Harris County).

E. "Director" means the Regional Administrator or an authorized representative.

F. "Discharge" for the purpose of this permit, unless indicated otherwise, refers to discharges from the Municipal Separate Storm Sewer System (Municipal Separate Storm Sewer System).

G. "Flow-weighted composite sample" means a composite sample consisting of a mixture of aliquots collected at a constant time interval, where the volume of each aliquot is proportional to the flow rate of the discharge.

H. "Illicit connection" means any man-made conveyance connecting an illicit discharge directly to a municipal separate storm sewer.

I. "Illicit discharge" is defined at 40 CFR 122.26(b)(2).

J. "Individual Residence" refers, for the purposes of this permit, to single or multi-family residences. (e.g. single family homes and duplexes, townhomes, apartments, etc.)

K. "Landfill" means an area of land or an excavation in which wastes are placed for permanent disposal, and which is not a land application unit, surface impoundment, injection well, or waste pile.

L. "Land application unit" means an area where wastes are applied onto or incorporated into the soil surface (excluding manure spreading operations) for treatment or disposal.

M. "Large or medium municipal separate storm sewer system" is defined at 40 CFR 122.26(b)(4) & (7).

N. "MEP" is an acronym for "Maximum Extent Practicable," the technology-based discharge standard for Municipal Separate Storm Sewer Systems established by CWA §402(p).

O. "MS4" is an acronym for "Municipal Separate Storm Sewer System" and is

used to refer to either a Large or Medium Municipal Separate Storm Sewer System (e.g. "the Dallas MS4").

P. "Municipal Separate Storm Sewer" is defined at 40 CFR 122.26(b)(8).

Q. "Part '#'" refers, unless otherwise indicated, to Part "#" of this permit (e.g. Part V.E.2.).

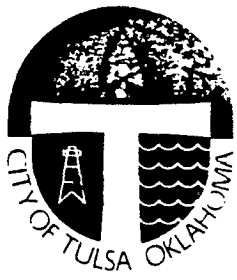
R. "Permittee" refers to any "person," as defined at 40 CFR 122.2, authorized by this NPDES permit to discharge to Waters of the United States.

S. "Point Source" means any discernible, confined, and discrete conveyance, including but not limited to, any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, landfill leachate collection system, vessel or other floating craft from which pollutants are or may be discharges. This term does not include return flows from irrigated agriculture or agricultural storm water runoff.

T. "Storm sewer", unless otherwise indicated, refers to a municipal separate storm sewer.

U. "Storm Water" means storm water runoff, snow melt runoff, and surface runoff and drainage.

V. "Storm Water Discharge Associated with Industrial Activity" is defined at 40 CFR 122.26(b)(14).



W. "Storm Water Management Program" refers to a comprehensive program to manage the quality of storm water discharged from the municipal separate storm sewer system. For the purposes of this permit, the Storm Water Management Program is considered a single document, but may actually consist of separate programs (e.g. "chapters") for each permittee.

X. "SWMP" is an acronym for "Storm Water Management Program."

Y. "Time-weighted composite" means a composite sample consisting of a mixture of equal volume aliquots collected at a constant time interval.

Z. "Waters of the United States" is defined at 40 CFR 122.2.

RE: Information of City of Tulsa storm water quality programs

Dear Mr. Radulescu:

Here is the information regarding the City of Tulsa's storm water quality programs. I am providing you this information freely with the condition that you provide me with information targeting municipal storm water quality programs in your region. I am always interested in comparing Tulsa's programs to those from other regions . This information may be used to make improvements to existing programs.

If you have any questions or comments please feel free to contact me at (918) 591-4379.

Sincerely,

Scott D. VanLoo
Environmental Compliance Specialist

Dear Mr. Farrington:

Enclosed is the Annual Report for the NPDES Municipal Storm Water Discharge Permit #OKS000201 for the period of July 1, 1996, through June 30, 1997. Further, "I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations."

If you have any questions regarding this submittal, please contact me at (918)591-4378.

Sincerely,

Douglas E. Wilson

1. ***The status of implementing the storm water management program(s) (status of compliance with any schedules established under this permit shall be included in this Section).***

The storm water management program (Part II) of the City of Tulsa's municipal storm water discharge permit consists of eleven separate programs. In order to effectively address the status of each program, each program will be addressed individually.

Part II(A)(1) Structural Controls and Storm Water Collection System Operation

The City of Tulsa's storm water management program includes provisions for the maintenance of both above and below ground structural storm water controls including detention ponds, inlets, conduits and channels. The purpose of this program is to assure proper operation of these structural controls for better control of storm water runoff and improved water quality. The following table is an inventory of the work performed on those structures during this reporting period.

Maintenance of Storm Water Structural Controls

Channels/Streams/ Detention Ponds	1,116 acres	mowing	12 x/year of mowable property
Channels/Streams/ Detention Ponds	1,452 acres	weed control (herbicide)	All parcels 1x/year for broad leaf weed control, and 336 acres 4x/year for growth control
Channels/Streams/ Detention Ponds	1,800 acres	cleaning	3,255 cubic yards/period
		siltation removal (roadside ditching)	195,237 linear feet/period
		siltation removal (ponds/streams)	36,549 linear feet/period
Storm Sewer Pipes	1,200 miles	inspect flush/clean repair or replace	1.66 miles/period 1.82 miles/period 141 units/period
Catch Basin/Inlets	47,000 units	inspect & clean repair	5,360 units/period 318 units/period
Pump Stations	6 units	clean interior, inspect. & maintain	1,663 maintenance activities/period

R0012959

Part II(A)(2) Areas of New Development and Significant Redevelopment

The Stormwater Management Criteria Manual (adopted in 1994) is a comprehensive manual designed to assist engineers, designers and construction operators in all aspects of storm water runoff control before, during and after construction activities are complete. This includes both water quality and quantity. This manual is utilized by Projects Administration of the Public Works Department as well as site development engineers during the design and review phases of all new developments and significant redevelopment projects that occur within the City of Tulsa. Additionally, the Watershed Development Regulations (Title 11-A, Ordinance #16959) list the current practices regarding regulation of new development and significant redevelopment for the control of storm water runoff rates and quality.

During this reporting period, anyone planning to develop or redevelop areas of Tulsa followed an extensive planning, designing and review process with the City of Tulsa. This insured the area targeted for development met all city requirements, including reducing the discharges of pollutants during and after construction was completed. This process involved Project Administration, Development Services, Field Engineering and Design Engineering of the City of Tulsa and focused attention on storm water quality.

Part II(A)(3) Roadways

The Street Maintenance Section of the Public Works Department, through the utilization of private contractors, swept arterial streets 8 times removing 5,049 cubic yards of debris from a total of 3,948 miles during this reporting period. Emphasis was placed on sweeping after deicing material was no longer required as a result of a snow or ice event. Residential streets were swept 4 times removing 14,378 cubic yards of debris from a total 6,700 miles during this reporting period. Site Specific Hourly Sweeping involved 433 hours. Expressway sweeping for the Oklahoma Department of Transportation (ODOT) totaled 191 miles removing 1,427 cubic yards of material.

Also, the removal of trash was performed on all city street right-of-ways prior to mowing. The specifics of this task is discussed in Part II(A)(6)(c) Floatables.

Part II(A)(4) Flood Control Projects

The Projects Administration group of Tulsa's Public Works Department performed project design review of 19 major flood management projects designed during this reporting period. This included a determination of whether all criteria established by the city's Stormwater Management Criteria Manual had been met or exceeded including consideration of existing water quality. Where possible, water quality treatment principles were incorporated into the design of these flood control projects.

R0012960

Part II(A)(5) Pesticide, Herbicide and Fertilizer Application

The application of pesticides, herbicides and fertilizers was performed by the City of Tulsa's Public Works Department and the Park and Recreation Department. The City of Tulsa required all city employed pesticide applicators as well as all contract applicators to be licensed and subject to all of the regulations under the Oklahoma Pesticide Applicators Law. Surface Drainage & Vegetation Maintenance personnel of the Public Works Department that applied pesticides, herbicides and fertilizers received in-house training during this reporting period. Parks and Recreation Department employees that applied pesticides, herbicides and fertilizers received annual training. In addition, workshops and conferences were held on the proper application and disposal.

The City of Tulsa Community Affairs Section began work on a brochure which addresses the proper application and disposal of pesticides, herbicides and fertilizers during this period. This brochure's target audience is the public and is expected to be finalized during the reporting period of 97/98.

Through the continuation of two City of Tulsa sponsored household pollutant collection events held during this reporting period 11,801 lbs. pesticides/poisons were collected from the public and disposed of in an environmentally friendly manner.

ODOT has 16 certified applicators that apply pesticides, herbicides and fertilizers in the Tulsa area. Each applicator attended annual training that instructed them on the proper use, application and disposal of pesticides, herbicides and fertilizers.

Part II(A)(6) Illicit Discharge and Improper Disposal

a.) Non-storm water discharges

The Quality Assurance Section of the city's Public Works Department performed 208 investigations that involved possible illicit discharges to the storm and sanitary sewer during this reporting period. Ordinance #18588 was adopted during the 94/95 reporting period and continues to be utilized for the removal of non-storm water discharges through enforcement actions (see Section 6, "Summary of Enforcement Actions, Inspections, and Public Education").

Once an illicit discharge was identified, the responsible party was required to either stop the discharge, redirect the discharge to the sanitary sewer or obtain an NPDES waste water discharge permit from the Oklahoma Department of Environmental Quality/U.S. EPA. The reporting of illicit discharges and improper disposal to the storm sewer system was reported to the Quality Assurance Section by concerned citizens (via the Mayors Action Center or directly from a citizen), other city departments and government agencies.

R0012961

b.) Sanitary sewer overflows

In a continuing effort to eliminate sanitary sewer overflows during this reporting period the city's Engineering Services Section contracted with consulting engineers to conduct sanitary sewer evaluation surveys in several drainage areas and have let several construction contracts for rehabilitation of manholes, sanitary sewer lines and construction of sanitary sewer relief lines. In addition, Engineering Services is currently evaluating the construction of two flow equalization basins in the Flatrock and Coal creek drainage basins.

As addressed earlier in Part II(A)(1), Tulsa's Underground Collection Section continues to utilize aggressive inspection, repair and cleaning programs for the sanitary sewer system in order to eliminate sanitary overflows. The following items were performed under the supervision of Underground Collections during this reporting period:

- Five homes with sanitary sewer discharges to the storm sewer were identified. Per city direction, these home owners are now in the process of repairing defective plumbing and connecting to the sanitary sewer.
- At the intersection of 8th & Cheyenne a city sanitary sewer line cross connection to the storm sewer was located and corrected.
- A city contractor identified and corrected 95 cross connections between the storm and sanitary sewers while performing a sanitary sewer evaluation survey in the Coal creek drainage basin.

c.) Floatables

Tulsa has taken a very aggressive approach toward floatable control. Utilization of existing programs has had an impact on reducing litter. The "Pride in Tulsa" organization is instrumental in a series of programs which target litter control, such as:

- Operation Cleansweep, April 20-27, 1997 (20,000 people remove litter at various sites in Tulsa),
- Environmental Summit (educational program for middle and high school aged children),
- Pride Partners (area businesses who take pride in Tulsa through donations, clean-ups and recycling), and
- Free dump days at the landfill.

The Metropolitan Environmental Trust (M.e.t.) was also responsible for many of these activities planned around Earth Day, through their planning and performance. The M.e.t. created and maintains a web page for recycling at address WWW.WEBTEK.COM/METRECYCLE. The M.e.t also operates 12 recycling depots giving citizens accessible locations for the collection of materials for recycling. These items include plastics, paper products, glass, aluminum, batteries, oil and antifreeze. They are also used for the distribution of environmental educational information. See "Collection of Used Motor Vehicle Fluids and Household Hazardous Wastes" for data concerning this program.

R0012962

The city's Community Affairs Section utilized utility bill stuffers and pamphlets to educate the public regarding their responsibility to reduce floatable pollution in storm water runoff. Data was obtained by Surface Drainage & Vegetative Management during this reporting period regarding floatable make-up and quantity through the use of two floatable monitoring locations (see Section 4-Monitoring Data).

Through assistance from the Oklahoma Turnpike Authority, Oklahoma Department of Environmental Quality and Oklahoma Tourism and Recreation Department, Oklahoma Department of Transportation (ODOT) reinstated the "Don't Lay that Trash on Oklahoma" anti-litter campaign at a state wide cost of $350,000. The ODOT, at a cost of 1.1 million dollars, began the development of a heavily publicized anti-litter campaign called "Oklahoma, Keep Our Land Grand"during this reporting period. This program is scheduled to begin during the summer of 1997 and will utilize TV, radio, highway signs and other advertisements. Additionally, ODOT held the ninth annual "Trash Off" Day in Tulsa on April 12. Other clean-up efforts which were utilized included the "Adopt a Highway" which included 20 groups in the permit area and inmate litter removal.

The City of Tulsa's Park and Recreation Department emptied approximately 450 trash containers placed at 120 parks and 25 storm water detention sites 2 to 3 times per week. The pickup frequency was reduced slightly during the off season. Fifty two dumpster type containers at 38 park sites were also emptied weekly by the City's Waste Systems Section. Trash containers were placed in parks to serve special events and scheduled activities. In addition, Park and Recreation Department maintenance crews picked up loose trash from parks as needed.

The Street Maintenance Section of the City of Tulsa continued to utilize litter crews which removed approximately 107,000 bags of litter from expressways and streets during this reporting period. These crews consisted of inmate work crews and city private contractors.

d.) Collection of used motor vehicle fluids and household hazardous wastes

The city continues to support the M.e.t.'s recycling depots which accept oil, antifreeze and batteries, as well as other recyclable materials. All depots are accessible to the public 24 hours per day, 7 days per week and are located in areas that are easily accessible to the public. The amount of material received by these depots for the last fiscal year of July 1, 1996 through June 30, 1997 can be found on the following table:

oil	46,015 gals.
antifreeze	3,757 gals.
plastics	293,857 lbs.
aluminum	135,020 lbs.
glass	1,158,458 lbs.
batteries	58,709 lbs.
newspaper	6,161,378 lbs.
magizines	718,879 lbs.

R0012963

The city sponsored two household pollutant collection events during this reporting period. They were both held on a weekend. The event dates were October 26 & 27, 1996 and April 5 & 6, 1997. Both events were a success with 6,575 gallons of oil, 505 gallons of antifreeze, 33,827 cans of paint and 17,530 pounds of flammable liquid collected from 4,180 participants. Thousands of pounds of other household hazardous wastes were brought to the events and thereby removed from the waste stream. These programs were also used to distribute educational material to the public regarding locations of the recycling depots, and environmentally friendly alternatives for chemicals used in the household.

These programs were so successful that two events are planned for the reporting year of 97-98.

In a continued effort to develop and implement the most effective household hazardous waste collection program given limited resources, the City of Tulsa, through the M.e.t., held a permanent location household hazardous waste pilot program from March 15 through May 31, 1997. This pilot program had varying hours of operations which included weekdays and extended weekends. This program was a success due to the fact that alot of important information was obtained including:

- The handling and disposal of household hazardous waste can be change as long as it is recled or safely disposed.
- Facility use or disposal charge is not a popular idea.;
- The scheduling for the disposal of material by each participant is not necessary.
- It is more desirable to dispose of the material at the next bi-annual household pollutant collection event rather than immediately.

As a result and given the fact that the current programs are very successful, no permanent household pollutant collection facility is planned for establishment in the near future.

e.) Locate and eliminate illicit discharges and improper disposal

The Quality Assurance Section of the Public Works Department performed dry weather field screening on over 14% (264 outfalls) of the City of Tulsa's storm sewer system during the reporting period of June 1, 1996 through May 31, 1997. This brought the total permit area screened to 63.2% (413 outfalls) since the beginning of this program in October of 1994.

The City of Tulsa is compliant with the compliance schedule for the complete dry weather field screening of the entire permit coverage area by June 1, 1999.

The Underground Collections Section (UCS) of the city's Public Works Department continued efforts to locate sanitary and storm sewer cross connections during this reporting period. This was accomplished through the use of TV inspection and smoke testing techniques. Additional work completed during the fiscal year of 96-97 included:

352,757 feet of sanitary sewer TV inspected
8,765 feet of storm sewer TV inspected
123 storm and sanitary manholes raised to grade

R0012964

141 main line storm sewer repairs
325 main line sanitary sewer repairs

In most cases, these repairs result in the elimination of storm water infiltrating into the sanitary sewer which helps to reduce overflows or illicit discharges to the storm sewer from the sanitary sewer. In either case, the repairs resulted in the improvement of storm water quality.

Rehabilitation projects supplemented UCS efforts by correcting known storm sewer problem areas that were primarily structurally related (see b. Sanitary Sewer Overflows).

As previously mentioned, the investigation/complaint procedures used by the city's Quality Assurance Section have been very effective in locating illicit discharges and improper disposal practices during this reporting period/season (see "Public Education - Public reporting of illicit discharges and improper disposal").

f.) Removal of illicit discharges

Once illicit discharges are located by Quality Assurance, the responsible party is required to halt the discharge, redirect the discharge to the sanitary sewer or obtain an NPDES wastewater discharge permit from the U.S. EPA. The responsible party is given 30 days to comply. If compliance could not be attained by the party within 30 days, enforcement action in the form of an expeditious schedule of compliance was taken. With the adoption of the Ordinance #18588, the Quality Assurance Section placed nine parties on compliance schedules. The result was full compliance for all nine parties.

g.) Maintain a list of NPDES permit holders within the City of Tulsa

The Quality Assurance Section maintains a list of NPDES industrial storm water and wastewater permit holders which operate within the city limits. This list includes the name, location, and NPDES permit number, as well as contact person, SIC codes, and other pertinent information for each NPDES permit holder. This information is obtained during inspections and is updated regularly. The Customer Services Division of the City of Tulsa maintains a list of NPDES construction storm water permit holders. Building permits are not issued for construction sites larger than 5 acres until an NPDES storm water discharge permit has been obtained and a pollution prevention plan is in place.

Part II(A)(7) Spill Prevention and Response

This requirement was met through the coordination of the Tulsa Fire Department (TFD) and their Hazardous Materials unit, along with Tulsa City-County Health Department and the City's Quality Assurance Section. All agencies and city sections responding to spills are required to follow the newly adopted storm water quality ordinance. This ordinance requires the removal of the pollutant rather than flushing of this pollutant into the storm sewer unless there is an immediate threat to life and health.

For this reporting period the Tulsa Fire Department responded to a total of 561 incidents involving spills and/or releases that could potentially threaten the separate storm sewer system. The reported spill incidents from the previous fiscal year 95/96 totaled only 97 spill incidents. This increase is attributed largely to how the TFD has changed the way

R0012965

they respond to spills. The Fire Dept. is employing the use of satellite haz-mat companies strategically located within the city's five district response areas. These personnel are trained and equipped to either emulsify or absorb spills if possible. Emulsification is an allowable provision in the storm water quality ordinance if there is an immediate danger to public health and safety. The 95/96 fiscal year figure of 97 spills reflected only those that required a response from the Haz-Mat unit(s) and went beyond the capability of the satellite companies.

Additionally, spill prevention was discussed during each of the 600 sanitary and storm sewer inspections performed by the city's Quality Assurance Section during this reporting period.

Part II(A)(8) Industrial & High Risk Runoff

A program to identify, monitor and control pollutants from municipal landfills; treatment storage and disposal facilities for municipal waste; facilities subject to EPCRA Title III, Section 313 reporting requirements; and any other industrial and commercial discharge the City determines contributes substantial pollutant loading to the City's storm sewer system was implemented during this reporting period. This program contains procedures and priorities for inspections and monitoring, and establishes implementation of control measures for such discharges. A data base of industrial storm water sources discharging to the City's storm sewer was maintained. Six hundred storm water runoff inspections were performed during this reporting period. As a result, nine enforcement actions were taken in order to eliminate illegal or illicit discharges.

This program also allows inspectors to educate owners and operators of industry on the storm water quality regulations and requirements as per Ordinance #18588 and the city's NPDES Municipal Storm Water Discharge Permit.

Part II(A)(9) Construction Site Runoff

This requirement was met by the Customer Services Section (Building Inspections and Development Services) and the Engineering Services Divisions of the city's Public Works Department.

a.) The use and maintenance of structural and nonstructural best management practices (BMPs) to reduce pollutants discharged to the city's storm sewer from construction sites has been achieved through the enforcement of Title 11-A Chapter 3 (Watershed Development Regulations) and the PFPI and building permit. The Development Services Section issued 18 "Earth Change" permits (permits required by developer for any earth change activity within the city that is greater than 1 acre) during this reporting period. These permits require the operator to have adequate erosion control measures in place and maintained throughout the life of the project. Prior to receiving an earth change permit, applicants were required to submit an executable NOI and acceptable storm water pollution prevention plan for all sites disturbing at least 5 acres.

b.) The Public Works Department inspected 21,505 construction sites during this reporting period. Of those, Customer Services performed 21,424 (14,028 commercial and 7,396 residential) and Engineering Services performed 81. Appropriate structural

R0012966

and nonstructural erosion control measures (BMPs) were inspected during these aforementioned site inspections. If the existing erosion control methods were inadequate, additional structural or nonstructural BMPs were required. Approximately five percent of the inspections performed by Customer Services resulted in some type of enforcement action during this reporting period, while approximately 20 notices of violations were issued by Engineering Services. All violation notices issued by Engineering Services consisted of a statement of the violation along with a time period for correction.

Inspections were performed by both the Customer Services and Engineering Services Divisions of the Public Works Department as a result of both scheduling and citizen complaints.

c.) On April 7, 1997 the Blue Thumb Project sponsored a meeting at the Tulsa Metropolitan Home Builders Association which involved builders and contractors from the Tulsa area. Guest speakers included EPA officials, Bob Reeves and Thea Lomax. Current NPDES storm water regulations that pertain to construction sites were discussed.

On April 19, 1997, representatives from the city's Public Works Department gave presentations to area builders, developers and contractors. The meeting focused on the recently announced changes in the EPA erosion control regulations and how they would apply to developing and building in the City of Tulsa.

An ODOT committee drafted a manual called "ODOT Storm Water Management Guidelines for Design and Construction Activities" during this reporting period. This manual focuses on upgrading erosion control practices both as how they are specified on the construction plans and how these practices are applied in the field. Distribution and implementation is scheduled for the Fall of 1997.

ODOT sponsored a two day long course on erosion and sediment control. This training targeted the project level inspectors, project engineers, designers, contractors, foreman, superintendents and other project personnel. The content of the course included storm water runoff, sediment and erosion control, construction site stabilization, pollution prevention plans and related subjects as they apply to highway and bridge construction. This course was first held in October and was attended by approximately 100 people.

d.) The City of Tulsa's Engineering Services constructed 24 storm water pollution prevention plans for city operated construction sites, such as capital improvements, during this reporting period.

Additionally, the notification of the building permit applicants of their responsibility under the NPDES permitting program was also accomplished during the building permit application review process by the Development Services Section. Through the platting process and the privately financed public improvements, Development Services screened proposed developments to determine the appropriate compliance requirements and notified the applicants of those requirements, including NPDES erosion and sediment control requirements, prior to issuing building permits.

Development Services provided both the summary guidance and the full manual of EPA published guidance books Storm Water Management for Construction Activities - Developing Pollution Prevention Plans and Best Management Practices to assist developers and design engineers in the preparation of a storm water pollution prevention plans. Anyone required to obtain an NPDES storm water discharge permit submitted a

R0012967

storm water pollution prevention plan along with an executed NOI to Development Services for review prior to receiving a watershed development permit. During the review process of the storm water pollution prevention plan, Development Services utilized the EPA Construction General Permit Requirements Preconstruction Checklist. The Homerville example, found in the EPA's Storm Water Management For Construction Activities guidance manual, was used as guidance for construction storm water pollution prevention plans.

Part II(A)(10) Public Education

Educating the public on the prevention of pollution at the source as well as what is required by the city's municipal storm water discharge permit has been the focus of several of our efforts. This required the involvement of Community Affairs and Quality Assurance Sections as well as the Metropolitan Environmental Trust and the Blue Thumb Project during this reporting period. Public education was accomplished through the distribution of educational material, public speaking and sponsoring of city wide environmental awareness events on numerous topics which relate to the city's storm water permit.

The Blue Thumb Program continues to be an important part of Tulsa's public education for non-point source pollution. This EPA funded program is coordinated by the OSU Cooperative Extension and Tulsa County Conservation District. The program's goal is to make the citizens of Tulsa aware of non-point source pollution and to encourage the adoption of practices that protect Tulsa's urban watersheds. This program has greatly contributed to the education of the public through the organization and training of citizen watershed monitoring groups, monthly newsletters called "Blue Thumb Prints" and "Data Dip Net", organization and sponsorship of an annual resource management conference and local creek clean-up, supervision of an aggressive storm sewer stenciling program and numerous non-point source demonstrations at area schools.

The M.e.t. created numerous pamphlets and other material which focused on the proper management and disposal of commonly generated household pollutants. These pamphlets are distributed to the public at various locations and events throughout the Tulsa metropolitan area.

a.) Public reporting of illicit discharges and improper disposal

Several publications created by the Community Affairs Section of the City of Tulsa, asked citizens to be observant and immediately report illegal or illicit discharges to the Mayors Action Center. These publications included numerous utility bill stuffers (City Life), pamphlets ("1996 Regulatory Floodplain Guide" and "1997 Official Notices of Flood Hazard") and City News articles. Additionally, during numerous public speaking engagements by City of Tulsa personnel, invitations were extended for citizens to call the Mayors Action Center to report any unusual or illegal discharges to the city's storm sewer.

Other assistance came from the Blue Thumb Program which developed brochures stating "Report any illegal dumping to the city of Tulsa Public Works Department" and includes telephone numbers to report 24 hour a day. These brochures were placed in areas

R0012968

regularly accessible to the public such as all thirteen recycling depots, the household pollutant collection events, City Hall and various locations.

Increased public education on the reporting of illicit discharges and improper disposal has resulted in Quality Assurance performing an average of 247 investigations each of the last two reporting periods versus 147 during the first year of the permit. This has resulted in an average increase of 160% in the number of investigations in the last two reporting periods

While performing inspections, Quality Assurance personnel informed citizens to report any unusual discharge into the city's storm sewer to the Quality Assurance Section or the Mayors Action Center immediately.

On October 12, 1996, the city's Underground Collections Section had a booth at Safe Kids Fall Fire and Safety Extravaganza Day. During both activities educational material was distributed regarding not only the unsafe practice of playing in the sewer system but also illegal dumping into the storm sewer.

b.) Proper management and disposal of used motor vehicle fluids

Public education in the area of the proper management and disposal of used motor vehicle fluids was accomplished through the creation of utility bill stuffers in conjunction with the city's household pollutant collection events by the Community Affairs Section.

Also, the Blue Thumb Program's stenciling of approximately 643 storm sewer inlets during this reporting period is important because storm sewer inlets appear to be the main discharge point of used motor vehicle fluids into the storm sewer.

The M.e.t. created and distributed numerous pamphlets on the proper management and recycling of many household pollutants including automobile fluids such as oil and antifreeze. These pamphlets are readily available to the public at City Hall, the M.e.t. office, INCOG offices, all thirteen recycling depots and the household pollutant collection events.

c.) Proper use, application, and disposal of pesticides, herbicides and fertilizers

Public education in the proper use, application and disposal of pesticides, herbicides and fertilizers was accomplished during this reporting period through the distribution of pamphlets created by the M.e.t. as well as the numerous notices placed in City Life (utility bill stuffer) by Community Affairs. Community Affairs also created and made available pamphlets which contain information on this educational topic. These pamphlets include the 1996 Guide to Regulatory Floodplains, the 1997 Official Notice Flood Hazard Information mailer and the 1997 Official Notice Repetitive Loss mailer.

Public education about the proper application of pesticides, herbicides and fertilizers was performed during this reporting period by the Oklahoma State University (OSU) Extension Service through their Master Gardeners Program. This program contacted approximately 30,000 residents of Tulsa County. The OSU Extension Service also operated a telephone hotline staffed by trained personnel to answer questions regarding various horticultural issues including the proper application and disposal of pesticides, herbicides and fertilizers. This service is offered five days a week, from 9 a.m. to 4 p.m., and is backed with numerous brochures available to the public. Oklahoma Educational Television Association (OETA) broadcasts the OSU production "Oklahoma Gardening"

R0012969

to local residents twice a week. Host, Brenda Simons, consistently emphasizes proper handling, use and disposal of these products to a viewing audience of approximately 60,000 each week. OSU Extension Service will continue these successful programs in to the next reporting period.

Part II(A)(11) Monitoring Programs

All monitoring requirements were met through the continuation of the dry weather field screening program, and the implementation of the wet weather field screening and industrial & high risk runoff programs during this reporting period.

a.) Dry Weather Field Screening

This program has been implemented by the Quality Assurance Section. This program was previously mentioned in this report in Part II(A)(6)(e).

b.) Wet Weather Field Screening

A total of 34 monitoring sites were chosen which represent the watersheds that make up the city's storm sewer system. This program will be used to identify watersheds within the City of Tulsa that may have reduced storm water runoff quality during storm events. A secondary benefit of this program is to gauge the effectiveness of other storm water management programs and implemented best management practices. During this reporting period, 20 of the 34 wet weather field screening sites were monitored. All the analyses were completed in accordance with 40 CFR Part 136 and will be reviewed during the next reporting period.

Baseline monitoring of all 34 monitoring sites has begun. This will give the City of Tulsa a baseline for water quality during normal flow conditions.

c.) Industrial & High Risk Runoff

The Industrial & High Risk Runoff monitoring began during this reporting period. This monitoring took the form of both the collection of self monitoring storm water runoff sample results from eight industries and the sampling of one industry by the Quality Assurance Section. Additional monitoring will take place during the reporting period of 97\98.

R0012970

2. *Proposed changes to the storm water management program(s)*

During this reporting period it was determined that minor changes were required to one program in order to improve its effectiveness. This program is Part II(A)(11)(b) the Wet Weather Screening Program. Wet weather field screening procedures were changed to include a QA/QC Section and correct the address of one monitoring location. No other changes were made to any of the storm water management programs during this reporting period. A copy of the revised Wet Weather Field Screening Program can be found as Attachment A.

R0012971

3. Revisions, if necessary, to the assessment of controls and the fiscal analysis reported in the permit application under 40 CFR 122.26(d)(2)(v)and (d)(2)(vi)

No revisions to the "Assessment of Controls" or "Fiscal Analysis" were needed during this reporting period.

R0012972

4. A summary of the data, including monitoring data, that is accumulated throughout the reporting year.

Data was obtained from three monitoring programs during this reporting period. Each of the sources are explained in the following paragraphs with associated data.

Storm Event Monitoring Data

The first source of data was the storm event monitoring. Storm event samples were collected during the three monitoring periods which make up this reporting period, as required. The five required monitoring locations were sampled plus a sixth. Analysis was performed using methods found in 40 CFR Part 136. The following is a summary of the data from each monitoring period:

Wet Weather Screening Data

The second program in which monitoring data was obtained was the wet weather field screening program. There are 34 individual watersheds in the jurisdiction of the City of Tulsa, each with a monitoring location. Twenty of those watersheds were monitored during this reporting period. All samples were grab samples, as defined by the Standard Operating Procedures for Wet Weather Field Screening. Data consists of both field and laboratory analysis. All laboratory analysis was performed using methods found in 40 CFR Part 136. The following is summary of that data:

OUTFALL #	1	2	4	5	6	13	14

Floatable Monitoring Summary

Data was obtained from two floatable monitoring locations. Inspections were performed after various rainfall events during this reporting period. If floatables were present during an inspection, they were collected and data was gathered regarding the quantity in cubic yards and make-up in percent organic and inorganic. A summary of the data is as follows:

Station: Osage 1101 W. Pine Street

Drainage area: 722 acres or 1.21 square miles

Date	Inspection	Collection (yds.3)	% Organic	% Inorganic
07/09/96	yes			
07/23/96	yes			
08/14/96	yes			
08/28/96	yes

R0012982

5. Annual expenditures for the reporting period, with a breakdown for the major elements of the storm water management program and the budget for the year following each annual report.

The annual expenditures for compliance with the City's NPDES Municipal Storm Water Discharge Permit can be found in the table that follows. Cost of implementation of individual requirements, such as wet weather field screening are not subdivided because many of the permit's requirements were already being completed as part of another task performed by the City. The fiscal analysis reflects the annual budget for compliance with the permit. It is projected that the cost to complete the permit requirements would increase at least 10% if individual cost accounting would be required on every item.

Fiscal Analysis Summary - Storm Water Management Programs

PROGRAM COMPONENT	FISCAL YEAR 96/97	FISCAL YEAR 97/98
LEGAL AUTHORITY		
	$19,971	$20,370
CHARACTERIZATION DATA

R0012984

6. A summary describing the number and nature of enforcement actions, inspections and public education programs during this reporting period.

Enforcement Actions

Fourteen enforcement actions were taken during this reporting period by the Quality Assurance Section of the City of Tulsa. They were:

1. Interstate Tool
   1044 North Columbia Place
   Tulsa, OK

   A storm water inspection revealed a scrap metal bin located directly above a storm sewer drop inlet and a large volume of metal punch pieces and associated oil inside the storm sewer. Interstate Tool was placed on a Consent Order to remedy this situation. This facility "plugged" the subject storm drain and is currently compliant.

2. Pyromet Group
   10325 East 58th Street
   Tulsa, OK

   This facility was placed on a consent order to remove a discharge of overflow water from a cooling tower which flowed into the storm sewer. This discharge was rerouted to the sanitary sewer and the facility is currently compliant.

3. Cartec
   2524 South Harvard Ave.
   Tulsa, OK

   Cartec was issued a notice of violation for a spill of approximately 20 gallons of oil into the storm sewer. Cartec cleaned up this spill and moved waste oils/antifreeze storage inside. Cartec is currently compliant.

4. John Zink
   11920 East Apache
   Tulsa, OK

   An inspection revealed non-contact cooling water from test furnaces which discharged to the storm sewer. As a result, the company was placed on a consent order to obtain compliance within a specified amount of time. The order required either the redirection of the discharge to the sanitary sewer, stop the discharge or obtain an NPDES wastewater discharge permit from the EPA. The company plumbed the discharge to the sanitary sewer and is currently in compliance.

R0012985

5. *Braden Manufacturing*
   5199 North Mingo Road
   Tulsa, OK

   During a facility inspection a wash basin from an equipment maintenance garage, and several drinking-water fountains which discharged to the storm sewer were discovered. The company was placed on a consent order to attain compliance. The company removed the subject wash basin as well as all but one water fountain. The remaining fountain was plumbed to the sanitary sewer. The company is currently in compliance.

6. Borden/Meadow Gold
   215 North Denver
   Tulsa, OK

   A leaking water chiller discharging into the storm sewer was located at this facility. The company was placed on a consent order to attain compliance. The company investigated, found and repaired a leak in the subject water chiller. The company is currently compliant.

7. Labels One Inc.
   5151 South 110th East Ave
   Tulsa, OK

   During a facility inspection two sink waste drains discharging to the storm sewer were identified. As a result, the company was placed on a consent order to obtain compliance within a specified amount of time. The order required either the redirection of the discharge to the sanitary sewer or cease the subject discharge. The company plumbed the discharge to the sanitary sewer and is currently in compliance.

8. Lot Maintenance Inc.
   5305 South. 24th West Ave
   Tulsa, OK

   Lot Maintenance Inc. was issued a Notice Of Violation for washing residual material from drums into the street which subsequently flowed into the storm sewer system. The operator ceased this practice as soon as they were told this was in violation of City of Tulsa Ordinance #18588. This contractor is currently in compliance.

9. John Zink Company
   11920 East Apache
   Tulsa, OK

   John Zink Company was issued a Notice Of Violation for failure to notify the City of Tulsa "in writing" as outlined in their consent order. John Zink had satisfactorily remedied the illicit discharge of "furnace testing" water prior to the violation. The facility is currently compliant.

R0012986

10. Labels One Inc.
5151 South 110th. East Ave.
Tulsa, OK

Labels One Inc. was issued a Notice Of Violation for failure to notify the City of Tulsa "in writing" as outlined in their consent order. The owners of this facility had satisfactorily remedied the illicit discharge of "waste drains" to the storm sewer.

11. Metal Services
640 West 41st. Street
Tulsa, OK

Metal Services was issued a Notice Of Violation for powerwashing sediment from forklifts, other industrial machinery/equipment and metal parts which subsequently discharged to the storm sewer. This practice has ceased. However, the operator has filed an application with ODEQ (Oklahoma Department Of Environmental Quality) for a permit to discharge process wastewater. They are currently compliant.

12. Walterbach Homes
Box 904141
Tulsa, OK

City of Tulsa personnel responded to a citizen complaint of paint being discharged to the storm sewer. The subject discharge was traced to the source which was a home building site operated by Walterbach Homes. This resulted in the issuance of a Notice Of Violation. Subsequently, the discharge was halted and the operator is currently compliant.

13. Orbit Valve Service Co. Inc.
East 46th Place, Unit D
Tulsa, OK

A storm water inspection revealed a wash basin and a hydrotesting unit which discharged to the storm sewer system. The operator was placed on a consent order to remedy these illicit discharges within seven days. The wash basin was removed from service and the hydrotest water discharge was rerouted to the sanitary sewer within the required time frame. The facility is currently compliant.

14. Buck Construction Co.
9520 East 55th Street
Tulsa, OK

A Notice Of Violation was issued to Buck Construction Co. for discharging paint to the storm sewer. The operator ceased the discharge and is currently in compliance.

R0012987

If during a construction site inspection it was demonstrated that a noncompliant situation existed, enforcement actions were taken. Enforcement action was taken against 5 percent of those construction sites inspected by the Customer Services Section. Approximately 20 notices of violation were issued by the city's Engineering Services Section.

Inspections

As stated previously in Section 1 of this report, the city's Underground Collections Section performed inspections on 66.8 miles of sanitary sewer and 1.66 miles of storm sewer during fiscal year of 96-97.

The Quality Assurance Section performed a total of 970 inspections during this reporting period. These consist of both storm water quality and industrial pretreatment inspections. The industrial pretreatment inspections focus on wastestream types and disposal techniques primarily to the sanitary sewer and secondarily, to the storm sewer from industrial and commercial facilities. The storm water quality inspections consist of both inspections and surveys focusing on sources of pollutants in storm water runoff only.

As mentioned in Section 1 of this report, Customer Services performed 21,424 (14,028 commercial and 7,396 residential) and Engineering Services performed 81 construction/erosion control inspections during this reporting period to insure compliance with the city's permit.

Public Education Programs

The public education programs utilized by the City of Tulsa have been described in Section 1 of this report. Tulsa realizes that public education plays an important role in the reduction of nonpoint source pollution. The major programs are as follows:

- Distribution of literature at recycling depots and household hazardous waste events.
- Utility bill stuffers targeting illicit discharges and improper disposal, household hazardous waste, used automobile fluids and pesticides, herbicides and fertilizer application and disposal.
- Public speaking at industrial and social organizations including Metropolitan Tulsa Builders Association, Oklahoma Pretreatment Coordinators Meeting, Oklahoma Campus Safety Association, Blue Thumb Volunteers and Blue Thumb Resource Management Conference.
- Articles in the "City News", a monthly publication with a circulation of approximately 6000, regarding recycling, the household pollutant collection events, reporting of illegal or illicit discharges, recycling of antifreeze and oil and the importance of protecting water quality.
- Earth Day activities including Operation Clean Sweep, free dump day at the landfill and free mulch give away.
- Blue Thumb Resource Conference.

R0012988

- On May 17, 1997, in conjunction with National Rivers Clean-up Week (May 10-17, 1997) the City of Tulsa and the Blue Thumb Project sponsored a volunteer clean-up of approximately 3 miles of Mooser Creek. Over 30 people removed approximately 60 trash bags of trash and brought attention to the importance of urban water quality.
- Blue Thumb Volunteers stenciled approximately 643 curbs near storm sewer inlets with the wording "DUMP NO WASTE, DRAINS TO RIVER" during this reporting period. This brings the total number of inlets stenciled since the beginning of this project to a 3,843.

Many of these programs are completed through the cooperative efforts of other groups, such as The Metropolitan Environmental Trust (The M.e.t.) and the Tulsa County Soil Conservation Service - Blue Thumb Program.

As stated earlier (Section 1 Part II.a.) the "Don't Lay That Trash On Oklahoma" campaign was resurrected by ODOT during this reporting period. This co-permitee also sponsored in-house training programs on controlling erosion at construction sites, as well as "Trash Off" day and "Adopt a Highway" anti-litter programs. The state wide "Oklahoma, Keep Our Land Grand" anti-litter program was developed and is scheduled for implementation during the next reporting period.

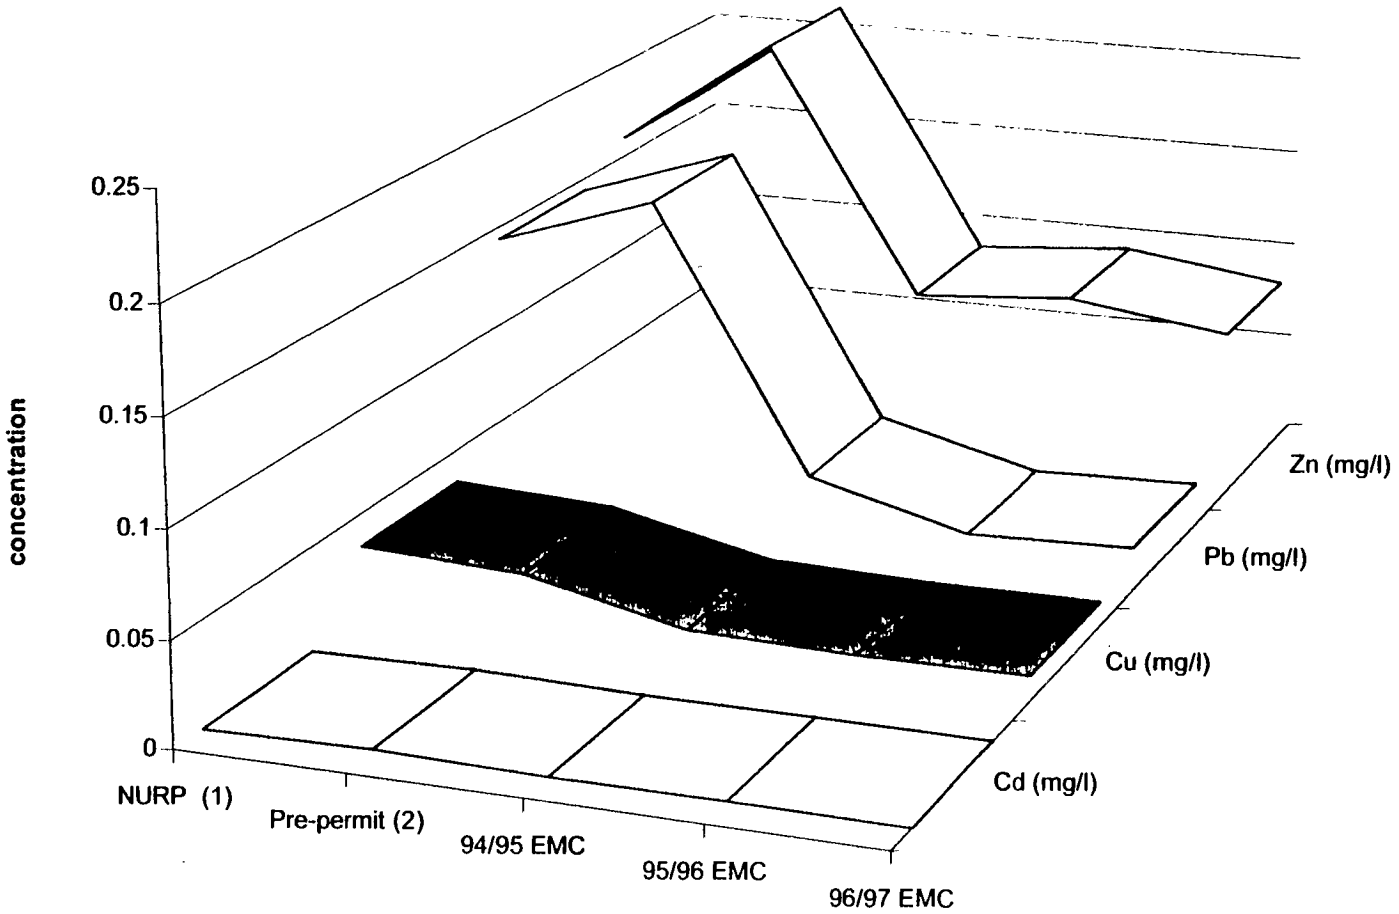
During the performance of investigations and inspections, City of Tulsa representatives maintain the philosophy to first educate industrial representatives and responsible parties on storm water best management practices as well as their responsibility in the area of storm water quality. Enforcement actions are taken when deemed necessary to insure permit compliance.

R0012989

7. Identification of water quality improvements or degradation.

In order to identify water quality improvements or degradation, the event mean concentration (EMC) for this reporting period was compared against the EMC calculated for the last two reporting periods as well as the permit application period and the EMC data obtained from the Nationwide Urban Runoff Program study. This has resulted in the following table.

95/96 EMC Data Comparison Table



Parameter	96/97 EMC	95/96 EMC	94/95 EMC	NURP Results (1)	Pre-permit Results (2)
Cd (mg/l)	<0.010	0.0002	<0.002	no results	0.0015
Cu (mg/l)	0.0118	0.011	0.013	0.034	0.030
Pb (mg/l)	0.0215	0.019	0.039	0.144	0.170
Zn (mg/l)	0.0853	0.096	0.090	0.160	0.215
BOD (mg/l)	7.1	10	7	9	9.4
COD (mg/l)	47.2	60	52	65	70.2
O&G (mg/l)	5.8	1.5	3	no results	no results
Phosphorus (T) (mg/l)	0.2677	0.324	0.271	0.333	0325
Phosphorus (D) (mg/l)	0.2129	0.245	0.171	0.120	0.115

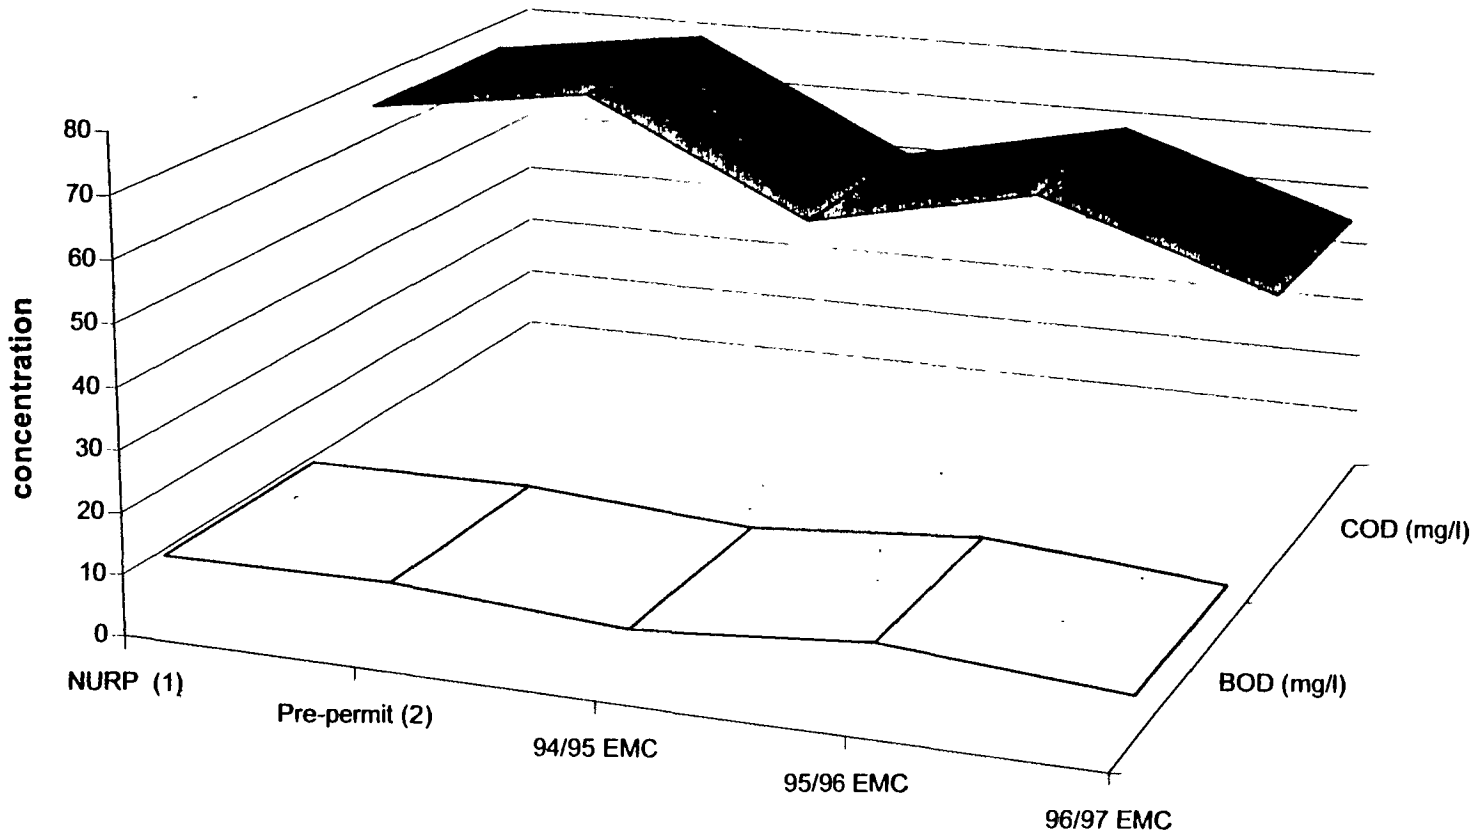
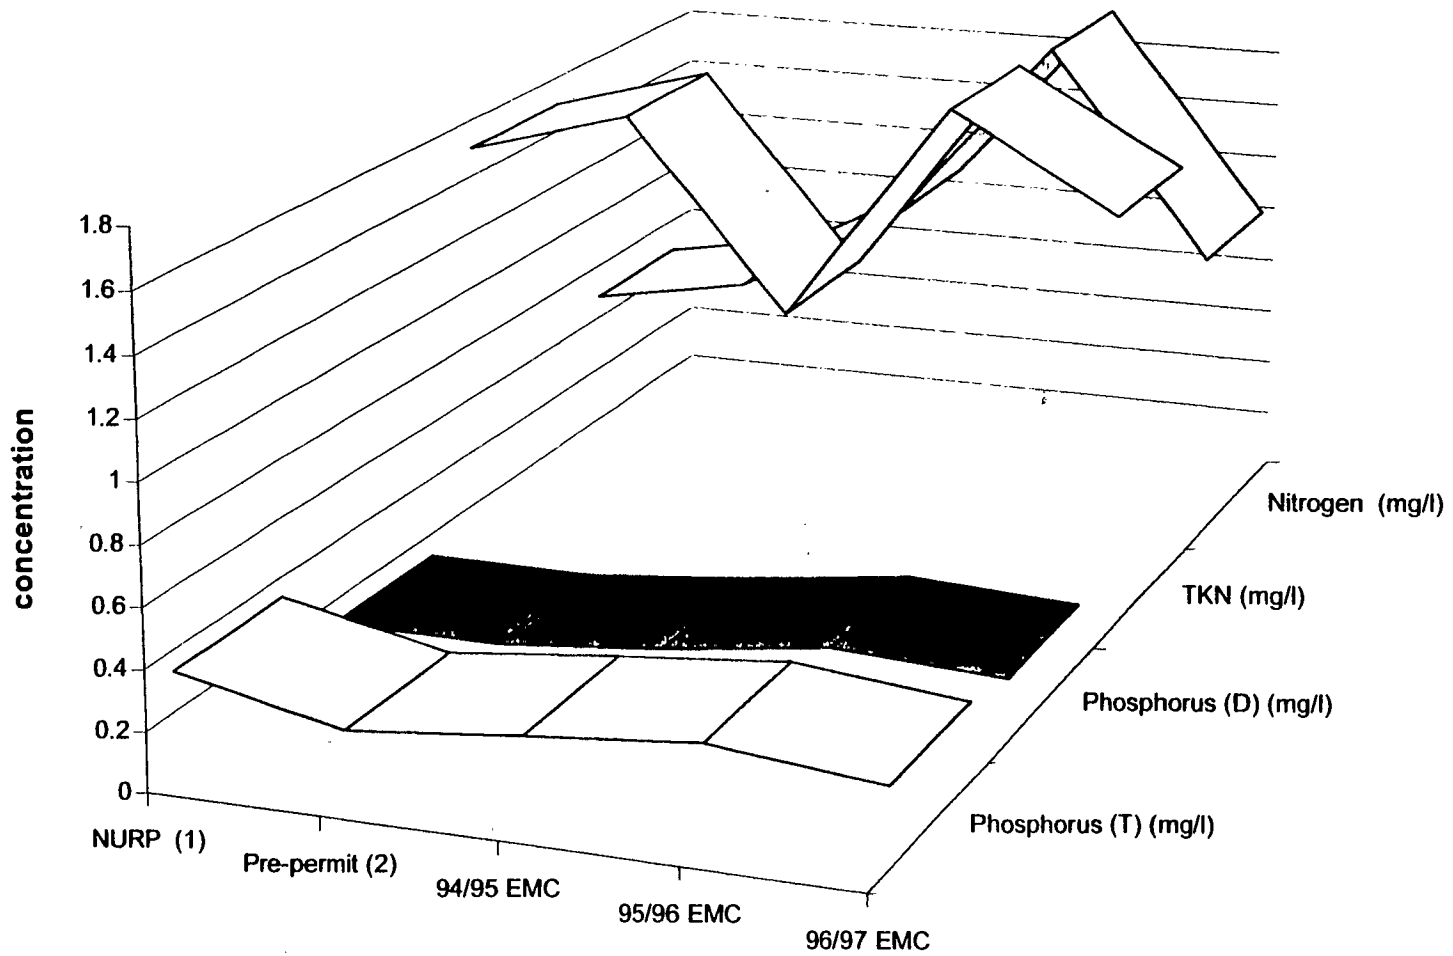
(1) Reference: U.S. EPA Results of Nationwide Urban Runoff Program, Washington, D.C. Tables 6-12 & 6-17.
(2) Reference: Part 2 Application for NPDES Municipal Storm Water Discharge Permit, submitted to U.S. EPA, Table 3-11.
* No analysis completed for this data.

The following charts give a simple graphical representation of the above table.



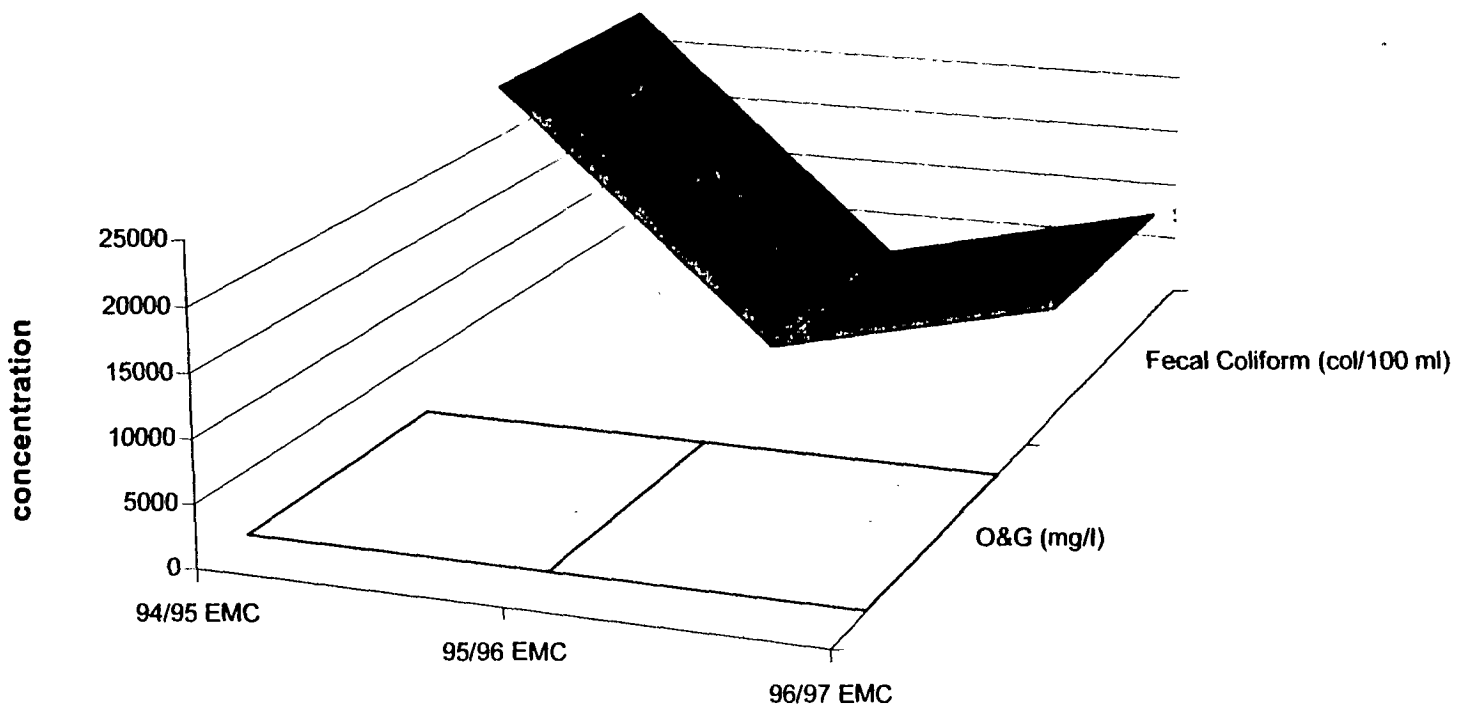
R0012990

Metals



R0012991

BOD, COD



R0012992

Phosphorus (total & dissolved), TKN, Nitrogen

R0012993

Oil & Grease, Fecal Coliform

R0012994

After reviewing the charts the following conclusions were drawn.

- There was a reduction in the concentration of three of four metals analyzed with the cadmium showing no change in concentration.
- There is not enough data to determine an overall trend for fecal coliform and oil & grease.
- Long term trends show that nitrogen and total kjeldahl nitrogen(TKN) are erratic at best, but appear to have decreased in concentration during this reporting period.
- Both total and dissolved phosphorus appears to have remained at a constant level.
- Total dissolved solids (TDS) concentrations continue to increase while total suspended solids (TSS) were reduced slightly.

STANDARD OPERATING PROCEDURES
FOR
WET WEATHER FIELD SCREENINGS

CITY OF TULSA, OKLAHOMA
DEPARTMENT OF PUBLIC WORKS
ENVIRONMENTAL OPERATIONS DIVISION
QUALITY ASSURANCE SECTION

REVISION DATE : July 17, 1997

OBJECTIVE : These procedures are designed in order to insure the completion of the Wet Weather Field Screening requirement found in the City's Municipal Storm Water Discharge Permit # OKS000201. The wet weather field screening program was developed in order to identify watersheds within the City which have a poor quality discharge during storm events. Once these areas of reduced water quality are identified other storm water quality programs can be implemented.

The wet weather field screening program can also be used to gauge the effectiveness of other storm water permit programs and storm water best management practices (BMP). If results are not what were anticipated, then corrective action can be taken.

These procedures will update the Storm Water Management Program (Part II.A.) of the City's Municipal Storm water Discharge Permit. Implementation of these procedures shall commence by January 1, 1996.

WORK GROUP : These procedures will be implemented and used by personnel of the Industrial Pretreatment group of the Quality Assurance Section of the Public Works Dept.

Wet Weather Field Screening Procedures

I. Identification of Screening Location for Each Watershed

Within the corporate boundary of the City of Tulsa there are a number of individual watersheds. Each watershed will be represented by at least 1 wet weather field screening location. Thirty four screening locations have been selected. They are:

Watershed	Screening Location
1) Upper Mingo - Sugar Creek - Southpark - Ford Creek - Catfish Creek - Upper Mingo - Alsuma Creek	N/W corner of Hicks Park (bridge)

	Watershed	Screening Location
2)	Fulton Creek / Bell Creek	behind 3235 South 93rd East Ave.
3)	Audobon Creek	2500 South 92nd East Ave (South East corner of Rockwell detention pond on northside of creek)
4)	Jones Creek / Mill Creek	1120 South 89th East Ave (bridge)
5)	Tupelo Creek	5th Street & South Mingo (bridge)
6)	Cooley Creek	North of US 169 & Admiral Blvd (bridge)
7)	Lower Mingo	46th Street North @ Mingo Creek (bridge)
8)	Swan Creek	2700 South Riverside Drive (outfall)
9)	Coal Creek	5600 East Mohawk Park Drive (bridge)
10)	Flat Rock Creek	US 75 @ Flat Rock Creek (bridge)
11)	Dirty Butter Creek	36th Street North @ Dirty Butter Creek (bridge)
12)	Valley View Creek Channel	833 East 46th Street North (bridge)
13)	Harlow Creek Tributary	6216 West Edison (bridge)
14)	Harlow Creek	4701 West Edison (north bridge)
15)	Parkview Ditch	1710 West Charles Page (bridge)
16)	Civic Center (DT) / Oak Creek	East bank US 75 @ Arkansas River (E1SW)
17)	Elm Creek	2200 South Riverside Drive (B1SW)
18)	Crow Creek	Crow Creek @ Riverside Dr (Pedestrian bridge)
19)	Joe Creek	Joe Creek @ Riverside Drive (bridge)
20)	Fred Creek	81st Street @ Fred Creek (bridge)
21)	Vensel Creek	South Delaware @ Vensel Creek (bridge)
22)	Cherry Creek / Redfork Creek	4900 South Elwood Ave (bridge)
23)	Mooser Creek	5200 South Elwood Ave (bridge)
24)	Fry Ditch #2	10524 South 76th East Ave (bridge)
25)	West Branch of Haikey Creek	8000 South Garnett (bridge)
26)	Adams Creek	17625 East 51st Street (bridge)
27)	Spunky Creek (south)	3300 South 193rd East Ave (bridge)
28)	Spunky Creek (north)	1400 South 193rd East Ave (bridge)
29)	Perryman Ditch	5600 South Riverside Drive (outfall)
30)	Nickel Creek	3100 West 91st Street South (bridge)
31)	Hager Creek	702 West 91st Street South (bridge)
32)	Little Haikey Creek	10500 East 101st Street South (bridge)
33)	Flat Rock Creek Tributary	Flat Rock Creek Trib & US 75
34)	Brookhollow Creek	2900 South Mingo Road (bridge)

Each screening location has been chosen prior to the program implementation using the following criteria :

- Screening location would best represent the entire watershed
- Screening location is accessible by sampling crews,
- Screening location is safe for sampling crews during wet weather events.

The screening of these 34 watersheds will be completed as per the City's compliance schedule milestone (Part III,A,6). At least 50% of these watersheds will be screened by July

1, 1997 and 100% by July 1, 1999. Depending on the results, additional screening may be required. Baseline screening will be performed provided the resources are available.

II. Pre-storm Event Procedures

Some portions of the wet weather field screening must be performed during a storm event. This places the group responsible for the completion of these procedures at the mercy of the weather, which can be unpredictable.. Therefore, pre-storm event planning and preparation is a high priority. The following items must be completed during the pre-storm event preparation.

1. Become familiar with screening locations;
2. Monitor weather conditions;
3. Obtain and prepare equipment and bottles necessary to perform wet weather field screening;
4. Place crews on standby after normal business hours once conditions appear favorable for a storm event;
5. Target watersheds in which screening must occur;
6. Notify the laboratory

III. Storm Event Procedures

A storm event is defined as "a rainfall event with a magnitude of 0.1 inch or greater which occurs after a period of 72 hours with less than a 0.1 inch of rainfall. Rainfall information can be found in the rainfall information sheet obtained daily from Customer Services (596-1846). This sheet is located either near the Storm water Watershed Map or in the file marked NovaStar Rain Data. Once a storm event occurs the following items must be completed:

1) Obtain wet weather field screening samples at targeted watershed screening locations. All samples must be grab samples for each field screening location and must be taken during the first two hours of the storm event. Each sample must be properly labeled and immediately cooled to less than 4 degrees C.

2) Field screening analysis for each screening locations sampled must be performed. This includes:

   Visual Inspection for :
   - Odor,
   - Color,
   - Clarity, and
   - Floatables.

Parameters to be sampled and analyzed are:

Parameters	Container type	Sample Volume	Container Number
° Water Temperature	plastic	250ml	1
° pH	plastic	250ml	1
° Hardness	plastic	250ml	1
- Fecal Coliform	plastic (whirlpak)	100ml	2
- Cd (cadmium)	plastic	1000ml	3
- Zn (zinc)	plastic	1000ml	3
- Cu (copper)	plastic	1000ml	3
- Pb (lead)	plastic	1000ml	3
- TDS	plastic	1000ml	4
- TSS	plastic	1000ml	4
- Oil & Grease	glass	2000ml	5
- COD	plastic	1000ml	6
- TKN	plastic	1000ml	6
- Nitrogen (total)	plastic	1000ml	6
- Phosphorus (total)	plastic	1000ml	6
- Phosphorus (dis.)	plastic	1000ml	6
- Ammonia	plastic	1000ml	6
- BOD5	plastic	1000ml	7
- Phenol	glass (amber)	1000ml	8

° Analysis will be performed by Industrial Pretreatment using EPA Approved Methods
- Analysis will be performed by the Quality Assurance Laboratory using EPA Approved Methods
Shaded areas represent individual bottles, (i.e. . Cd, Zn, Cu, Pb would be one bottle of 1000 ml).

4) Complete "Wet Weather Field Screening" sheet (Attachment A) for each field screening location.

5) Complete a chain of custody form for each screening location

6) Transport all field screening samples along with the proper chain of custody to the Northside Laboratory, except for the fecal coliform, which is delivered to the Mohawk Laboratory.

IV. QA/QC

In order to insure the implementation of sound sampling procedures, at least one quality control/quality assurance sample must be obtained with every sampling event. The QA/QC samples will consist of field blanks and duplicate analyses. Field blanks consist of filling sample bottles with reagent grade analyte free deionized water while in the field. The field blanks will be submitted to the laboratory for analysis for the following parameters:

- Zinc (total)
- Fecal Coliform
- Cadmium (total)
- TKN
- Copper (total)
- Phosphorus (dissolved)
- Phenol
- TSS
- TDS
- Oil & Grease
- COD
- Nitrogen (total)
- Phosphorus (total)
- Lead (total)
- BOD5
- Ammonia

Each sampling crew must obtain a field blank with each set of samples they are obtaining. For example:

sampling crew X is required to obtain samples from watershed #1 and #2. They would obtain one field blank and have it analyzed for the above parameters. If there are 3 sampling crews involved with the collection of 10 samples then three field blanks would be collected and turned into the laboratory for analysis.

Duplicate analyses will also be performed for one out of every ten samples analyzed by Industrial Pretreatment for hardness.

Matrix spikes and duplicates analysis will be performed by Quality Assurance Laboratories.

V. Post Storm Event Procedures

Once the field work is completed then the completion of the necessary office work is required to finish up wet weather field screening for the targeted screening locations. The extent of the follow-up work is dictated by the results of the field screening. The following procedures must be implemented during post storm event wet weather field screening:

1) Complete the following paper work within 48 hours of the end of the rainfall event sampled; "Storm Event Check List," "Rainfall Data Information Sheet," and "Storm Event Data Sheet." (see attachments).

2) All completed "Wet Weather Field Screening" sheets and laboratory analysis reports must be reviewed by an Environmental Compliance Specialist.

3) If results reveal "unusually high pollutant concentrations" in runoff, then one or any combination of the following actions may be employed :
   a) Implementation of a storm water management program found in the Permit;
   b) Revision of storm water BMP;
   c) Implement further wet weather field screening upstream if the screening location in order to locate source(s) of pollutants.

3) "Unusually high pollutant concentrations" are defined as those pollutants found in concentration above the typical values of the same pollutants in previous storm event samples.

Once corrective action is taken in the watershed with "unusually high pollutant concentrations", re-screen the watershed to determine if runoff quality has improved. If runoff quality has not improved then continue to implement aforementioned actions until runoff quality improves.

Data from the "Wet Weather Field Screening" sheets and the laboratory results should now be entered into the WETWETH.MDB database (attachment B).

VI. Report / Data Usage

The data obtained during the wet weather field screening will be used for report generation. A report will be completed by July 1 annually. The report will include :

1) The number of locations screened from July 1st through June 30th;
2) Results of all screenings;
3) The number of screened locations with poor quality runoff;
4) Actions taken to address poor quality runoff; and
5) All follow-up screening data.

Copies of this report will be distributed for review.

VII. Note

1) Storm event monitoring must take precedence over wet weather field screening during each storm event sampling period.

2) Direct any questions regarding this SOP or dry weather field screening to Scott VanLoo.

THIRD ANNUAL REPORT

THE BROWARD COUNTY EPA NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM (NPDES) MUNICIPAL SEPARATE STORM SEWER SYSTEM (MS4) PERMIT (NPDES NUMBER FLS000016, EFFECTIVE DATE DECEMBER 1, 1996)

A. LIST OF CONTACTS AND RESPONSIBLE PARTIES

The following persons are either responsible for or had significant input into the preparation of the annual report:

CITY OF COCONUT CREEK
Mr. Brij Garg
City Engineer
City of Coconut Creek
4800 West Copans Road
Coconut Creek, FL 33063
Phone: 973-6786
Fax: 973-6794

CITY OF COOPER CITY
Mr. James Molaschi
Assistant Engineer
City of Cooper City
11791 SW 49 Street
Cooper City, FL 33330-4454
Phone: 434-5519
Fax: 680-3159

Mr. George Haughney
Utility Director
Phone: 434-5519
Fax: 680-3159

CITY OF CORAL SPRINGS
Mr. Louis Aurigemma
City Engineer
City of Coral Springs
9551 West Sample Road
Coral Springs, FL 33065
Phone: 345-2161
Fax: 345-2169

CITY OF DANIA
Mr. Robert Palm
Public Works/ Utilities Director
City of Dania
100 West Dania Beach Blvd.
Dania, FL 33004
Phone: 921-8700 Ext. 321
Fax: 923-1109

TOWN OF DAVIE
Mr. John E. Doherty
Assistant Town Engineer
Town of Davie
6591 S.W. 45th Street
Davie, FL 33314
Phone: 797-1113
Fax: 797-2095

CITY OF DEERFIELD BEACH
Mr. Donald Freedland
City of Deerfield Beach
210 Goolsby Blvd.
Deerfield Beach, FL 33442
Phone: 480-4390
Fax: 480-4393

CITY OF HALLANDALE
Mr. Carlos Adorisio
Assistant City Engineer
City of Hallandale
400 South Federal Highway
Hallandale, FL 33009
Phone: 457-1623
Fax: 457-1624

TOWN OF LAUDERDALE-BY-THE-SEA
Mr. Bill Mason
Public Works Director
Town of Lauderdale- by- the- Sea
4501 Ocean Drive
Lauderdale-by-the-Sea, FL 33308
Phone: 776-0576
Fax: 776-1857

CITY OF LAUDERDALE LAKES
Ms. Sharen Parrish
Director of Public Works & Engineering Svc
City of Lauderdale Lakes
4300 N.W. 36 Street
Lauderdale Lakes, FL 33319
Phone: 731-1212 Ext. 255
Fax: 733-5126

Mr. Jose Roussean
Assistant Superintendent
(954) 731- 1212 Ext. 256

CITY OF LAUDERHILL
Mr. Donald Giancoli
Acting Director of Environmental and
Engineering Services Department
City of Lauderhill
2000 City Hall Drive
Lauderhill, FL 33313
Phone: 730-2961
Fax: 730-4241

Mr. Charles E. Cuyler
Facilities & Transporation
Maintenance Superintendent
Phone: 730-2962

CITY OF LIGHTHOUSE POINT
Mr. Art Graham
City of Lighthouse Point
2200 N.E. 38th Street
Lighthouse Point, FL 33064
Phone: 946-7386
Fax: 784-3446

CITY OF MARGATE
Mr. Steven Ivanic
Engineer
City of Margate
1001 West River Drive
Margate, FL 33063
Phone: 972-0828 Beeper# (954) 896-6725
Fax: 978-3489

Mr. Emilio C. Esteban, P.E.
Director
Phone: 972-0828
Fax: 978-3489

CITY OF MIRAMAR
Mr. Evan Cross
Public Works Operations Manager
City of Miramar
13900 Pembroke Road
Miramar, FL 33027
Phone: 442-4022
Fax: 442-4027

Rafael Pena
Public Works Operations Administrator
City of Miramar
13900 Pembroke Road
Miramar, FL 33027
Phone: 442-4023
Fax: 442-4027

CITY OF NORTH LAUDERDALE
Mr. Mike Shields
Director of Public Works/ Utilities
City of North Lauderdale
701 S.W. 71 Avenue
North Lauderdale, FL 33068
Phone: 724-7070
Fax: 720-2064

Mr. William Peck
Superintendent of Public Works
Phone: 724-7070
Fax: 720-2064

CITY OF OAKLAND PARK
Mr. Robert D. Frank
Public Works Director
3650 N.E. 12 th Avenue
Oakland Park, FL 33334
Phone: 561-6280
Fax: 561-6296

Mr. David C. Womacks
Streets and Stormwater Manager
Phone: 561-6271
Fax: 561-6296

CITY OF PARKLAND
Mr. Charles Dabrusco
City Engineer
City of Parkland
6500 Parkside Drive
Parkland, FL 33067
Phone: 753-5040
Fax: 341-5161

TOWN OF PEMBROKE PARK
Mr. Todd Larson
Town of Pembroke Park
3150 S.W. 52nd Avenue
Pembroke Park, FL 33023
Phone: 966-4600, ext 1212
Fax: 966-5186

CITY OF PEMBROKE PINES
Mr. Andrew Mack
Assistant Engineer
City of Pembroke Pines
13975 Pembroke Road
Pembroke Pines, FL 33027
Phone: 435-6511
Fax: 435-6755

Mr. Shawn Denton
Assistant Director of Public Services
City of Pembroke Pines
13975 Pembroke Rd.
Pembroke Pines, FL 33027
Phone: 437-1111
Fax:

CITY OF PLANTATION
Mr. Gus Khavanin
City Engineer
City of Plantation
400 N.W. 73 Avenue
Plantation, FL 33317
Phone: 797-2282
Fax: 797-2761

Ms. Alina Sardinas
Assistant City Engineer
Phone: 797-2282

CITY OF POMPANO BEACH
Mr. William Flaherty
City of Pompano Beach
1201 NE 5th Ave., P.O. Box 1300
Pompano Beach, FL 33061
Phone: 786-4061
Fax: 786-4028

Kristen Smeltzer, P.E.
Civil Engineer
Phone: 786-4061
Fax: 786-4028

VILLAGE OF SEA RANCH LAKES

B. OVERALL EVALUATION OF THE SWMP

Objective of the Program

Broward County is complying with the requirements of the NPDES MS4 Permit by implementing a comprehensive Storm Water Management Program (SWMP). The intent of the SWMP is to reduce the amount of pollutants, generally to the maximum extent possible, entering waters of the United States through the MS4 of unincorporated Broward County and the other co-permittees for the Broward County MS4 permit.

Nine stormwater management programs are required to be developed and implemented within the first three years of the permit. Within these nine programs, there are 102 activities or tasks that are required to be performed.

Major Findings

The following major findings of the program include the following:

- $ Dry field screening revealed that no illicit discharges to the MS4 were evident in 50 major outfalls in Broward County.
- $ Co-permittee inspection and maintenance activities at stormwater treatment ponds and exfiltration trenches compared favorably with EPA goals.
- $ Five out of 53 Stormwater drainage complaints received resulted in warning notices.
- $ Two golf courses in Broward County were investigated for pesticide and nutrient runoff. Some pesticides and nutrients were found in small quantities near surface water bodies.

Major Accomplishments

Some of the major accomplishments of the program include the following:

- $ Completion of the 50-site dry field screening and monitoring of five wet field sites.
- $ NPDES Annual Workshop has provided a valuable resource for the co-permittees to coordinate and discuss activities for the implementation of Stormwater management programs.
- $ An Educational Workshop was given for Best Management Practices on Erosion and Sedimentation control. Twenty five people were certified by the state after passing an examination.
- $ Broward County DPEP gave a presentation to the painting and decorating contractors about potential pollution problems and solutions as part of their public outreach program.
- $ Household Hazardous Waste Collection Program collected flammable, toxic, corrosive and reactive waste from Broward County residents. Educational material associated with disposal techniques for oils, toxins, and household waste materials were distributed to public.
- $ Some of the co-permittees have started public out reach programs on how to protect surface water from getting contaminated.
- $ Forty-eight facilities were inspected for non-domestic direct discharge.
- $ Construction sites with area greater than five acres were inspected for sedimentation and erosion control measures. General contractors were informed about Notice of Intent (NOI) to EPA and Best

Management Practices for construction runoff.

- $ Enforcement action was taken against five vehicle wash facilities that were out of compliance.
- $ Best management practices for marine facilities were developed and distributed to the public.
- $ The city of Tamarac started a comprehensive street improvement program. The summary of the program has been included in attachment 20.

Strengths

Co-permittees are pro-active in public education about pollution control to the storm drains. More cities are installing pollution control baffles for control of debris, grease and oils in their catch basins.

More Co-permittees are working towards creating more accurate data base of their outfalls with new available technology like geographical information system. This will help in the future for dryfield screening and maintenance of those outfalls.

Weaknesses

Some of the work performed by DPEP are also requirements of the City of Fort Lauderdale and the City of Hollywood permits which is a duplicate work efforts.

The five year Broward County permit ends on December 2001. However, DEP is proposing to charge fee from September 1, 2000 as they receive delegation from EPA. The DEP fee will be an extra financial burden for all co-permitees that was not expected.

There is uncertainty as to how much the DEP permit fees will be. It could be a big burden for small co-permittees in the Broward County.

The City of Weston which was part of the unincorporated Broward County is now an incorporated city. To our knowledge, Weston has not been added as a co-permittee on the Broward County permit.

Future Direction of Program

The long-term future direction of the program is dependent upon the involvement of the state and federal agencies. Delegation of the NPDES MS4 Stormwater permitting program to Florida Department of Environmental Protection may institute changes which are unknown at this time. FDEP Phase II Storm Water management program may also affect the future direction of the program. Our understanding from representatives of DEP is that current co-permittees will remain co-permittees regardless of whether their population now exceeds 100,000 or weather they qualify under the Phase II regulations.

C. SUMMARY TABLE FOR STORM WATER MANAGEMENT PROGRAM ELEMENT STATUS/COMPLIANCE

PROGRAM ELEMENT	PERMITTEE	REQUIREMENT	ACTIVITY SCHEDULE			COMMENTS
			Activities Required by SWMP	Complied with	Activities Accomplished during calendar year	
Structural Controls	Coconut Creek	Canals Inspected	15 miles, once/ mos.	YES	10 miles, once/ mos	Copies of Inspection Report Forms Available Upon Request
		Canals Maintained	As needed	N/A	7 miles maintained	Copies of Inspection Report Forms Available Upon Request
		Inlets and Catch Basins Inspected	1400 units once/3 months	YES	1400 units once/3 mos	critical units inspection 3 mos
		Inlets and Catch Basins Maintained	As needed	N/A	283 units once/yr	Copies of Inspection Report Forms Available Upon Request
		Storm Water Treatment Ponds Inspected	2 semi-annually	YES	2 semi-annually	Copies of Inspection Report Forms Available Upon Request
		Channel Control Structures Inspected	5 units once/month	YES	5 units/mos	Out falls were inspected
	Cooper City	Stormwater Pump Station Inspected	1 unit once/mos	YES	1 unit once/mos	Records available on request
		Stormwater Treatment Ponds Inspected	1 once/mos	YES	1 once/mos	Records available on request
		Channel Control Structures Inspected	25 unit once/mos	YES	25 unit once/mos	Records available on request
	Coral Springs	Canals Inspected/ Maintained	Not applicable	N/A	Not applicable	Drainage district inspects and maintained the canal
		Lakes/detention Ponds Inspected/ Maintained	Not applicable	N/A	Not applicable	No lakes or Detention ponds owned by the city
	Dania	Inlet and Catch Basins Inspected	872 unit twice/yr	YES	899 units twice/yr	Records are available on request
		Inlets and Catch Basins Maintained	872 unit twice/yr	YES	899 units twice/yr	Records are available on request
		Canals Inspected	8 miles twice/month	YES	8 miles inspected	Records are available on request
		Canals Maintained	As needed	YES	8 miles maintained	Records are available on request
		Stormwater Pump Station Inspected	1 unit once/month	YES	1 unit twice/yr	Records are available on request
		Storm Treatment Pond-dry Retention or Detention Maintained	maintained once per month	YES	maintained once per month	Records are available on request

R0013013

PROGRAM ELEMENT	PERMITTEE	REQUIREMENT	ACTIVITY SCHEDULE			COMMENTS
			Activities Required by SWMP	Complied with	Activities Accomplished during calendar year	
		Grate Inlets Inspected	As needed	YES	Checked and cleaned after every storm	Records are available on request
	Davie	Inlets and Catch Basins inspected	2307 Unit once/year	YES	2307 Unit once/year	Records are available on request
		Lakes/detention Ponds - Acres	4 once/mos	N/A	4 once/mos	Records are available on request
	Deerfield Beach	Canals Inspected	10 miles twice/yr	YES	10 miles twice/yr	Records are available on request
		Canals Maintained	As needed	YES	10 miles twice/yr	Records are available on request
		Exfiltration Trench	15 miles twice/yr	YES	15 miles twice/yr	Records are available on request
		Stormwater Treatment Dry Ponds	2 times /yr	YES	2 times/yr	Records are available on request
		Stormwater Treatment Wet Ponds	2 times/yr	YES	2 times /yr	Records are available on request
	Hallandale	Canals Inspected	8.2 miles once/mos	YES	8.2 miles/mos	Schaffer Canal was also inspected
		Stormwater Lift Station	4 units once/mos	YES	4 units once/mos	Inspected and maintained Records are available
		Swales	N/a	N/A	N/a	Maintained by the property owner
	Lauderdale by the Sea	Catch Basins Inspected	23 units 4 times/yr	YES	23 units 4 times/yr	Records are available on request
		Infiltration Trenches	20 units 4 times/yr	YES	20 units 4 times/yr	Records are available on request
	Lauderdale Lakes	Canals Inspected	11 surface Acres/Week	YES	11 surface Acres/Week	Records are available on request
		Canals Maintained	69 Surface Acres/ 6 mos	YES	69 Surface Acres/ 6 mos	Records are available on request

D. NARRATIVE REPORT

The narrative report is set up in the following manner. The SWMP element's objective (in bold) is followed by each individual NPDES MS4 Permit annual report requirement (in italics) under general discussion of element, strengths and weaknesses, assessment of controls, revisions, and compliance status of the elements. The Narrative Report section of the Annual report primarily discuss those SWMP Elements which were not included within the SWMP Summary Table.

1. Operation and Maintenance of Structural Controls and Storm Water Collection Systems

Objective: reduce the discharge of pollutants to the maximum extent practical

General Discussions:

Conduct inspections and maintenance of the structural controls and storm water collection systems discharging to the MS4 within each permittee's jurisdictional area. Maintain an internal record keeping system to track inspections and maintenance activities performed on structural controls during the permit term. Annually, assess the accomplishments of your inspection and maintenance program as compared to the target goals outlined in Table II.A.1.b. on pages 5 - 13 of this permit.

The Summary Table in Section C of this report, entitled "Co-Permittees Activities Accomplished During Calendar Year" summarizes the co-permittee inspection and maintenance (I&M) activities at structural controls and storm water collection systems. This program is very effective. Some of the co-permittees have added more staff and resources to fulfill this requirement.

Strengths and Weaknesses:

Co-permittees achieved the target goals outlined in Table II.A.1.b. This enables entities responsible for the system to evaluate the condition of the facilities and the need for maintenance repairs and replacement. A weaknesses of the program is that level of detail varies from co-permittee to co-permittee based on the level of information given at the time of permit application.

Assessment of Control:

Current controls are adequate for complying with the permit requirements.

Revisions:

No revisions are required or requested for this element.

Compliance Status:

Compliance achieved.

2. *Control of Discharges from Areas of New Development and Significant Redevelopment*

Objective: to reduce discharge of pollutants from MS4s, which receive discharges from areas of new development and significant redevelopment.

Activities completed:

Broward County achieves compliance through stormwater management construction/operation licensing from DPEP, and FDOT achieves compliance through their drainage connection permits. FDOT District four has updated the report form for outfall inspections (Appendix I-1 of Attachment 23) to identify connections to FDOT District Four's MS4 and other relevant information.

General Discussion:

Continue to implement the Broward County Land Use Plan which contains objectives and policies relating to drainage and storm water management that provide controls for areas of new development and significant redevelopment. For areas of new development, adhere to the treatment performance standards set forth in the State Water Policy.

Broward County continues to implement the land use plans. An updated Broward County Land Use Plan was adopted on November 19, 1996. The Plan's Drainage and Natural Aquifer Groundwater Recharge Element contains the following objectives:

- $ Objective 7.1. The Office of Environmental Services (OES) shall implement drainage improvement to remove Group One Deficiencies by 2010, and South County (SC) and Central County (CC) deficiencies by 2015.
- $ Objective 7.2. Stormwater management facilities shall be provided to meet the County's short-term and long-term future surface water management needs.
- $ Objective 7.3. Continue to maximize the use of Stormwater management system facilities so as to encourage compact urban growth patterns.
- $ Objective 7.4. Stormwater management facilities shall be designed, constructed and operated in a manner that conserves potable water resources.
- $ Objective 7.5. Maintain and protect groundwater recharge of the surficial aquifer systems so as to maintain all of the functions of the Biscayne Aquifer.

New development in the areas outside of the independent districts must receive a stormwater management construction/operation license from DPEP. These licenses must comply with State Water Policy, as stated in Broward County Code, Section 27-200 (b)(1)h:

> No surface water management license shall be issued in the absence of reasonable assurances by the applicant that the surface water management system is consistent with the state water policy, Chapter 62-40, F.A.C.

Employ new FDOT Drainage Connection Permit requirements which include a "certification of water quality" to be provided by the connecting entity.

The FDOT Turnpike District has implemented the drainage permit requirement as per Chapter 14-86 which includes a "certification of water quality" to be provided by the connecting entity. Procedures and maintenance responsibilities for post-development operation and maintenance are established in Chapter 14-86 of Florida Statutes, and outlined in drainage connection permit application issued by the FDOT.

FDOT District Four accomplishes the control of development and significant redevelopment through the Drainage Connection Permit. A blank copy of the Drainage Connection Permit Application and Permit are provided in Appendix B of District Four report in Attachment 23. It should be noted that receipt of a Drainage Connection Permit does not alleviate the applicant from obtaining a state Stormwater management permit. FDOT District Four is planning to document applicants that actually connect to the MS4, by using the database being developed, and in the review of the Drainage Connection Permit applications (see Appendix I-1 of Attachment 23).

Strengths and Weakness:

This SWMP protects the environment and the plan consistent with all drainage districts throughout Broward County. The weakness of the program is only 19 co-permittees receive stormwater management licenses from DPEP and rest of them receive licenses from independent drainage districts. The independent drainage districts are not co-permittees with Broward County.

The strength of the FDOT Drainage Connection Permit is that it requires applicants to certify compliance with Florida Administrative Code Rule 14-86 that states that "the quality of water conveyed by the connection meets all applicable water quality standards or minimum design and performance standards." Thus the permit serves to minimize impacts of new and significant redevelopment on the water quality. A weakness of the Drainage Connection Permit is that there is no distinction between on-site retention and an actual "connection" to the MS4. Generally, FDOT District Four does not permit new connections to the MS4; however, the wording of the permit does not allow for identification of the few exceptions, the actual connections to the MS4. The review process has been updated to rectify this weakness (see Appendix I-1 in Attachment 23).

Assessment of Controls:

Broward county meets compliance requirements in its jurisdiction. FDOT employs non-structural controls to adequately meet compliance in this area. These controls are the Drainage Connection Permit and the general practice not allowing new connections by permittees to the FDOT MS4. Issuance of Drainage Connection Permits has enabled the FDOT to inventory drainage connections tied to the FDOT systems and to control the quality of discharges to FDOT MS4.

Revisions:

No revisions are required or requested for this element.

Compliance Status:

Compliance Achieved

3. Operation and Maintenance of Public Streets, Roads, and Highways

Objective: Operate and maintain public streets in a manner to reduce the discharge of pollutants to the maximum extent possible.

Activities Completed:

All the co-permittees achieved their target during the third year period of this report.

General Discussion:

Implement the litter control program(s) for highways and streets within each permittee's jurisdictional area, as described within the SWMP of the Part 2 application, and properly dispose of the collected material. Perform scheduled maintenance on storm water structures (i.e. catch basins, etc.) and roadside ditches and properly dispose of accumulated sediments. Maintain an internal log documenting these maintenance activities. If these activities are performed by others under a contractual agreement, then the permittee shall retain copies of the contractual agreement which specifies the maintenance activities to be performed and the schedule of frequency.

The Summary Table in Section C of this report, entitled "Co-Permittee Activities Accomplished During Calendar Year" summarizes the co-permittee maintenance schedule and inspection and maintenance (I&M) activities associated with public streets and roads.

Provide a description, for incorporation into the permit, of the standard practices employed to reduce the pollutants in storm water runoff from areas associated with road repair and from all municipally-owned or operated equipment yards and maintenance shops that support road maintenance activities.

This was provided in the First Annual report as required by the permit.

Actively support and promote on a regular basis participation in the Broward Clean and Beautiful Program (an affiliate of Keep America Beautiful, Inc). Provide a summary of the activities performed under this program, within jurisdictional limits, to maintain the public streets, roads and highways.

Formed in 1993, Broward Beautiful (formerly Broward Clean and Beautiful Program) is a public service organization whose goal is to initiate, develop, coordinate, and direct programs for county-wide beautification in cooperation with the citizens, local governments, and businesses of Broward County, Florida. A 14-member Broward Beautiful Board of Directors, appointed by the Broward County Board of County Commissioners, approves of Broward Beautiful fund disbursements.

Broward Beautiful relies on partnerships of business, government, and local groups and employs proven techniques to improve the community appearances. Broward Beautiful's Award Program

recognizes businesses that implement landscaping that beautifies and conforms to basic Broward Beautiful design criteria. The Broward Beautiful Community Grant Program has been established to provide financial assistance to qualifying organizations looking to improve and preserve the natural beauty and environment of Broward County. Grant applications were made available in the year 1999.

The Broward Beautiful Program continues to receive the support of Broward County and the other co-permittees:

- $ The Executive Director of Broward Beautiful is Jennifer Fields Schaufele, Assistant to the DPEP Director.
- $ Roy Gold of Coral Springs is a member of the Broward Beautiful Board of Directors.
- $ The Broward County Commission has supplied $149,000 to support the Broward Beautiful program in Fiscal Year 1999 (October 1998 to September 1999).
- $ Staff support, postage, office space, copying, and other services have been provided in-kind by the DPEP.
- $ As part of the Great Florida Cleanup, Broward Beautiful and DPEP performed a one-day beach cleanup on September 18, 1999. DPEP provided $3,224 of support for the program for T-shirts, publicity, etc.
- $ Florida Department of Transportation has designated $350,000 of "beautification money" to Broward Beautiful.
- $ DPEP and Broward Beautiful sponsored the annual Waterway Cleanup, where debris is removed from Broward County waterways.

Some of the co-permittees like the City of Oakland Park started a program called "Adopt a Street" for beautification. Flyers distributed to the public are in Attachment 25 which gives the list of streets adopted in the year 1999 and available streets for future adoption.

Coordinate the "Adopt-A-Highway" program for local organizations to be identified with specific highway cleanup and beautification projects. Conduct routine inspections of each FDOT maintenance facility to verify that BMPs are operational and to determine changes necessary to improve runoff quality.

The FDOT statewide "Adopt -A-Highway" program has been in place since 1990. This program is effective on allowing the general public to participate on cleaning up state roadways and promoting a cleaner environment. The FDOT has coordinated, through the local maintenance offices, 2340 volunteers who have cleaned up around 300 miles of roadway within the District Four and Turnpike. This program is effective on allowing the general public to participate on cleaning up state roadways and promoting a cleaner environment. FDOT has a web-page address is http: www.dot.state.fl.us moreDOT adopt.htm.

The FDOT District four and FDOT Turnpike don't have maintenance yards facilities within the limits of Broward County MS4 Permit area.

Strengths and Weakness:

The litter control program eliminates blockages in storm drains and reduces the possibilities of flooding. The work is labor intensive. There has been some concern that sediments removed may be considered hazardous material which is very expensive to dispose of.

Assessment of Control:

Current controls are adequate for complying with the permit requirements.

Revisions:

No revisions are required or requested for this element.

Compliance Status:

Compliance achieved by all co-permittees.

4. Ensure Flood Control Projects Consider Water Quality Impacts

Objective: Assess water quality impacts on receiving water for flood management projects

Activities Completed:

Areas of new development and new flood control projects in Broward County received a Stormwater Management Construction/Operation license. The list of those sites inspected this year is in Attachment 13.

The association of water quality facilities and flood control facilities for FDOT is governed by state regulations (Chapters 62-25 and 62-40) which require the treatment of stormwater runoff within all facilities constructed after 1985. FDOT structures comply with these requirements and require systems that connect to FDOT facilities to comply as well. It should be noted, however, that FDOT District Four has no requirements under this section of the permit.

General Discussion:

Ensure that all new developments, significant redevelopments and new flood control projects adhere to the performance standards set forth in the State Water Policy.

Areas of new development, significant redevelopment, and new flood control projects must receive a stormwater management construction/operation license. These licenses must comply with State Water Policy, as stated in Broward County Code, Section 27-200 (b)(1)h:
