#### **ENHANCED WATERSHED MANAGEMENT PROGRAM**

#### 1.0 INTRODUCTION

In order to satisfy the Los Angeles Municipal Separate Storm Sewer System (MS4) Permit (Permit) requirements, the City of Torrance (City) has developed this Enhanced Watershed Management Program (EWMP) for the Machado Lake Watershed portion within the jurisdiction of Torrance called TMDL Implementation Area (Implementation Area). The MS4 Permit was adopted on November 8, 2012, by the Los Angeles Regional Water Quality Control Board (Regional Board) and became effective December 28, 2012. The MS4 Permit was created for the purpose of protecting the beneficial uses in the receiving waters in the Los Angeles County region by ensuring that MS4s in the County of Los Angeles are not causing or contributing to exceedances of applicable water quality objectives. The MS4 Permit allows the permittees to customize their stormwater programs through the development and implementation of a EWMP to achieve compliance with certain receiving water limitations and water quality based effluent limits.

This EWMP documents the results of an effort to address impairments in the Machado Lake watershed with a comprehensive, phased approach of best management practice (BMP) implementation for the City. To develop this plan, BMPs to treat stormwater and dry weather flows to reduce nutrients, sediment, and other pollutants such as metals, bacteria, and toxics were identified and selected. As part of that process, benefits of management activities were estimated in terms of pollutant load reductions or improvement in water quality, to meet waste load allocations (WLAs) defined by approved total maximum daily loads (TMDLs) established for waters within the Machado Lake watershed.

#### 1.1 Regulatory Framework

The Los Angeles Regional Water Quality Control Board (LARWQCB or Regional Board) adopted Waste Discharge Requirements (WDRs) for MS4 discharges within the Coastal Watersheds of Los Angeles County on June 18, 1990, (Order No. 90-079; NPDES Permit No. CA0061654). The WDRs were later amended on December 13, 2001 (Order No. 01- 182; NPDES Permit No. CAS004001 [as amended]). The current MS4 Permit (Order No. R4-2012-0175; NPDES Permit No. CAS004001) was adopted on November 8, 2012 and became effective on December 28, 2012.

October 2016

The MS4 Permit contains effluent limitations, receiving water limitations (RWLs), Minimum Control Measures (MCMs), TMDL provisions, and outlines the process for developing watershed management programs (WMPs), including the EWMP. The MS4 Permit incorporates the TMDL WLAs applicable to dry- and wet-weather as Water Quality-Based Effluent Limitations (WQBELs) and/or Receiving Water Limitations (RWLs). Part V.A (pages 38-39) of the MS4 Permit requires compliance with the WQBELs and/or RWLs as outlined in the respective TMDLs.

#### 1.1.1 Relevant TMDLs

A TMDL is a regulatory term used to describe a value of the maximum amount of a pollutant that a water body can receive while still meeting water quality standards. Attachment N of the MS4 Permit, titled "TMDLs in Dominguez Channel and Greater Harbor Waters Watershed Management Area" lists information on TMDLs and incorporates WQBELs and RWLs relevant to the DC WMG including the TMDLs identified in Table 1.1

Table 1.1 provides a summary of the various existing and pending TMDLs associated with each body of water the City discharges into.

Table 1.1	Summary of TMDLs for City of Torrance				
Body of Water	TMDL Name	Pollutant <sup>(1)</sup>	Resolution Number	Effective Date	
Machado Lake	Nutrient	Nitrogen, Phosphorus	R08-006	11 March 2009	
	Trash	Trash	2007-006	6 March 2008	
Lake	Toxics	Pesticides, PCBs	R10-008	2 September 2010	

#### Notes:

- (1) Interim, final, and phased WLA are listed in Chapter 3 where applicable.
- (2) The Resolution Name for what is referred to here as the Dominguez Channel Toxics TMDL is "Los Angeles and Long Beach Harbors Toxic and Metals TMDLs." Dominguez Channel discharges into the Los Angeles and Long Beach Harbors.

#### 1.2 EWMP Overview

The Machado Lake trash TMDL is being addressed this year (2016) with the Machado Lake TMDL Project and therefore not addressed in this EWMP. The process of BMP selection considered cost-effectiveness to promote a practical and implementable plan. This report also includes integrated approaches that consider BMPs that can address multiple pollutants cost-effectively, while considering parallel water resources planning strategies for the watershed.

The report is organized into nine sections that in summary provide the following information:

 Section 1 provides background information on the Machado Lake watershed and its impairments and associated TMDLs.

- Section 2 provides more detailed descriptions of the Implementation Area, including the geologic setting, land uses, hydrology, and hydraulics.
- Section 3 characterizes, evaluates, and prioritizes pollutants and their sources within the Implementation Area.
- Section 4 details an evaluation of existing programs, mainly nonstructural in nature, to address the pollutants of concern.
- Section 5 presents candidate sites for structural BMP implementation and describes the regulatory and permit requirements that might apply to the proposed BMPs and that might affect the timing, feasibility, and cost of management alternatives.
- Section 6 presents an alternatives evaluation of different structural and nonstructural BMP management options.
- Section 7 includes a discussion of the integrated nature of the plan and its relation to other water resources efforts in the region.
- Section 8 documents schedules for implementing BMPs to meet phased WLA schedule.
- Section 9 presents cost estimates for the BMP alternatives.

#### 1.3 Machado Lake Watershed

The Machado Lake watershed is situated within the Dominguez Channel Watershed Management Area. Machado Lake is separate from Dominguez Channel and discharges, under storm conditions, to the Los Angeles Harbor. Machado Lake is considered a freshwater reservoir or lake approximately 40 acres in size located adjacent to Vermont Avenue south of its intersection with Pacific Coast Highway (USEPA, 2014b). The Basin Plan has identified the existing beneficial uses as WARM, WILD, RARE, WET, REC-1, and REC-2. Machado Lake is comprised of upper and lower basins separated by a lower earthen dam. The upper basin contains the 40-acre recreational lake created by the impoundment of stormwater runoff while the lower basin is a seasonal freshwater marsh of roughly 63 acres. The Wilmington Drain is a LACFCD facility managed by LACDPW tributary to Machado Lake. The earthen bottom section is characterized as a soft bottom vegetated channel, approximately 3,000 feet long. This portion of Wilmington Drain spans from Pacific Coast Highway to just north of Lomita Boulevard, bordered by mostly residential land uses to the west and the Interstate 110 to the east. Just south of Interstate 110 and upstream, the channel is concrete lined. Beneficial uses for the Wilmington Drain were identified based on the tributary rule, therefore have the same beneficial uses as Machado Lake (LARWQCB, 1994).

October 2016

#### 1.3.1 Geographic Setting

Machado Lake has a total drainage area of approximately 23 square miles and is located within the Dominguez Channel Watershed Management Area, although it is not tributary to the Dominguez Channel. Machado Lake overflows into Wilmington Drain during peak storm events. The lake itself is under the jurisdiction of the City of Los Angeles, while the drainage area is within the jurisdiction of several cities and unincorporated portions of Los Angeles County (County). The lake is located in the Ken Malloy Harbor Regional Park (KMHRP), which is a 231-acre Los Angeles City Park serving the Wilmington and Harbor City areas. The lake was originally created for inclusion into Harbor Regional Park in 1971, and intended for boating and fishing.

A map of the Machado Lake watershed and the different jurisdictions located within the drainage area is shown on Figure 1.1. The figure includes the boundary of the Machado Lake watershed and major storm drains.

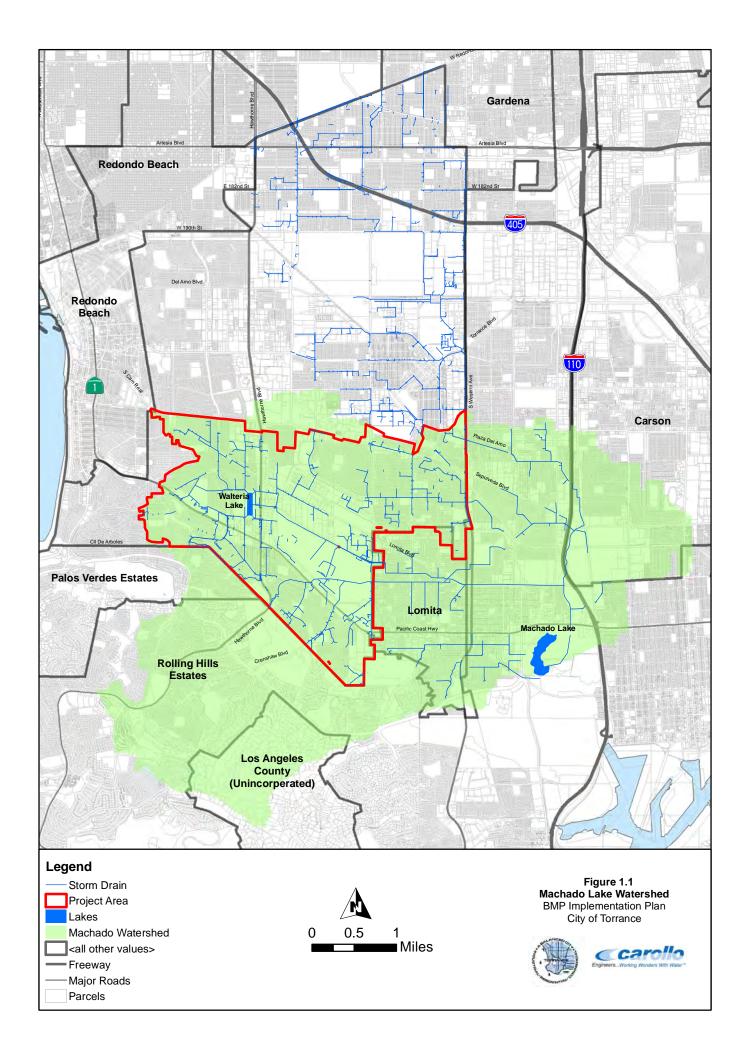

The Machado Lake watershed can be divided into six primary subdrainage areas. These subdrainages are:

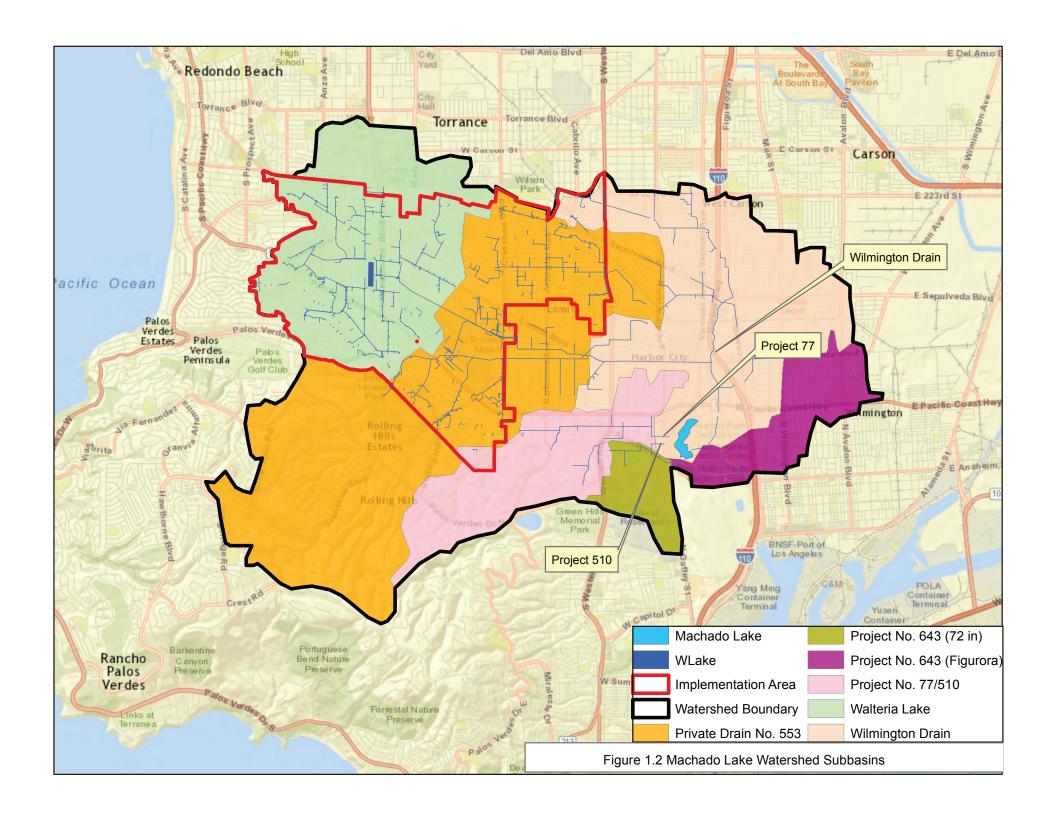

- The Walteria Lake
- Project 77/510
- Wilmington Drain
- Project 643 (72-inch Storm Drain)
- Project 643 (Figueroa Drain)
- Private Drain 553

Figure 1.2 shows the six subdrainage areas in Machado Lake watershed. As shown on the Figure, the Implementation Area drains the Walteria Lake, Project 77/510 and Private Drain 553.

#### 1.3.2 Machado Lake Responsible Agencies

The responsible parties located within the Machado Lake Watershed include the cities of Los Angeles, Torrance, Carson, Lomita, Rolling Hills, Rolling Hills Estates, Rancho Palos Verdes, Redondo Beach, and Palos Verdes Estates, and unincorporated Los Angeles County.

#### 1.3.3 TMDL Implementation Area

The area of Torrance located in the Machado Lake watershed accounts for 30 percent of the total drainage area. The portion of City Redondo Beach is about 0.2 percent of the entire watershed and flows to a City of Torrance catch basin. However, the City of Redondo Beach has requested this portion draining to Torrance be removed from the Machado Lake Implementation Plan since it is being covered in the Beach Cities Group EWMP. For the purposes of this report, this area of Torrance located within the watershed is called the TMDL Implementation Area (Implementation Area).

The Implementation Area shown on Figure 1.1 is approximately 2,288 acres and includes Walteria Lake Sub Area and 237th Street Sump. These two sub areas are designated 85<sup>th</sup> Percentile Basins since they capture and retain storms events greater than the 85<sup>th</sup> percentile, 24-hour storm runoff.

#### 1.3.3.1 Walteria Lake

The Walteria Flood Control Basin (Walteria Basin or Lake) is a man-made basin located in the City of Torrance. The Lake was built in 1962 by the Los Angeles County Flood Control District (LACFCD). Walteria Lake has a perimeter of approximately one mile and extends to an approximate depth of 100 feet. Walteria Lake's watershed is approximately 2,287 acres.

By jurisdictional area, Walteria Lake's watershed is 92.61 percent Torrance, 7.35 percent Palos Verdes Estates, and 0.04 percent Redondo Beach. The primary function of Walteria Lake is to provide flood protection. During storm and dry weather conditions Walteria Lake receives runoff from the surrounding sub watersheds. The water in the Lake is discharged during the dry season to pump out accumulated dry weather flows

and after storm events to maintain flood protection for the adjacent communities. The discharge is pumped through the Project No. 584 storm drain and flows through the drainage network where it eventually discharges to Wilmington Drain. The Wilmington Drain is a soft-bottom open channel maintained by LACFCD. Surface water in Wilmington Drain can flow via gravity or an unmanned pump station into Machado Lake. To ensure the downstream capacity is available for other storm flows, Walteria Lake is only pumped down after runoff in the watershed subsides.

In October 2014, a Special Study Monitoring Program was commenced to analyze Walteria Lake (Special Study). The objective of the Special Study was to:

 Compare the mass of pollutants entering Walteria Basin and the mass of pollutants discharged.

Assess inflow and outflow compared to TMDL waste load allocations.

As part of the Special Study, LACFCD is monitoring the 4 inlets to Walteria Lake. The City of Torrance is monitoring the discharges from Walteria Lake during pumping events. The Special Study spans 2 years, and preliminary results have been available since late 2015.

Pending the final results of the Special Study, an appropriate Regional BMP will be identified. A variety of BMPs are currently being investigated including:

- Application of aluminum sulfate to Walteria Lake.
- A diversion of the outflows from Walteria Lake to the Torrance Airport for infiltration into groundwater.
- Use of water collected in Walteria Lake to irrigate a nearby park or open space.

As the Special Study is completed in late 2016, funding and selection of appropriate BMPs will be determined. A BMP implementation strategy for Walteria Lake will be refined and reported through adaptive management.

#### 1.3.3.2 Madrona Marsh and Sump

The Madrona Marsh and Sump watershed discharges stormwater into Walteria Lake watershed. Madrona Marsh Restoration and Enhancement Project installed passive wetland treatment system to treat water in the sump for nutrients and other pollutants. Madrona Sump Dredging Project will remove nutrient and toxic rich sediments, therefore not part of this plan.

#### 1.3.3.3 237th Street Sump

The 237th Street Sump located in the implementation area is one of the active groundwater replenishment basins that are used to percolate stormwater into the groundwater basin. The 237th Street Sump which serves a drainage area of about 70 acres has no outlet, and is sized to capture runoff from at least the 85th Percentile, 24-hour storm event. Since this basin is designated as 85th Percentile Basin, stormwater improvements are not proposed. The sump has a capacity of about 2.5 ac-ft and the 85th Percentile 24-hour storm volume is approximately 2.48 ac-ft.

#### 1.3.3.4 Discharge Locations

The City's stormwater system discharges into Machado Lake at several locations, which are indicated on Figure 1.3. As shown on this figure, these points of discharge are primarily located along the east boundary of the City's service area. The stormwater collection system shown on Figure 1.3 also shows how stormwater is routed throughout the Implementation Area. In general, the routing is as follows:

- Stormwater from the Walteria Lake Sub Area is ultimately routed to Machado Lake
  via the Project No. 584 storm drain which eventually discharges to Wilmington Drain.
  That is, discharge from Walteria Lake is pumped through the Project No. 584 storm
  drain and flows through the drainage network where it eventually discharges to
  Wilmington Drain.
- Stormwater from the Airport Sub Area is routed to Machado Lake via Project 584 and Wilmington Drain.
- Airport Southeast Sub Area does not drain directly into Machado Lake. Drainage from this area exit the City in an easterly direction where it is comingled with drainage from other agencies prior to flowing into Machado Lake via Project 77 and Project 510 storm drains.
- Walnut Sump Sub Area drains southeasterly to discharge into Wilmington Drain.
- Stormwater from the Baseball Field Sub Area is routed to Machado Lake via Wilmington Drain.

#### 1.4 Water Quality Impairments

#### 1.4.1 <u>Designated Beneficial Uses</u>

The existing beneficial uses of Machado Lake, as defined by the Los Angeles Regional Water Quality Control Board in the Basin Plan, include recreation (REC 1 and REC 2) and aquatic life support (WARM, WILD, RARE, and WET). The Basin Plan applies the municipal supply (MUN) beneficial use designation to Machado Lake, qualified by an asterisk, as a potential future use. Conditional designations are not recognized under federal law and are not water quality standards requiring TMDL development at this time. The Basin Plan designates beneficial uses to "all other inner areas." These beneficial uses for Implementation Area are shown in Table 1.2.

October 2016

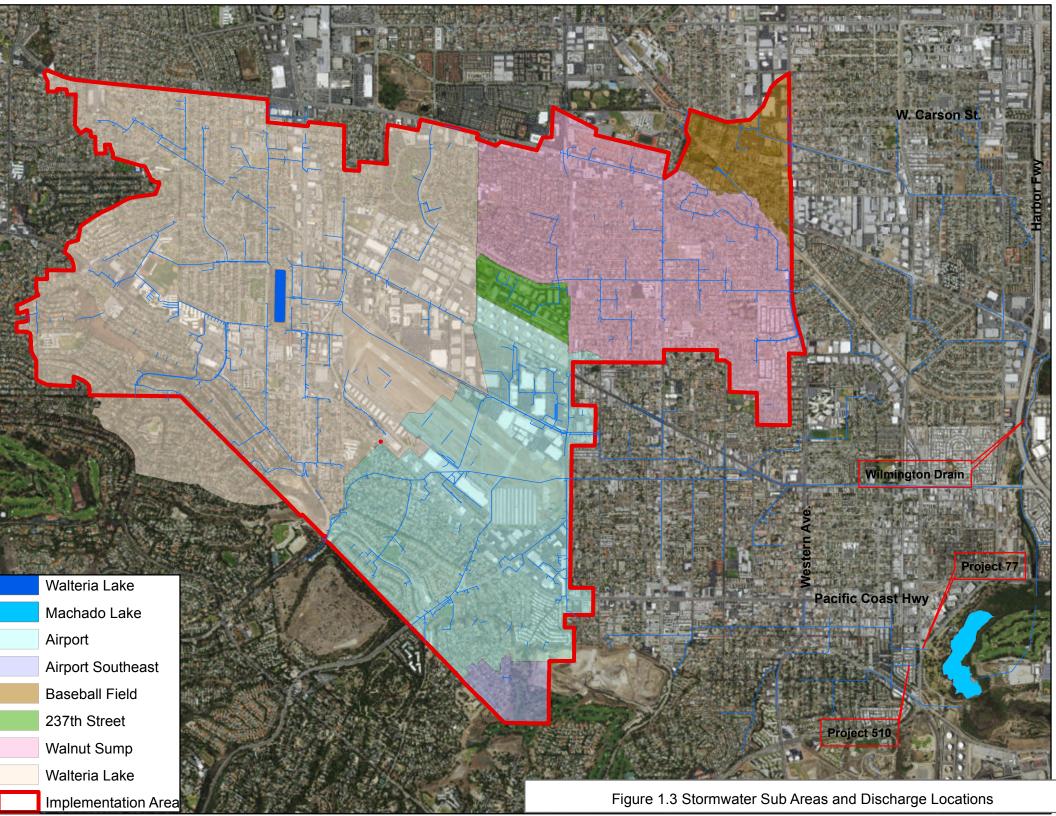

Table 1.2	Summary of TMDL Implementation Area Water Bodies			
w	ater Body	Existing Beneficial Uses	Potential Beneficial Uses	
Machado Lake	Machado Lake	WARM, WILD, WET, REC-1, REC-2	None	
Machado Lake	Wilmington Drain <sup>(1)</sup>	WARM, WILD, WET, REC-1, REC-2	None	
Note: (1) Beneficial uses based on the tributary rule (LARWQCB, 1994).				

#### 1.4.2 <u>2010 Section 303(d) List</u>

Section 303(d) of the Clean Water Act (CWA) requires that "Each State shall identify those waters within its boundaries for which the effluent limitations are not stringent enough to implement any water quality standard applicable to such waters." The CWA also requires states to establish a priority ranking for 303(d) listed impaired waters and establish TMDLs for such waters. A TMDL is defined as the "sum of the individual waste load allocations for point sources and load allocations for nonpoint sources and natural background" (40 CFR 130.2) such that the capacity of the water body to assimilate pollutant loadings (the Loading Capacity) is not exceeded. TMDLs are required to account for seasonal variations and include a margin of safety to address uncertainty in the analysis.

Nutrient enrichment to Machado Lake has resulted in high algal productivity; algal blooms have been observed in the lake during summer months. High nutrient concentrations also contribute to excessive and nuisance macrophyte growth. Algae respiration and decay remove oxygen from the water column, leaving insufficient oxygen for fish and other organisms to breathe. The decay of algal blooms and other eutrophic related impairments can also create offensive odors. This nutrient enrichment, or nitrification of the ecosystem, causes impaired Warm Freshwater Habitat (WARM), Water Contact Recreation (REC 1), and Non-contact Water Recreation (REC 2) beneficial uses in Machado Lake. Because of the high nutrient concentrations, algal blooms, odors and eutrophic conditions, Machado Lake was placed on the Clean Water Act 303(d) list of impaired waterbodies in 1998, 2002, and 2006. A schedule for developing TMDLs in the Los Angeles Region was established in a consent decree (Heal the Bay Inc., et al. v. Browner C 98-4825 SBA) approved on March 22, 1999.

The consent decree combined waterbody-pollutant combinations in the Los Angeles Region into ninety-two (92) TMDL analytical units. In accordance with the consent decree, the Nutrient TMDL addresses nitrogen and phosphorus compounds and related effects for Machado Lake (analytical unit #76).

#### 1.4.2.1 Waterbody Pollutant Combinations

Machado Lake is listed in the 1998, 2002, 2006, and 2008 Clean Water Act 303(d) lists of impaired water bodies as impaired due to chlordane, DDT, Dieldrin, Chem A, and PCBs in tissue. In addition to these approved 303(d) listings, there are sufficient data to document chlordane, DDT, and PCB impairments in sediment. The impairments were addressed in the Toxics TMDL. Chem A chemicals are bioaccumulative pesticides, which include chlordane and Dieldrin, and were addressed specifically through chlordane and Dieldrin. Clean Water Act 303(d) listing for Machado Lake and Wilmington Drain are presented in Table 1.3. TMDLs have been completed for nutrients, toxics, and trash.

Identification of the water quality priorities is a key component of the EWMP process. Part VI.C.5.a (page 58-60) of the MS4 Permit outlines the pertinent elements of the prioritization process as follows:

- 1. Water quality characterization (VI.C.5.a.i, page 58) based on available monitoring data, TMDLs, 303(d) lists, storm water annual reports, etc.;
- 2. Water body-pollutant classification (VI.C.5.a.ii, page 59) to identify water body-pollutant combinations that fall into three MS4 Permit-defined categories;
- 3. Source assessment (VI.C.5.a.iii, page 59) for the water body-pollutant combinations in the three categories; and
- 4. Prioritization of the water body-pollutant combinations (VI.C.5.a.iv, page 60).

The three MS4 Permit defined categories are:

- Category 1 (Highest Priority): Water body-pollutant combinations for which water quality based effluent limitations and/or receiving water limitations are established in Part VI.E, TMDL Provisions, and Attachments L through R of the Municipal Separate Stormwater Sewer System (MS4) Permit.
- Category 2 (High Priority): Pollutants for which data indicate water quality impairment
  in the receiving water according to the State Water Resources Control Board's Water
  Quality Control Policy for Developing California's Clean Water Act Section 303(d) List
  (State's Listing Policy) and for which MS4 discharges may be causing or contributing
  to the impairment.
- Category 3 (Medium Priority): Pollutants for which there is insufficient data to indicate
  water quality impairment in the receiving water according to the State's Listing Policy,
  but which exceed applicable water limitations contained in Order R4-2012-0175 and
  for which MS4 discharges may be causing or contributing to the exceedance.

The water body pollutant classifications (WBPCs) were classified into one of the three MS4 Permit categories (Category 1-3). Those WBPCs with a TMDL were classified as

Category 1, those WBPCs listed on the State's 303(d) list as impairing a particular water body segment were classified as Category 2, and those remaining WBPCs without an associated TMDL or on the State's 303(d) list, but showing exceedances of water quality criteria were classified as Category 3. A summary of these categorizations is presented in Table 1.3.

Table 1.3 W	Table 1.3 Water Body Pollutant Combinations for Machado Lake Watershed				
Water Body	Category 1 (TMDL)	Category 2 (303(d) List)	Category 3 (Other)		
Machado Lake	Trash, Total Phosphorous, Total Nitrogen, Ammonia, Chlorophyll-a, PCB (sed.), DDT (sed.), Chlordane (sed.), Dieldrin (sed.), Dissolved Oxygen	None	<i>E. coli</i> , pH		
Wilmington Drain	None	Coliform Bacteria, Copper (diss.), Lead (diss.)	Total Nitrogen, DDT (sed.), PCB (sed.), Chlordane, Dieldrin (sed.)		

The Machado Lake Trash TMDL states that agencies can comply with the WLAs by installing full capture trash screens on catch basins that discharge into Machado Lake through a progressive eight-year implementation schedule. Full capture trash screen must be installed on 20 percent of a city's catch basins by March 6, 2012 with 20 percent more each year until 100 percent of catch basins have trash screens by March 6, 2016.

The City is complying with the TMDL requirements through a joint project with the Cities of Lomita, Carson, Rolling Hills Estates, Palos Verdes Estates, and Rancho Palos Verdes to install Automatic Retractable Screens and/or Connector Pipe Screens onto catch basins that are tributary to the Machado Lake. Work within the City of Torrance also includes the installation of No Parking signs for Street Sweeping within the portion of Torrance tributary to Machado Lake.

#### 1.5 Objectives of the EWMP and Approach

This EWMP outlines the management actions that may be necessary to ultimately attain compliance with the Machado Lake Nutrient and Toxics TMDLs (LARWQCB, 2009), within the Implementation Area of the Machado Lake watershed. The EWMP also includes management actions to reduce copper, lead, and bacteria loads to the Wilmington Drain which eventually discharges into Machado Lake. The Wilmington Drain is listed on the State's 303(d) List for copper, lead, and coliform bacteria. The BMP Implementation Plan calls for an integrated, adaptive management approach to utilize available resources effectively and efficiently. As new information becomes accessible through monitoring, the continued study of drainage patterns, diagnosis of problem sources, and new technologies

for dry and wet weather treatment, and the plan may be modified as necessary. Implementation of the management actions described by the plan depends on feasibility, available funding, site-specific conditions, and various other factors.

#### 1.5.1 Focus of the Plan

The Machado Lake EWMP must include implementation methods, a schedule, and proposed milestones to achieve compliance of the TMDL WLAs. The EWMP development requires identifying and selecting BMPs to treat stormwater or reduce pollutant loads, as well as developing estimates of benefits in terms of load reductions to meet WLAs. However, the BMP selection process must consider the cost-effectiveness to provide assurance that plans are practical and implementable.

The goal of the EWMP is to address current TMDLs except trash, with consideration of future potential TMDLs. The nutrient TMDLs is considered the primary focus of this implementation plan. A secondary focus is placed on toxics through removal of suspended sediments that toxics are associated with. The third focus is placed on copper, lead, and bacteria. The fourth focus is on trash because reporting on progress toward the trash TMDL implementation occurs annually and through a separate process. However, proposed BMPs that address trash have the potential to provide added benefit in addressing other pollutants, which is assessed in this Implementation Plan. Total nitrogen (TN), total phosphorus (TP), copper, lead, and bacteria source characterizations are provided in the plan.

This EWMP includes integrated approaches that consider BMPs that can address multiple pollutants cost-effectively. Additional benefits of BMPs, such as water storage/recharge and reuse, providing recreation space, improved natural habitat, source control, and public education, are considered in this Implementation Plan.

This EWMP also describes management options that are limited to the portion of Torrance located within the Machado Lake watershed. This area is termed the *TMDL Implementation Area* (Implementation Area) in this report and is represented in red on Figure 1.1. Some of the proposed nonstructural or programmatic BMPs, such as staff training or education programs, could apply citywide.

The Rolling Hills Estates watershed is a tributary of the Implementation Area, and flows directly to Walteria Lake, therefore not addressed in this plan.

#### 1.5.2 TMDL Target

Key factors influencing the level of BMP implementation are the stormwater management targets expected to be achieved. For this project, multiple TMDLs and associated WLAs for stormwater runoff have been established for Machado Lake, which must be considered as a priority for developing the BMP Implementation Plan. The following provides a summary

of applicable wet weather TMDL WLAs and implementation requirements, and methods for translating the requirements into management targets to address wet weather pollution.

#### 1.5.2.1 Nutrients

The Machado Lake Nutrient TMDL was developed by the LARWQCB on May 1, 2008. The U.S. Environmental Protection Agency (USEPA) approved the Nutrient TMDL on March 11, 2009, and the approval letter was posted on April 8, 2009. The Nutrient TMDL was developed to address nutrient-related beneficial use impairments including the following Section 303(d) listings: eutrophication, algae, ammonia, and odor.

The City is subject to the requirements of the Machado Lake Eutrophic, Algae, Ammonia, and Odors (Nutrient) TMDL per the LARWQCB's Resolution R08-006. Under the Regional Board's resolution, the City shall submit to the Regional Board's Executive Officer a Monitoring and Reporting Plan (MRP) within 1 year of the effective date of the resolution or propose a Special Study Work Plan following the requirements of one of three optional studies. The Special Study Work Plan details the approach proposed by the City to perform Optional Study No. 3, to assess compliance with the WLA on a mass basis for total nitrogen and total phosphorus originating from the City's Implementation Area. The Special Study Work Plan is complete and turned in to the Regional Board.

Resource agencies, local governments, project implementers, the scientific community, environmental groups, decision-makers at the city, county, state, and federal levels, and many others have continued to take meaningful steps towards the restoration of Machado Lake and its basin. Among these efforts, restoration activities are expanding through continued implementation of erosion control, stormwater management, and riparian restoration projects, development of the Machado Lake Nutrient TMDL that is providing a quantitative, science-based approach for pollutant reduction, and a strong research/monitoring effort to evaluate key ecological processes and response to water quality improvement projects. The Machado Lake Nutrient TMDL allows for the establishment of annual mass-based WLAs for TP and TN equivalent to monthly average concentrations of 0.1 milligram per liter (mg/L) TP and 1.0 mg/L TN, based on approved flow conditions. When the concentration based WLAs are met under the approved flow condition of 8.45 hm<sup>3</sup>/yr (cubic hectometers or million cubic meters/year), the annual mass of the TP discharged to the lake will be 845 kilogram (kg) and the annual mass of TN discharged to the lake will be 8,450 kg. The City accounts for about 30 percent of the Machado Lake Watershed. Table 1.4 lists the interim and final WLAs based on this area. The interim WLAs for both total phosphorus and total nitrogen have been met as shown in Appendix B.

Table 1.4 Interim and Final WQBELS for Machado Lake Nutrient TMDL				
Dry Weather Wet V		et Weather		
Nutrient TMDL	Interim WLA	Deadline	Final WLA	Deadline
Total Phosphorus	1.25 mg/L	March 11, 2014	0.1 mg/L	September 11, 2018
Total Nitrogen	2.45 mg/L	March 11, 2014	1.0 mg/L	September 11, 2018

#### 1.5.2.2 Toxics

Machado Lake is listed as impaired for chlordane, Chem-A, DDT, Dieldrin, and PCBs. The LAWQCB adopted the Machado Lake Toxics Total TMDL on September 2, 2010 (LARWQCB, 2010) and was approved by the State Water Quality Control Board and the USEPA. The pollutants listed within the Toxics TMDL include organochlorine (OC) pesticides and polychlorinated biphenyls (PCBs). These pollutants are associated with suspended sediments; therefore, the WLAs were calculated based on the fraction of suspended solids loading produced by each stormwater discharger, and assigned for both dry and wet weather. Compliance is measured either at the storm drain outfall of the permittee's drainage area, at representative storm drain outfalls representing the combined discharge of cooperating parties (if a coordinated compliance option is chosen by multiple permittees), or at an alternative compliance point approved by the Regional Board Executive Officer.

The WLAs assigned to Municipal Separate Storm Sewer Systems (MS4) permittees in the Toxicity TMDL BPA are concentration-based allocations (equal to the sediment numeric targets), and are listed in Table 1.5. The Toxics TMDL requires compliance with these WLAs by September 30, 2019.

Suspended solids serve as carriers of toxics such as pesticides, dioxins and PCBs. Removal of suspended solids therefore, will also lead to toxics removal. This EWMP addresses toxics through the removal of sediments. Removal of toxics is calculated as a fraction of suspended sediments removed by proposed stormwater treatment devices. This EWMP relied on toxics data developed from the Dominguez Channel Flow Monitoring Program.

Estimated baseline load for toxics is presented in Section 3 of this report.

Table 1.5 MS4 Permittees Toxics TMDL Waste Load Allocations				
	Numeric Target for Sediment	Waste Load Allocation for Suspended Sediment-Associated Contaminants <sup>(1)</sup>		
Parameter of Concern	Concentration (µg/kg dry weight)	Concentration (μg/kg dry weight) Period	Compliance Averaging Period	
Total PCBs	59.8	59.8	3-year average	
DDT (all congeners)	4.16	4.16	3-year average	
DDE (all congeners)	3.16	3.16	3-year average	
DDD (all congeners)	4.88	4.88	3-year average	
Total DDT	5.28	5.28	3-year average	
Chlordane	3.24	3.24	3-year average	
Dieldrin	1.9	1.9	3-year average	
Note:				

#### 1.5.2.3 Bacteria, Copper and Lead

The Implementation Area contributes runoff to the Wilmington Drain, Project 77, and Project 510 storm drain lines as shown on Figure 1.3. Over 80 percent of the Machado Lake Subwatershed drains to Machado Lake through Wilmington Drain. Wilmington Drain is listed on the State's 303(d) List for copper, lead, and coliform bacteria. Table 1.6 shows the compliance schedule.

Table 1.6	Summary of Schedule for Interim and Final Milestones			
	Schedule			
	Interim	Final	_	
Pollutant	(09/30/17)	(09/30/32)	Source	
Lead	122.88 µg/L	42.7 μg/L	Vehicle brake pads, atmospheric deposition, soil erosion	
Copper	898.87 µg/L	69.7 μg/L	Vehicle tires, galvanized metal, atmospheric deposition	
REC-2 WQO				
Fecal Coliform	4000 #/100 mL <sup>(1)</sup>		Wastewater treatment plants, on-site septic systems, domestic and wild animal manure	
Noto:				

17 October 2016

<sup>(1)</sup> The WLA applies to all MS4 Permittees including the County, Caltrans, General Construction and, industrial Stormwater Permittees, and other non-stormwater NPDES Permittees.

<sup>(1)</sup> Obtained from Los Angeles Regional Water Quality Control Board (LARWQCB) Basin Plan Chapter 3 titled Water Quality Objectives, dated May 2, 2013 Section on In Waters Designated for Non-contact Water Recreation (REC-2)

#### 1.5.2.4 Trash

The Machado Lake Trash TMDL requires that trash be eliminated in Machado Lake and on its shoreline either through assessment and collection or installation of full capture systems on discharges to the lake. The City is identified as a point source for trash based on being a permittee under the Los Angeles County Municipal Separate Storm Sewer System (MS4) NPDES permit. Based on the Machado Lake TMDL, the City's WLA is zero trash, meaning no trash may be discharged to the lake through the City's storm drains which discharge stormwater to the lake.

Figure 1.4 Automated Retractable Screens

The Machado Lake Trash TMDL became effective in March 2008. The trash monitoring and reporting plan (TMRP) was submitted to the LARWQCB in September 2008, and conditionally approved in December 2008. The City has implemented trash controls in the drainage areas to comply with March 6, 2016 final deadline. Therefore no further trash controls are proposed in this EWMP. The trash control project installed Automated Retractable Screens (ARS) and Connector Pipe Screen (CPS) systems as shown on Figure 1.4 that capture debris and prevent it from entering the Storm Drain System.

#### 1.5.3 Scheduled Total Maximum Daily Load

Wilmington Drain, to which all of the County areas drain shown on Figure 1.1, is listed in the 303(d) list as impaired for metals (copper and lead) and bacteria. The additional pollutants of concern listed in Machado Lake are scheduled for TMDL development in 2014 or 2019. This EWMP also addresses metals and bacteria impairments in Wilmington Drain.

### 1.6 Reasonable Assurance Analysis and Watershed Control Measures

As part of the EWMP plan, a Reasonable Assurance Analysis (RAA) is conducted on a watershed level. The RAA consists of an assessment, through quantitative analysis or modeling, to demonstrate that the activities and control measures (i.e., BMPs) identified in the Watershed Control Measures section of the EWMP are performed to demonstrate that applicable water quality based effluent limitations and/or receiving water limitations with compliance deadlines during the permit term will be achieved.

Watershed Control Measures are subdivided into:

- Minimum Control Measures,
- Non-Stormwater Discharge Measures,
- TMDL Control Measures, and
- Other control measures.

Schedules are developed for strategies, control measures, and BMPs to be implemented. The schedules will measure progress every two years during the permit term and incorporate:

- Compliance deadlines occurring within the permit term for all applicable interim and/or final water quality based effluent limitations and/or receiving water limitations to implement TMDLs,
- Interim deadlines and numeric milestones within the permit term for any applicable final water quality based effluent limitation and/or receiving water limitation to implement TMDLs, where deadlines within the permit term were not otherwise specified, and
- 3. Watershed priorities related to addressing exceedances of receiving water limitations.

#### 1.7 Adaptive Management

An adaptive management process will be implemented every two years from the date of program approval, adapting the EWMP to become more effective, based on, but not limited to the following:

- 1. Progress toward achieving the outcome of improved water quality in MS4 discharges and receiving waters through implementation of the watershed control measures.
- 2. Progress toward achieving interim and/or final water quality based effluent limitations and/or receiving water limitations, or other numeric milestones where specified, according to established compliance schedules.
- 3. Achievement of interim milestones.
- 4. Reopening of TMDLs.
- 5. Re-evaluation of the highest water quality priorities identified for the Watershed Management Area based on more recent water quality data for discharges from the MS4 and the receiving water(s) and a reassessment of sources of pollutants in MS4 discharges.

- 6. Availability of new information and data from sources other than the Permittees' monitoring program(s) within the Watershed Management Area that informs the effectiveness of the actions implemented by the Permittees.
- 7. Regional Water Board recommendations.
- 8. Recommendations for modifications to the EWMP solicited through a public participation process. Based on the results of the iterative process, modifications necessary to improve the effectiveness of the EWMP will be reported in the Annual Report, and as part of the Report of Waste Discharge (ROWD).

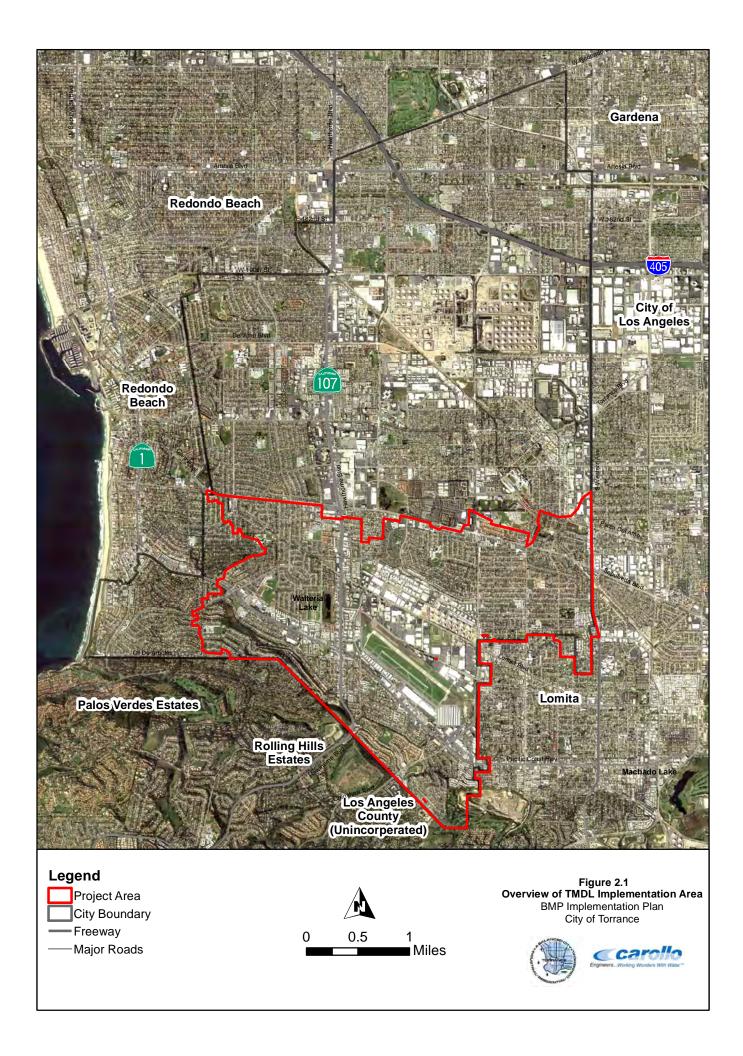

Any necessary modifications to the EWMP will be implemented upon acceptance by the Regional Water Board Executive Officer within 60 days of submittal if the Regional Water Board Executive Officer expresses no objections.

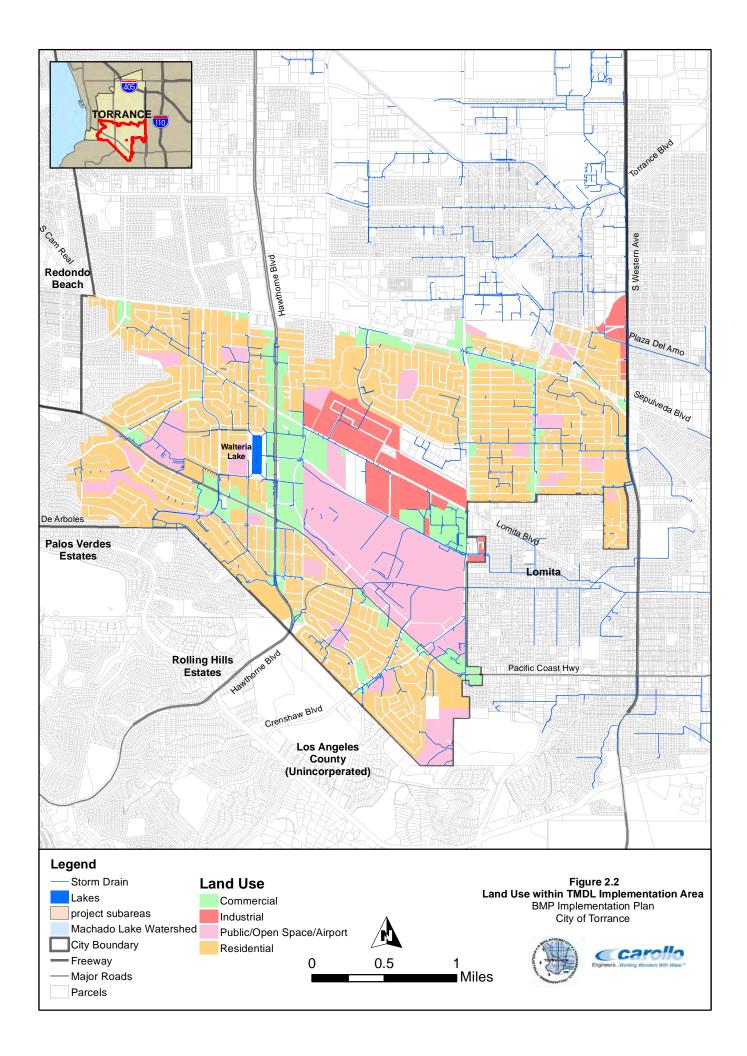

#### 2.0 CITY OF TORRANCE TMDL IMPLEMENTATION AREA

The City is located about 15 miles south of Downtown Los Angeles (LA), in southern LA County, just north of the Palos Verdes Hills. The City was incorporated on May 12, 1921, and is just over 20.5 square miles in area. The City is bounded by Redondo Beach on the west and north, Lawndale and Gardena on the north, LA on the east, Lomita to the southeast, and Rolling Hills Estates and Palos Verdes Estates on the south. The City is also bounded by approximately 4,000 feet of Santa Monica Bay coastline. The City's storm conveyance systems are interconnected with neighboring city systems. Neighboring cities located at generally higher elevation such as Rolling Hills Estate and Palos Verde Estate discharge stormwater into the City's and/or LA County's storm conveyance systems located within the City's boundaries. Figure 2.1 shows an aerial view of the watershed and Figure 2.2 gives an overview of land uses in the Implementation Area.

The Implementation Area is about 4,241 acres, which equals approximately 32 percent of the City of Torrance. The Implementation Area also includes a very small area of Redondo Beach that drains directly to a Torrance catch basin. The land use category with the largest proportion within the Implementation Area is residential (43 percent), while open space accounts for about 18 percent. Residential land uses include high-density single family (HDSF), multi-family residential (MFR), and mobile homes. The land uses in the Implementation Area are listed in Table 2.1.

Table 2.1 Land Use in TMDL Implementation Area					
Land Use	Acreage	% TMDL Implementation Area			
Residential	1,810	43			
Commercial	419	10			
Industrial	256	6			
Transportation	996	23			
Open Space	758	18			
Total	4,239	100			

#### 2.1 Geologic Setting and Soil

The soils found within the Machado Lake watershed are predominantly loam and clay. The most common soil type is Ramona Loam, which is observed in the Implementation Area. Ramona Loam is a compact soil with a large runoff coefficient at high rates of precipitation. Areas such as the Rolling Hills Estates and the lands along Highway 1 are composed of several different classifications of clay and loam such as Diablo Clay Loam and Montezuma Clay. Surficial soil infiltration rates range from about 0.027 to 0.81 inches per hour.

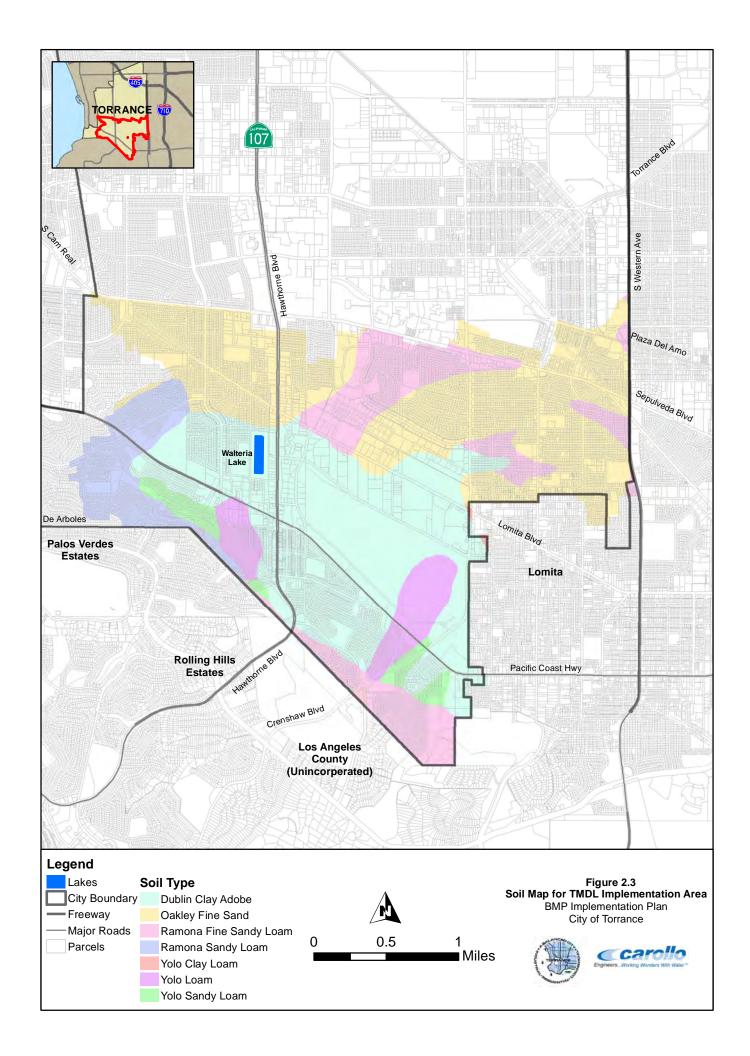

The predominant soil types found in the Implementation Area are listed by percentage in Table 2.2. The soil types found across the Implementation Area are displayed on Figure 2.3.

Table 2.2 Soil Types Distribution	
Soil Classification <sup>(1)</sup>	Percentage of Soil within TMDL Implementation Area
Ramona Loam	21.4%
Yolo Sandy Loam	8.0%
Dublin Clay Adobe	35.3%
Oakley Fine Sand	35.4%
Total	100.0%
Note: (1) LACDPW 2006 Hydrology Manual	

## 2.2 Watershed Hydrology

As shown on Figure 1.1, the Machado Lake watershed is located in the southwestern area of the Dominguez Channel watershed and includes portions of the Cities of Los Angeles, Torrance, Lomita, Rolling Hills, Rolling Hills Estates, Carson, Palos Verdes Estates, Rancho Palos Verdes, Redondo Beach, and the communities of unincorporated Los Angeles County, including Wilmington and Harbor City. As shown, a large portion of the Machado Lake watershed consists of the hilly regions of Rolling Hills Estates and Rolling Hills. This portion of the watershed is unique, as it consists of relatively steep hills with drainage into the canyons.

Machado Lake is about 40 acres in area, while the Machado Lake wetlands cover an area of approximately 64 acres. The lake and wetlands are located within the Ken Malloy Harbor Regional Park in the southeastern corner of the Machado Lake Watershed. Both Machado Lake and the Machado Lake wetlands serve as flood retention basins for the Machado Lake Watershed.

#### 2.3 Watershed Hydraulics

As the Implementation Area is highly urbanized, stormwater drainage is primarily conducted through an extensive network of underground storm drain facilities. The Los Angeles County Department of Public Works maintains the system of storm drains in the City of Rolling Hills Estates. The primary use of the Dominguez Channel and all other open channels in the Dominguez Channel watershed (including Wilmington Drain, Machado Lake, and Madrona Marsh) is flood protection.

Machado Lake receives urban and storm water runoff from a complex network of storm drain systems. The first of three primary storm drain channels that flow into Machado Lake is the Wilmington Drain. Approximately 65 percent of the runoff from the Machado Lake Watershed flows through the Wilmington Drain into Machado Lake. The other two primary storm drain channels as shown on Figure 1.2 are the Project No. 77 Drain and the Harbor City Relief Drain. Several smaller storm drains also discharges into Machado Lake, including Project No. 643's Figueroa Street Outlet and a 72-inch diameter storm drain outlet. Machado Lake discharges at the southern end by overflowing a concrete dam into the Machado Lake wetland. Water discharges from the wetland through the Harbor Outflow structure and into the West Basin of the Los Angeles Harbor.

The Walteria Lake, located within the City's boundaries, is owned and operated by LA County Flood Control District. It is approximately 1,005 acre-feet in capacity and receives raw stormwater mainly from Rolling Hills Estates, Palos Verdes Estates, and the City of Torrance. Effluent from the lake is pumped at a maximum rate of 57 cubic feet per second (cfs) through a force main system into a 54-inch diameter drain line that lies under Skypark Drive. The discharge eventually leaves the City near the intersection of Crenshaw Boulevard and Amsler Street.

# 3.0 POLLUTANT SOURCE CHARACTERIZATION AND PRIORITIZATION

This section identifies the potential sources of the pollutants of concern derived from both point and nonpoint sources. The discussion is provided in several parts: monitoring reports, modeling results, specific pollutant sources, and a source prioritization. Watershed monitoring results are summarized for reference in Appendix B. The focus of this characterization and prioritization is primarily within the Implementation Area. Both wet and dry conditions are discussed. The City's Pollutant Load and Analysis Tool (PLAT) was used to quantify the baseline pollutant loading of nutrients and other pollutants from the Implementation Area.

# 3.1 Characterization of Stormwater and Non-stormwater Discharge Quality

In order to begin to identify the sources of pollutants identified in the Waterbody Pollutant Categorization and prioritize implementation measures to address them, an analysis of stormwater and non-stormwater discharges from the MS4 was conducted using available data and information, including the following sources:

- Monitoring Reports and Data
  - Machado Lake Special Study
  - Port of Los Angeles Ambient Water Quality Monitoring Data (2005-2008)
  - City of Los Angeles Machado Lake Nutrient TMDL Monitoring Data (2011-2012)
  - County of Los Angeles Machado Lake Nutrient TMDL Monitoring Data (2012)
  - Los Angeles County 1994-2000 Integrated Receiving Water Impacts Report
- Basin Plan Amendments
  - Machado Lake Trash TMDL
  - Machado Lake Pesticides and PCBs TMDL
  - Machado Lake Nutrient TMDL

### 3.1.1 <u>Machado Lake Special Study - Nutrient TMDL Monitoring</u>

To meet the Nutrient TMDL's Optional Study #3 requirements and the aforementioned objectives, an approach that utilized existing water quality sampling information, and hydrologic modeling to characterize current wet and dry weather loading from the Implementation Area was followed. The Nutrient TMDL's Optional Study #3 is one of the main monitoring reports and data reviewed for this EWMP. Water quality samples were collected monthly at each monitoring location. During the wet season, dry weather sampling events were scheduled seven days after measurable precipitation, or after flow rates had returned to base levels typical of the season, whichever period was shorter.

A total of eight monitoring sites were selected for the Special Study. The characteristics of the monitoring sites are presented in Tables 3.1 and 3.2. Figure 3.1 shows the monitoring sites and associated drainage areas. Drainage areas were determined using GIS layers, provided by the City, of storm drains and the flow paths of Wilmington Drain. Land use calculations were determined using a GIS layer obtained from the City.

Monitoring for nitrogen and phosphorus constituents was performed during the Special Study. The monitoring results for total nitrogen, total phosphorus, and flow rate are displayed on Figure 3.2 and summarized in Table 3.3. Table 3.3 shows data gathered during the flow monitoring period between February and December of 2012. This data was used characterize the pollutants generated within the Implementation Area and also used for model calibration. The amount of pollutants entering the City from neighboring cities is represented by monitoring locations Tor-S6, Tor-S7, and Tor-S9. Monitoring sites Tor-S1, Tor-S2, Tor-S4 and Tor-S5 measure pollutants and flow leaving the city boundary. The locations of monitoring sites Tor-S1 through Tor-S9 are indicated on Figure 3.1 as S1 through S9.

The water quality sampling data was reviewed to identify whether site location or the timing of events affected the concentrations observed. The data set was reviewed in this way by constituent group, constituent, and, as necessary, constituent fraction (e.g., total and dissolved phosphorus). An analysis of sample variance showed that neither the site location nor event timing had any significant effect on the concentrations of the constituents measured during the study.

### 3.2 Potential Sources of Pollutants of Concern

The pollutants addressed in this section are toxics, metals, nutrients, bacteria, and trash. To generally describe the potential sources in the watershed, pollutant sources have been divided into the following categories: NPDES sources, road infrastructure, atmospheric deposition, and wastewater from sanitary sewer and SSOs. Typical sources of these pollutants are summarized in Table 3.4.

Table 3.1	Monitoring Sites for the Special Study - Nutrient TMDL Monitoring							
Sampling Location Name	Map ID	Description	Primary Land Use	Lat-/ Long- itude	Upstream Storm Drain Name	Diameter (in) and Material		
Tor-S1	S1	Located 40 ft north and 80 ft east of the intersection of Plaza Del Amo and Western Avenue. Basin name.	RES	33.82/ 118.31	City	36 RCP		
Tor-S2	S2	Approximately 50 ft west of 246th Place and Pennsylvania Avenue intersection.	RES	33.80/ 118.33	City	33 RCP		
Tor-S3	S3	Effluent of Walteria Lake, approximately 300 ft west of Hospital Drive and Skypark Drive intersection.	RES	33.81/ 118.35	Walteria Lake	54		
Tor-S4	S4	Approximately 210 ft north and 85 ft east of 236th Street and Western Avenue intersection.	RES	33.81/ 118.31	City	9'- 2"Wx11'H RCB		
Tor-S5	S5	About 25 ft west of intersection of Bani Avenue and 250th Street (two pipes intersect from south and west).	RES	33.80/ 118.33	City	8'-9"Wx9'- 7"H RCB		
Tor-S6	S6	Approximately 600 ft east of Estates Lane and Crenshaw Boulevard.	RES	33.79/ 118.34	Rolling Hills E.	36 RCP		
Tor-S7	S7	About 730 ft south of Rolling Hills Road and Madison Street intersection. Will monitor dry weather flow originating from Rolling Hills Estates.	RES	33.79/ 118.35	Rolling Hills E.	10'x10' RCB		
Tor-S9	<b>S</b> 9	About 830 ft east and 120 ft south of Paseo de las Tortugas and Vista Montana intersection. Will monitor dry weather flow originating from Palos Verdes Estates.	RES	33.80/ 118.36	Palos Verdes Estates	42 RCP

### 3.2.1 NPDES Sources

There are two categories of pollutants sources, point sources and non-point sources. Point source discharges are regulated through National Pollutant Discharge Elimination System (NPDES) permits. Point sources include stormwater and urban runoff through the MS4 and other NPDES discharges. Stormwater runoff in the Implementation Area is regulated through several types of permits including MS4 permits, a statewide stormwater permit for Caltrans; a statewide Construction General Permit (CGP); and a statewide Industrial General Permit (IGP). The NPDES IGP regulates stormwater discharges and authorized non-stormwater discharges from several specific categories of industrial facilities, including manufacturing facilities, landfills, and transportation facilities. Furthermore, the NPDES CGP regulates stormwater discharges from construction sites that result in land disturbances equal to or greater than one acre. Point source discharges from IGP, CGP, residential, commercial and transportation activities can be a significant source of pollutant loads.

Non-point sources, by definition, include pollutants that reach waters from a number of land uses and are not regulated through NPDES permits. Non-point sources include existing contaminated sediments within the watershed and direct air deposition to the waterbody surface. These sources can enter the MS4 and contribute pollutants through it to receiving waterbodies.

The following provides additional discussion regarding the presence of pollutants in stormwater runoff within the Implementation Area.

### 3.2.1.1 Copper and Lead

While the available Annual Reports do not indicate a clear source of lead in this subwatershed, the Regional Board Final Staff Report for the TMDL for Metals in Ballona Creek states that urban runoff, or the wash-off of pollutant loads accumulated on the land surface, is likely a substantial source of metals during both wet and dry weather (Regional Board, 2005). Indirect atmospheric deposition was estimated to account for 19 percent of the typical annual load for lead in the Ballona Creek Watershed (LARWQCB, 2005). Wet weather EMCs for lead, based on the Los Angeles County EMC dataset, show that the highest concentrations are expected from agricultural land uses, followed in order by industrial, commercial, high density single family residential, and transportation, multi-family residential, educational, and open space land uses (Geosyntec Consultants Wright Water Engineers, 2012). Other Los Angeles region land use studies have found that high density single family residential has the highest EMCs, followed by industrial and commercial land uses (Stein et al., 2007). These potential sources were evaluated for BMP implementation as part of the RAA.

### 3.2.1.2 Bacteria

Fecal coliform is listed in the 303d list for Dominguez Channel. Fecal Coliforms are used as indicator of possible sewage contamination because they are commonly found in human and animal feces. Although they are generally not harmful themselves, they indicate the possible presence of pathogenic (disease-causing) bacteria, viruses, and protozoans that also live in human and animal digestive systems. Therefore, their presence in streams suggests that pathogenic microorganisms might also be present and that swimming and eating shellfish might be a health risk. Since it is difficult, time-consuming, and expensive to test directly for the presence of a large variety of pathogens, water is usually tested for coliforms and fecal streptococci instead. Antroponic sources of fecal contamination to surface waters include wastewater treatment plants, on-site septic systems, domestic and wild animal manure, and storm runoff. Non-antropogenic sources of fecal coliform include soils, (sediments), vegetation, decaying organic material, biofilms/regrowth, and atmospheric deposition.

### 3.2.1.3 Nutrient

Excessive input of nutrients (such as nitrogen and phosphorus) is the primary cause of eutrophication of surface waters, in which excess nutrients stimulate algal growth which leads to increased turbidity, decreased levels of oxygen, and odor problems. Possible sources of nutrients include runoff from residential and commercial areas due to landscaping activities and use of fertilizer for lawns and gardens. Activities such as washing cars can contribute nutrients to the watershed since many of the detergents used contain phosphorus. Other sources of nutrients include food wastes and domestic animal waste. These pollutants build up and are then washed into the waterways through the storm drain system when it rains. These kinds of loads are typically highest during the first major storm flush and even after extended periods of dry weather when pollutants have accumulated. Other major categories of nutrients sources include:

- Manure Within the Implementation Area equestrian activities are not very common within private and public stables, and residential areas. Horse manure, if improperly managed, has the potential to pose a significant source of nutrients in runoff.
- Golf courses golf courses are a major source of nutrients since fertilization activities and watering rates are generally much greater than in residential and commercial areas. The excess nutrients accumulated in the soils can be transported to waterways through excessive irrigation or stormwater runoff.
- Air deposition of nitrogen due to air pollution, the predominate species being NHO<sub>3</sub> (nitric acid), NO<sub>2</sub> (nitrogen dioxide) and NH<sub>3</sub> (ammonia).
- Agricultural land use is limited in the Implementation Area and therefore is not a significant source of nutrients.

### 3.2.1.4 Toxics

The most significant toxic pollutants including legacy pollutants are PAH compounds, PCBs, DDT, chlordane, and dieldrin. Non-point sources of toxics may include leaking motor oil, tire wear, and vehicular exhaust. Polychlorinated biphenyls (PCBs) are mixtures of synthetic organic chemicals that were commonly used for various applications from approximately 1929 until 1979 when the U.S. banned PCB manufacturing, processing, distribution, and use. PCBs are a ubiquitous environmental contaminant and, like DDT, they have persisted in the aquatic environment and continue to accumulate in fish tissue even though production of PCBs was banned 25 years ago. PCBs may also still exist in products made before 1977 such as transformers, old fluorescent lighting fixtures, household caulking, paints, and waxes (USEPA).

# 3.3 Reasonable Assurance Analysis Approach

A key element of the EWMP is the Reasonable Assurance Analysis (RAA), which is prescribed by the Permit as a process to demonstrate "that the activities and control measures will achieve applicable WQBELs and/or RWLs with compliance deadlines during the Permit term" (Permit Section C.5.b.iv.(5), page 63). While the Permit prescribes the RAA as a quantitative demonstration that identified watershed control measures will be effective, the RAA also promotes a modeling process to support the EWMP Group with selection of control measures. In particular, the RAA was used to evaluate the many different scenarios/combinations of institutional, distributed, and regional control measures that could potentially be used to comply with the RWLs and WQBELs of the Permit, and was then used to select the control measures specified in the EWMP Implementation Plan.

This section describes key elements of the RAA including the following:

- Modeling system used for the RAA
- Baseline critical conditions and required pollutant reductions
  - Baseline model calibration
  - Water quality targets
  - Critical conditions for wet weather and dry weather
  - Selection of limiting pollutants
  - Required interim and final pollutant reduction
- Representation of control measures in RAA
- Approach for selecting control measures for the EWMP Implementation Plan

The purpose of the RAA is to demonstrate that the implementation scenarios proposed in the EWMP will meet the MS4 Permit effluent and receiving water limits for priority pollutants of concern within the Implementation Area. This is done by demonstrating load reductions for the 85th Percentile, 24-hour storm and the 90th percentile load. Load reductions are used instead of concentrations. This is necessary for two reasons: first, the entire watershed is not participating as part of the this EWMP and the approaches they are taking may be different than Torrance; second, capture and infiltration systems will reduce the loads delivered, but may not change concentrations of flows that reach the regulated water bodies. Total loads in the water bodies will be tied to contributions from all entities within the watershed. For these reasons, load reductions are considered a better metric for analysis.

### 3.3.1 RAA Modeling System Used

The City developed a Stormwater Quality Master Plan (SQMP) in 2011 to address increasingly stringent regulatory requirements and stormwater related issues caused by continued development pressure. As part of the SQMP, the portion of the Machado Lake Watershed within the City was modeled utilizing a tool referred to as the PLAT, a module linking a number of publicly available models including: USEPA's PLOAD, the Program for Predicting Pollution Particle Passage thru Pits, Puddles, & Ponds (P8), USEPA's SWMM 5.0, and USEPA's SUSTAIN. WMMS and N-SPECT model (Nonpoint Source Pollution and Erosion Comparison Tool) were used to validate PLAT model results. The general concept of PLAT is illustrated on Figure 3.3.

Even though PLAT was developed before the guidelines (RWQCB, 2014) for developing a RAA was published, only few enhancements were made to meet RAA modeling requirements. The enhancements include converting the original XP-SWMM model (a proprietary software) to EPA SWMM 5.0 model. PLAT methodology is comprised of three main evaluations:

- Model Calibration/verification In the absence of field data specific to Torrance, LA County WMMS and N-SPECT models were used to calibrate/validate some modules of PLAT.
- 2. Annual load estimation and initial BMP Screening. impervious cover information derived from satellite imagery, EMC and PLOAD model were used to compute annual pollutant load, characterize pollutant hotspots, and perform initial BMP screening analysis to select BMPs for detailed evaluation.
- 3. Detailed Load and BMP Evaluation Uses EPA SWMM 5, P8, and SUSTAIN models for comprehensive water quality modeling to identify priority subbasins based on BMP need, BMP sizing and optimization, and evaluation of management alternatives.
- 4. The USEPA SWMM 5.0 and P8 models are the two main components of PLAT used to develop this RAA. SWMM and P8 models are described in more details below.

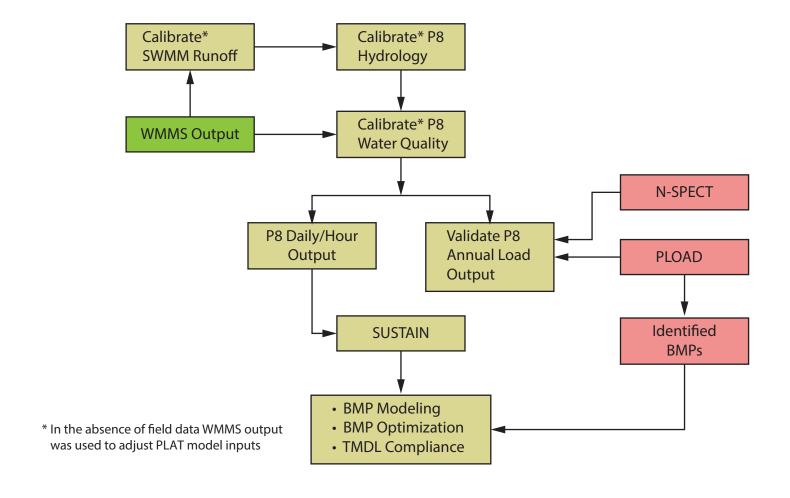

Figure 3.3 General Concept of PLAT Analysis

### 3.3.1.1 Watershed Model - EPA SWMM 5.0

EPA's Storm Water Management Model (SWMM) is used throughout the world for planning, analysis, and design related to stormwater runoff, combined and sanitary sewers, and other drainage systems in urban areas. There are many applications for drainage systems in non-urban areas as well.

SWMM is a dynamic hydrology-hydraulic water quality simulation model. It is used for single event or long-term (continuous) simulation of runoff quantity and quality from primarily urban areas. The runoff component operates on a collection of sub catchment areas that receive precipitation and generate runoff and pollutant loads. The routing portion transports this runoff through a system of pipes, channels, storage/treatment devices, pumps, and regulators.

SWMM tracks the quantity and quality of runoff made within each sub catchment. It tracks the flow rate, flow depth, and quality of water in each pipe and channel during a simulation period made up of multiple time steps. SWMM 5 has recently been extended to model the hydrologic performance of specific types of low impact development (LID) controls.

### 3.3.1.2 BMP Selection and Performance Model - P8 Model

'P8' abbreviates "Program for Predicting Polluting Particle Passage Through Pits, Puddles, and Ponds," which more or less captures the basic features and functions of the model. It has been developed for use by engineers and planners in designing and evaluating runoff treatment schemes for existing or proposed urban developments. Design objectives are typically expressed in terms of percentage reduction in suspended solids or other water quality component.

P8 has been used by state and local regulatory agencies as a consistent framework for evaluating proposed developments. Depending on applications, other models could be either too simple (easily used, but ignoring important factors) or too complex (requiring considerable site-specific data and/or user expertise). P8 attempts to strike a balance to between those extremes.

Predicted water quality components include total suspended solids (sum of the individual particle fractions), total phosphorus, total Kjeldahl nitrogen, copper, lead, zinc, and total hydrocarbons. Simulated BMP types include detention ponds (wet, dry, extended), infiltration basins, swales, buffer strips, or other devices with user-specified stage/discharge curves and infiltration rates. A simple water budget algorithm can be used to estimate groundwater storage and stream base flow in watershed-scale applications.

### 3.3.2 <u>Baseline Critical Conditions and Required Pollutant Reductions</u>

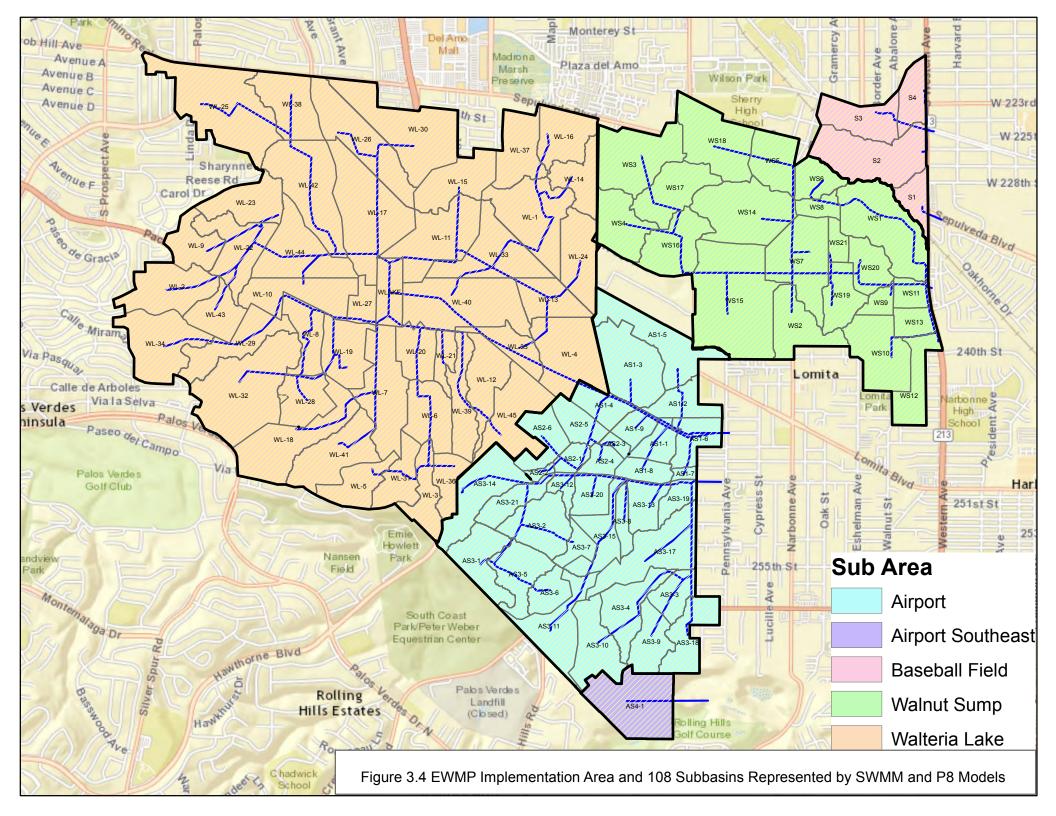

The following subsections describe the application of the SWMM and P8 models to simulate current conditions, identify critical conditions, and calculate required pollutant reductions. The calculated required reductions drive the extent of the control measures to be implemented under the EWMP.

### 3.3.2.1 Baseline Model Development and Calibration/Verification

A fundamental element of the RAA is simulating baseline/existing conditions in the watershed prior to implementation of control measures. For the Implementation Area RAA, baseline conditions were simulated using the SWMM and P8 watershed models in PLAT, including predictions of flow rate and pollutant concentrations over a 10-year period, as follows:

- The simulation period is October 1, 2001 to September 30, 2011.
- Simulated pollutants include total suspended solids, fecal coliform, total copper, total lead, total nitrogen, and total phosphorous. Toxics loads were estimated from total suspended solids load output.
- An hourly time step was used to simulate the flow rate and pollutant concentration at each of the 107 subbasins outlets shown in Figure 3.4 and the resultant downstream conveyance system.
- The model explicitly accounts for effects of major hydraulic structures in the Implementation Area including impoundments such as Walteria Lake.

There was no significant flow and water quality data for the Implementation Area during the development of PLAT. Recently calibrated WMMS' LSPC's output was therefore used to adjust PLAT input parameters. This process is referred to as calibration/verification in this EWMP. These calibrated WMMS parameters included in Appendix C were used without any adjustments in LSPC to perform a 10-year simulation. The LSPC output was summarized by sub area. For planning purposes the Implementation Area was subdivided into five sub areas as shown on Figure 3.5. The characteristics of the sub areas are summarized in Table 3.5.

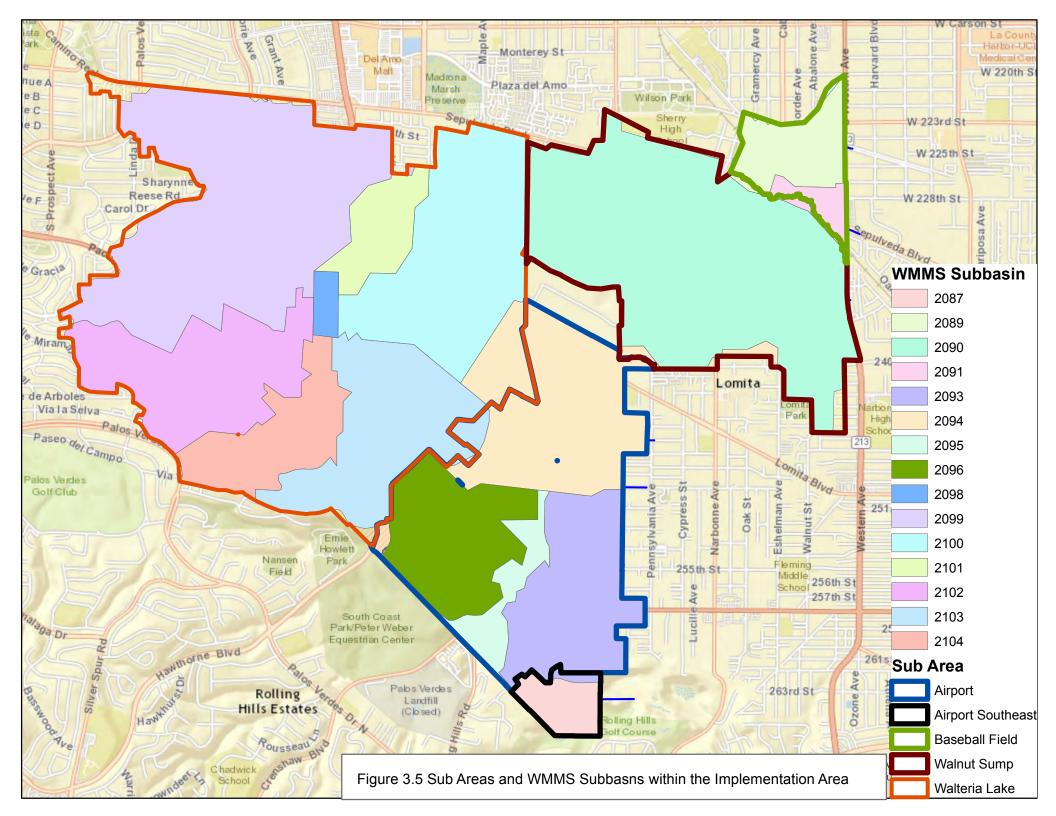

Table 3.5	Summary	y of Sub Areas in the Implementation Area	
Sub Area	Area (ac)	WMMS Subbasins	No. of SWMM Subbasins
Airport	975	2093, 2094, 2095 and 2096	35
Airport Southeast	70	2087	1
Walnut Sump	923	2090	21
Baseball Field	155	2089 and 2091	4
Walteria Lake	2,118	2090, 2098, 2099, 2100, 2102, 2103 and 2104	46

It was assumed that the calibrated WMMS model meets the RAA calibration standards and therefore provides a reasonable approach to validate SWMM in the absence of significant field data specific to the Implementation Area. As field data for the Implementation Area becomes available in the near future through sampling efforts by the City, SWMM will be recalibrated to the observed values. The comparison of the calibrated hydrology model to the RAA Guidelines is shown in Table 3.6. The annual volume values were obtained by summing the daily flow output from SWMM. The baseline SWMM model performs quite well for representing existing hydrologic and water quality conditions. Details of the baseline model development and calibration are presented in Appendix C.

	nmary of Hy MM Model	drology Calibration Perfo	rmance by Basel	ine
Sub Area	Drainage Area (ac)	Model Period	Hydrology Parameter	SWMM vs. WMMS
Airport	975	10/01/2001 - 09/30/2011	Annual Volume	9.20%
Airport Southeast	70	10/01/2001 - 09/30/2011	Annual Volume	-10.62%
Walnut Sump	923	10/01/2001 - 09/30/2011	Annual Volume	12.41%
Baseball Field	155	10/01/2001 - 09/30/2011	Annual Volume	11.72%
Walteria Lake	2,118	10/01/2001 - 09/30/2011	Annual Volume	9.47%

### 3.3.2.2 Current/Baseline Loading

A baseline analysis was performed as part of the RAA which represents the current watershed condition with the currently implemented stormwater programs. Stormwater runoff was simulated based on the time series record of rainfall between October 2001 and September 2011. This period represents the most recent 10 years of record as required by the MS4 Permit. The water quality constituent mass loading is estimated by multiplying the stormwater runoff volume by the water quality constituent concentration.

The baseline hydrology and simulated constituent loading serves as the basis for compliance. Watershed control measures, including structural and non-structural BMPs, will be implemented over time to meet the required load reductions. The load reductions represent the difference between the baseline conditions and the water quality objectives. The 85th Percentile, 24-hour rainfall event baseline simulation is based on the LACFCD 85th Percentile rainfall isohyets and unit hyetograph, consistent with the Standard Urban Stormwater Mitigation Plan (SUSMP) and Low Impact Development (LID) methods used within the County.

Table 3.7 summarizes the results of the SWMM and P8 simulations for the water years beginning the first day of October and ending the final day of September from 2001 to 2011 for each sub area. The sub areas are shown on Figure 3.5. The table compares the major water quality constituents with adopted TMDLs and identifies the annual load and corresponding volume for each year analyzed. The average annual loads are also provided for the simulation period. Table 3.7A lists the annual flow volumes and loads by sub area and Table 3,7B summarizes the average annual load by sub area for the ten years evaluated. In Table 3.7C, a summary of toxics baseline loads are provided by sub area. The toxics loads are assumed to be directly related to the simulated TSS load. Thus, toxics loads were computed as follows:

Toxic Load 
$$\left(\frac{g}{yr}\right) = TSS \ load \ \left(\frac{kg}{yr}\right) \times measured \ toxics \ concentration \left(\frac{\mu g}{kg}\right) \times 10^{-6}$$

# 3.4 Estimated Required Pollutant Load Reduction

The Implementation Area RAA examines the average annual load, 85th percentile, 24-hour storm event volume and the 90th percentile constituent load to estimate the limiting pollutant and the corresponding volumes of required treatment. The limiting pollutant is the constituent with the highest mass load associated with a relevant TMDL. This subsection discusses the limiting pollutant evaluation, 85th percentile, 24-hour storm volume, and the 90th percentile, 24-hour storm load. These factors establish the control measure implementation requirements. Evaluation of the limiting pollutant requires estimating the volumes and loads associated with the average annual load, 85th percentile, 24-hour runoff volume and the 90th percentile load for baseline conditions and multiple pollutants. Once these values are estimated, the limiting pollutant can be evaluated. The limiting pollutant is that pollutant for which the greatest amount of volume control is required to achieve the 90th percentile load reduction.

### 3.4.1 <u>Nutrient and Toxics Load Reduction</u>

In order to perform the RAA for nutrients and toxics, the annual results listed in Table 3.7a were compared to the average annual results in Table 3.7b. Water years with annual TP results comparable to the average annual TP results were selected. The RAA simulation periods listed in Table 3.8 for TP, TN, and toxics were used for all the sub areas in the Implementation Area.

Table 3.8 Bas	seline Constituent Load fo	or TP, TN, and TSS <sup>(1)</sup> -	Implementation Area						
Constituent	Simulation Period	Volume (ac-ft)	Load (kg/yr)						
TP	10/01/09 - 9/30/10	1,653.58	920.01						
TN	10/01/09 - 9/30/10	1,653.58	6,929.41						
TSS	10/01/09 - 9/30/10	1,653.58	487,362.3						
Note: (1) Toxics loads we	,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,								

The average annual loads summarized in Table 3.8 for TN, TP and toxics (TSS load) were compared with the Machado Lake TMDL allocations. A summary of the pollutant loadings from the Implementation Area, the Final TMDL allocations and ultimate required reductions for TN, TP and toxics are presented in Table 3.9. The annual nutrient loadings (TN and TP) from the Implementation Area listed in the table currently comply with the interim limit of total nitrogen, 7,370 kg/yr and total phosphorus of 3,760 kg/yr. Final nutrient WLAs are supposed to be attained by September 11, 2018.

According to the Table 3.9, 67 percent of total phosphorus load and 57 percent of total nitrogen load must be removed by the City to meet the final nutrient WLAs.

Table 3.9 Basel	ine Loading Ra	ates From Imple	mentation Area t	o Machado Lake
Constituent	Baseline Load <sup>(1)</sup> (kg/yr)	Allowable Load <sup>(2)</sup> (kg/yr)	Required Reduction (kg/yr)	Required Reduction <sup>(3)</sup> (%)
Total Nitrogen	6,929	3,008	3,921	56.6
Total Phosphorus	920	301	664	67.3
		Toxic Constitue (g/yr)	ent	
Total PCBs	47.93	9.88	38.05	79.4
Total DDT	28.04	0.87	27.17	96.9
Dieldrin	9.36	0.54	8.82	94.2
Chlordane	32.65	0.31	32.34	99.1

### Notes:

- (1) The annual nutrient baseline loadings from the TMDL Implementation Area listed in the table comply with the interim limit of total nitrogen, 7,370 kg/yr and total phosphorus of 3,760 kg/yr.
- (2) Concentration based WLAs are met under the approved flow condition of 8.45 hm<sup>3</sup>/yr.
- (3) Percent of pollutant amount that is required to be removed.

## 3.4.2 <u>Metal and Fecal Coliform Load Reduction</u>

Using the 90th percentile load days for metals and fecal coliform, the required pollutant reductions were calculated for attainment of final limitations. Selection of the storms utilizing this process provides a sound criterion for compliance by evaluating the range in volumes, concentrations, and loads to provide a treatment volume that has the potential to meet the criteria for the 85th percentile, 24-hour event, and 90th percentile load reduction. The variability in the data shows that selecting a storm is an important step in the analysis process. By selecting the appropriate storm, flows that exceed the capture volume will mainly have pollutant concentrations below the TMDL concentration limits due to dilution of remaining pollutants. The details of the selection process are provided in the following paragraphs. The results of the analysis are provided later to demonstrate compliance and the reasonableness of the approach.

The 90th percentile load related to entire Implementation Area was estimated using PLAT. The 90th percentile constituent loads represent the daily constituent loads that are greater than 89 percent and less than 10 percent of all simulated loads at the output station. The method for estimating the 90th percentile load was to sort all flow days under wet weather conditions from the calibrated hydrology simulation model for the time series beginning on October 1, 2001 and ending on September 30, 2011.

The hourly and daily mass loads were the product of the simulated storm volume and the simulated hourly constituent concentration for the Implementation Area flows. The 90th percentile load was estimated from the simulated daily load. The volume capture for the 90th percentile load was estimated on the day of the actual event.

Baseline simulations were run with no storm runoff volume reduction. Table 3.10 summarizes the water quality constituents and the date of the 90th percentile event derived from the simulated model results following the criteria previously outlined in the preceding paragraph. The volume associated with the 90th percentile load is shown along with the expected (modeled) and objective concentrations and loads.

Table 3.10	90th Percentile Constituent Load - Implementation Area						
			Concentration (µg/L) and MPN/100mL		Load (kg)

### 3.5 Pollutant Source Prioritization

To help develop implementation strategies, a prioritization of pollutant loading by sub area and potential sources was developed. The effort is concentrated on wet weather loading, with the assumption that BMPs targeted for the watershed would be designed to treat both wet and dry weather flows that drain to the BMP.

Wet weather loads generated from the TMDL Implementation Area were converted to area loads (e.g., pounds per acre per year [lb/ac/yr]) for use in the pollutant source prioritization. This provides a normalized view for targeting management in that it shows where the rates

are highest. Area loads for each constituent were then ranked with a score 1 through 4 by sub area. Values were assigned quartiles as follows:

- A score of 1 for the lowest 25th quartile<sup>1</sup>,
- A score of 2 for values between the 25th and 50th quartile,
- A score of 3 for values between the 50th and 75th quartile, and
- A score of 4 for the highest quartile.

The final rankings for wet weather area-based loads are shown in Table 3.11.

Table 3.11 Wet Weather Load Ranking by TMDL Implementation Area (Area Loads)					
TMDL	Pa	arameter Sco	re		
Implementation Area	TSS	TN	TP	Total Score	Priority Rank
Airport	4	4	4	12	1
Walnut Sump	4	2	3	9	2
Baseball Field	3	3	3	9	2
Airport Southeast	1	2	2	5	3
Walteria Lake	2	1	1	4	4
Rank: 1 – Highest Priori	ty 4 – Lowest F	Priority			

# 3.6 Volume and Load Reduction Strategies

Various load reduction strategies were used to achieve compliance through the RAA including institutional (non-structural) and structural BMPs. Control measures are implemented strategically throughout the compliance period at specific time steps so that the interim and final WQOs are met. The three types of control measures that are the focus of the volume and load reduction strategy are institutional BMPs (MCMs and LID ordinances), regional projects, and distributed projects (green streets). Details can be found in Sections 4 and 5. The schedule of implementation is discussed in Section 8 and represents a feasible implementation timeline considering regional BMP implementation will take a long time while MCMs and distributed BMPs may be implemented with less planning, engineering, and design effort.

### 3.6.1 85th Percentile Basin Identification

Wherever feasible, the City wants to capture and retain all non-stormwater runoff and all stormwater runoff from the 85th percentile, 24-hour storm event generated from the

52 October 2016

<sup>&</sup>lt;sup>1</sup> A quartile is one of the 4 subdivisions that have been grouped into four equal sized sets based on their statistical rank.

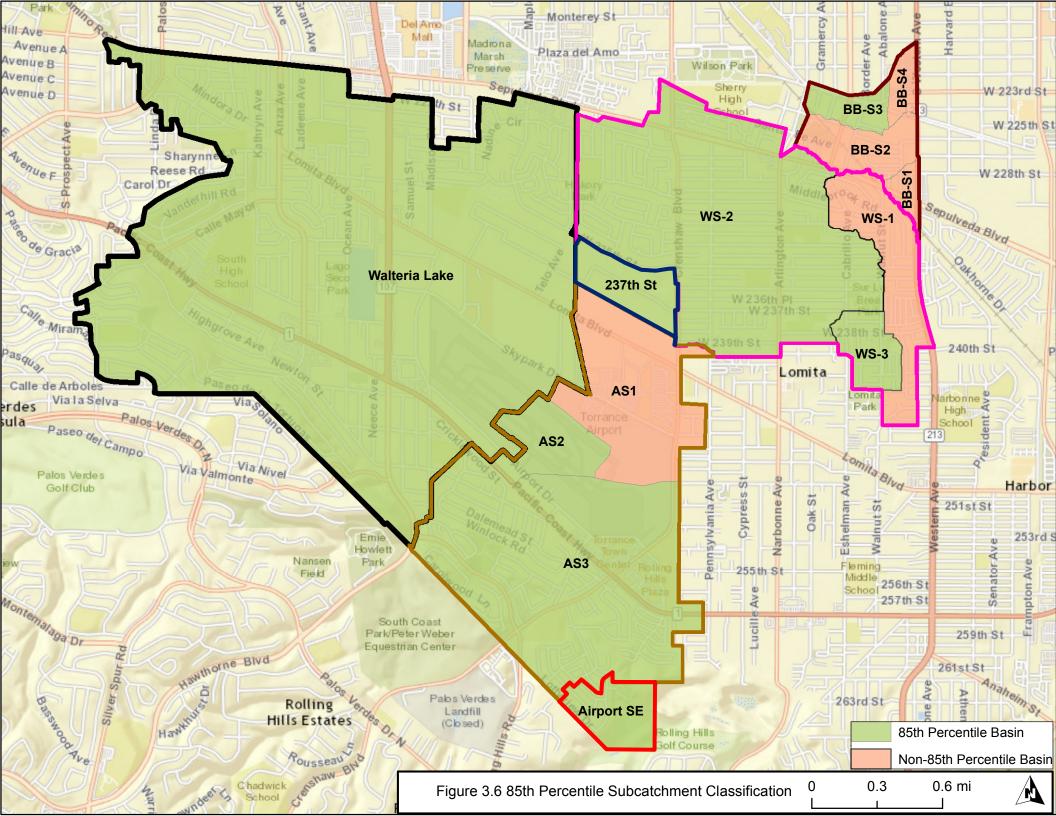

Implementation Area. However, it is not feasible to identify a single site within the Implementation Area to install a regional BMP to capture and retain the 85th Percentile, 24-hour design storm volume. The sub areas were therefore delineated into several subcatchments for BMP implementation purposes. Based on the proposed BMP capacities (detailed in Section 5.3.1) the subcatchments were classified into two:

- 85th Percentile Basin
- Non-85th Percentile Basin

The applicability of the BMPs serving these subcatchments to capture and retain the 85th percentile, 24-hour runoff volume was investigated. Calculations were performed to determine the approximate size required to capture the 85th-percentile, 24-hour storm volume for the subcatchments. The 85th-percentile, 24-hour storm volume was determined using SWMM modeling and the County of Los Angeles Modified Rational Method which uses drainage area, runoff coefficient, and the 85th Percentile, 24-hour storm depth as input. The 85th percentile, 24-hour storm event represents the rainfall event that is greater than 85 percent of all rainfall events over 0.1 inches in a 24-hour period. The 85th percentile, 24-hour isohyetal map developed by LACDPW was used to estimate the appropriate rainfall value of 0.85 in for the Implementation Area. This design storm is identified in the RAA Guidelines as an acceptable critical condition, and capture of design storm volumes by BMPs is a specified compliance metric in the Permits for TMDLs.

The stormwater volume from the 85th Percentile, 24-hour storm event calculated for each subcatchment is listed in Table 3.12 and Figure 3.6 shows the 85th Percentile subcatchment classification.

Table 3.12 Su	ubcatchment Clas	sification

	BB-S4	24	1.12	No

### 4.0 DEVELOPMENT OF INSTITUTIONAL SOLUTIONS

As part of the development of the EWMP, the Permit specifies that watershed control measures (or BMPs) shall be identified to:

- 1. Ensure that stormwater discharges meet receiving water and effluent limits as established in the Permit.
- Reduce overall impacts to receiving waters from stormwater and non-stormwater runoff.

BMPs are grouped into two broad categories, structural and institutional. Structural BMPs are physically constructed control measures that alter the hydrology or water quality of stormwater or non-stormwater. Institutional (nonstructural) BMPs are source control measures that prevent the release of flow/pollutants or transport of pollutants, but do not involve construction of physical facilities. Minimum control measures (MCMs), such as street sweeping, are a subset of institutional BMPs. This section summarizes MCMs measures which reduce the current pollutant load to meet past and future compliance requirements.

A comprehensive program has been developed and ready to be implemented to reduce or eliminate the amount of pollutants in stormwater and urban runoff. This program meets a variety of regulatory requirements, including those of the LARWQCB adopted Order R4-2007-0042 for municipal stormwater and urban runoff discharges within the County (LARWQCB 2007b). An evaluation was conducted to identify opportunities for improvements to existing programs and new programs that would help meet TMDL WLAs and to determine the level of success in implementing these programs. Existing institutional BMPs are described in Section 4.1.1 and new institutional BMPs are proposed in Section 4.1.2. Considered holistically, these existing, improved, and new programs are expected to contribute to the reduction of TMDL pollutant loads and contribute to meeting WLAs.

### 4.1 MCMs/Institutional BMPs

In general, institutional solutions include pollution prevention actions and source control activities that prevent or minimize the amount of pollution entering urban runoff. Pollution prevention actions seek to control constituents of concern before their release to the environment. Typical pollution prevention actions include conservation and reuse activities. Source control activities target pollutants from specific sources to reduce or eliminate the concentrations of those pollutants entering the municipal separate storm sewer systems (MS4). Typical source control activities include, but are not limited to:

- Issuance of local ordinances
- Street sweeping
- Product bans by either the State or Federal government

For pollution prevention and source control measures to be effective, the parties involved need to be educated about the measures, incentives should be provided to use the measures, and enforcement should be available to ensure the measures are implemented. Both pollution prevention and source control measures are proposed as complementary components of non-structural solutions, which may provide more effective treatment at a lower cost than many structural solutions. The City will implement existing and proposed MCMs as written in the LA County MS4 Permit.

# 4.1.1 <u>Summary of Existing MCMs/Institutional BMPs</u>

The following provides a summary of existing Institutional BMPs that were evaluated to determine if enhancements could be made to specifically support TMDL implementation. A summary of the City's existing institutional BMPs relevant to nutrients, toxics, bacteria and sediment reduction and flow reductions are presented in Table 4.1. The description provides an overview of relevant programs that could directly support stormwater pollution control.

Table 4.1 Exist	Table 4.1 Existing MCMs/Institutional Solutions Conducted by City of Torrance			
МСМ	BMP Type	Description		
Public Information and Participation Program	Education	Encompasses several outreach campaigns. Those that most directly address nutrients are the Smart Gardening Program, pet waste outreach, and fats, oils and grease outreach.		
Industrial/ Commercial Facilities Control Program	Enforcement	Tracks, inspects, and ensures compliance with permits for industrial and commercial facilities. Controls pollutant transport.		
Development Planning	Source Control	Focuses on mitigating the long-term hydrologic and pollutant effects of the built environment and changes in land use. Includes establishing requirements for post-construction BMPs, reviewing plans to ensure that proposed drainage plans meet water quality and hydrologic performance standards, and ensuring long-term operation and maintenance of post-construction BMPs.		
Development Construction Program	Enforcement	Addresses runoff from public and private construction projects through the use of stormwater pollution prevention plans (SWPPPs), training of staff engaged in construction activities, and compliance inspections. Through runoff prevention, controls the transport of nutrients and toxics.		

Table 4.1 Existing MCMs/Institutional Solutions Conducted by City of Torrance			
МСМ	BMP Type	Description	
Public Agency Activities Program	Source Control	Applies BMPs to infrastructure and facility operation and maintenance activities of Public Agencies to reduce pollutant sources. This includes sewer system maintenance, corporation yard, and recreational facility management.	
Illicit Connections/Illicit Discharge Program	Enforcement	IC/ID removal prevents the discharge of a variety of pollutants including nutrients and toxics from entering the storm drain system.	
Catch basin filter Clean Out	Source Control	Catch basin filters are cleaned at least annually, with higher priority catch basin filters cleaned semi-annually or quarterly. For industrial catch basin filters, the optimal cleaning frequency appears to be between quarterly and semiannual; for residential catch basin filters, the optimal frequency appears to be annual. For commercial catch basin filters, the optimal frequency is semiannual.	
Catch basin filter <sup>(1)</sup>	Source Control	In an effort to reduce trash as part of the Machado Lake Trash TMDL, catch basin filter could be installed in portions of watershed. Catch basin filter proposed with Machado Lake Trash TMDL Project.	
Street Sweeping	Source Control	Curbed streets are swept weekly with vacuum sweepers in the city. Much of Torrance is not signed for street sweeping. This will be corrected with Machado Lake Trash TMDL Project.	
Impervious Cover Disconnection	Source Control	Employ rooftop disconnection techniques.	
County Ordinance No. 2008-000S2U	Enforcement	Prohibits wash down of paved surfaces, irrigation runoff, and requires car washing BMPs.	
Restaurant Training	Education	An education program that includes restaurant BMP guidelines, a watershed model showing the potential for oil and grease to affect the watershed, a PowerPoint presentation, and collateral material for restaurant owners, including posters, buckets with BMPs printed on them, and brochures. Torrance does this as part of Clean Bay Certification Program.	
County Ordinance Title 10 Animals, Chapter 10.40.060, B. Notes:	Enforcement	Requires pet owners to pick up and properly dispose of their pet's waste.	

- (1) Although normally considered structural BMPs, for the purposes of the model, catch basin filter were accounted for as a nonstructural BMP.
- (2) Torrance has ban on smoking in Public Parks and Torrance Beach.

Enhancements to the existing institutional BMPs and additional institutional BMPs can be considered and are discussed in the following section.

### 4.1.2 <u>Enhanced Institutional BMPs</u>

Enhanced institutional BMPs may include new non-structural solutions and enhancements of existing institutional solutions. Specific sources of nutrients and toxics and their associated institutional solutions are listed in Table 4.2. The institutional solutions listed in Table 4.2 are detailed in Table 4.3. Sanitary sewer maintenance is covered in other areas of the Implementation Plan. Note that the costs presented in Table 4.3 are per year, and total implementation costs include an estimated rate of inflation of 3 percent over the life of the program.

Table 4.2 Potential	Institutional Solutions by Pollutant Source
Pollutant Source	Associated Potential Nonstructural Solution(s)
Irrigation overflow	<ul> <li>Smart Gardening Program, with evapotranspiration controller irrigation enhancement</li> <li>Public Agency Activities Program – landscape and recreational facilities management focus</li> </ul>
Landscape fertilizer	<ul> <li>Smart Gardening Program</li> <li>Public Agency Activities Program – landscape and recreational facilities</li> <li>management focus</li> <li>Development Planning – post construction BMPs</li> </ul>
Catch basin <sup>(1)</sup>	<ul> <li>Development Planning – post construction BMPs</li> <li>Catch basin<sup>(1)</sup></li> <li>Catch basin clean outs – increased frequency</li> <li>Catch basin inserts – install inserts where other structural BMP retrofits options are infeasible due to ownership/space constraints. Inserts should be selected that are capable of removing nutrients.</li> </ul>
Streets and parking lots	Street and parking lot sweeping – more efficient sweepers and increased frequency
IC/ID	<ul> <li>More aggressive identification and removal of illicit connections</li> <li>Add stencils and re-stencil storm drains, as needed</li> </ul>
Sewage	<ul> <li>Public Agency Activities Program – sewer systems maintenance, overflow, and spill prevention focus</li> <li>Public Information and Participation Program – fats, oils, and grease outreach</li> <li>Recreation Vehicle Sewage Disposal Sites – Public Information</li> </ul>
Horse manure	Public outreach
Pet waste	Public outreach, providing bags and receptacles at parks, etc.
Green waste	Public outreach
Sediment	<ul> <li>Industrial/Commercial Facilities Control Program</li> <li>Development Planning</li> <li>Public Agency Activities Program – materials storage facilities/corporation yards management focus</li> </ul>

were accounted for as a nonstructural BMP

Table 4.3 Propo	Table 4.3 Proposed New and Enhanced Institutional BMP Descriptions				
Institutional BMP	Description	New/Enhanced Program	Targeted Pollutant	Annual Cost	
Add stencils and restencil storm drains, as needed	Audit storm drains to determine where stencils are not present or are faded. Efforts should initially be focused in Island 1 where field investigations noted faded or missing storm drain labels	Enhanced: Public Agency Activities Program	Nutrients and toxics	\$5K per year	
Catch basin clean outs	Modify program to use more aggressive techniques and increase frequency to clean 60% of catch basin filters monthly and 40% of catch basin filters semi-annually.	Enhanced: Public Agency Activities Program	Nutrients and toxics	\$100K per year	
Catch basin inserts <sup>(1)</sup>	Expand installation of trash catch basin inserts to cover more areas in the city; catch basin inserts should be capable of removing trash, nutrients, and toxics. As an example, Kristar's FloGard Perk Filter has been approved by Washington Dept. of Ecology's TAPE program 5 as "basic treatment" meaning that third party monitoring data has validated its ability to remove at least 80% TSS and 50% TP. Regular maintenance is necessary to retain pollutant removal performance	Enhanced: TMDL Implementation	Nutrients and toxics	\$20K (includes yearly O&M)	
Downspout disconnection program	Establish a downspout disconnection program to incentivize the disconnection of residential rooftop downspouts. See Section on Integrated Water Resource Considerations for additional information, page 36	New	Nutrients and toxics	\$50K/ year	
Fats, oils, and grease outreach	Target restaurants and residents in the TMDL Implementation Area for additional FOG outreach to educate them about the potential of sewage overflows caused by FOG blockages	Enhanced: PIPP	Nutrients	\$5K/ year	
Green waste outreach	Target residents and institutional land uses in TMDL Implementation Area for additional proper management of green waste.	New	Nutrients	\$5K/ year	
Horse manure outreach	Target residents for outreach about horse manure management.	New	Nutrients	\$5K/ year	
Illicit connection removal	Enhance program so that 40% of the system is surveyed and 20% of identified IC is removed	Enhanced: ID/IC Program	Nutrients and toxics	\$75K \$2,500/illicit connection removal <sup>2</sup>	

Institutional BMP	Description	New/Enhanced Program	Targeted Pollutant	Annual Cost
Industrial/ Commercial Facilities Control Program	Enhancement may include more in-depth training for inspectors and staff that addresses nutrient and toxics specific BMPs. Strengthening partnerships with enforcing agencies may also improve enforcement escalation procedures	Enhanced: Industrial Commercial Facilities Program	Nutrients and toxics	\$5K/ year
Landscape and recreational facilities management	Enhancements are similar to the Smart Gardening Program, with application to landscape and recreational facilities managed by the City. The enhancements include switching to non-phosphorus organic fertilizers or using no fertilizer, adding soil amendments to lawns, converting a goal of 25% of lawn to native vegetation and using ET controllers. Outreach may include trainings for City staff that manage or maintain landscape and recreational facilities	Enhanced: Public Agency Activities Program	Nutrients and toxics	\$10K/ year
Materials storage facilities/ corporation yards management	Training for City staff in charge of materials storage facilities and corporation yards with focus on activities and materials that may contribute to nutrient and toxic pollution to storm drain	Enhanced: Public Agency Activities Program	Nutrients and toxics	\$5K/ year
Oil pump ESC outreach	Work with oil pump parcels located throughout the TMDL Implementation Area to ensure that sediment does not leave the site during the wet season.	New	Nutrients and toxics	\$10K/ year
Pet waste outreach	Target residents, pet stores, and animal shelters in TMDL Implementation Area for additional pet waste outreach	Enhanced: PIPP	Nutrients	\$50K/ year
Post construction requirements for new development and redevelopment	This program may be enhanced with additional training for Development Planning Staff. The focus would be education in planning for and maintaining post-construction BMPs that are effective in reducing nutrients toxics, and runoff	Existing: Development Planning Program	Nutrients and toxics	\$25K
Sewer system maintenance, overflow, and spill prevention	Enhance sewer system maintenance and target staff working in the TMDL Implementation Area for SSO response and spill prevention training.	Enhanced: Public Agency Activities Program	Nutrients	\$20K • \$1,700/mi to clean sewer pip

Institutional BMP	Description	New/Enhanced Program	Targeted Pollutant	Annual Cost
Smart Gardening Program	This program includes outreach to reduce inputs (fertilizers, pesticides, water, etc.) to landscape, controlling nutrient sources and irrigation runoff.  Field investigations showed evidence of lawn irrigation runoff in the majority of residential neighborhoods in all three Islands. This program should aggressively target the population within the TMDL Implementation areas. This program may be additionally enhanced to include evapotranspiration (ET) controllers to further reduce irrigation runoff. It may also encourage residents to change to non-phosphorus organic fertilizers or use no fertilizer, add soil amendments to lawns, and convert lawn to natural vegetation.	Enhanced: Public Agency Activities Program	Nutrients and toxics	\$60K/ year
Street and parking lot sweeping	Increase frequency of sweeping to 2x/weekly	Enhanced: Public Agency Activities Program	Nutrients and toxics	\$80K/ year <sup>(4)</sup>

# 4.2 Public Information and Participation Program

The County of Los Angeles Department of Public Works' Countywide Stormwater/Urban Runoff Public Education, Used Motor Oil and Used Oil Filter Recycling, Household Hazardous Waste/Electronic Waste Collection, and Smart Gardening programs help achieve the Public Information and Participation Program (PIPP), public outreach mandates and address nutrients and toxics pollution. Public community events, paid media campaigns, media relations efforts, and distribution of collateral materials are part of the standard public outreach practices for the above-mentioned environmental education programs. Visit <a href="https://www.CleanLA.com">www.CleanLA.com</a> for information about these programs.

The Smart Gardening Program consists of learning centers and workshops that educate homeowners about conservation (of fertilizers, pesticides, water, etc.) when gardening and landscaping, which reduces the amount nutrients and toxics in the environment. The Smart Gardening Program could be enhanced to help facilitate TMDL implementation by identifying learning centers and/or holding workshops in the Implementation Area.

Tip cards with Smart Gardening Program information could be tailored to address specific concerns (discontinuing irrigation overspray as a pollutant transport mechanism, controlling excess nutrients from fertilizer, pesticide alternatives, etc.) and sent to residences within the Implementation Area.

### 4.3 Institutional BMPs Recommendations

As a result of the review of the existing programs that address the TMDL pollutants, the following are recommended enhancements and additional BMPs that would offer additional water quality benefits and contribute to TMDL implementation:

- **Enhancing the Smart Gardening Program** so it would extend the reach of the water conservation and pollution-prevention messages to the Machado Lake watershed.
- Conducting TMDL-specific stormwater training that emphasizes activities and BMPs that can cause or mitigate the TMDL pollutants of concern.
- Enhancing commercial and industrial facility inspections to avoid that activities associated with these businesses become new sources of pollutants.
- Improving enforcement escalation procedures to more effectively address known sources of pollution.
- **Improving street sweeping technology** to more effectively reduce sediment-bound pollutants from road surfaces.
- Reducing irrigation return flow through a variety of water conservation initiatives.

The remainder of the discussion and analysis pertaining to non-structural solutions focuses on those seven recommended BMPs, which are expected to contribute substantially to reductions in pollutant loads. Table 4.4 shows the extent to which each BMP enhancement or new BMP addresses the TMDLs. All the proposed BMPs address nutrients and toxics; TMDL-Specific Stormwater Training addresses trash.

Table 4.4 Summary of Recommended Institutional BMPs

### 5.0 DEVELOPMENT OF STRUCTURAL SOLUTIONS

Meeting WLAs for the nutrient and toxics TMDLs, and Category 2 and 3 pollutants targets in the Implementation Area will take advantage of the institutional BMPs, but structural solutions will provide the majority of the necessary load reductions required. However, structural BMPs are also the most costly, so careful consideration was made in identifying opportunities for structural BMPs and collecting appropriate information to make cost-effective decisions regarding implementation.

Identification and assessment of opportunities for structural BMPs were focused on publicly owned land in the Implementation Area. Both distributed and centralized structural BMPs were considered. Distributed structural BMPs refer to those practices that provide the control and/or treatment of stormwater runoff at the site level. Typical BMPs in this category include, but are not limited to the following:

- Porous pavement
- Grassed swales
- Bioretention
- Water-harvesting systems
- Catch basin filters
- Practices that can be implemented on individual parcels or in the parkway to store, infiltrate, and treat runoff from that parcel.

Centralized BMPs refer to stormwater treatment, storage, or infiltration facilities that provide benefits on a larger scale (e.g., regional). Such projects can include neighborhood-scale or larger-scale facilities such as:

- Spreading grounds
- Flood control facilities
- Park space that provides treatment/infiltration of runoff from nearby areas.

The BMPs presented above are all not equally suitable to all site conditions and performance goals across watersheds. Consequently, several important site specific factors were considered when identifying those BMPs to include in the project analysis.

The following sections describe the process used to assess opportunities for implementing structural BMPs; both distributed and centralized. Section 6 describes the evaluation of BMP alternatives using an optimization process.

## 5.1 Summary of Structural Solutions

A phased approach is necessary for implementing structural solutions. The first priority was given to approaches that do not require obtaining land tenure, which may be projects within publicly owned right-of-ways or programs that encourage private owners to implement structural BMPs within their own properties. The next phase will involve public acquisition of property on which structural solutions can be implemented. The creation of public-private partnerships to implement structural solutions will also be considered. A summary of the pollutant removal mechanisms and capabilities of structural BMPs is provided in Table 5.1.

Table 5.1	Pollutant Removal Mechanisms and Capabilities of Structural BMPs						
Structural BMP	Pollutant Removal Mechanism	Total Nitrogen	Total Phosphorus	Toxics <sup>(1)</sup>	Metals	Bacteria	
Infiltration Basin	Infiltration	Н	Н	Н	Н	Н	
Detention Basin	Settling	М	M	М	М	M	
Constructed Wetland	Biological Uptake, Settling	М	Н	Н	М	Н	
Catch basin filter	Settling, Filtration	L	M	М	М	L/M	
Bioretention	Adsorption, Settling, Biological Uptake, Infiltration	М	Н	Н	Н	Н	
Porous Pavement	Infiltration	М	Н	Н	Н	Н	

#### Notes:

H: high; M: medium; L: low

Scoring modified from International BMP Database, 2010.

- (1) Performance data is not widely available for this pollutant class; assumed that removal efficiency would be similar to sediments since these pollutants are largely associated particulates.
- (2) Phosphorus index of fill soils in bioretention areas will cause a high total phosphorus outflow; high TP removal efficiency is dependent on the fill soils having a low P-index.

Nitrogen removal by bioretention areas can be increased using a design variation that creates an anaerobic zone below the drainpipe.

# 5.2 Assessment of Opportunities for Distributed Structural BMPs

It was not feasible within the Implementation Plan to identify and size each distributed structural BMP in the Implementation Area. Rather, within specific classifications of land characteristics (e.g., impervious roads, land use, soil type), general assumptions were established that provide insight regarding the types and benefits of distributed BMPs that can be implemented at a larger scale. That resulted in identifying key distributed structural BMP projects that could be considered for TMDL implementation planning.

Two major categories of distributed structural BMPs were identified, which were based on site characteristics and the types of BMPs determined feasible: 1) catch basin filter distributed BMPs and 2) other distributed BMPs on public land. The following provides detailed discussions for these categories and the proposed projects for TMDL implementation.

## 5.2.1 Catch Basin Filter Distributed BMPs

Storm drain systems in developed areas typically begin with inlets at the street level. Stormwater inlets have a variety of names, and there are regional differences in terminology. In California, storm drain inlets are routinely called catch basin.

As discussed in Section 3, roads represent a major source of TMDL pollutant loads, and therefore treating road runoff is considered a key strategy for multi-pollutant TMDL implementation. Because of the number and spatial distribution of catch basin in the Implementation Area, they represent an excellent opportunity for treating pollutants in addition to trash. Appendix G provides performance data for the catch basin filters proposed for the Implementation Area.

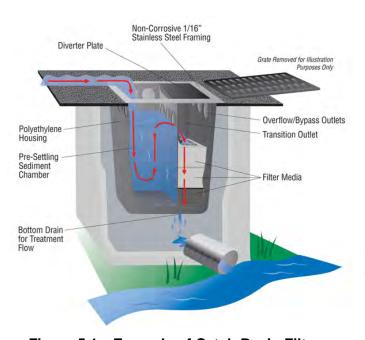

Figure 5.1 Example of Catch Basin Filter

#### 5.2.1.1 Catch Basin Filter

Catch basin filters, as illustrated on Figure 5.1, are devices designed specifically to capture trash, oil/grease, other floatables, sediment, organics, and other pollutants—can offer additional pollutant removal benefits. On the basis of a synthesis of available studies, catch basin filters are expected to treat and remove a significant fraction of sediment (and associated metals and toxics) with treatment focused on runoff from the transportation network. The treatment efficiency of catch basin filters for bacteria is poorly studied and unknown but is likely to be very low unless the insert has a design element targeting

bacteria. Such devices tend to have a 1- to 3-year warranty and would need maintenance or replacement after that. Catch basin filter can replace full capture devices upon installation depending on whether the space they occupy is compatible with the full capture device. Some devices (such as the Abtech Smart Sponge<sup>™</sup>) can be installed in tandem with existing full capture devices.

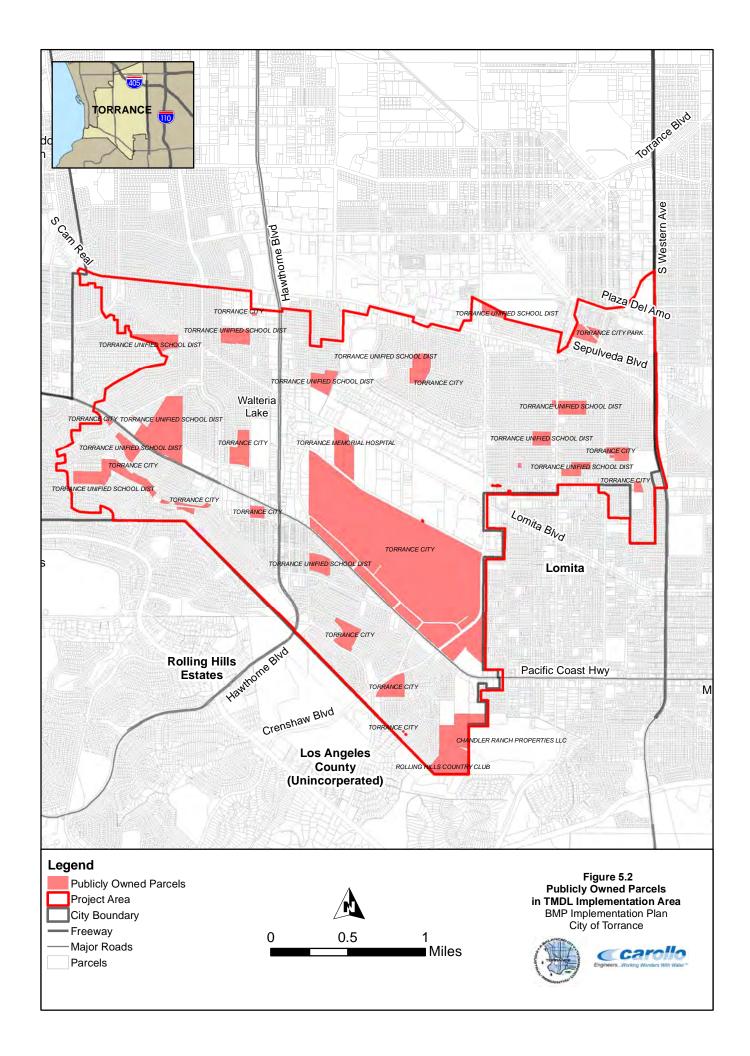

Implementing catch basin filters throughout the Implementation Area is highly applicable because of the high density of catch basins. The Implementation Area includes almost 811 catch basins, which equates to approximately 1 catch basin every 200 to 300 lineal feet of storm drain. The distribution of catch basins within the Implementation Area is summarized in Table 5.2.

Table 5.2 Summary of Catch Basins by Sub Area							
Sub Area	Storm Drain Length (mi)	Number of Catch Basin	Catch Basin Density (CB/mi)				
Walteria Lake	25	373	15				
Airport and Airport Southeast	14	173	12				
Walnut Sump	9	242	27				
Baseball Field	1.4	23	17				
Total	50	811	16				

The City is currently in the process of installation of full capture devices for compliance with the trash TMDL. Implementing catch basin filters would require retrofitting or replacing the full capture devices that have been installed. For the TMDL Implementation Plan, implementing catch basin filters is assumed to focus on replacing existing full capture devices with catch basin filters, which is a more resource intensive, conservative approach. The catch basin filters the City proposes to use will have design elements targeting bacteria. During actual implementation, other more cost-effective approaches for full capture device retrofit could be employed. The schedule for implementing catch basin filters in the Implementation Area considers maximizing the operational period of installed full capture devices, thus improving the return on the investment. Implementing catch basin filters would involve internal planning, conducting a pilot study to gain approval from the LARWQCB for attaining the trash TMDL requirements (for cases where full capture devices are being retrofitted or replaced), installing the devices, and maintaining the sediment-removal insert as part of the existing catch basin filter maintenance activities.

#### 5.2.1.2 Other Distributed BMPs on Public Land

Before stormwater enters the storm drain systems, opportunities are available for the storage, infiltration, and treatment of runoff within publicly owned right-of-ways or parcels. Such areas include road right-of-ways or other properties owned by public agencies for various purposes (e.g., parks, schools, storage, and utilities). Figure 5.2 shows the publicly owned parcels within the Implementation Area. In combination with road right-of-ways, these areas represent a significant opportunity for on-site stormwater treatment.

### 5.2.2 <u>Low Impact Development</u>

The County of Los Angeles adopted a low impact development (LID) ordinance on January 1, 2009, which directly influences the selection and use of structural BMPs. New development and future redevelopment within the City are subject to LID requirements. The requirements are intended to result in runoff quantities and quality that mimic the runoff from undeveloped areas, up to and including runoff from a 50-year design storm event.

Development projects with four or fewer residential units are required to implement two LID BMP alternatives as specified in the County LID Standards Manual. LID BMP alternatives include, but are not limited to the following measures:

- Disconnecting impervious areas
- Installing porous pavement
- Dry wells
- Conforming to landscaping and irrigation requirements
- Installing green roofs

Developments with five or more units or nonresidential developments are required to provide infiltration for excess runoff volume. Runoff from these developments that mimics the natural hydrograph must meet treatment requirements. Redevelopment projects where at least 50 percent of the impervious surfaces are altered must mitigate the entire project area. Redevelopment projects that alter less than 50 percent of the impervious area only need to mitigate the alteration.

Implementation of LID BMPs within the Implementation Area provides an opportunity to reduce the loading of pollutants by reducing concentrations of pollutants in runoff and reducing the volume of runoff.

Both development and redevelopment are largely driven by the strength of the economy. Currently, the rate of development is near a historic low and as a result, estimates for gains from LID and the schedule for those gains are difficult to quantify. As part of the adaptive management implementation, the effects of implementing LID BMPs through development and redevelopment will be tracked though the monitoring and reporting program. Increased levels of development or redevelopment should result in decreases in pollutant loading from the Implementation Area, reducing the need for additional structural controls. Stagnation of development in the Implementation Area may lead to an extended schedule or require additional structural controls to attain TMDL WLA levels.

## 5.3 Assessment of Opportunities for Centralized Structural BMPs

To identify, evaluate, and ultimately select the optimal combination of centralized structural BMPs to address pollutant load reductions for the Implementation Area, key information was required. Investigations were performed to identify and assess potential sites for placing centralized structural BMPs on public land. Priority locations of centralized structural BMPs were publicly owned properties to reduce the need for land acquisition. Additional consideration was made regarding the necessity for implementing centralized structural BMPs on private land. Results of this assessment provided information necessary to support TMDL implementation planning.

## 5.3.1 <u>Site-Screening Methodology</u>

An initial analysis was conducted to identify all publicly owned parcels in the Implementation Area. That initial screening resulted in approximately 24 parcel groups as shown on Figure 5.2. The 24 parcel groups included any publicly owned land with no analysis of the suitability for a centralized BMP. Most of the sites provide adequate space for a centralized BMP. They are not too steep, or are within a feasible distance of a stormwater drainage system.

Additional screening was performed to further narrow potential sites for additional investigation. Additional field investigations were performed for identified locations to assess site and drainage area characteristics and identify the ideal BMP that could be constructed at the site.

Subsequently, GIS analysis was performed of land ownership parcels and site characteristics to identify potential sites for centralized BMP placement on publicly owned parcels. Considerations in the analysis included the following:

- Land cost—Land costs were minimized by identifying publicly owned parcels.
- Percent impervious—Areas with higher percent imperviousness would produce more runoff during typical rain events. Higher impervious areas were targeted for greater potential volume reduction and water quality improvements.
- Space requirements—Sites were evaluated to determine if space is available to implement an appropriately sized BMP.
- Watershed treatment area—The size of the drainage area for each site was
  evaluated on the basis of available storm drain or Digital Elevation Model (DEM) data.
  Sites were identified that provide sufficient space for BMPs to adequately
  treat/store/infiltrate runoff from their respective drainage areas.

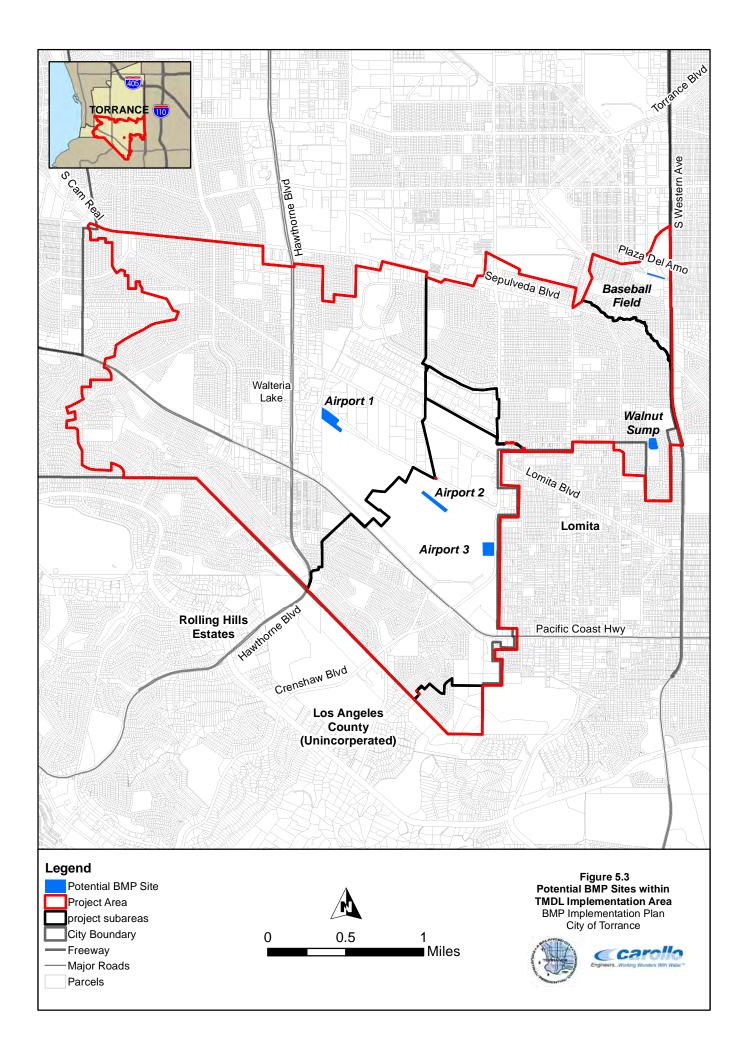

- Soil type—Soil type was evaluated as an initial estimate of the infiltration rate and capacity of the soils. Sites with infiltration rates suitable for infiltration BMPs were further investigated.
- Slope—Slopes of sites were considered on the basis of DEM or other available topography data sets. Sites with moderate slopes (less than 10 percent for GIS purposes) were considered for centralized BMPs. Slope was verified in the field investigation, and sites where the slope is inappropriate for a centralized BMP were eliminated.
- Multi-benefit use—Sites were identified that could serve multiple purposes. For
  instance, some stormwater practices, such as infiltration basins or grassed swales,
  could serve a dual purpose of stormwater management and community park space.
   Several parks could be altered to provided stormwater treatment and storage.

Those criteria were evaluated to identify sites where centralized BMPs would be feasible. Sites that could provide enough space to effectively treat the drainage area associated with the site, that have soils suitable for infiltration, and that are publicly owned (to reduce land acquisition costs) were preferred. Sites that could provide a multi-benefit use, such as parks or parking lots where belowground storage could be used, were considered ideal. From the GIS screening analysis, a list of potential locations for centralized BMPs was developed to address stormwater runoff from the Implementation Area.

This GIS screening and additional field investigations narrowed the sites to the following five sites (which are also depicted on Figure 5.3):

- Airport 1 A1
- Airport 2 A2
- Airport 3 A3
- Walnut Sump
- Baseball Field

Details regarding the proposed structural BMP improvements are presented in subsequent subsections, while general observations and strategies used to develop these BMP concepts are described below.

Because existing site layouts and features can have an effect on where and what type of BMPs can be installed on a site, site layouts and on-site structures were photographed and documented to support evaluation of the site for centralized BMPs. The considerations included the following:

- Effects on surrounding areas—Any nearby structures, including storm drains and utilities, were documented. Any effects that could occur to surrounding structures because of settlement issues were noted.
- Maintenance/accessibility—Every BMP must be maintained at some level for the BMP to continue to function as it was designed. BMPs were considered that maximize access for maintenance purposes.
- Research potential—Research of stormwater BMPs is ongoing and necessary to fill
  existing data gaps and to continue to support the City in developing BMP standards.
  Monitoring protocol would be considered and incorporated into the design of each
  BMP that is implemented.

The individual site characteristics and summary of field investigations and BMP recommendations are described below. The description includes results of field tests to evaluate infiltration rate, water table depth and soil quality; more detailed maps of potential BMP sites; and photographs of the watershed treatment area and available BMP area for each site. Centralized structural BMP options for the sites were narrowed down to specific BMP types and sizes during the process of evaluating nonstructural and structural solutions.

The watershed treatment areas for each of the five identified sites, unless otherwise noted, are residential with concentrated or dispersed density configurations. Residential areas are known to generate high levels of nutrients, such as nitrogen and phosphorus, typically from over fertilization and excess irrigation. Detergents used to wash cars in residential areas can contain high levels of phosphorus. Residential areas are also a source for metals and bacteria. While the largest portion of the watershed treatment areas are residential, there are also institutional and commercial areas in many of the watersheds. Institutional and commercial areas are typically a source of metals, nutrients, and PAHs. Additional pollutant source discussion is included in each site discussion where additional detail is required.

On the basis of observed conditions at all the potential BMP sites, two types of centralized BMPs can be implemented in the open space at the five sites: underground storage/infiltration basins and extended dry detention/infiltration basin. Three of the potential BMP sites, A1, A2, and A3 are located at the Torrance Airport, one at Walnut Sump and the last site is located under the road near Torrance Baseball Field. The sites were also selected to eliminate or minimize the need for pump stations. Each centralized BMP is suitable for treating nutrients, bacteria, toxics, metals, and other pollutants typically delivered with suspended sediment (e.g., organic pesticides, PAHs) in stormwater.

Infiltration basins require high infiltration rates and are not designed to store water for extended periods. Underground storage/infiltration systems are suitable in areas with hydrologic soil group (HSG) C soils and soils in the lower range of HSG B where infiltration is possible but could take longer.

The five sites investigated do not have hard surface areas such as tennis courts, basketball courts, playgrounds, skateboard parks, and parking areas. These identified sites do not require a structural foundation and therefore could be used for belowground storage and treatment. Storm chambers installed below these surfaces would provide additional treatment while still allowing the areas to be used for recreation and parking.

The type and size of the BMP were determined through further optimization analysis and reported in Section 6. The BMPs are planned to infiltrate water within a few days, reducing possible public health risks from stagnant water such as mosquitoes and drowning. An infiltration basin could still be used for recreation and open space activities between storm events and during the dry season. Belowground BMPs could have overlying space available for recreation or parking regardless of the weather.

Each of the investigated centralized BMP sites has ample open space to provide access for maintenance. Observed maintenance at each site includes regular mowing similar to the required maintenance for an aboveground-centralized BMP. To maintain infiltration functionality, sediment would need to be removed when infiltration rates are reduced twenty-five to fifty percent from the design infiltration rate. Infiltration rates can be restored by removing accumulated sediment and disking or aerating the surface. Sediment from belowground BMPs would have to be removed annually or as needed.

Considering current usage, ample space would be available for construction activities at each investigated site. While the focus of each of the potential centralized BMPs is TMDL compliance, implementing such BMPs also aligns with several integrated water resources planning objectives. In addition to the intended BMP objective of water quality improvement, a centralized BMP at each of the proposed site would contribute to flood protection, water conservation, groundwater replenishment, and improved aesthetics.

### 5.3.2 Utility Search

Prior to recommending a BMP site, a utility search was conducted. Known utilities companies contacted for utility information regarding the project area include:

- Sempra Gas utility
- Southern California Edison Electric utility
- Metropolitan Water District of Southern California (MWDSC)

Utility information obtained from the companies was included in the database created for this project. Analysis of the utility information indicates that there appears to no potential conflict with the proposed projects. The utility information is included in Appendix D.

## 5.3.3 <u>Geotechnical Investigation</u>

Accurately identifying the HSG of the existing soils is also an important first design step in computing BMP design treatment volume and appropriate runoff reduction credit. The initial screening of the on-site soils was conducted to identify basic soil characteristics related to stormwater management, such as the HSG and other features relevant to construction activities (e.g., erosion and sediment control). Also, through the initial screening areas where more detailed soil investigation and field determinations may be needed to refine the limits of the different HSGs as defined in the soil survey were identified. The initial screening also included the identification of locations deemed suitable for infiltration BMPs and therefore further detailed geotechnical investigations.

Due to concern regarding infiltration rates at the Torrance Airport, a geotechnical investigation of this site was conducted using three soil borings. Details of this subsurface investigations are summarized in Appendix E. In summary, it can be concluded that the boring logs indicate that the top layer below surface at the Airport consists of a thin layer of silty sand followed by sandy clay, alluvium, and clay deposits. At depths ranging from 25 to 45 feet below surface, a sand layer is present. This layer would be most suitable for infiltration of stormwater. Hence, substantial excavation would be required to install the underground infiltration galleries at this site, which results in higher cost and difficult access for maintenance. More details regarding this BMP site is provided later in this section.

### 5.4 Sub Area Volume and Load Reduction Evaluation

Using the values extracted from other EWMPs and published articles the average removal efficiency for each pollutant was estimated. The results are presented in Table 5.3.

Part VI.C.4.c.i.(1) of the MS4 Permit requires Permittees to develop and implement LID ordinances applicable to new and re-development projects meeting specified thresholds of disturbance. Average annual re-development rates released by the City of Los Angeles (LAR UR2 WMA, 2015) were used to project the area within the Implementation Area that is expected to be developed between the modeled milestone dates. It can be assumed that the new and re-development projects will implement BMPs as required by the MS4 Permit, thus providing a load reduction based on the 85th percentile rainfall. Table 5.4 summarizes the percent of area re-developed at each of the milestone dates.

Using the land use information summarized in Table 2.1 and Table 5.4 the percent of area re-developed and expected volume reduction at each of the milestone dates were estimated.

Areas being re-developed, as a result of the LID ordinances enforced within the Implementation Area, were modeled using volume reduction BMPs sized for the 85th percentile storm depth. Table 5.5 summarizes the volume reduction associated with the redeveloped area within each sub area in the Implementation Area.

Table 5.3 Average Pollutant per Constituent								
	Nor	Non-modeled BMP Removal Efficiency (%)						
Constituent	MCMs	Private Redevelopment and LID Incentives	Catch Basin Filter

## 5.4.1 Walteria Lake Sub Area

The Walteria Lake Sub Area is served by Walteria Lake, which acts as an extended wet detention basin. The lake is located west of Hawthorne Boulevard, between 234<sup>th</sup> Street and 238th Street. It has a surface area of about 26 acres with tributary area of nearly 2,287 acres. The total capacity of Walteria Lake is approximately 1,005 ac-ft, which is about ten times larger than the 85th Percentile 24-hour storm volume.

Stormwater is pumped from the lake through a 54-inch diameter force main. During big storms and/or pumping conditions, there is a high potential for sediment resuspension. This may lead to high pollutant discharge into Machado Lake. To prevent pollutant discharge into Machado Lake and thereby meet WLAs, discharge from Walteria Lake during pumping periods would be diverted at two locations to proposed BMP sites A1 and A2 as shown on Figure 5.4. However, A1 and A2 are designed based on Torrance watershed only. Additional capacity to treat flow volume pumped from Walteria Lake is not part of this report. A1 could be expanded with financial participation from the LACFCD.

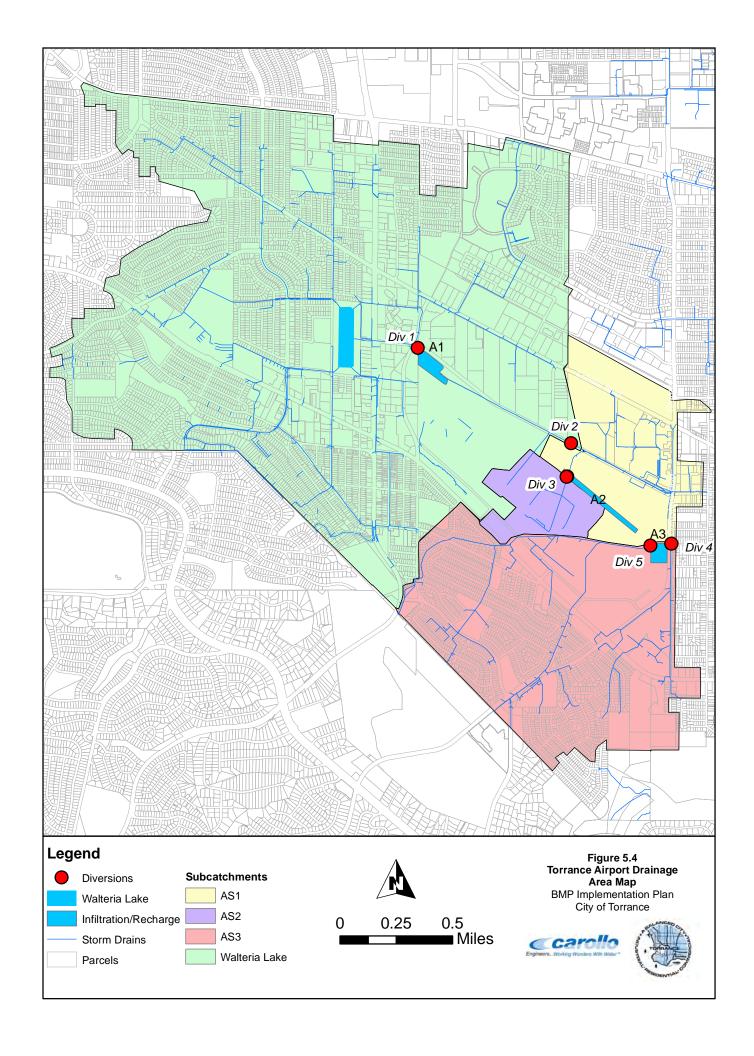

#### 5.4.2 Airport Sub Area

The Airport Sub Area is about 60 percent impervious with a concentrated impervious configuration and moderate road density. There are three proposed BMP sites all located at Torrance Airport (A1, A2, and A3). These are open areas and are well maintained, suggesting the use of fertilizers that have high levels of nutrients and some metals, such as copper, adding another source of nutrients and metals to the stormwater runoff from the area.

For the purposes of BMP implementation, the Airport Sub Area was subdivided into three subcatchments, AS1, AS2 and AS3 as shown on Figure 5.4. The subcatchments were delineated based on drainage characteristics and storm drain layout. Based on site characteristics and storm drain layout, only runoff generated from AS2 and AS3 can cost-effectively be diverted to the three proposed sites. Therefore, only distributed BMPs (catch basin filters) were considered for AS1.

Several scenarios of diverting runoff from AS2 and AS3 to the proposed BMP sites were investigated. The scenarios analyzed can be summarized as follows:

- 1. Divert runoff from AS2 and AS3 individually to the BMP sites:
  - a. divert runoff from AS3 to A3 and
  - b. runoff from AS2 to A2
- 2. Divert combined runoff from AS2 and AS3 to A1-A2. A1-A2 is the combination of sites A1 and A2.
- 3. Divert combined runoff from AS2 and AS3 to A3

Based on the results of the analysis, the scenario where runoff is diverted individually to the BMP sites was eliminated.

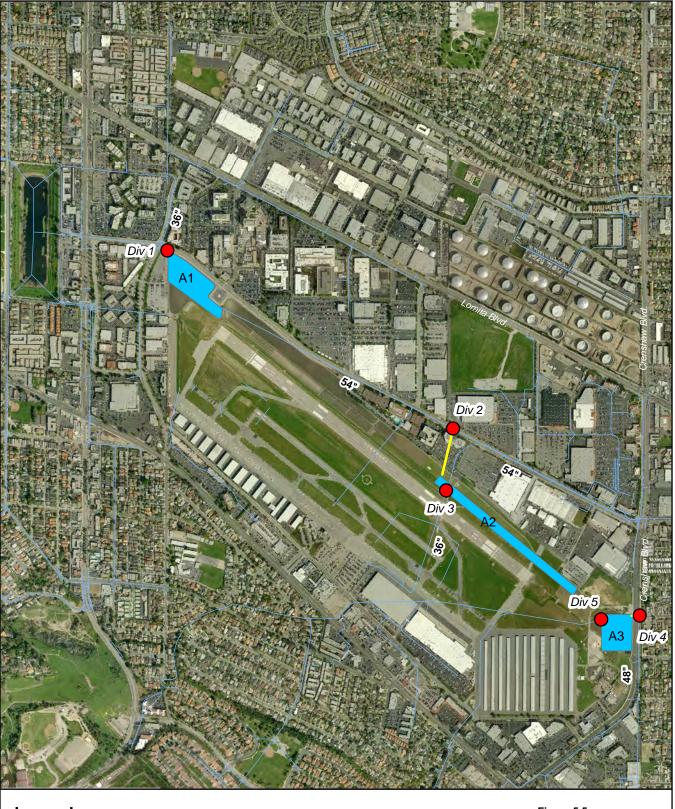

The applicability of BMP sites A1-A2 and A3 to capture and retain the 85th percentile, 24-hour runoff volume from both AS2 and AS3 was investigated. Calculations were performed to determine the approximate BMP size required to capture the 85th-percentile, 24-hour storm volume from the subcatchments. Table 3.12 summarizes the 85th Percentile, 24-hour runoff volume generated from each subcatchment. The total surface area and volume requirements for each proposed BMP site are also summarized in Table 5.6. As shown in the table, the proposed BMP sites A1-A2 and A3 have adequate capacities to implement underground storage/infiltration systems to retain and infiltrate stormwater generated from AS2 and AS3. The total depth of the proposed underground storage/infiltration system will range between 4 and 8 feet.

The proposed BMP sites A1-A2 and A3 were also evaluated to determine if the soils at the sites meet infiltration requirements. Based on geotechnical evaluation, BMP site A3 is the least feasible site to implement underground storage/infiltration due to the presence of a thick clay layer. The clay layer can excavated and replaced with engineered soils. The combined capacity of A1-A2 is approximately 34.4 ac-ft. Thus, A1-A2 has enough capacity to capture and infiltrate the 85th percentile runoff from subcatchments AS2 and AS3. The BMP site A3 also has enough capacity to capture and retain the 85th Percentile, 24-hour storm volume. Subcatmments AS2 and AS3 can therefore be designated as 85th Percentile Basins. All the runoff captured at A1-A2 and A3 will be discharged through infiltration. The Airport Sub Area subcatchments scenarios are depicted on Figure 5.5.

Table 5.6 Summary of BMP Requirements for Airport Sub Area								
Subcatchment Treated	Proposed BMP Site	Drainage Area Treated (ac)	Percent Imperviousness	85th Percentile 24-hr Volume (ac-ft) <sup>(3)</sup>	Proposed BMP Capacity (ac-ft) <sup>(1)</sup>			
AS2 and AS3	A1 <sup>(2)</sup> -A2 <sup>(4)</sup>	726	58	30.8	34.4			
AS2 and AS3	A3 <sup>(5)</sup>	640	59	27.2	32.8			

#### Notes:

- (1) Proposed BMP capacity is based on minimum depth of 4 feet
- (2) Discharge from Walteria Lake Sub Area could be diverted to A1. Surface area of A1 = 5.6 ac
- (3) The 85th percentile 24-hour storm depth = 0.85 in.
- (4) Surface area of A2 = 3 ac
- (5) Surface area of A3 = 8.2 ac
- (6) Drainage area within Torrance. Total tributary area is about 2,290 ac.
- (7) Walteria Lake is an existing BMP

Stormwater Recharge Project
City of Torrance

Tables 5.7 and 5.8 show pollutant loads generated from subcatchments AS1, AS2, and AS3. These three subcatchments represent approximately 46 percent of the Implementation Area excluding Walteria Lake Sub Area and generate about 47 percent of the TSS load from the Implementation Area (excluding Walteria Lake). Therefore, for the City to meet the TMDL requirements, stormwater generated from these subcatchments must be managed using watershed-based strategies that combine structural and institutional or non-structural BMPs.

### **Subcatchment AS1**

AS1 is a treatment subcatchment. That is, runoff volume reduction is minimal. Stormwater generated from AS1 will be treated solely with distributed and institutional BMPs. The distributed and institutional BMPs recommended for implementation in AS1 include:

- Street sweeping toxics and other pollutants released to the urban environment during dry weather conditions are likely to adsorb on street sediments, which provide mechanism for metals to reach downstream waterbodies. Street sweeping removes sediment, debris, and other pollutants from road and parking lots surfaces.
- Catch Basin Filter/Cleanouts continuation of catch basin filter cleaning programs will contribute to removal of sediments prior to entering the storm drains. The pollutant removal mechanisms of catch basin filters are: screening, sedimentation, flotation, and absorption. Debris and large particles are removed by screening; smaller particles and sediment along with associated hydrocarbons, metals, nutrients, toxics and pathogens are removed by settling; and hydrocarbons that are not associated with sediment are removed by absorption.

Through extensive research review this EWMP uses the pollutant removal efficiencies summarized in Table 5.3. Toxics removal is assumed to be directly related to sediment removal efficiency. The assumptions underlying the modeling efforts are discussed in Section 6.

Subcatchment AS1 has a total drainage area of about 249 acres with average imperviousness of about 60 percent. All of the stormwater runoff from AS1 will be treated by a total of 57 catch basin filters. All the 57 catch basins will be retrofitted to allow the installation of full capture filters. Table 5.9 presents the expected outcome after implementation of distributed and institutional BMPs in subcatchment AS1. Some of the catch basin filters considered have reported bacteria removal capabilities as shown in Appendix G. Since catch basin filters generally have moderate bacteria removal efficiency conservative removal efficiency was applied as shown in Table 5.9. The proposed catch basin filters will have design elements targeting bacteria.

The City will evaluate the existing street sweeping program (e.g., method, frequency, and equipment) to determine potential to modify the program to further reduce bacteria on street surfaces. Where opportunities exist, changes will be made to the program. If it is determined that a change in equipment can provide water quality benefits, the City will work to explore funding opportunities to upgrade/replace equipment.

### Subcatchments AS2 and AS3 - 85th Percentile Basins

Both institutional and structural BMPs are recommended for subcatchements AS2 and AS3. Enhanced MCMs including street sweeping and underground storage/infiltration system will be implemented to capture and retain runoff generated from these subcatchments.

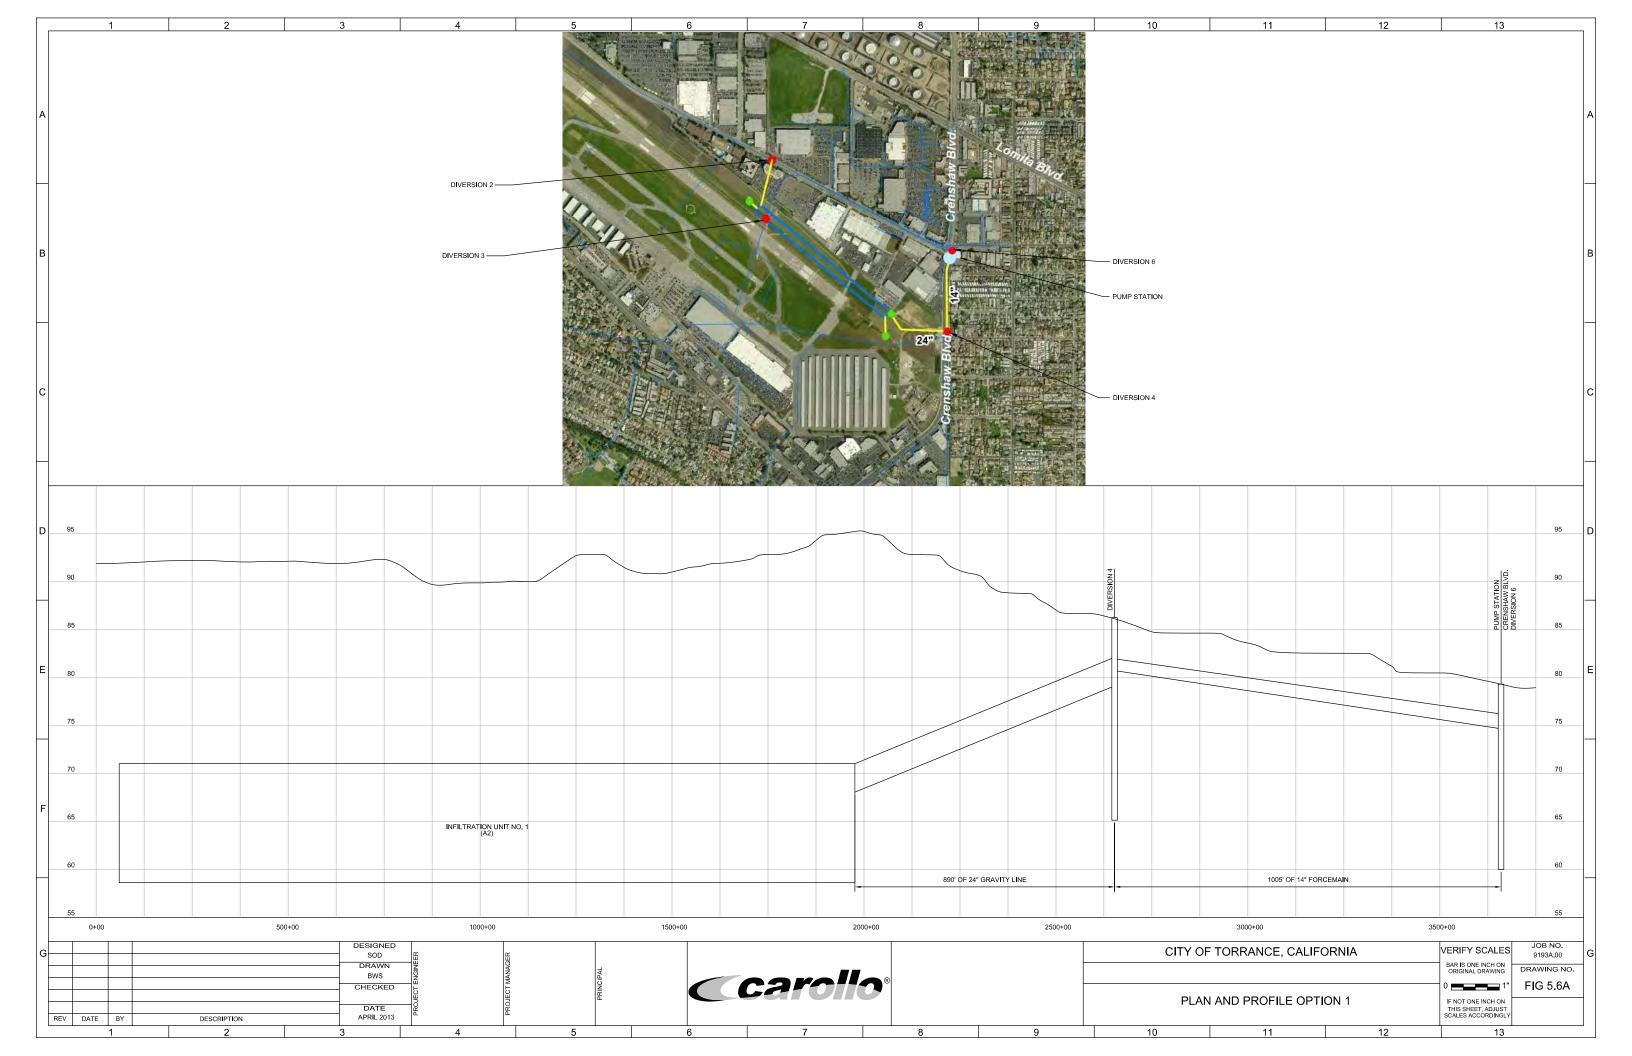

Two options listed below were evaluated regarding the underground storage/infiltration system.

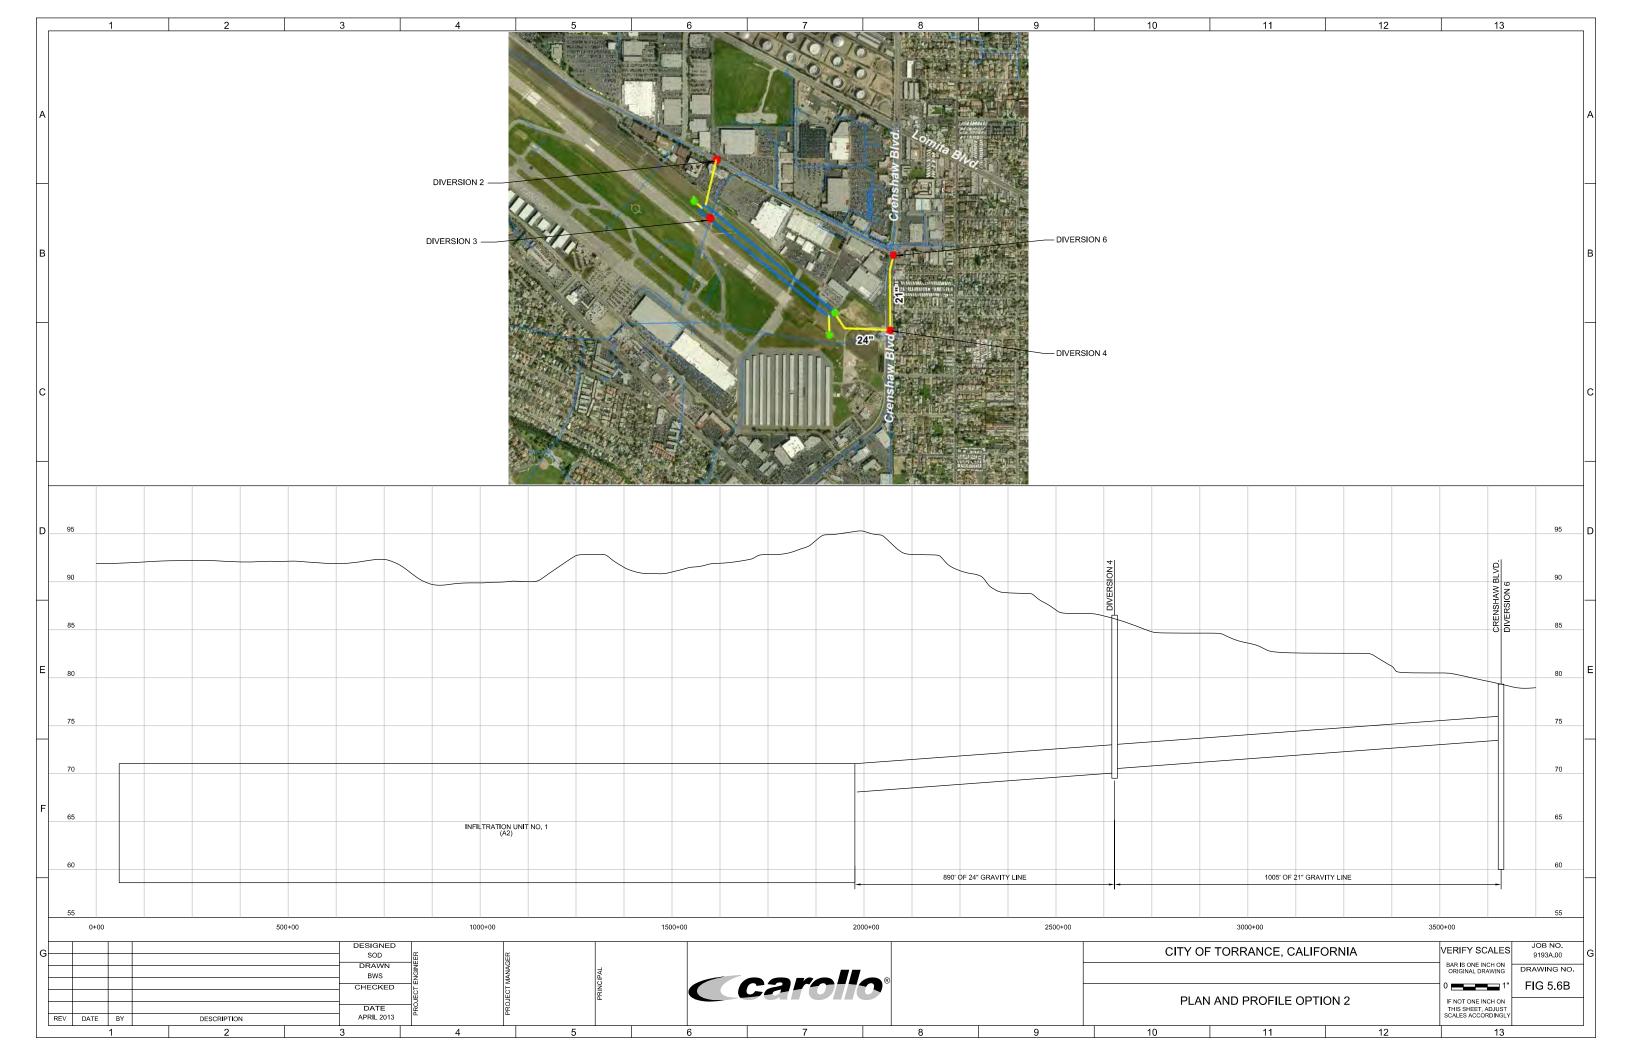

- 1. **Option 1 -** Divert the combined runoff from AS2 and AS3 generated from storms less or equal to the 85th Percentile, 24-hour event to BMP site A1-A2.
- 2. **Option 2 -** Divert the combined runoff from AS2 and AS3 generated from storms less or equal to the 85th Percentile, 24-hour event to BMP site A3.

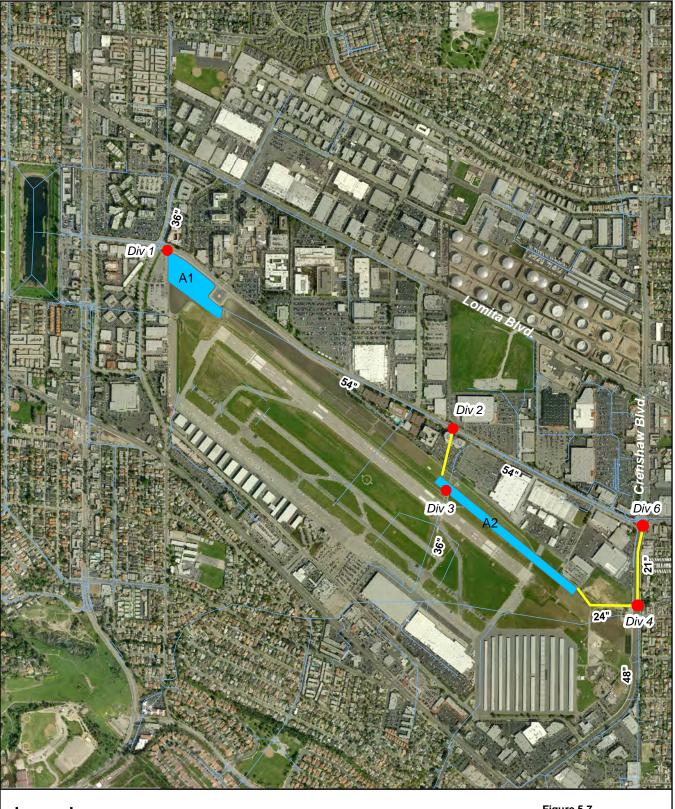

**Option 1**: In this option, the underground storage/infiltration system will be implemented at BMP sites A1 and A2. The combined volume of the proposed BMPs at A1 and A2 is approximately 34.4 ac-ft. The total runoff volume generated from the 85th percentile 24 hour storm is about 30 ac-ft. Thus, the proposed BMP sites have enough capacity to handle this storm event. However, the underground storage/infiltration system will be implemented in two phases. In phase 1, a 4 feet deep underground storage/infiltration system will be implemented at Site A2. The EWMP calls for an integrated, adaptive management approach to utilize available resources effectively and efficiently. If through continued study of drainage patterns, diagnosis of problem sources, and new technologies for dry and wet weather treatment, it is realized that more treatment is needed in the Airport treatment area, BMP site A1 will be considered for implementation of additional storage/infiltration system in Phase 2. Thus, the implementation of underground storage/infiltration system in Phase 2 will depend on the effectiveness of the Phase 1 BMP.

In Phase 1, runoff generated from subcatchments AS2 and AS3 will be diverted to Site A2 (12 acre-ft). Under this phase, two scenarios have been identified and illustrated on Figures 5.6 and 5.7. In scenario 1, stormwater runoff will be diverted from Crenshaw Blvd and Amsler Street, and pump through a 14-inch diameter forcemain to another diversion system at Crenshaw Blvd and 250<sup>th</sup> Street. From here, the stormwater will flow by gravity to the infiltration system at Site A2. To improve infiltration in this area, the infiltration system will be located at a depth not less than 40 feet from the ground surface.

In scenario 2, stormwater diverted from storm drains at Crenshaw Blvd and Amsler Street, and Crenshaw and 250<sup>th</sup> Street will flow by gravity into the infiltration system at Site A2. Stormwater from Crenshaw Blvd. and Amsler Street will be conveyed through a 21-inch pipe to Crenshaw and 250<sup>th</sup> Street. From here, the stormwater will be conveyed through a 24-inch pipe to the infiltration system for treatment.

New Conveyance - Gravity Lines

Inflitration/Recharge

Storm Drains

2,000 Feet Figure 5.7
Recommended BMP
at Torrance Airport
Stormwater Recharge Project
City of Torrance

**Option 2**: This is the preferred option. In this option, stormwater diverted from storm drains at Crenshaw Blvd and Amsler Street, and Crenshaw and 250<sup>th</sup> Street will flow by gravity into the infiltration system at Site A3. Stormwater from Crenshaw Blvd. and Amsler Street will be conveyed through a 21-inch pipe to Crenshaw and 250<sup>th</sup> Street. From here, the stormwater will be conveyed through a 24-inch pipe to the infiltration system at Site A3.

Table 5.10 presents the expected outcome after implementation of institutional and structural BMPs to capture and retain stormwater runoff from subcatchments AS2 and AS3. The results are summarized for only Option 2, which is the recommended option. The load reductions in the table are based on both volume reduction and treatment by the MCMs. Table 5.10A summarizes the results for TSS, TP, TN, and toxics and Table 5.10B presents the results summary for metals and bacteria. As explained earlier TSS was used as a surrogate pollutant for toxics. The calculation for toxics load is based on the equation presented in Section 3.3.2.2.

#### Notes:

- (1) Based on 02/18/2005 simulation
- (2) Based on 04/12/2010 simulation
- (3) Based on 02/21/2011 simulation
- (4) Concentrations shown in Table 3.10

The storage requirements summarized in Table 5.6 were incorporated into the water quality model to simulate the effectiveness of the BMPs. All assumptions used in the pre-BMP model scenario were retained. The simulations do not include non-structural BMPs such as street sweeping and catch basin filter. The nonstructural BMPs were evaluated separately.

### 5.4.2.2 Recommended BMP Implementation in Airport Sub Area

The Airport Sub Area subcatchments, AS1, AS2, and AS3 represent approximately 46 percent of the Implementation Area excluding Walteria Lake Sub Area. They generate about 47 percent of TSS load from the Implementation Area (excluding Walteria Lake Sub Area). The City has to implement BMPs to treat stormwater generated in this area in order to comply with the established TMDLs in the Machado Lake Watershed.

In addition to street sweeping, catch basin filters and other institutional BMPs discussed earlier, proposed site A3 is recommended for implementation of underground storage/infiltration system. The site was selected based on space availability, soil conditions, and cost effectiveness.

An eight feet deep underground storage/infiltration system will be installed at Site A3 to receive stormwater runoff through 21- and 24-inch diameter gravity pipes. Stormwater diverted from storm drains at Crenshaw Blvd and Amsler Street, and Crenshaw and 250<sup>th</sup> Street will flow by gravity into the infiltration system at Site A3. Stormwater from Crenshaw Blvd. and Amsler Street will be conveyed through a 21-inch to Crenshaw and 250<sup>th</sup> Street. From here, the stormwater will be conveyed through a 24-inch pipe to the infiltration system for treatment at A3.

The recommended BMP implementation in the Airport Sub Area can be summarized as follows:

- 1. Practice enhanced MCMs in subcatcments AS1, AS2 and AS3 as written in the LA County MS4 Permit.
- 2. Install 57 catch basin filters in subcatchment AS1. The proposed catch basin filters will capture runoff from the entire subcatchment AS1.
- 3. Divert up to the 85th Percentile, 24-hour stormwater runoff from AS2 and AS3 to the proposed BMP Site A3.

In addition to contributing to meeting the TMDL reduction requirement of improving water quality, a centralized BMP at the Torrance Airport would provide other water resources benefits. A centralized BMP at Torrance Airport would be designed to increase infiltration providing additional groundwater replenishment to the groundwater basin. Storage provided by the BMP would reduce potential flooding in the watershed treatment area. Further benefits could be determined during implementation.

### 5.4.2.2.1 Potential Partnership with Peninsula Cities

There is an opportunity for the Peninsula Cities to "financially partner" with the City of Torrance on the proposed Airport Project at BMP site A3. The cities include Rolling Hills Estate, Rancho Palos Verdes, Palos Verdes Estates, and Los Angeles County unincorporated. Table 5.11 shows the drainage areas tributary to the proposed BMP at Site A3.

As a result of the potential partnership, the capacity of the BMP at Site A3 will increase by about 100 percent and the total construction cost is estimated to increase from about \$7,000,000 to about \$14,000,000.

#### 5.4.3 Airport Southeast Sub Area

The Airport Southeast Sub Area is designated an 85th Percentile Basin and is located in the Project No. 77/510 subbasin as shown on Figure 1.2. Tables 5.12 and 5.13 summarize the Airport Southeast Sub Area baseline loadings. Since runoff generated from storm events less or equal to the 85th Percentile, 24-hour storm event will be diverted to the stormwater facility being installed by a developer, no improvements is proposed in this

EWMP for this sub area. The new stormwater facility will capture and retain the 85th Percentile, 24-hour runoff volume.

## 5.4.4 Walnut Sump Sub Area

The watershed treatment area that will be treated by the Walnut Sump is about 62 percent impervious with a concentrated impervious configuration and moderate road density. For BMP implementation purposes, this sub area was subdivided into three subcatchments, WS-1, WS-2 and WS-3 as shown on Figure 5.8.

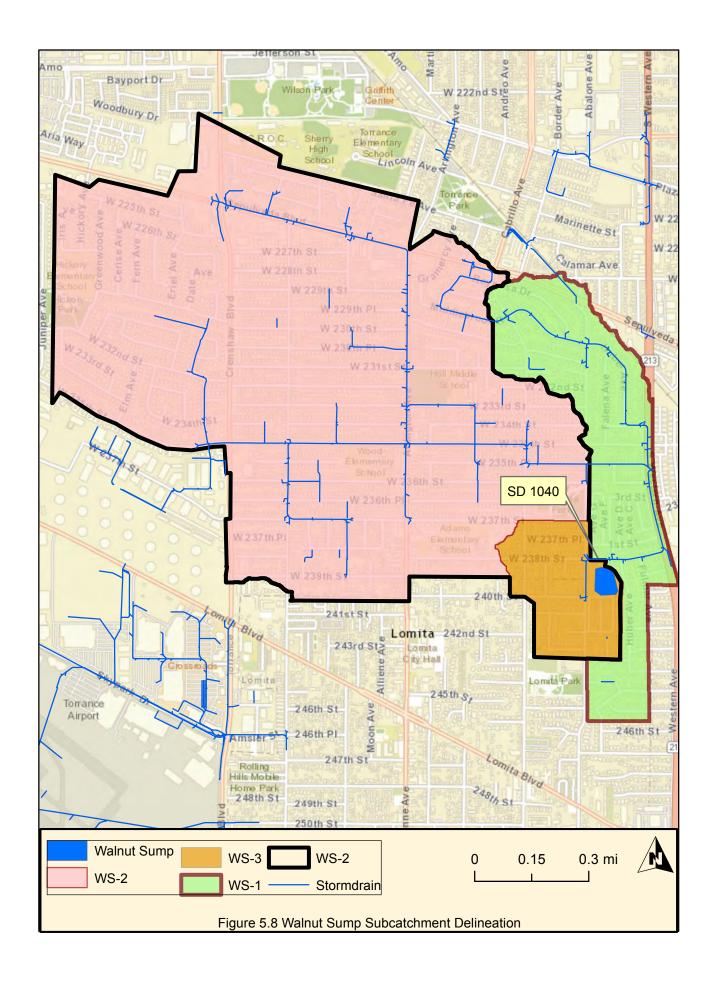

Table 5.14 and 5.15 show pollutant load generated from subcatchments WS-1, WS-2, and WS-3. These three subcatchments represent approximately 43 percent of the Implementation Area excluding Walteria Lake Sub Area and generate about 59 percent of the TP load from the Implementation Area (excluding Walteria Lake). Therefore, for the City to meet the TMDL requirements, stormwater generated from these subcatchments must be managed using watershed-based strategies that combine structural and institutional or non-structural BMPs.

- (2) Based on 04/12/2010 simulation
- (3) Based on 02/21/2011 simulation
- (4) Concentrations shown in Table 3.10

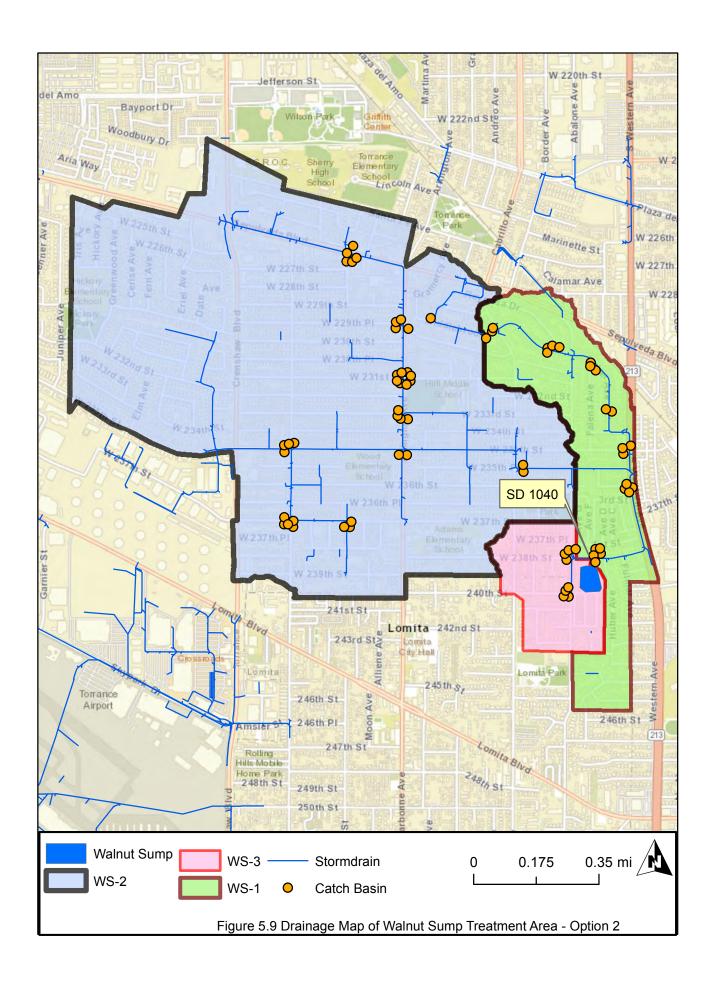

Two treatment options have been identified for this sub area. Both options include street sweeping. Option No. 1 will use the existing Walnut Sump to treat and infiltrate at least the 85th percentile storm runoff generated from subcatchments WS-2 and WS-3. If more treatment is needed in this sub area in order to achieve TMDL compliance Option No. 1 will be expanded to include 50 catch basin filter in WS-1. The catch basins will be retrofitted to allow the installation of full capture filter to capture fine sediments and other pollutants. Walnut Sump, which will receive stormwater from this sub area has adequate capacity to store and infiltrate the 85th percentile 24 hour runoff as shown in Table 5.16.

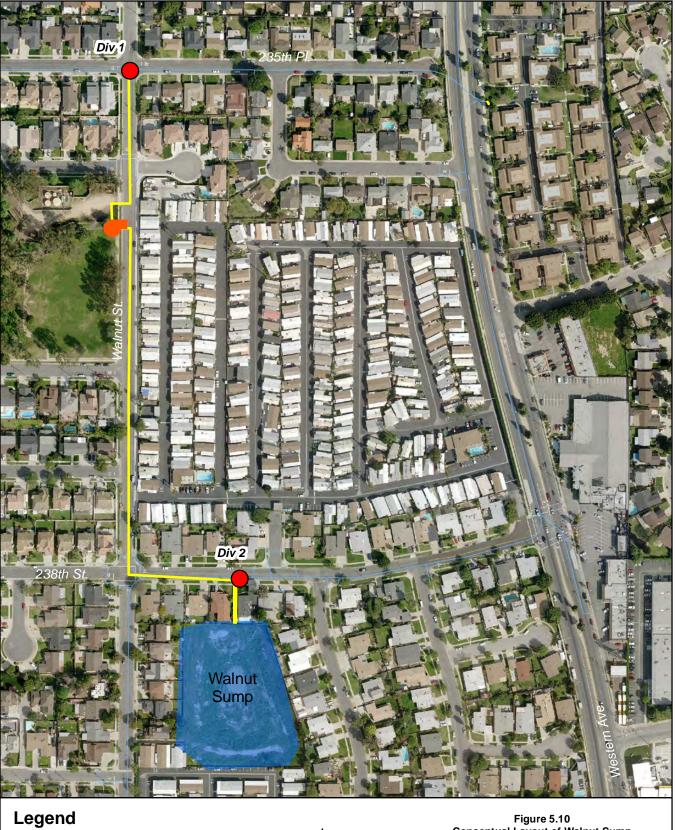

Table 5.16	6 Summary of BMP Requirements – Walnut Sump							
Option	Drainage Area Treated (ac)	Percent Imperviousness	85th Percentile 24-hr Volume (ac-ft) <sup>(1)</sup>	Walnut Sump Capacity (ac-ft)	No. of Catch Basin Filter			
Option No. 1	742	61	39.1	50	50			
Option No. 2	922	62	-	-	150			
Note: (1) The 85th pe	_'							

In Option No. 1, stormwater runoff from WS-3 will be diverted to Walnut Sump in Phase I. In Phase II, stormwater from WS-2 will be diverted from the existing 9.2' x 11' RCB" storm drainpipe at 235<sup>th</sup> St. and Walnut St. through a new 60-inch diameter gravity pipe to a stormwater lift station to be located at 236<sup>th</sup> Street and Walnut Street. From the lift station, stormwater will be pumped through an 18-inch forcemain to Walnut Sump pre-treatment area for further removal of heavy sediments, oil, grease, and floatable wastes. Hydrodynamic Separator unit will be used for the pre-treatment. The pretreated stormwater runoff will then be conveyed to the Walnut Sump main storage area for storage and infiltration. If needed, 50 catch basin filters will be installed in WS-1 in Phase III. Option No. 1 is the preferred option.

Option No. 2 consists of installing catch basin filters in WS-1, WS-2, and WS-3 to capture fine sediments and other pollutants as shown on Figure 5.9. Under this option, stormwater from WS-1, WS-2 and WS-3 will be treated by a total of 150 catch basin filters. The catch basins will be retrofitted to allow the installation of full capture screens.

Figure 5.9 shows the conceptual layout of Option No. 1 and Figure 5.10 shows detail design concept of Option No. 1. Figure 5.11 shows the details of the proposed Walnut Sump storage/infiltration system.

The storage requirements summarized in Table 5.16 were incorporated into the water quality model to simulate the effectiveness of the BMPs. All assumptions used in the pre-BMP model scenario were retained. The simulations do not include non-structural BMPs such as street sweeping and catch basin filter. Table 5.17 presents the expected outcome after implementation of institutional and structural BMPs to treat stormwater runoff from subcatchments WS-1, WS-2, and WS-3. The results are summarized for only Option No. 1, which is the recommended option. The load reductions in the table are based on both volume reduction and treatment by the MCMs. Table 5.17A summarizes the results for TSS, TP, TN, and toxics and Table 5.17B presents the results for metals and bacteria.

# 5.4.4.1 Recommended BMP Implementation at Walnut Sump

The overall objective of the Implementation Plan is compliance with the Machado Lake nutrients and toxics TMDLs. The primary objective for this project location, therefore, is to remove toxics and nutrients from the existing storm drains. These objectives may in general be met by implementing BMPs or a combination thereof. Option No. 1 which is discussed above is recommended for this sub area. In addition to street sweeping and other non-structural BMPs, the structural BMP (Option No. 1) proposed for the Walnut Sump drainage area includes the following elements:

Stormwater lift station

(1) Concentrations listed in Table 3.10

Note:

- 60-inch gravity main
- 18-inch force main
- Flow diversion facility

- Hydrodynamic separator
- Above ground storage/infiltration area – Walnut Sump
- Overflow piping

The recommended plan (Option No. 1) for this sub area will be implanted in three phases as outlined below:

- Phase 1 Flow diversion from WS-3 and upgrades to Walnut Sump
- 2. Phase 2 Flow diversion from WS-2 to Walnut Sump, new piping and pump station
- Installation of 50 catch basin filters in WS-1

In addition to contributing to meeting the TMDL reduction requirement of improving water quality, a centralized BMP at Walnut Sump would provide other water resources benefits. A centralized BMP at this location would be designed to increase infiltration providing additional groundwater replenishment to the groundwater basin. Storage provided by the BMP would reduce potential flooding in the watershed treatment area. Further benefits could be determined during implementation. For example, the actual BMP design could include additional vegetation that would enhance habitat area in the area and Public Education.

The implementation will be carried out in phases as listed below: Phase I – Divert flow from storm drain SD 1040 shown on Figure 5.8.

- 1. Phase II Install catch basin filters in WS-1
- 2. Phase III Diversion and pump station for WS-2

In addition to contributing to meeting the TMDL reduction requirement of improving water quality, a centralized BMP at walnut Sump would provide other water resources benefits. A centralized BMP at this location would be designed to increase infiltration providing additional groundwater replenishment to the groundwater basin. Storage provided by the BMP would reduce potential flooding in the watershed treatment area. Further benefits could be determined during implementation. For example, the actual BMP design could include additional vegetation that would enhance habitat area in the area and Public Education.

### 5.4.5 Baseball Field Sub Area

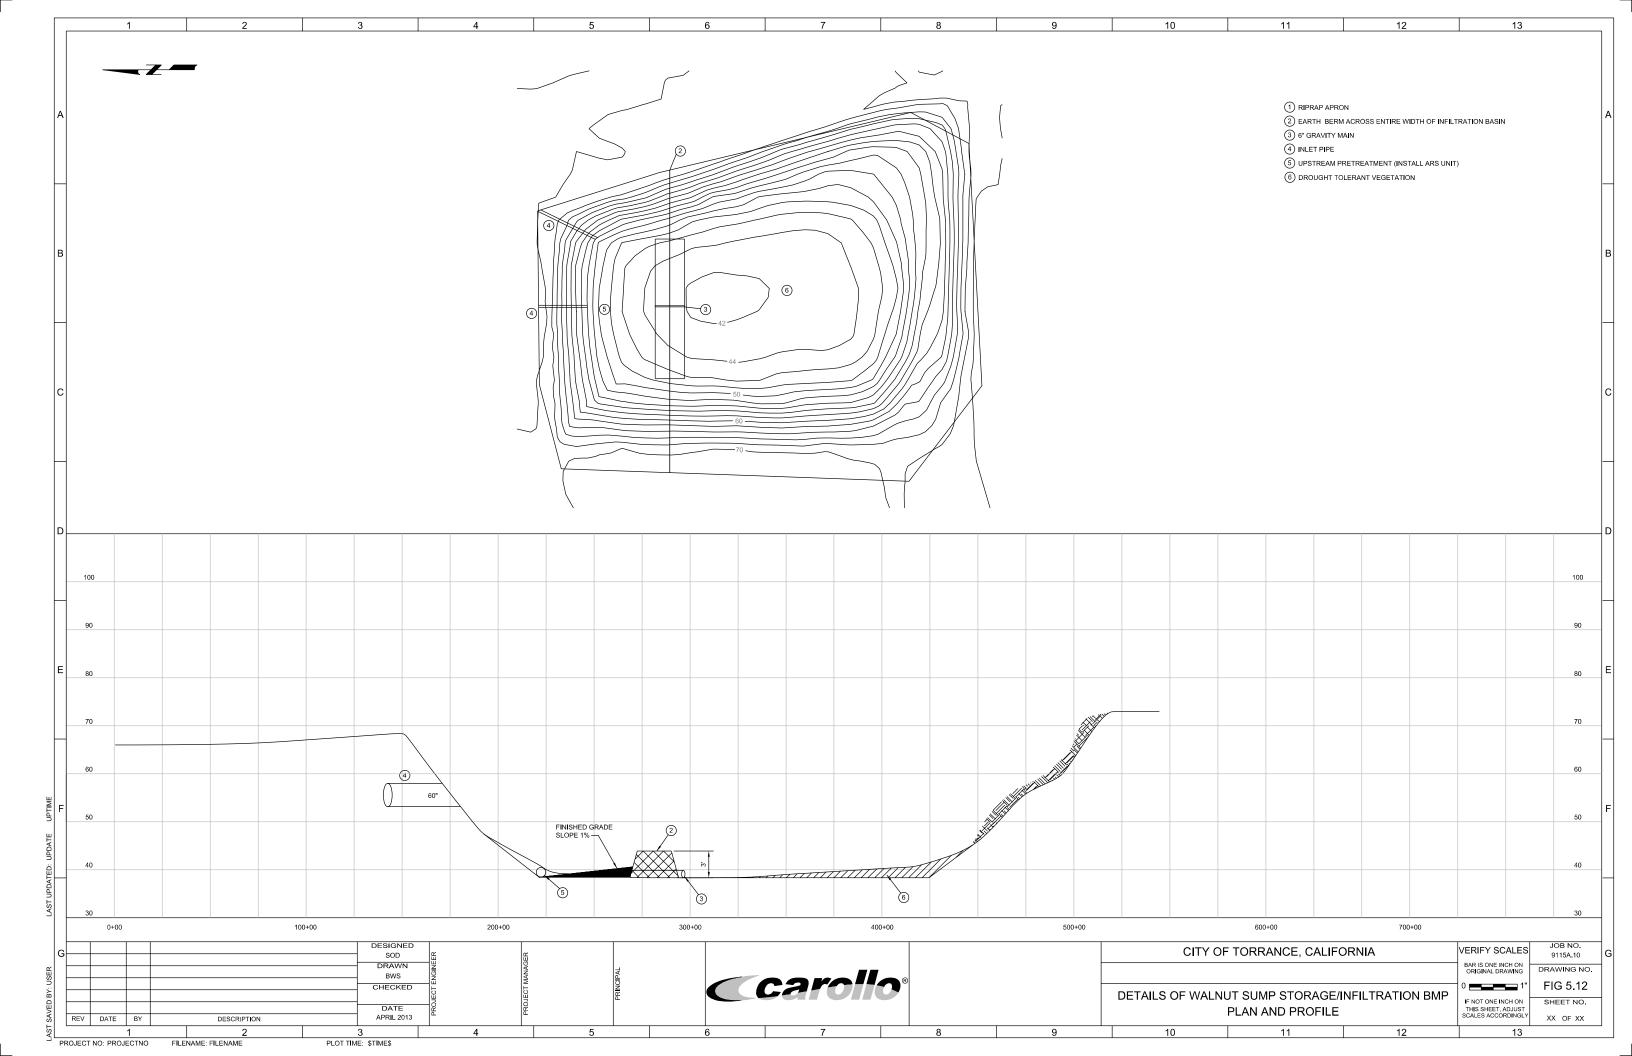

The watershed treatment area that will be treated by the Baseball Field underground storage/infiltration system is about 60 percent impervious with a concentrated impervious configuration and moderate road density. This treatment area has adequate surface area, about 0.73 acres to treat the 85th percentile 24-hour storm water quality volume generated from this sub area. For BMP implementation purposes, this sub area was subdivided into four subcatchments; BB-S1, BB-S2, BB-S3 and BB-S4. Table 5.18 and 5.19 show pollutant load generated from subcatchments BB-S1, BB-S2, BB-S3 and BB-S4.

Table 5.18 Baseball Field Sub Area Nutrient and Toxics Baseline Load Summary - 10/01/2009 - 09/30/2010								
			Pollutant	Load (kg/yr)				
Subcatchment	Volume (ac-ft)	TSS		TP	TN			
BB-S1	15.92	3,557.46		17.32	128.19			
BB-S2	59.38	13,265.46		64.60	478.02			
BB-S3	31.87	7,118.59	,	34.66	256.52			
BB-S4	19.91	4,446.83		21.65	160.24			
			Pollutant	: Load (g/yr)

BB-S4	0.89	0.02	0.28	0.01	1.60	1.29E+13			
Notes: (1) Based on 02/18			0.20	0.01	1.00	1.232110			

- (2) Based on 04/12/2010 simulation
- (3) Based on 02/21/2011 simulation
- (4) Concentrations shown in Table 3.10

Two treatment options have been identified for this sub area. Option No. 1 will treat about 25 percent of the stormwater generated from the Baseball Field Sub Area (155 ac). Thus, under this option, only stormwater runoff from subcatchment BB-S3 shown on Figure 5.12 will be treated. Stormwater generated from the remaining subcatchments BB-S1, BB-S2, and BB-S4 will be captured by 19 catch basin filters. The catch basins will be retrofitted to allow full capture filters. These catch basin filters are of the same type as the ones proposed for the Airport and Walnut Sump sub areas and will cover the entire subcatchments.

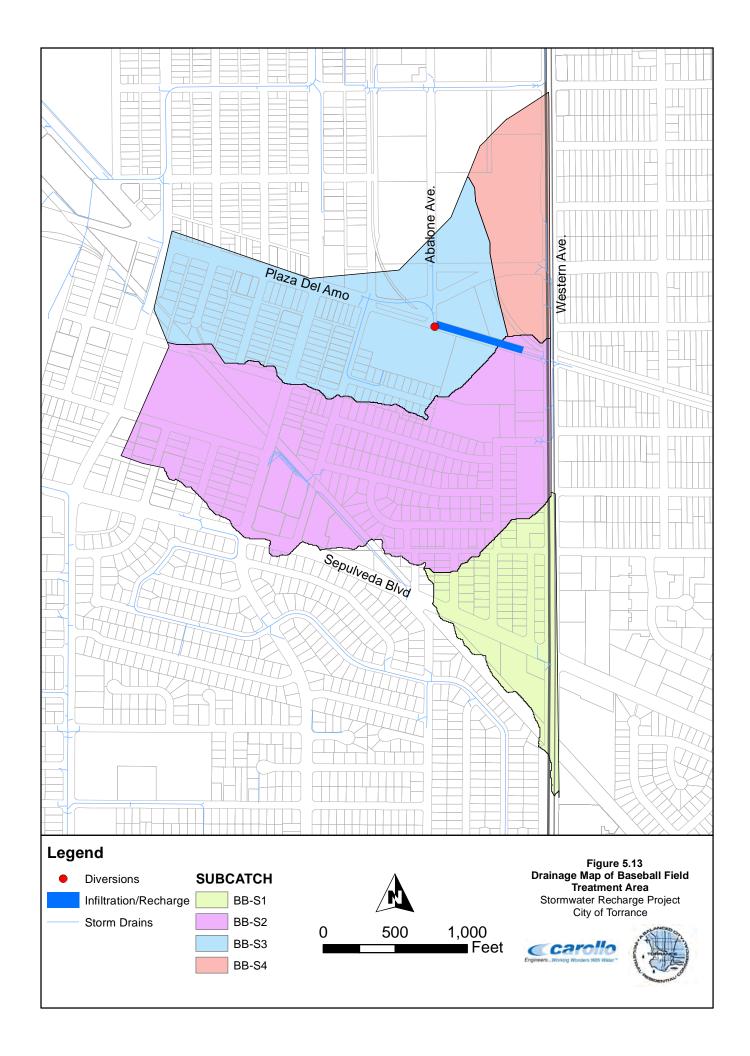

Option No. 2 will treat the 85th percentile 24-hour storm water volume generated from the entire Baseball Field Sub Area, BB-S1, BB-S2, BB-S3, and BB-S4. Figure 5.12 shows the drainage map of this treatment area and Figure 5.13 is the conceptual layout of this treatment system.

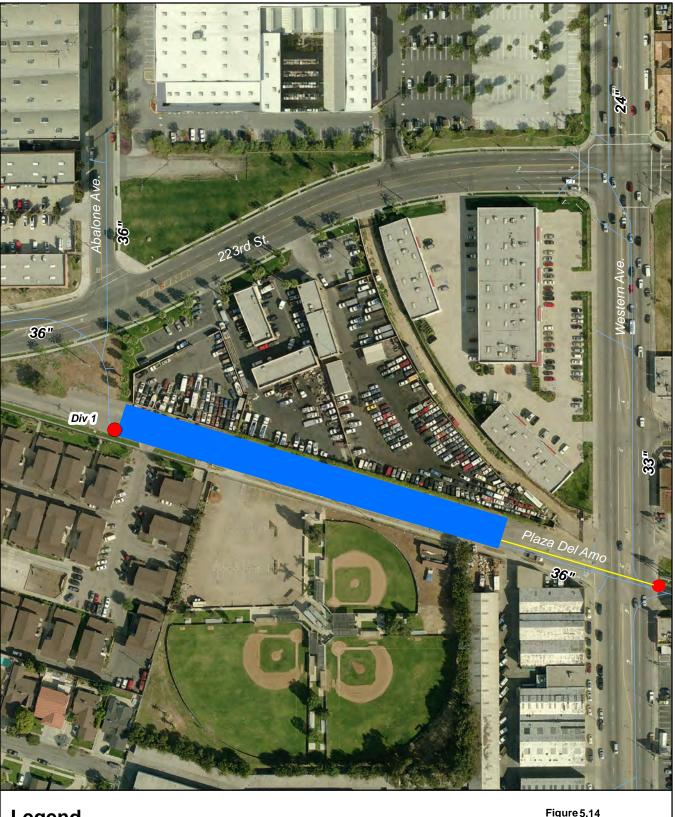

In Option No. 1 (recommended option), stormwater will be diverted from the existing 36-inch diameter pipe at Plaza Del Amo and Western Avenue through a short diversion pipe into the BMP system. Option No. 2 will be considered for implementation when through monitoring and modeling it is found out that more treatment is needed in this subarea. Option No. 2 will capture stormwater runoff generated from BB-S1, BB-S2, BB-S3, and BB-S4. Stormwater runoff will be diverted from existing drain at Plaza Del Amo and Western Ave. to the infiltration unit located at the baseball field. This option also includes the installation of 23 full capture filter screens. Figure 5.13 shows conceptual layout and detail design concept of both options.

Table 5.20 summarizes the storage requirements for this treatment basin and Figure 5.14 presents the expected outcome after implementation of institutional and structural BMPs to treat stormwater runoff from the Baseball Field Sub Area. The results are summarized for only Option 1, which is the recommended option in Table 5.21. The load reductions in the table are based on both volume reduction and treatment by the MCMs. Table 5.21A summarizes the results for TSS, TP, TN, and toxics and Table 5.21B presents the results for metals and bacteria.

Figure 5.14 shows the plan and profile of the two options discussed above and Figure 5.15 is the detailed design concept.

<b>Table 5.20</b>	Summary of BMP Requirements – Baseball Field								
Option	Area Treated (ac)	Percent Imperviousness	Treatability	24 hr 85th Percentile Volume (ac-ft)	BMP Capacity (ac-ft)

Note:							
(1) Concentrations listed in Ta	ble 3.10						

In addition to contributing to meeting the TMDL reduction requirement of improving water quality, a centralized BMP at Baseball Field would provide other water resources benefits. A centralized BMP at this location would be designed to increase infiltration providing additional groundwater replenishment to the groundwater basin. Storage provided by the BMP would reduce potential flooding in the watershed treatment area. Further benefits could be determined during implementation. This BMP could be constructed without interfering with baseball field.

# 5.5 Additional Structural Options for TMDL Implementation

Through additional monitoring, pollutant source characterizations, and site investigations throughout the duration of the TMDL implementation schedule, additional options for structural BMPs could be identified that can enhance or replace those BMPs identified in this plan. This is especially true for dry weather, when flows are highly variable throughout the storm drain system, and specific areas could require special methods treating storm drain flows before they discharge to receiving waters. For storm drains with particularly high dry weather flows and associated pollutant loads where other nonstructural or structural BMPs are not providing a remedy, specific mechanical BMPs can be implemented. Such BMPs could include diversions to wastewater treatment plants or on-site treatment facilities that provide ultraviolet disinfection or other forms of treatment.

Likewise, for wet weather, certain mechanical BMPs can be installed in problem storm drains where other nonstructural and structural BMPs are not providing a solution. Several stormwater BMPs are available for this purpose, which are based on a range of technologies that continue to evolve through continued research and development. This TMDL Implementation Plan is intended to be iterative and adaptive to allow for modifications as additional studies of the drainage system and diagnoses of problem sources are achieved and as new technologies for dry and wet weather treatment continue to emerge.

# 5.6 Regulatory Requirements and Environmental Permits

Consultation with regulatory agencies and the acquisition of permits is required before project components can be constructed. The following sections summarize regulatory permits and approvals relevant to the implementation of the Water Quality Enhancement Projects in the Machado Lake watershed.

#### 5.6.1 Environmental Assessment

In accordance with the California Environmental Quality Act (CEQA), local agencies are required to identify the significant environmental impacts of their actions and to avoid or mitigate those impacts, if feasible. Every development project that requires discretionary governmental approval will require at least some environmental review pursuant to CEQA, unless an exemption applies. The Water Quality Enhancement Projects discussed in the previous section will likely require the preparation of a Negative Declaration.

### 5.6.2 U.S. Army Corps of Engineers

Section 404 of the Federal Clean Water Act regulates the discharge of dredged, excavated, or fill material in wetlands, streams, rivers, and other waters of the United States. The U.S. Army Corps of Engineers (USACE) is the federal agency authorized to enforce Section 404 and issue permits for certain authorized activities conducted in these waters. Based on the proposed area for the projects, it is unlikely that a Section 404 permit will be required. If

required and jurisdictional, Section 404 permitting could potentially be completed under the nationwide permit program. Coverage under the nationwide program can be authorized within three to four months from the time the permit application is deemed complete.

#### 5.6.3 U.S. Fish and Wildlife Service

The U.S. Fish and Wildlife Service (USFWS), Department of the Interior, is responsible for administering the Federal Endangered Species Act, which prohibits activities affecting threatened and endangered species unless authorized by a permit from the USFWS. The Endangered Species Program is charged with issuing permits for activities that could potentially affect native endangered or threatened species, including Incidental Take Permits associated with Habitat Conservation plans. The USACE will consult with USFWS regarding endangered species issues as part of the Section 404 process. A biological resources report for the project site may be required as part of the permit application package to the USACE.

## 5.6.4 California Department of Fish and Game

The regulatory functions of the California Department of Fish and Wildlife (CDFW) include the review of CEQA documents as a responsible agency. In addition, CDFW issues streambed or lakebed alteration agreements for projects with impacts to waters of the State, issues permits for take of threatened and endangered species for authorized activities, approves and permits the take of birds, mammals, reptiles, amphibians, nongame fish, and plants for scientific or educational purposes, and the take of threatened, endangered, or candidate species for management purposes. The Water Quality Enhancement Projects may require a CDFW Code Section 1602 Streambed Alteration Agreement.

#### 5.6.5 State Water Resources Control Board

Construction activities disturbing one or more acres must obtain coverage under the National Pollutant Discharge Elimination System (NPDES) General Permit for Discharges of Stormwater Associated with Construction Activity Water Quality Order No. 2009-0009-DWQ (Construction General Permit, or CGP). Construction activity subject to this permit includes clearing, grading, and disturbances to the ground such as stockpiling or excavation. To obtain coverage under the CGP, the City will designate a Legally Responsible Person to electronically file Permit Registration Documents (PRDs) with the State Water Resources Control Board (SWRCB). PRDs include a Notice of Intent, Risk Assessment, Site Map, Stormwater Pollution Prevention Plan (SWPPP), annual fee, and certification. A project-specific SWPPP will need to be developed and implemented to reduce polluted discharges from entering the storm drain system and local receiving waters during construction activities. The CGP requires all permitted dischargers to develop and implement a SWPPP that:

- Identifies all pollutant sources including sources of sediment that may affect the quality of stormwater discharges associated with construction activity from the construction site.
- Identifies and eliminates non-stormwater discharges.
- Specifies BMPs to reduce or eliminate pollutants in stormwater and authorized nonstormwater discharges from the site during construction.
- Incorporates BMP inspection and maintenance routines.
- Identifies a sampling and analysis strategy and sampling schedule for discharges that have been discovered through visual monitoring to be potentially contaminated by pollutants not visually detectable in runoff.

The City or construction contractor will need a Qualified SWPPP Developer to prepare the SWPPP, and then a Qualified SWPPP Practitioner will need to implement the plan during construction. The SWPPP must address the use of appropriately selected, correctly installed, and properly maintained pollution control BMPs.

# 5.6.6 Regional Water Quality Control Board, Los Angeles Region

Under Section 401 of the Clean Water Act, applicants for Section 404 Permits must first obtain a Water Quality Certification documenting that the proposed activity will comply with state water quality standards. If the project is determined to be under USACE jurisdiction, a Section 401 Water Quality Certification will be required for the project.

If the project is not under USACE jurisdiction, the LARWQCB may require coverage under Waste Discharge Requirements instead. Protection of beneficial uses during construction and operation are key issues. Construction dewatering may be necessary because of high groundwater. Dewatering activities will require coverage under the General NPDES Permit and Waste Discharge Requirements of Discharges from Construction and Project Dewatering to Surface Waters in Coastal Watersheds of Los Angeles and Ventura Counties. To obtain permit coverage, a Report of Waste Discharge and application must be filed with LARWCQB at least 30 days prior to discharge.

Even though the installation of Water Quality Enhancement Projects is generally encouraged by the LARWQCB, concerns may be raised with the potential of projects using on-site infiltration of stormwater to affect the water quality of the underlying groundwater. Prior to implementing projects such as infiltration basins/trenches, flow through planters, porous pavement, etc., the City would need to conduct a technical analysis evaluating the possibility of groundwater impacts. The analysis will determine the depth to groundwater, its designated beneficial uses, and the historical uses of the site. There are cases where projects may be infeasible – if the depth to groundwater is less than 5 feet from the surface, if drinking water wells are present within 100 feet of the proposed infiltration site, or if the

site is a brown field with potential pollutant mobilization through the soil, etc. Consultation with LARWQCB staff is recommended.

### 5.6.7 South Coast Air Quality Management District

Construction activities in the South Coast Air Basin are subject to South Coast Air Quality Management District's (SCAQMD) Rule 403. Rule 403 sets requirements to reasonably regulate operations that periodically may cause fugitive dust emissions into the atmosphere by requiring actions to prevent, reduce, or mitigate fugitive dust emissions. The construction contractor will need to implement dust control measures during project construction.

As shown in the previous sections, a number of nonstructural and structural BMP options were identified that can support TMDL implementation. An evaluation of those practices was performed, including optimizing the most cost-effective combination of BMPs to support meeting WLAs for the TMDL Implementation Area. The evaluation analysis for the Nutrient and Toxics TMDLs uses an integrated approach, considering reductions for both classes of pollutants. The evaluation analysis uses the identified suite of structural and nonstructural projects discussed in Sections 4 and 5 to determine the set of actions that will most likely be implemented in an effort to achieve the TMDL requirements. The analysis is a demonstration of how the identified projects may achieve compliance. As the implementation is an adaptive management process, the precise suite of actions and the timing may be changed to use resources more cost effectively. The adaptive management approach will allow changes in the type and quantity of structural and nonstructural BMPs to ensure cost effective measures are being implemented. Flexibility in the schedule and makeup of the Implementation Plan are key to adaptive management.

The quantification analysis is based on the reductions from both nonstructural and structural BMPs that work together to reduce the concentration and load of constituents. Generally nonstructural BMPs consist of pollution prevention activities and source control activities that reduce the amount of the constituent entering the MS4 system, ultimately reducing the concentration in stormwater. Nonstructural activities also encourage the effective use of water, aiming to reduce dry-weather flows. In this way, nonstructural activities reduce the constituent load entering structural BMPs located downstream of the sources.

Removal of suspended sediments by the proposed BMPs will be used a surrogate to assess compliance of Toxics. Toxics removal will be estimated as a fraction of suspended solids removed by the BMPs.

#### 6.1 Evaluation of Structural Solutions

**SOLUTIONS** 

# 6.1.1 <u>Watershed Modeling and Optimized BMP Selection Approach</u>

Watershed modeling tools linked to a BMP simulation system were used to evaluate and optimize quantitative load reduction scenarios to address TMDL implementation efforts in the TMDL Implementation Area of the Machado Lake watershed. The watershed model is based on existing commonly used to simulate and evaluate BMPs Brief descriptions of the watershed model and BMP simulation model is provided below.

# 6.1.1.1 P8 - Hydrologic Modeling Using a Continuous Simulation Model

The P8 watershed modeling system utilizes a modeling approach that has been used to support numerous TMDL developments throughout the country. The P8 model is a continuous simulation model and generates runoff characteristics based on rainfall, soil characteristics and infiltration rates, evapo-transpiration, antecedent conditions, and land use specific pollutant loading characteristics. Meteorological data from 2005 to 2013 were used to calibrate the model. Existing meteorological data, hydraulic data, land use information, and monitoring data were used to calibrate each sub-watershed to most accurately simulate the runoff and pollutant load.

The P8 model simulates hydrology, sediment, and general water quality was combined with a stream fate and transport model. Wet-weather loading estimates are developed using the modeled constituents including TN, TP, TSS, and Toxics. Based on the model results from 2005 to 2013, a daily or average annual load was calculated for TSS, TN, TP and Toxics. Annual load results were compared with the WLAs to calculate the load reduction needed to meet those WLAs and presented in Table 3.7.

#### 6.1.1.2 Optimization BMP Design Approach

The optimization BMP design approach uses GIS information and time-series data for watershed runoff flows and pollutant concentrations (generated by the watershed model), integrates a process-based BMP simulation, and applies optimization techniques for the most cost-effective BMP planning and selection.

Based on comprehensive site evaluation and financial analysis, the City selected five sites for centralized BMP Implementation. Optimization of BMP design approach was therefore not comprehensively performed.

### 6.1.1.3 BMP Simulation Process

The BMP simulation system uses process-based simulation for BMP function and removal efficiency and accepts flow and water quality time-series data generated internally by P8 as input data. Process-based simulation of BMPs provides a technique that is sensitive to local climate and rainfall patterns. BMP effectiveness can be evaluated and estimated over a wide range of storm conditions, site designs, and flow routing configurations.

The storage/infiltration BMPs used in the study included underground and aboveground storage/infiltration systems. The primary benefits of these BMPs are storage and infiltration, which enable runoff volume and rate reduction. These type BMPs also provide water quality benefits via filtration, settling of sediment, and pollutant decay.

The PLAT was used to estimate the average annual load of TN, TP, and TSS from the TMDL Implementation Area. The model-calculated annual loadings for these constituents are presented in Table 3.7. Additionally, the final WLA and the resulting required reduction for nutrients are included in Table 3.7. The model's estimate for current annual loading of nitrogen is less than the interim WLA, but would require a 30 percent reduction to meet the final WLA. The current loading of phosphorus estimated by the PLAT is also less the interim WLA, but would require a 54 percent reduction in average phosphorus loading by 2018. Load reductions of TSS are are used to estimate toxics removal.

# 6.2 Nonstructural Quantification Analysis

The Watershed Treatment Model (WTM) is used to assess the effectiveness of nonstructural BMPs on the dry weather and annual loading of nutrients and suspended solids from the TMDL Implementation Area. The WTM was developed by the Center for Watershed Protection with funding by the USEPA in June 2010. The WTM is a spreadsheet-based model that calculates annual pollutant loads and runoff volumes and accounts for the benefits of a full suite of stormwater treatment practices to determine reductions in pollutant loads. The WTM is used for the TMDL Implementation Area in the Machado Lake watershed to determine the accumulated effectiveness of implementing dry weather BMPs for the control of nutrients and suspended solids.

The WTM uses both environmental inputs (e.g., area of land use types, soil types, etc.) and inputs about BMPs. Environmental inputs are used to determine current loads and inputs about BMPs determine the percent reduction in loads.

#### 6.2.1 Illicit Connection Removal

Illicit connections to storm drains are sources of a variety of pollutants including nutrients. This source control is applicable to residential and commercial areas in the TMDL Implementation Area. However, the load reduction impact of such program is dependent on the presence and extend of illicit connections in the TMDL Implementation Area. The costs of a field investigation, water sample analysis, and illicit connections trace or to confirm reconnection to the sewer system (via dye, video, or smoke testing) can be highly variable and depend on the extent and nature of the problem. Literature review indicates that the cost of removal of one illicit connection and its reconnection to the sewer system is roughly \$2,500 (Marcoux, 2004 and Brown et al., 2004), which makes this is an expensive option. However, the City's NPDES Permit already requires inspection of the storm drain system for illicit connections and removal of the connections, and increased effort to identify illicit connections would enhance the City's illicit connection program. For the purposes of this evaluation, it was assumed that:

- 0 percent of residents have illicit connections. Previous audits by the City of all city storm drain found no illicit connections.
- 10 percent of businesses have illicit connections,
- 40 percent of the sanitary sewer is surveyed for illicit connections,
- 20 percent of illicit connections are corrected.

Assumptions were based on best professional judgment because the number of illicit connections varies depending on local habits, municipal outreach, and enforcement. The number of illicit connections identified and corrected would be dependent on the resources the City can allocate to this program.

# 6.2.2 Catch Basin Filter Cleanout

Regular catch basin filter cleanout prevents pollutants from flowing through and into the storm drain system. Sediment, debris, and gross particulate matter are the targeted pollutants with the cleanout of catch basin filters, but removal of particulate-bound pollutants, including nutrients and toxics, occurs through the physical removal of sediments. Catch basin filter cleanouts can be prioritized as follows:

- Priority A: These catch basin filters are cleaned quarterly.
- Priority B: These catch basin filters are cleaned semi-annually.
- Priority C: These catch basin filters are cleaned annually.

Review of the City's program showed that most catch basin filters were Priority C. However, the model only allows input of semi-annual or monthly cleanouts. Therefore, semi-annual cleanouts were selected. Other inputs were based on best professional judgment. The assumption of semiannual cleanouts may overestimate current load removal and therefore underestimate the percent reduction in loads that could be achieved from increased cleanout frequency.

For the purposes of this evaluation, it was assumed that:

- The impervious area drains to the catch basin filters,
- Catch basin filters are currently cleaned semi-annually,
- In the future, 60 percent of catch basin filters will be cleaned quarterly,
- In the future, 40 percent of catch basin filters will be cleaned semi-annually,

#### 6.2.3 Street Sweeping

Street sweeping uses mechanical pavement cleaning practices to minimize pollutant transport to receiving water bodies. Sediment, debris, and gross particulate matter are the targeted pollutants, but removal of other particulate-bound pollutants, such as nutrients and toxics, can be accomplished simultaneously.

The City's Permit requires that the City prioritize street sweeping as follows:

- Priority A: These streets and/or street segments shall be swept at least two times per month.
- Priority B: Each street and/or street segments is swept at least once per month.
- Priority C: These streets and/or street segments shall be swept as necessary but in no case less than once per year.

For the purposes of this evaluation, it was assumed that:

- Publicly owned roads and parking lots are currently swept weekly.
- All roads in TMDL Implementation Area are currently swept with vacuum sweepers.
- The future program will use vacuum sweepers.

City roads are currently being swept weekly. However, the majority of streets lack proper no-parking signage to allow street sweeping trucks to effectively sweep along the curbs. The City is implementing a signage program to allow enforcement on non-parking days and increase the effectiveness of the current street sweeping program. The City uses both mechanical and the more effective vacuum sweepers. The street sweeping cost (including O&M) of vacuum street sweepers is \$360/curb mile based on a monthly sweeping frequency (in 2005 dollars) (Shilling, 2005).

#### 6.2.4 Residential Irrigation and Fertilizer Reduction

Over irrigation leads to runoff, increasing flows within the stormwater system. Additionally, urban irrigation runoff can be high in TSS and nutrients. The nutrients in urban irrigation runoff are typically from fertilizers, which are often overused. Effective outreach can teach residents not to overwater and to test the soil to determine the appropriate amount of fertilizer to apply. In addition, evapotranspiration (ET) controllers have been successfully used to reduce irrigation runoff. The cost of this outreach is highly dependent on the approach, which could vary from internet outreach sites to homeowner incentives to educational displays at retail stores.

For the purposes of this evaluation, it was assumed that:

- Half of runoff from the TMDL Implementation Area is dry weather flow.
- An irrigation reduction program would reduce irrigation flows by 20 percent.
- Enhanced outreach of television and radio spots would be necessary to reach and convey the message of controlling irrigation and using proper amounts of fertilizer.

# 6.2.5 Results of Watershed Treatment Model

The results of the above combined inputs to the WTM are listed in Table 6.1. The reductions are based on percent of dry weather load and the percent of annual runoff load (e.g., street sweeping has benefits in both wet and dry weather). These reductions are considered approximate estimates due to the environmental characterization assumptions made for the model and the assumptions listed in the previous sections.

Table 6.1 Estimated Reductions in Nutrients and TSS from Non-Structural BMPs								
Percent Reduction <sup>(1)</sup>								
Flow Condition	Total Nitrogen	Total Phosphorus	Total Suspended Solids	Toxics				
Dry Weather Runoff	21%	15%	33%	33%				
Annual Runoff	23%	10%	26%	26%				
Note: (1) Load reduction Section 6.2.	ns as predicted b	y the Watershed Tre	atment Model with inputs o	liscussed in				

WTM requires a number of inputs to assess current conditions and the effectiveness of specific source controls. The WTM is the best available tool for modeling and estimating reductions because there is very little reliable literature about load reduction in stormwater through implementation of nonstructural BMPs. WTM results will need to be compared with and used in conjunction with stormwater quality and quantity data to evaluate the effectiveness of the nonstructural BMPs.

As shown in Table 6.1, the use of nonstructural BMPs is estimated to reduce TP loading by 10 percent on an annual basis. Therefore, the remaining 44 percent of the required 54 percent reduction will need to be through the use of structural BMPs. Similarly, structural BMPs need to remove the remaining 8 percent of the required 31 percent of TN removal as calculated with the models and assumptions stated in this report.

# 6.3 Structural Quantification Analysis

The PLAT calculates the distribution of structural BMPs to provide the required load reductions at the optimal cost. In setting the load reductions levels for structural BMPs in the PLAT, the anticipated reductions through implementation of non-structural BMPs are subtracted from the total load reductions necessary to achieve the TMDL WLAs. Structural BMPs considered in the PLAT include rainwater capture and reuse, bioretention, porous pavement, and centralized treatment. The initial recommendations for structural BMPs optimized by the PLAT are presented in Table 6.2.

Table 6.2 Optimized Sizing of Centralized BMPs from PLAT <sup>(1)</sup>									
	Total	Impervious	Centralized E (ac-	Total BMP Treatment					
Sub Area	Area (ac) <sup>(1)</sup>	Area (%)	Aboveground	Underground	Capacity (ac-ft)				
Airport - AS2	86	45	N/A	1.5	12.0				
Airport - AS3	640	59	N/A	28	32.8				
Airport - Walteria	391	60	N/A	20.5	22.4				
Walnut Sump	-	-	39.5	n/a	50				
Baseball Field	-	-	N/A	1.0	2.9				
Note: (1) Overall removal									

The final mix of BMPs will depend on funding available for installation and the measured gains in nutrients and toxics reductions as projects are implemented. Refinements to the model based on Machado Lake watershed water quality and quantity monitoring may also change the amounts and relative distributions of BMPs in future reconsideration of the Nutrients TMDL.

# 6.3.1 Retrofit through Redevelopment

Additionally, the City will adopt an ordinance requiring LID components when greater than 50 percent of the impervious area is modified. Residential areas within the TMDL Implementation Area are generally established with low levels of redevelopment. The commercial and industrial areas may experience a moderate rate of redevelopment and would be subject to the City's LID ordinance.

For purposes of this evaluation, it is assumed that 15 percent of the 675 acres commercial, industrial, and institutional area in the area will experience redevelopment over the course of the Implementation Plan. In addition, the rate of redevelopment is assumed to be 2.5 percent per year between 2013 and 2018. This rate is based on the levels experienced in the TMDL Implementation Area of LA County over the past 20 years and is expected to be similar in the TMDL Implementation Area over the life of the Implementation Plan.

Future rate of redevelopment are largely a function of the economic health of the region as a whole and is outside the control of the City. In the future, if the levels of LID through redevelopment becomes more significant that assumed for this study, it could be possible, that less structural BMPs are required in the TMDL Implementation Area to meet the WLAs.

# 6.4 Quantification Analysis Results

A summary of the required BMP capacity volumes and identified volumes though City projects, redevelopment, and identified opportunities is presented in Table 6.2. The remaining BMP capacity (i.e., the BMP capacity not identified through retrofit of City lands, conceptual opportunities, or redevelopment) may be provided through private installation of BMPs or the installation of structural BMPs within leased properties or acquisition of land within the TMDL Implementation Area. Leasing land area will require negotiation with lessees on properties where leases will expire during the implementation period. Private installation of BMPs may occur through incentive programs, or ordinances. Stormwater fees may be developed to provide a funding mechanism for future BMPs and fund (not oversee) the programs discussed in the BMP Implementation Plan. To attain the WLAs, it may not be necessary for the City to acquire land outside the Implementation Area to implement BMPs. Successful implementation of the programs to attain WLAs will require the multidepartmental detailed planning which is beyond the scope of the BMP Implementation Plan. The BMP Implementation Plan is rooted in an adaptive management approach, allowing the City to assess the true effectiveness of non-structural BMPs, and monitoring to better refine the annual average load of the pollutants of concern. To attain WLA, City may need to work with LACFCD and Rolling Estates to expand Project A1 at the Torrance Airport.

# 6.5 Quantification Analysis Conclusions

Due to the reasonable amount of existing publicly owned land within the TMDL Implementation Area in the Machado Lake watershed, centralized structural BMPs can be implemented in areas currently owned by the City. This avoids lengthy negotiations between landowners and the City, incentive programs, City ordinances, and stormwater fees may need to be developed and instituted, and land acquisition may be necessary.

The monitoring program will provide stormwater sampling data to assess the site-specific level of nutrients associated with the sediment leaving TMDL Implementation Area. The measured pollutant levels from the monitoring program may provide more site-specific pollutant loading scenarios from the watershed, which would help reevaluate reductions required to meet the WLAs. Currently, TP is the limiting constituent driving the number of BMPs. Additionally, the Nutrients TMDL is due to be reevaluated by 2016, and the reevaluation will include the information from special studies and the results of monitoring programs. The Nutrients TMDL reevaluation may be used to refine the loading capacity of Machado Lake, ultimately changing the WLAs. If, through monitoring, the loadings from the TMDL Implementation Area reveal that nonstructural BMPs are more effective than assumed by the WTM, or the levels of constituents in the runoff from TMDL Implementation

Area are lower than currently thought to exist, BMP implementation will need to be adjusted accordingly.

#### 6.6 Reasonable Assurance

The main objective of this implementation plan is capture 85th percentile runoff and infiltrate it, wherever possible. This is in addition to non-structural BMPs including enhanced street sweeping, public education and catch basin filter inserts. The City is already performing street sweeping and public education. The proposed BMPs have sufficient capacity to capture and infiltrate the 85th percentile runoff. The expected pollutant removal is summarized in Table 6.3.

The proposed BMPs have sufficient capacity to capture and infiltrate the 85th percentile, 24-hour volume from Subcatchments AS2, AS3, WS-2, WS-3, and BB-S3, while the remaining Subcatchments (including ASI, WS-1, BB-S1, BB-S2, and BB-S4) will be addressed through distributed BMPs and non-structural BMPs (such as catchbasin filters and street sweeping), and may be addressed through additional structural BMPs in the future.

The Walteria Lake which acts as a BMP serving the Walteria Lake Sub Area has sufficient capacity to capture and retain the 85th percentile, 24-hour volume from Walteria Lake Sub Area. The 85th percentile, 24-hour volume generated from the Airport Southeast Sub Area will be captured by an infiltration BMP being installed by a developer, and thus no more BMPs are proposed for this sub area.

## 7.0 MULTI-BENEFITS ANALYSIS

This BMP Implementation Plan outlines the management actions that may be needed to ultimately attain the WLAs of the Machado Lake Nutrient TMDL (LARWQCB, 2009) in the City's TMDL Implementation Area of the Machado Lake watershed. Although the primary intention of the proposed structural and nonstructural BMPs is to reduce nutrients load to Machado Lake, the ancillary benefits include water supply improvement, community enhancement, and sediment reductions. This section describes the additional benefits that may be achieved as the management actions are implemented. It should be noted that they do not necessarily benefit the City directly.

# 7.1 Water Supply

#### 7.1.1 Irrigation Reduction

Irrigation reduction is a proposed nonstructural BMP. Irrigation reduction has the direct water supply benefit of reducing the amount of potable water used for irrigation. Irrigation reductions could be achieved through outreach to residents and implementation of evapotranspiration controllers. Irrigation reductions will be aided by Ordinance No. 2008- 0052U, which prohibits runoff from lawns and landscaping on to hardscape (streets, sidewalks). This ordinance also limits fertilizer running onto the street, thus reducing nutrient loads to stormwater. Field monitoring data show that irrigation runoff is insignificant and therefore the City may continue to monitor this in the future.

# 7.2 Community Enhancement Benefits

Water quality improvements benefit the community at large. These benefits include aesthetics, increases in property value, enhanced recreation opportunities, enhanced water supply, and lower costs for landscape maintenance. Ecosystem benefits are also realized from the improvements. Runoff reduction contributes to water conservation, provides habitat benefits through the reduction of the artificial dry weather flows, and reduces the cost of landscape maintenance. Improvements in Machado Lake water quality will provide the community with enhanced recreational opportunities. Water quality improvements are likely to improve wildlife viewing and fishing opportunities at the lake. Enhancements in habitat directly benefit the wildlife and provide habitat refuge in a highly urbanized area.

### 7.3 Toxics TMDL and Reduced Sediment to Machado Lake

Best management practices proposed to reduce nutrients in the Machado Lake BMP Implementation Plan include practices that will reduce sediment loads, especially as the WLAs for Toxics were assigned as a fraction of the suspended sediment loading to Machado Lake. Current sediment loading to the lake is estimated at 38,400 kg/yr. Reduction of sediment loading will provide for improved water quality in the lake, and will reduce future needs to dredge the lake.

Structural and nonstructural BMPs capture and remove sediment (TSS) from the watershed. Street sweeping and catch basin filter cleanouts are nonstructural practices that directly remove sediment loads from the watershed and manage them for proper disposal. Nonstructural practices also address the sources of sediment in the watershed, the public outreach, development construction, new development, and public works elements of the City's stormwater management program play a role in encouraging erosion control and reducing sediment inputs to the storm drainage system. Underground storage/infiltration systems are structural BMPs that prevent conversion of pervious areas to impervious cover during development. These practices reduce the quantity and rate of runoff from developed areas, thereby reducing the demand on the storm drain system. The expected reductions in sediment loading for dry and annual weather flows are listed in Table 7.1.

Table 7.1 Estimated Reductions in Stormwater TSS Loads					
Flow Condition	Percent Reduction in TSS <sup>(1)</sup>				
Dry Weather Flow	31%				
Wet Weather Flow	90%				
Note:  (1) Reductions based on nonstructural removal estimates and PLAT results within the TMDL Implementation Area.					

# 7.4 Multi-Benefit Summary

Precise benefit quantification is difficult given the absence of site-specific information and uncertainty about BMP performance and efficiencies. A summary of the ancillary benefits to the proposed structural and nonstructural BMPs within the Machado Lake Watershed are listed in Table 7.2.

 $\label{thm:control} October\ 2016 \\ \text{pw://Carollo/Documents/Client/CA/Torrance/9193A00/Deliverables/Final Report\ 02/Report/BMP\ Implementation\ Plan}$ 135 -This Page Left Blank Intentionally-

The estimated implementation schedules for the nonstructural and structural projects proposed as possible solutions to comply with WLAs from the TMDLs are discussed below. The schedules presented herein are sufficient for long-term planning. Through adaptive management and based on the future monitoring results and response of Lake Machado, the implementation schedules may be modified to reflect the increased knowledge of the watershed. Actual schedule for Implementation of BMPs will occur as funding becomes available.

#### 8.1 TMDL Schedule

The nutrient TMDL implementation schedule consists of a phased approach, with interim WLAs to be met by March 11, 2014 and full compliance by September 11, 2018. The schedules for required actions for both the Nutrient TMDL are outlined in Table 8.1. The full compliance of the Machado Lake toxics TMDL will be achieved by September 30, 2019. As stated earlier in this report and in Appendix B, the interim WLAs for total phosphorus and total nitrogen have been met.

Table 8.1	Schedule or Work Plan Elements	
ID	Work Plan Element	Schedule
1	Effective Date	March 11, 2009
2	Submit Monitoring Plan	September 12, 2011
3	Begin Monitoring and Implementation	60-days from approval
4	Information Item to LARWQCB on Implementation Progress	March 11, 2013
5	Interim Limits Apply	March 11, 2014
6	LARWQCB to Reconsider TMDL	September 11, 2016
7	Final WLA applicable	September 11, 2018

#### 8.2 Load Reduction Schedule

The Nutrient TMDL contains a phased compliance schedule, with interim limits effective in the first quarter of 2014 and final allocations effective the third quarter of 2018.

#### 8.3 Nonstructural Schedules

An estimated schedule for the nonstructural BMPs described in Section 4 Nonstructural Solutions is summarized in Table 8.2. The schedule accounts for the planning and design of the nonstructural BMP programs and the long-term implementation of the programs.

#### 8.4 Structural Schedules

An estimated schedule for completing the structural BMPs described in Section 5 is presented in Table 8.3. The schedule includes meeting planning and permitting requirements, preparing engineering design documents, bidding and constructing the BMPs and ongoing operations. The timeframe for funding has not been included in this schedule. In addition to the projects noted in the Table, the schedule accounts for the ongoing redevelopment activities that are expected to occur in the TMDL Implementation Area. The schedule also accounts for the ongoing opportunities to retrofit BMPs whether they are on public right-of-ways or private properties.

As discussed in Section 5.3.3., a geotechnical investigation was conducted at the Torrance Airport due to concern regarding infiltration rates at this BMP site. Details of this subsurface investigation are summarized in Appendix E. In summary, it can be concluded that the boring logs indicate that the top layer below surface is not suitable for infiltration and that substantial excavation (25-24 feet below surface) will be required to reach a sand layer that would typically yield higher percolation rates.

To verify if the proposed underground infiltration would work properly at this location, it is recommended that the City take a phased approach. First, it is recommended that the City conduct some percolation testing at the depth of the sand layer. If results are acceptable, it is then recommended that the City implement the project at Site A1 first, where the sandy layer is closest to ground surface (25 below ground surface) and then monitor the performance over multiple years. If the project meets expectations or if design alternations can overcome any identified issues, it is recommended that the City implement projects A2 and A3, where the sandy layer starts at 40 and 45 feet below surface, respectively.

BMPs on Public Lands	As needed							
BMP on private Property by Land Owner through Incentive Program <sup>(2)</sup>	As needed							

<sup>(1)</sup> Redevelopment of property is assumed to continue at a moderate pace comparable to the last 20 years and redevelopment will be in accordance with the LID ordinance and SUSMP requirements.

<sup>(2)</sup> Requires Public – Private partnership

#### 9.0 COST ESTIMATES

The cost estimates for the proposed actions outlined in the Implementation Plan are presented in this section. At the planning level, the costs provided will allow an order of magnitude effort necessary to implement structural and nonstructural BMPs in the Machado Lake Watershed to meet the WLAs of both the Nutrient and Toxics TMDLs using the current information on the loading from the TMDL Implementation Area and effectiveness of implementing BMPs. Changes to the TMDLs, the model estimated loads through watershed specific monitoring, or assumed effectiveness of identified BMPs will result in a change in the required BMPs and their associated costs. Cost estimates presented are at the level of detail necessary for planning and strategic decision-making. The BMPs are to be distributed uniformly across the TMDL Implementation Area, and site-specific issues that may result in excessive costs are likely to occur in a portion of the installations. Costs presented in here cannot consider site-specific issues and are likely to underestimate the final costs for applying the identified BMPs throughout the TMDL Implementation Area.

### 9.1 Best Management Practices Cost Estimates

The nonstructural costs estimates are presented in Table 9.1. An assumed 3 percent rate of inflation is used in the cost estimates to determine the cost estimates. Of the BMPs discussed in Section 4, the impervious cover reduction and sanitary sewer maintenance are not included in Table 8.3, as the impervious cover reduction ultimately is a component of the structural BMP program, and the sanitary sewer maintenance is required under the collection system permit.

Table 9.1 Nonstructural Best Management Practice Co	ost Estimates.							
Program	Cost (\$) <sup>(1)</sup>							
Catch basin filter Cleanouts	1,500,000							
Catch basin filter(2)	2,200,000							
Downspout Disconnection Program	200,000							
Fats, Oils and Grease Outreach	100,000							
Green Waste Outreach	100,000							
Illicit Connection Removal	200,000							
Industrial/ Commercial Facilities Control Program	100,000							
Pet Waste Outreach	500,000							
Post Construction Requirements	50,000							
Sewer System Maintenance	500,000							
Smart Gardening Program	500,000							
Street and Parking Lot Sweeping	1,500,000							
Total 7,450,000								
Note: (1)Program costs through 2018 using 3% rate of inflation								

Structural cost estimates are listed in Table 9.2. Implementation costs for the conceptual projects do not include engineering design, permitting, construction, building materials, or O&M. Information on these can found in Appendix F. The details of the five conceptual designs are presented in Section 5. As per the quantification analysis, structural BMPs are required in addition to the conceptual projects and projects situated on County lands. Typical costs for the additional projects are used to estimate the cost of projects on leased or private parcels. The costs do not reflect the costs of negotiation with landowners or the cost of land acquisition. The costs for additional projects are subject to change to reflect the specific site conditions. Detailed cost estimates can be found in Appendix F.

Table 9.2 Program Cost Estimates of Structural Best Management Practices									
Structural Best Management Practice Cost (\$)									
Conceptual Projects									
Walnut Sump	2,500,000								
Baseball Field	500,000								
Torrance Airport									
1. BMP at Site A1	5,007,000								
2. BMP at Site A2	2,000,000								
3. BMPat Site A3 (Recommended Option)	7,000,000								
TOTAL <sup>(1)</sup>	10,007,000								
Note: (1) Total cost that not include BMP costs at A1 and	A2								

#### 9.2 Cost Schedule

The schedule for implementation to achieve the TMDL WLA, requiring 54 percent reduction in phosphorus load, is summarized in Table 8.3. The schedules for nonstructural, structural, redevelopment, and leased property projects were used to distribute the implementation costs over time, ending in 2018, the compliance point for the Nutrients TMDL. The implementation path represented by Table 8.3 is a method of compliance with the Nutrients TMDLs. As the adaptive management and reevaluation of the Nutrient TMDL progresses, the required levels of pollutant loading and the compliance timeline may change. The actual costs and timing of implementation will depend on the specific site characteristics, special studies, and actual effectiveness of installed BMPs.

### 9.3 Financial Strategy

Financing the implementation of the Torrance EWMP is the greatest challenge confronting the City. In the absence of stormwater utility fees (aside from those specified for maintenance), the City has no dedicated revenue stream to pay for implementation of the EWMP. The City's annual budget for catch basin cleaning is about \$140,000 and the annual budget for street sweeping is approximately \$1,3000,000.

In addition to current uncertainties associated with costs and funding, there are multiple uncertainties associated with future risks. There will be many deadlines that must be met despite limited resources. The City will need to set priorities and seek funding in order to meet the various compliance deadlines. Therefore, to address the Water Quality Priorities (WQPs), the City is going to pursue a multi-faceted financial strategy. In addition, the City has coordinated the proposed compliance schedule (see Section 5) with the financial strategy.

The latest Los Angeles MS4 Permit has greatly magnified the financial challenges associated with managing stormwater. The absence of a stable stormwater funding mechanism not tied to municipal General Funds is becoming ever more critical. For that reason, the City Manager Committees of the California Contract Cities Association and the League of California Cities, Los Angeles Division, formed a City Managers' Working Group (Working Group) to review stormwater funding options after the LA County proposed Clean Water, Clean Beaches funding initiative did not move forward. The result was a Stormwater Funding Report 3 that notes, "the Los Angeles region faces critical, very costly, and seriously underfunded stormwater and urban runoff water quality challenges." The Report found that funding stormwater programs is so complex and dynamic, and the water quality improvement measures so costly, that Permittees cannot depend on a single funding option at this time. The City Managers' report includes a variety of recommendations, including: organizational recommendations; education and outreach program recommendations; recommendations for legislation, such as State Facilities, Stormwater Capture, and Use; Source Control or Fee Legislation; Clean Water, Clean Beaches recommendations; local funding options; and recommendations for the Regional Water Board.

A summary of funding options identified in the Stormwater Funding Report can be found below.

#### 9.3.1 Organizational

As recommended in the Stormwater Funding Report, the City will consider forming a core group of elected officials to form a committee, including members from the environmental community, the business community, and other stakeholders to improve communication and to reach consensus on fee issues. Additionally, the City plans to engage with other agencies to discuss future partnerships in stormwater programs.

### 9.3.2 Education and Outreach

The City plans to implement public outreach on a watershed-based level. With these efforts the Participating Agencies will have direct communications with the Governor and the Legislature on the funding needs.

#### 9.3.2.1 Legislation

The City has considered pursuing legislation in the following areas:

- Schools and Public Facilities (i.e., environmental liability waivers; state architect guidance on schools, etc.)
- Stormwater Capture and Reuse (i.e., provide a clear path to monetize the capture and use of stormwater)
- Source Control or Fee Legislation (i.e., pursue reduction of zinc in tires and/or a pertire zinc reduction fee)
- Special Assessment Districts (i.e., explore the special assessment district concept for funding stormwater projects)

#### 9.3.2.2 Clean Water

The Participating Agencies will consider a property owner/voter sentiment survey based on new factors and changed circumstances, including a list of specific projects, optional fee amounts and an "opt out" provision. Additionally, the Participating Agencies will explore the formation of the Urban Water Conservation District under the 1931 Act by determining the governance structure under 1931 Act. If it is Board of Supervisors governance, a protest hearing may be considered to vote for a stormwater capture and infiltration fee to fund other program aspects not covered under the 1931 Act Water Conservation District.

#### 9.3.3 Local Funding Options

Local funding options include:

- Adopting local fees.
- Street sweeping contracts to provide NPDES trash controls.
- Adoption of water conservation fees to provide funding for reducing irrigated runoff to conserve water and reduce dry weather discharges.
- Stormwater impact fees.
- Local, statewide, or regional fees on car rentals to contribute to copper and zinc cleanup costs and incorporate stormwater quality features into street and highway projects funded by bonds and other street funds.

#### 9.3.3.1 Transportation

Another consideration is future transportation bonds. This can be pursued by encouraging the Metropolitan Transportation Authority (MTA) to include funding stormwater quality features, such as Green Streets, in future bonds and encourage Council of Governments to develop strategic transportation plans that include mitigations designed to address water quality issues from transportation projects.

### 9.4 Assessment and Adaptive Management Framework

Adaptive management is a key component to the successful implementation, assessment, and refinement of the Machado Lake EWMP. Adaptive management is the process by which data are continually assessed in the context of improving and adapting programs to ensure the most effective strategies are implemented. In accordance with the MS4 Permit, every two years from the date of EWMP approval an adaptive management process will be implemented. The process will include consideration of the progress for the following elements as described in Part V1.C.8 of the MS4 Permit:

- 1. "Progress toward achieving interim and/or final WQBELS or RW limitations according to established schedules;
- 2. Progress toward achieving improved water quality in MS4 discharges and achieving RW limitations through implementation of the watershed control measures based on an evaluation of outfall based monitoring data and RW monitoring data;
- 3. Achievement of interim milestones:
- 4. Re-evaluation of the water quality priorities identified for the area based on more recent water quality data for discharges from the MS4 and the receiving water(s) and a reassessment of sources of pollutants in MS4 discharges;
- 5. Availability of new information and data from sources other than the Permittees' monitoring program(s) within the area that informs the effectiveness of the actions implemented by the Permittees;
- 6. Regional Water Board recommendations; and
- 7. Recommendations for modifications to the Watershed Management Program solicited through a public participation process."

As additional data become available through CIMP monitoring, BMP effectiveness studies, special studies such as the Toxics TMDL required Stressor ID Study, and other scientific studies, they will be integrated and assessed to determine whether programs in the EWMP should be altered to enable compliance in the most efficient manner.

The adaptive management framework will allow the EWMP Agencies to develop an overall program consisting of efficient solutions based on evolving watershed priorities.

October 21, 2013

Carollo Engineers 199 S. Los Robles Ave., Suite 530 Pasadena, CA 91101

Attention: John Meyerhofer,

Subject: 3 potential stormwater recharge project sites in the City of Torrance Project No. 43-2013-10-00001
Please refer to the above Job ID Number in all future correspondence.

Enclosed is a copy of our Atlas Sheet/s with the approximate locations of our gas mains for you to post to your proposed project plans. The dimensions and locations of the mains are believed to be reasonably correct but are not guaranteed.

The depths of our facilities vary and can only be confirmed by pot holing, or some other acceptable method of taking elevations.

It is extremely important that you furnish us with "signed" final plans, before construction, including profiles and subsequent plan revisions as soon as they are available. A minimum of twelve (12) weeks is needed to analyze the plans and design alterations for any conflicting facilities. Depending on the magnitude of the work involved, additional time may be required to clear the conflict.

Underground Service Alert (USA), (800) 442-4133 or (800) 227-2600, must be notified 48 hours prior to commencing work. Please keep us informed of construction schedules, pre-construction meetings, etc., so that we can schedule our work accordingly. If no action is taken on this project within 24 months, plans will be discarded. Please call Paul Blood at (310) 687-2011 for further assistance.

## Thank you,

Gale Etherly for Paul Blood

RE: Torrance

Enclosed are copies of the existing Southern California Edison overhead and/or underground facilities inventory maps covering the area of your proposed project.

Southern California Edison Company believes this information is correct for purposes intended by the Company and assumes no liability for its accuracy.

Should you need to contact an SCE service planner for review of preliminary or final plans, or to establish a service point, please contact:

SCE PLANNING SUPERVISOR 505 Maple Ave Torrance, CA 90503 (310) 783-9356

When contacting the SCE service planner, please include copies of the facilities inventory maps that are being provided to you. **SENDING YOUR PLANS TO ANY ADDRESS OTHER THAN THE ONE LISTED WILL CAUSE A DELAYED RESPONSE.** 

Thank you, and if you have any further questions, please call me at (714) 796-9932.

May 16, 2013

Mr. John Meyerhofer Carollo Engineers Suite 530 199 South Los Robles Avenue Pasadena, CA 91101

Dear Mr. Meyerhofer:

## <u>Utility Information Request — Storm Water Projects</u>

Thank you for your email dated May 2, 2013, requesting Metropolitan's utility information in the areas of your proposed storm drain improvements project located in various streets in the city of Torrance.

As shown on the enclosed maps, our 78-inch-inside-diameter prestressed-concrete Second Lower Feeder pipeline and appurtenant manhole structures are located along 220<sup>th</sup> Street and along Western Avenue, our 51-inch-inside-diameter welded-steel Palos Verdes Feeder pipeline and appurtenant manhole structures traverses in a northeasterly and southwesterly direction which also crosses Western Avenue, and our 84-inch-inside-diameter prestressed-concrete Sepulveda Feeder pipeline and appurtenant manhole structure are located along Western Avenue within your proposed project limits.

We are transmitting a copy of our "Guidelines for Developments in the Area of Facilities, Fee Properties, and/or Easements of The Metropolitan Water District of Southern

Mr. John Meyerhofer Page 2 May 16, 2013

California," and a prints of our Drawings B-22797 through B-22805, B-23305 through B-23310 and B-54584, for your information and use.

We request that our facilities be fully shown and identified as Metropolitan's on your project plans and that prints of the preliminary plans be submitted for our review and written approval as they pertain to our facilities. We also request that all applicable portions of the enclosed guidelines be incorporated in your plans.

We also request that new storm drain lines and manhole structure proposed to cross over or located within 10 feet from the edges of our pipelines must include secondary containment, which consists of either a continuous steel casing or HDPE pipe with fusion-welded joints. Alternatively, we will allow a storm drain line without double containment if HDPE pipe with fusion-welded joints is used.

We also request that a stipulation be added to your plans or specifications to notify Samuel Teare of our Water System Operations Group, telephone (323) 276-7623, at least two working days prior to starting any work in the vicinity of our facilities.

For any further correspondence with Metropolitan relating to this project, please make reference to the Substructures Job Number shown in the upper right-hand corner of the first page of this letter. Should you require any additional information, please contact Ken Chung, telephone (213) 217-7670.

Very truly yours,

Kieran M. Callanan, P.E. Manager, Substructures Team

**Proposed Torrance Airport Infiltration Galleries Project** 

3301 Airport Drive Forrance, California

Converse Project No. 13-31-225-01

Dear Mr. Sadeghi:

Converse Consultants (Converse) is pleased to present this Geotechnical Study Report for the design of Torrance Airport Infiltration Galleries Project in Torrance, California. Our services were performed in accordance with our proposal dated June 27, 2013.

Based on our field exploration, laboratory testing, geologic evaluation and geotechnical analysis, the site is suitable from a geotechnical standpoint for the proposed project, provided our conclusions and recommendations are implemented during design and construction.

We appreciate the opportunity to be of service to Carollo Engineers, Inc. If you should have any questions, please do not hesitate to contact us at (626) 930-1200.

#### **CONVERSE CONSULTANTS**

William H. Chu, P.E., G.E.

Senior Vice President/Principal Engineer

Dist: 4/Addressee

MM/SCL/WHC/amm

#### PROFESSIONAL CERTIFICATION

This report for the proposed Torrance Airport Infiltration Galleries Project located at 3301 Airport Drive in the City of Torrance, California has been prepared by the staff of Converse under the professional supervision of the individuals whose seals and signatures appear hereon.

The findings, recommendations, specifications or professional opinions contained in this report were prepared in accordance with generally accepted professional engineering and engineering geologic principles and practice in this area of Southern California. There is no warranty, either expressed or implied.

In the event that changes to the property occur, or additional, relevant information about the property is brought to our attention, the conclusions contained in this report may not be valid unless these changes and additional relevant information are reviewed and the recommendations of this report are modified or verified in writing.

Mohammad-Saad Malim, E.I.T

Staff Engineer

William H. Chu, G.E.

Principal Engineer, Senior Vice President

#### **EXECUTIVE SUMMARY**

The following is the summary of our geotechnical study, findings, conclusions, and recommendations, as presented in the body of this report. Please refer to the appropriate sections of the report for complete conclusions and recommendations. In the event of a conflict between this summary and the report, or an omission in the summary, the report shall prevail.

- The project site is located at 3301 Airport Drive in the City of Torrance, California
- Three (3) exploratory borings (BH-1 through BH-3) were drilled within the project site
  on September 3, 2013. The borings were advanced using a truck mounted 8-inch
  diameter hollow stem auger drill rig to depths of 51.5 feet below the existing ground
  surface (bgs). Every boring was visually logged by a Converse engineer and sampled
  at regular intervals and at changes in subsurface soils.
- The earth materials encountered during our investigation consist of existing fill soils placed during previous site grading operations and natural alluvial soils. The fill soils encountered to depths of f feet below ground surface (bgs) are described as silty sand and sandy clay. Deeper fills may be present at the other areas at the site based on our field observations of existing on-site structures. The alluvial soils below the fill primarily consist of clay and sand to a maximum depth of 51.5 feet below ground surface (bgs).
- Groundwater was not encountered in our exploratory borings drilled to a maximum depth of 51.5 feet below the ground surface. Review of LA County Department of Public Works groundwater monitoring well number 769 and 271N indicate the historical highest groundwater level is reportedly deeper than 80 feet below the ground surface. Groundwater is not anticipated during construction and will not need to be considered in design.
- The site is not located within a mapped Seismic Hazard Zone for liquefaction potential. Based on the results of our subsurface exploration, including the absence of groundwater within 50 feet, and our experience on similar projects, the site is not considered susceptible to liquefaction and seismically-induced settlement is negligible.
- Results of our study indicate that the site is suitable from a geotechnical standpoint for the proposed development, provided that the recommendations contained in this report are incorporated into the design and construction of the project.
- The proposed buildings can be supported on conventional shallow foundations embedded into compacted fill.
- Soil can be excavated with conventional heavy-duty earthmoving equipments.

- The near surface site soils have a high expansion potential. Mitigation measures for expansive soil are anticipated. We recommend that two feet of suitable, nonexpansive, sandy import materials approved by Converse be placed under planned footings and slabs.
- Based on the soil corrosivity test results, the near surface sols is not considered corrosive to concrete, However, the minimum saturated resistivity testing result indicates the onsite soil is considered corrosive to ferrous metal. Protections of underground metal pipe should be considered.
- Based on our field exploration, surficial clayey soils encountered up to 40 feet deep are not considered effective for planned infiltration systems. Sandy soils encountered below the clayey soil layers are relatively dense and also might not be conducive to good percolation rates. It is recommended that a specific percolation testing program be performed for any planned infiltration system to determine percolation rates at specific depths.

#### 1.0 INTRODUCTION

This report contains the findings and recommendations of our geotechnical study performed for the proposed Torrance Airport Infiltration Galleries Project located at 3301 Airport Drive in the City of Torrance, California as shown on Drawing No. 1, *Site Location Map*.

The purpose of this work was to evaluate the subsurface soil conditions, specifically the depths of clays and other impermeable layers, and provide geotechnical recommendations and design recommendations for the proposed project, including current standard of practice seismic and geotechnical engineering interpretations.

This report for geologic and geotechnical design parameters for the project described herein and is intended for use solely by Carollo Engineers, Inc and the City of Torrance. This report should not be used as a bidding document but may be made available to the potential contractors for information on faculty data only. For bidding purposes, the contractors should be responsible for making their own interpretation of the data contained in this report.

#### 2.0 SITE AND PROJECT DESCRIPTION

#### 2.1 Site Description

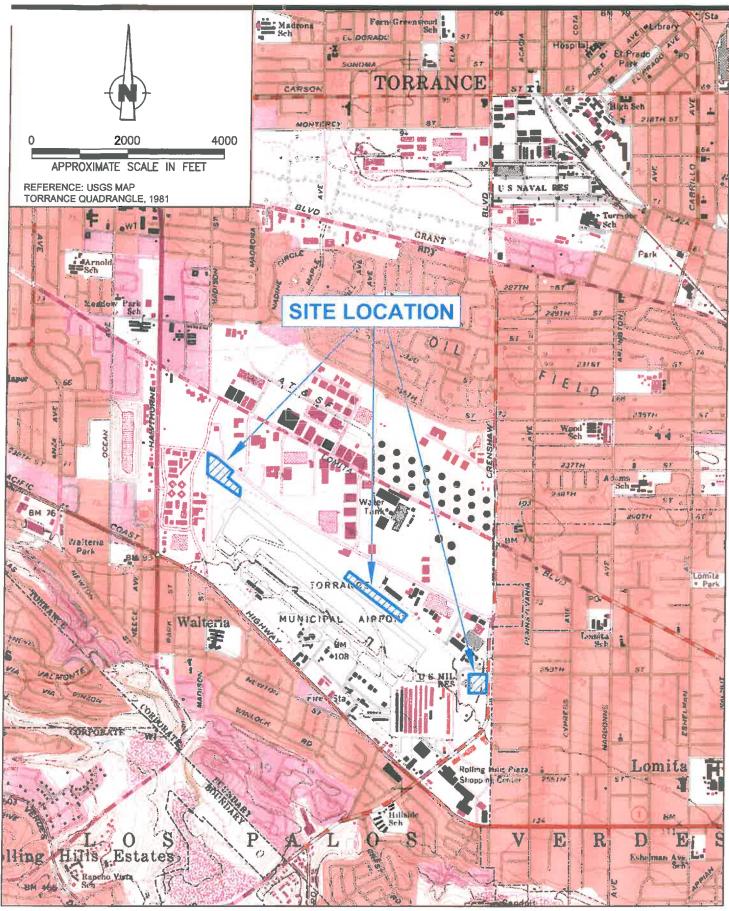

The project site is located at 3301 Airport Drive in the City of Torrance, California. The site currently consists of open fields adjacent to the Torrance Airport runway. The site is gently sloping towards the northwest and the ground elevation is about 90 feet above Mean Sea Level (MSL). The coordinates for the project site are: North latitude: 33.8017 degrees and West longitude: 118.3346 degrees. The project site is shown on Drawing No. 2, *Site Plan and Boring Locations*.

#### 2.2 Project Description

The proposed project consists of the construction of three (3) potential infiltration galleries at Area 1 (approximately 246,400 square feet), Area 2 (approximately 105,000 square feet), and Area 3 (165,000 square feet) within Torrance Airport as shown on Drawing No. 2, *Site Plan and Boring Locations*. The proposed infiltration galleries are planned to divert flow from Machado Lake.

#### 3.0 SCOPE OF WORK

The scope of our present study includes a review of the existing site plan, site reconnaissance, subsurface exploration, soil sampling, laboratory testing, preliminary

SITE LOCATION MAP

# SITE PLAN AND BORING LOCATIONS

TORRANCE AIRPORT INFILTRATION GALLERIES TORRANCE, CALIFORNIA

Project No.

Drawing No.

2

engineering analysis, and preparation of this report. Details of the tasks are addressed in the following sections:

#### 3.1 Site Reconnaissance

As a part of our project set-up task, available published geotechnical and geologic data were reviewed for the project area to ascertain regional geologic and groundwater conditions, and to screen for potential geologic hazards.

Converse representatives also visited the site prior to drilling to assess the site accessibility for drilling equipment, and to mark the boring locations on August 29, 2013. Underground Service Alert of Southern California was notified at least 48 hours prior to the field exploration.

# 3.2 Subsurface Exploration

Three (3) exploratory borings (BH-1 through BH-3) were drilled within the project site on September 3, 2013. The borings were advanced using a truck mounted 8-inch diameter hollow stem auger drill rig to depths 51.5 feet below the existing ground surface (bgs). Every boring was visually logged by a Converse engineer and sampled at regular intervals and at changes in subsurface soils. Detailed descriptions of the field exploration and sampling program are presented in Appendix A, *Field Exploration*.

California Modified Sampler (Ring samples), Standard Penetration Test samples, and bulk soil samples were obtained for laboratory testing. Standard Penetration Tests (SPTs) were performed in selected borings at selected intervals using a standard (1.4 inches inside diameter and 2.0 inches outside diameter) split-barrel sampler. The bore holes were backfilled and compacted with soil cuttings and cement by reverse spinning of the auger following the completion of drilling. Borings within paved areas were patched with asphalt cold-patch, with the patch thickness matching the surrounding pavement section.

The approximate locations of the exploratory borings are shown in Drawing No. 2, *Site Plan and Boring Locations*. The detailed description of the field exploration and sampling program are presented in Appendix A, *Field Exploration*.

#### 3.3 Laboratory Testing

Representative samples of the site soils were tested in the laboratory to aid in the classification and to evaluate relevant engineering properties. The tests performed included:

In situ moisture contents and dry densities (ASTM Standard D2216)

- Maximum dry density and optimum-moisture content relationship (ASTM Standard D1557)
- Percent Finer than Sieve No. 200 (ASTM D1140)
- Direct shear (ASTM Standard D3080)
- Consolidation (ASTM Standard D2435)
- Expansion Index (ASTM D4829)
- Atterburg Limits (ASTM D4318)
- Soil corrosivity tests (Caltrans 643, 422, 417 and 532)

The detailed description of the laboratory test methods and test results are presented in Appendix B, *Laboratory Testing Program*.

#### 3.4 Analyses and Report

Data obtained from the exploratory fieldwork and laboratory-testing program were analyzed and evaluated with respect to the planned construction. This report was prepared to provide the findings, conclusions and recommendations developed during our study and evaluation.

#### 4.0 SUBSURFACE CONDITIONS

#### 4.1 Regional Geologic Setting

The project site is located within the west coast portion of the Los Angeles Basin and underlain by alluvial soils as shown on Drawing No. 3, *Regional Geologic Map*.

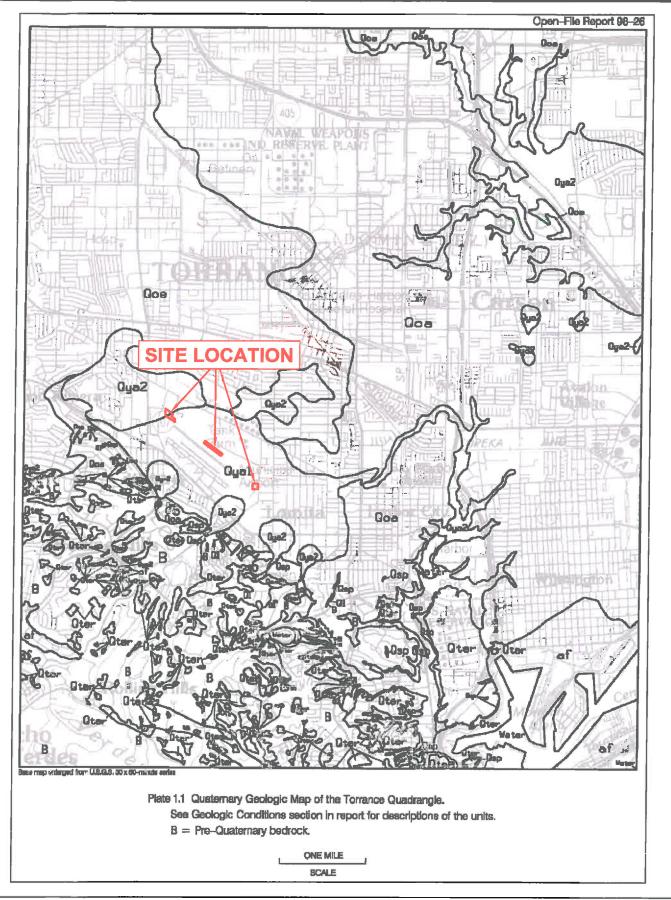

# 4.2 Subsurface Soil Profile of Project Site

The earth materials encountered during our investigation consist of existing fill soils placed during previous site grading operations and natural alluvial soils. Based on our field exploration, undocumented fill up to a maximum observed depth of five (5) feet were encountered in the borings. The fill soils encountered are described as silty sand and sandy clay. Deeper fills may be present at the other areas at the site based on our field observations of existing on-site structures. The alluvial soils below the fill primarily consist of clay and sand to a maximum depth of 51.5 feet below ground surface (bgs).

The detailed description of the materials encountered in each boring is presented in Appendix A, *Field Exploration*.

# 4.3 Groundwater

Groundwater was not encountered in our exploratory borings drilled to a maximum depth of 51.5 feet below the ground surface. Review of LA County Department of Public

# REGIONAL GEOLOGIC MAP

Works groundwater monitoring wells number 769 and 271N indicate the historical highest groundwater level is reportedly deeper than 80 feet below the ground surface. Groundwater is not anticipated during construction and will not need to be considered in design.

#### 4.4 Subsurface Variations

Based on results of the subsurface exploration and our experience, some variations in the continuity and nature of subsurface conditions within the project site should be anticipated. Because of the uncertainties involved in the nature and geologic characteristics of the earth material at the site, care should be exercised in interpolating or extrapolating subsurface conditions between or beyond the boring locations. If during construction, subsurface conditions differ significantly from those presented in this report; this office should be notified immediately so that recommendations can be modified, if necessary.

#### 5.0 FAULTING AND GEOLOGIC HAZARDS

Geologic hazards are defined as geologically related conditions that may present a potential danger to life and property. Typical geologic hazards in Southern California include earthquake ground shaking, fault surface rupture, landslides, and liquefaction.

# 5.1 Fault Surface Rupture and Active Faults

The project site is not located within a currently designated State of California Earthquake Fault Zone (formerly Alquist-Priolo Special Studies Zones) for surface fault rupture. No surface faults are known to project through or towards the site. The closest known fault to the project site is the Palos Verdes Hills Fault Zone located at approximately 1.2 km to the south-west.

#### 5.2 Liquefaction

Liquefaction is the sudden decrease in the strength of cohesionless soils due to dynamic or cyclic shaking. Saturated soils behave temporarily as a viscous fluid (liquefaction) and, consequently, lose their capacity to support the structures founded on them. The potential for liquefaction decreases with increasing clay and gravel content, but increases as the ground acceleration and duration of shaking increase. Liquefaction potential has been found to be the greatest where the groundwater level and loose sands occur within 50 feet of the ground surface. The site is not located within a mapped Seismic Hazard Zone for liquefaction (CDMG, 1998) as shown in Drawing No. 4, Seismic Hazard Zones Map.

Based on the results of our subsurface exploration, including the absence of shallow groundwater, high SPT blow counts, and our experience on similar projects we anticipate liquefaction potential to be very low and seismically-induced settlement to be negligible.

#### 5.3 Landslides

The site is not located within a Seismic Hazard Zone for required investigation for earthquake-induced landsliding (CDMG, 1999). The project site is relatively flat and not located near any hillside terrain. In the absence of significant ground slopes, the potential for seismically induced landslides to affect the proposed site is considered to be nil.

#### 6.0 SEISMIC ANALYSIS

# 6.1 CBC Seismic Design Parameters

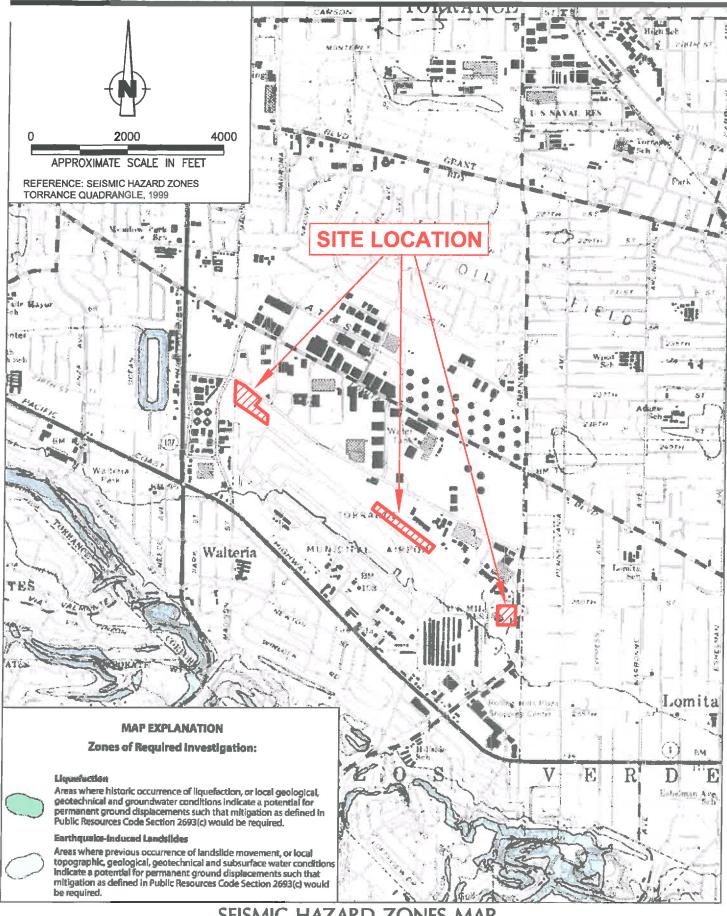

Seismic parameters based on the 2010 and 2013 California Building Code are calculated using the United States Geological Survey *U.S. Seismic Design Maps* website application. The seismic parameters are presented below.

Table No. 1, 2010 and 2013 CBC Seismic Parameters

Seismic Parameters	2010 CBC	2013 CBC
Site Class	D	D
Mapped Short period (0.2-sec) Spectral Response Acceleration, $S_{\text{S}}$	2.096 g	1.715 g
Mapped 1-second Spectral Response Acceleration, S <sub>1</sub>	0.872 g	0.665 g
Site Coefficient (from Table 1613.5.3(1)), F <sub>a</sub>	1.0	1.0
Site Coefficient (from Table 1613.5.3(2)), F <sub>v</sub>	1.5	1.5
MCE 0.2-sec period Spectral Response Acceleration, $S_{\text{MS}}$	2.096 g	1.715 g
MCE 1-second period Spectral Response Acceleration, $S_{\rm M1}$	1.308 g	0.997 g
Design Spectral Response Acceleration for short period, S <sub>DS</sub>	1.397 g	1.143 g
Design Spectral Response Acceleration for 1-second period, S <sub>D1</sub>	0.872 g	0.665 g
Seismic Design Category	D	D

# 6.2 Deaggregated Seismic Source Parameters

Based on our analyses utilizing the USGS 2008 NSHMP PSHA Interactive Deaggregation web site, the mean and modal earthquake magnitudes for a return time of 2475 years is calculated to be 6.92 and 7.19, respectively. The earthquake magnitude of 7.19 should be considered for seismic design at the project site.

#### 7.0 DESIGN RECOMMENDATIONS

#### 7.1 General Evaluation

Based on the results of our literature review, subsurface exploration, laboratory testing, geotechnical analyses, and understanding of the planned site improvements, it is our opinion that the proposed project is feasible from a geotechnical standpoint, provided the following conclusions and recommendations are incorporated into the project plans, specifications, and are followed during site construction. The following geotechnical findings should be considered for the planned projects:

- Groundwater was not encountered in our exploratory borings to a maximum depth of 51.5 feet. Groundwater is not anticipated during construction and will not need to be considered in design.
- It is our opinion that the proposed structures can be supported on conventional shallow foundations embedded into compacted fill.
- Due to existing surficial undocumented fill, we recommend over-excavation and re-compaction to be at least 5-feet from the existing ground surface, or 2-feet below bottom of footings, whichever is deeper at the structure area. Lateral overexcavation limits should extend at least 5 feet beyond edge of footings, where the space is available. For pavement and flatwork area, we recommend 2 feet over-excavation and re-compaction.
- Laboratory testing indicates the site soils have a high expansion potential.
   Mitigation measures for expansive soil are anticipated. We recommend that two
   feet of suitable, non-expansive, sandy import materials approved by Converse be
   placed under planned footings and slabs.
- The on-site soil is not considered corrosive to concrete. However, the minimum saturated resistivity testing result indicates the onsite soil is considered corrosive to ferrous metal. Protections of underground metal pipe should be considered.
- Soil can be excavated with conventional heavy-duty earthmoving equipments.
- Based on our field exploration, surficial clayey soils encountered up to 40 feet deep are not considered effective for planned infiltration systems. Sandy soils encountered below the clayey soil layers are relatively dense and also might not be conducive to good percolation rates. It is recommended that a specific percolation testing program be performed for any planned infiltration system to determine percolation rates at specific depths.

#### 7.2 Shallow Foundations

# 7.2.1 Vertical Capacity

We recommend the bottoms of continuous and square footings be founded at least 18 inches below lowest adjacent final grade on compacted fills. A minimum footing width of 24 inches is recommended for square footings and 15 inches for continuous footings. The allowable bearing value for footings with above minimum sizes is 2,000 psf for dead plus live load. The net allowable bearing pressure can be increase by 150 psf for each additional foot of excavation depth and by 150 psf for each additional foot of excavation width up to a maximum value of 3,000 psf.

The net allowable bearing values indicated above are for the dead loads and frequently applied live loads and are obtained by applying a factor of safety of 3.0 to the net ultimate bearing capacity.

#### 7.2.2 Lateral Capacity

Resistance to lateral loads can be provided by friction acting at the base of the foundation and by passive earth pressure. A coefficient of friction of 0.3 may be assumed with normal dead load forces. An allowable passive earth pressure of 300 psf per foot of depth up to a maximum of 3,000 psf may be used for footings poured against properly compacted fill. The values of coefficient of friction and allowable passive earth pressure include a factor of safety of 1.5.

#### 7.2.3 Settlement

The static settlement of structures supported on continuous and/or spread footings founded on compacted fill will depend on the actual footing dimensions and the imposed vertical loads. Most of the footing settlement at the project site is expected to occur immediately after the application of the load. Based on the maximum allowable net bearing pressures presented above, static settlement is anticipated to be less than 0.5 inch. Differential settlement is expected to be up to one-half of the total settlement over a 30-foot span.

#### 7.2.4 Dynamic Increases

Bearing values indicated above are for total dead load and frequently applied live loads. The above vertical bearing may be increased by 33% for short durations of loading which will include the effect of wind or seismic forces. The allowable passive pressure may be increased by 33% for lateral loading due to wind or seismic forces.

# 7.3 Slabs-on-grade

Slabs-on-grade should be supported on compacted fill and have a minimum thickness of four inches nominal for support of normal ground-floor live loads. Minimum reinforcement for slabs-on-grade should be No. 3 reinforcing bars, spaced at 18 inches on-center each way. The thickness and reinforcement of more heavily-loaded slabs will be dependent upon the anticipated loads and should be designed by a structural engineer. A static modulus of subgrade reaction equal to 150 pounds per square inch per inch may be used in structural design of concrete slabs-on-grade.

It is critical that the exposed subgrade soils should not be allowed to desiccate prior to the slab pour. Care should be taken during concrete placement to avoid slab curling. Slabs should be designed and constructed as promulgated by the ACI and Portland Cement Association (PCA). Prior to the slab pour, all utility trenches should be properly backfilled and compacted.

In areas where a moisture-sensitive floor covering (such as vinyl tile or carpet) is used, a 10-mil-thick moisture retarder/barrier between the bottom of slab and subgrade that meets the performance criteria of ASTM E 1745 Class A material. Retarder/barrier sheets should be overlapped a minimum of six inches, and should be taped or otherwise sealed per the product specifications.

# 7.4 Earth Pressures for Retaining Structures

The following design values can be used for the retaining walls, if proposed. The earth pressure behind any retaining wall depends primarily on the allowable wall movement, type of soil behind the wall, backfill slopes, wall inclination, surcharges, and any hydrostatic pressure. The following earth pressures are recommended for vertical walls with no hydrostatic pressure.

Table No. 2, Lateral Earth Pressures for Retaining Wall Design

Backfill Slope (H:V)	Cantilever Wall Equivalent Fluid Pressure (pcf)	Restrained Wall (psf)
Level	30 (triangular pressure distribution)	23H (uniform pressure distribution)

The recommended lateral pressures assume that the walls are fully back-drained to prevent build-up of hydrostatic pressure. Adequate drainage could be provided by means of permeable drainage materials wrapped in filter fabric installed behind the walls. The drainage system should consist of perforated pipe surrounded by a minimum one (1) square feet per lineal feet of free draining, uniformly graded, ¾ -inch washed, crushed aggregate, and wrapped in filter fabric such as Mirafi 140N or equivalent. The

filter fabric should overlap approximately 12 inches or more at the joints. The subdrain pipe should consist of perforated, four-inch diameter, rigid ABS (SDR-35) or PVC A-2000, or equivalent, with perforations placed down. Alternatively, a prefabricated drainage composite system such as the Miradrain G100N or equivalent can be used. The subdrain should be connected to solid pipe outlets, with a maximum outlet spacing of 100 feet.

Walls subjected to surcharge loads located within a distance equal to the height of the wall should be designed for an additional uniform lateral pressure equal to one-third or one-half the anticipated surcharge load for unrestrained or restrained walls, respectively. These values are applicable for backfill placed between the wall stem and an imaginary plane rising 45 degrees from below the edge (heel) of the wall footings.

Retaining walls greater than 12 feet should be designed to resist additional earth pressure caused by seismic ground shaking. A seismic earth pressure of 16H (psf), based on an inverted triangular distribution, can be used for design of wall.

#### 7.5 Soil Corrosivity Evaluation

Based on our review of soil corrosivity test results (see Appendix B), the pH and chloride content are not in the corrosive range to ferrous metal. The soluble sulfate concentration is not in the corrosive range to concrete. However the minimum saturated resistivity is in the corrosive range to ferrous metal. Protections of underground metal pipe should be considered.

A corrosion engineer may be consulted for appropriate mitigation procedures and construction design, if needed. General considerations for corrosion mitigation measures may include the following:

- Steel and wire concrete reinforcement should have at least three inches of concrete cover where cast against soil, unformed.
- Below-grade ferrous metals should be given a high-quality protective coating, such as 18-mil plastic tape, extruded polyethylene, coal-tar enamel, or Portland cement mortar.
- Below-grade metals should be electrically insulated (isolated) from above-grade metals by means of dielectric fittings in ferrous utilities and/or exposed metal structures breaking grade.

#### 7.6 Percolation Testing

Percolation testing was not part of the initial scope for this investigation. However, based on the findings of our field exploration, we recommend that a specific percolation

testing program be performed for any planned infiltration systems in layers of permeable soils to determine definite percolation rates at the desired depths for infiltration system design.

# 7.7 Site Drainage

Adequate positive drainage should be provided away from the structure foundations to prevent ponding and to reduce percolation of water into the foundation soils. We recommend that any landscape areas immediately adjacent to the foundation shall be designed sloped away from the foundation with a minimum 2 percent slope gradient for at least 10 feet measured perpendicular to the face of the foundation. Impervious surfaces within 10 feet of the structure foundation shall be sloped a minimum of 1 percent away from the structure.

#### 8.0 SITE GRADING AND EARTHWORK RECOMMENDATIONS

#### 8.1 General

Based on our review of soil boring and laboratory data, the upper five (5) feet of soils consisting of undocumented fills and loose to moderately dense native alluvial soils should be removed and recompacted to provide sufficient lateral resistance and a relatively uniform soil condition for the footings and slab. To help reduce the potential for differential settlement, variations in the soil type, degree of compaction, and thickness of the compacted fill placed underneath slab and/or footings should be kept uniform. Site grading recommendations provided in this report are based on our experience with similar projects in the area and our site-specific geotechnical evaluation.

The existing soils removed during over-excavation can be placed as compacted fill in structural areas after proper processing (free of vegetation, shrubs, roots and debris). Earthwork should be performed with suitable equipment and techniques to selectively screen/remove debris from soils placed as engineered fill. Following remedial grading, compacted fill soils are anticipated to have similar engineering characteristics with the underlying dense alluvial soils.

#### 8.2 Over-Excavation/Removal

For infiltration galleries, we recommend over-excavation be at least five (5) feet below existing grade, or two (2) foot below bottom of footing, or to the depth of undocumented fill, whichever is deeper for slab and foundation support. Deeper removal will be needed if firm soil conditions are not exposed on the excavation bottom. The lateral limits of the over-excavation should extend at least five (5) feet beyond the footing and slab areas, where space is available.

For pavement and concrete flatwork, we recommend over-excavation be at least two (2) feet below existing grade and two (2) feet laterally beyond the footprints, where space is available.

The exposed bottom of the over-excavation area should be scarified at least six (6) inches; moisture conditioned as needed to near-optimum moisture content, and compacted to 90 percent relative compaction. Over-excavation should not undermine adjacent off-site improvements. Remedial grading should not extend within a projected 1:1 (horizontal to vertical) plane projected down from the outer edge of adjacent off-site improvements.

If loose, yielding soil conditions are encountered at the excavation bottom, the following options can be considered:

- a. Over-excavate until reach firm bottom.
- b. Scarify or over-excavate additional 18 inches deep, and then place at least 18-inch-thick compacted base material (CAB or equivalent) to bridge the soft bottom. Base should be compacted to 90% relative compaction.
- c. Over-excavate additional 18 inches deep, and then place a layer of geofabric (i.e. Marifi HP570, X600 or equivalent), place 18-inch-thick compacted base material (CAB or equivalent) to bridge the soft bottom. Base should be compacted to 90% relative compaction. An additional layer of Geo-Fabric may be needed on top of base depending on the actual site conditions.

#### 8.3 Engineered Fill

All engineered fill should be placed on competent, scarified and compacted bottom as evaluated by the geotechnical engineer and in accordance with the recommendations presented in this section. Excavated site soils, free of deleterious materials and rock particles larger than three (3) inches in the largest dimension, should be suitable for placement as compacted fill. Any proposed import fill should be evaluated and approved by Converse prior to import to the site. Import fill material should have an expansion index less than 20.

Prior to compaction, fill materials should be thoroughly mixed and moisture conditioned within three (3) percent above the optimum moisture content. Fill soils shall be evenly spread in maximum 8-inch lifts, watered or dried as necessary, mixed and compacted to at least the density specified below. The fill shall be placed and compacted on a horizontal plane, unless otherwise approved by the Geotechnical Engineer. Upper 12 inches below pavement subgrade should be compacted to at least 95 percent of the laboratory dry density in accordance with the ASTM Standard D1557 test method. All fill, if not specified otherwise elsewhere in this report, should be compacted to at least

90 percent of the laboratory dry density in accordance with the ASTM Standard D1557 test method.

#### 8.4 Excavatability

Based on our field exploration, the earth materials at the site may be excavated with conventional heavy-duty earth moving and trenching equipment. The onsite materials will contain demolition debris, gravel, cobbles and/or boulders. Earthwork should be performed with suitable equipment and methods for removal of debris from the engineered fill.

#### 8.5 Expansive Soil

The near surface soils have a "High" expansive potential. Mitigation measures for expansive soil are anticipated. We recommend that two (2) feet of suitable, non-expansive, sandy import materials approved by Converse be placed under planned footings and slabs.

#### 8.6 Shrinkage and Subsidence

Soil shrinkage and/or bulking as a result of remedial grading depends on several factors including the depth of over-excavation, and the grading method and equipment utilized, and average relative compaction. For preliminary estimation, bulking and shrinkage factors for various units of earth material at the site may be taken as presented below:

- The approximate shrinkage factor for the undocumented fill soils is estimated to range from ten (10) to fifteen (15) percent.
- The approximate shrinkage factor for the native alluvial soils is estimated to range from ten (10) to fifteen (15) percent.
- For estimation purposes, ground subsidence may be taken as 0.1 feet as a result of remedial grading.

Although these values are only approximate, they represent our best estimates of the factors to be used to calculate lost volume that may occur during grading. If more accurate shrinkage and subsidence factors are needed, it is recommended that field-testing using the actual equipment and grading techniques be conducted.

#### 9.0 CONSTRUCTION CONSIDERATIONS

# 9.1 Temporary Excavations

Based on the materials encountered in the exploratory borings, sloped temporary excavations may be constructed according to the slope ratios presented in the following table:

Table No. 3, Slope Ratios for Temporary Excavation

Maximum Depth of Cut (feet)	Maximum Slope Ratio* (horizontal: vertical)
0 – 4	vertical
4 – 8	1:1
>8	1.5:1

<sup>\*</sup>Slope ratio assumed to be uniform from top to toe of slope.

Any loose utility trench backfill or other fill encountered in excavations will be less stable than the native soils. Temporary cuts encountering loose fill or loose dry sand should be constructed at a flatter gradient than presented in the table above. Surfaces exposed in slope excavations should be kept moist but not saturated to minimize raveling and sloughing during construction. Adequate provisions should be made to protect the slopes from erosion during periods of rainfall. Surcharge loads, including construction, should not be placed within five (5) feet of the unsupported excavation edge. Temporary excavations less than six (6) feet vertical may be proceeded with "A-B-C" slot cut method. The width of each slot should be less than eight (8) feet.

All applicable requirements of the California Construction and General Industry Safety Orders, the Occupational Safety and Health Act of 1987 and current amendments, and the Construction Safety Act should be met. The soils exposed in cuts should be observed during excavation by the project's geotechnical consultant. If potentially unstable soil conditions are encountered, modifications of slope ratios for temporary cuts may be required.

# 9.2 Geotechnical Services during Construction

This report has been prepared to aid in the foundation plans and specifications, and to assist the architect, civil and structural engineers in the design of the proposed structures. It is recommended that this office be provided an opportunity to review final design drawings and specifications to verify that the recommendations of this report have been properly implemented.

Recommendations presented herein are based upon the assumption that adequate earthwork monitoring will be provided by Converse. Footing excavations should be observed by Converse prior to placement of steel and concrete so that footings are founded on satisfactory materials and excavations are free of loose and disturbed materials. Trench backfill should be placed and compacted with observation and field density testing provided by this office.

During construction, the geotechnical engineer and/or their authorized representatives should be present at the site to provide a source of advice to the client regarding the geotechnical aspects of the project and to observe and test the earthwork performed. Their presence should not be construed as an acceptance of responsibility for the performance of the completed work, since it is the sole responsibility of the contractor performing the work to ensure that it complies with all applicable plans, specifications, ordinances, etc.

This firm does not practice or consult in the field of safety engineering. We do not direct the contractor's operations, and cannot be responsible for other than our own personnel on the site; therefore, the safety of others is the responsibility of the contractor. The contractor should notify the owner if he considers any recommended actions presented herein to be unsafe.

#### 10.0 CLOSURE

The findings and recommendations of this report were prepared in accordance with generally accepted professional engineering and engineering geologic principles and practice. We make no other warranty, either expressed or implied. Our conclusions and recommendations are based on the results of the field and laboratory studies, combined with an interpolation and extrapolation of soil conditions between and beyond boring locations. If conditions encountered during construction appear to be different from those shown by the borings, this office should be notified.

Design recommendations given in this report are based on the assumption that the earthwork and site grading recommendations contained in this report are implemented. Additional consultation may be prudent to interpret Converse's findings for contractors, or to possibly refine these recommendations based upon the review of the final site grading and actual site conditions encountered during construction. If the scope of the project changes, if project completion is to be delayed, or if the report is to be used for another purpose, this office should be consulted.

This report was prepared for Carollo Engineers, Inc. for the subject project described herein. We are not responsible for technical interpretations made by others of our exploratory information. Specific questions or interpretations concerning our findings and conclusions may require a written clarification to avoid future misunderstandings.

# APPENDIX A FIELD EXPLORATION

#### **APPENDIX A**

#### FIELD EXPLORATION

Field exploration included a site reconnaissance and subsurface exploration program. During the site reconnaissance, the surface conditions were noted, and the approximate locations of the boring were determined. The exploratory borings were approximately located using existing boundary and other features as a guide and should be considered accurate only to the degree implied by the method used. The various field study methods performed are discussed below.

#### **Exploratory Borings**

Three (3) exploratory borings (BH-1 through BH-3) were drilled within the project site on September 3, 2013. The borings were advanced using a truck mounted 8-inch diameter hollow stem auger drill rig to depths of 51.5 feet below the existing ground surface (bgs). Encountered earth materials were continuously logged by a Converse professional staff and classified in the field by visual examination in accordance with the Unified Soil Classification System (USCS). Where appropriate, field descriptions and classifications have been modified to reflect laboratory test results.

Ring samples of the subsurface materials were obtained at frequent intervals in the exploratory borings using a drive sampler (2.4-inches inside diameter and 3.0-inches outside diameter) lined with sample rings. The steel ring sampler was driven into the bottom of the borehole with successive drops of a 140-pound driving weight falling 30 inches, using an automatic hammer. Samples are retained in brass rings (2.4-inches inside diameter and 1.0-inch in height). The central portion of the sample was retained and carefully sealed in waterproof plastic containers for shipment to the Converse laboratory. Blow counts for each sample interval are presented on the logs of borings. Bulk samples of typical soil types were also obtained.

Standard Penetration Tests (SPTs) were performed in selected borings at selected intervals using a standard (1.4 inches inside diameter and 2.0 inches outside diameter) split-barrel sampler. The bore holes were backfilled and compacted with soil cuttings by reverse spinning of the auger following the completion of drilling and patched with asphalt.

It should be noted that the exact depths at which material changes occur cannot always be established accurately. Changes in material conditions that occur between driven samples are indicated in the logs at the top of the next drive sample. A key to soil symbols and terms is presented as Drawing No. A-1, *Soil Classification Chart*. The log of the exploratory boring is presented in Drawing Nos. A-2a through A-4b, *Log of Borings*.

# APPENDIX B LABORATORY TESTING PROGRAM

Geotechnical Study Report Torrance Airport Infiltration Galleries Project 3301 Airport Drive Torrance, California September 27, 2013 Page B-1

#### **APPENDIX B**

#### LABORATORY TESTING PROGRAM

Tests were conducted in our laboratory on representative soil samples for the purpose of classification and evaluation of their relevant physical characteristics and engineering properties. The amount and selection of tests were based on the geotechnical requirements of the project. Test results are presented herein and on the Logs of Borings in Appendix A, *Field Exploration*. The following is a summary of the laboratory tests conducted for this project.

#### **Moisture Content and Dry Density**

Results of moisture content and dry density tests, performed on relatively undisturbed ring samples were used to aid in the classification of the soils and to provide quantitative measure of the *in situ* dry density. Data obtained from this test provides qualitative information on strength and compressibility characteristics of site soils. For test results, see the Logs of Borings in Appendix A, *Field Exploration*.

#### Percent Finer than Sieve No. 200

The percent finer than sieve No. 200 tests were performed on four (4) representative soil samples to aid in the classification of the on-site soils and to estimate other engineering parameters. Testing was performed in general accordance with the ASTM Standard D1140 test method. Test results are presented in the Logs of Borings in Appendix A, *Field Exploration*.

#### **Atterberg Limits**

Atterberg limits test were performed on three (3) representative samples to assist the classification of the soil and fill materials according to ASTM Standard D4318 test method. The test results are presented in the following table and on Drawing No. B-1, *Atterburg Limits Results*.

Table No. B-1 Atterberg Limit Test Results

Boring No.	Depth (feet)	Soil Classification	Liquid Limit (%)	Plastic Limit (%)	Plastic Index (%)
BH-2	10	Fat Clay (CH)	63	20	43
BH-2	20	Clay (CL)	49	15	34
BH-2	30	Fat Clay (CH)	60	19	41

#### **Maximum Density Test**

One (1) representative bulk sample was tested in the laboratory to determine the maximum dry density and optimum moisture content. The tests were conducted in accordance with the ASTM Standard D1557 laboratory procedure. The test results are presented in Drawing No. B-2, *Moisture-Density Relationship Results*.

#### **Direct Shear**

Direct shear tests were performed on one (1) sample remolded to 90% relative compaction. For each test, three brass sampler rings were placed, one at a time, directly into the test apparatus and subjected to a range of normal loads appropriate for the anticipated conditions. The sample was then sheared at a constant strain rate of 0.01 inch/minute. Shear deformation was recorded until a maximum of about 0.25-inch shear displacement was achieved. Ultimate strength was selected from the shear-stress deformation data and plotted to determine the shear strength parameters. For test data, including sample density and moisture content, see Drawing No. B-2, *Direct Shear Test Results*.

Table No. B-2, Direct Shear Test Results

Daring No.	Depth	· I SOULLISESTICATION -		Ultimate Strength Parameters		
Boring No.	(feet)	Son Classification	Friction Angle (degrees)	Cohesion (psf)		
BH-2	0 – 5*	Sandy Clay (CL)	31	450		

Note: Sample remolded to 90% relative compaction

#### Consolidation

Consolidation test was performed on one (1) relatively undisturbed in-situ sample. Data obtained from this test procedure was used to evaluate the settlement characteristics of the foundation soils under load. Preparation for this test involved trimming the sample and placing the one-inch high brass ring into the test apparatus, which contained porous stones, both top and bottom, to accommodate drainage during testing. Normal axial loads were applied to one end of the sample through the porous stones, and the resulting deflections were recorded at various time periods. The load was increased after the sample reached a reasonable state equilibrium. Normal loads were applied at a constant load-increment ratio, successive loads being generally twice the preceding load. The sample was tested at field and submerged conditions. The test results, including sample density and moisture content, are presented in Drawing No. B-4, *Consolidation Test Results*.

#### **Expansion Index**

One (1) representative bulk samples were tested to evaluate the expansion potential of material encountered at the site. The test results are presented in the following table:

Table No. B-3, Expansion Index Test Results

Sample Locatio n	Depth (ft)	Soil Description	Expansion Index	Expansion Potential
BH-1	0-5	Sandy Clay (CL)	94	High

#### **Soil Corrosivity**

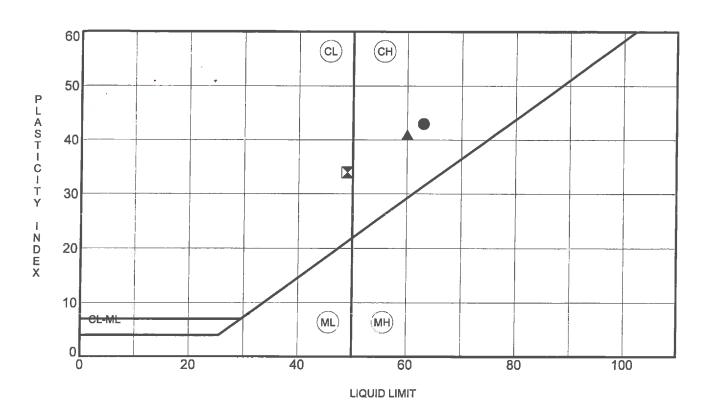

One (1) representative soil samples were tested to evaluate minimum electrical resistivity, pH, and chemical content, including soluble sulfate and chloride concentrations. The purpose of these tests is to determine the corrosion potential of site soils when placed in contact with common construction materials. These tests were performed by Environmental Geotechnology Laboratory, Inc. (EGL), located in Arcadia, California. The test results received from EGL are included in the following table:

Table No. B-4, Corrosivity Test Results

Boring No.	Sample Depth (feet)	pH (Caltrans 643)	Soluble Chlorides (Caltrans 422) ppm	Soluble Sulfate (Caltrans 417) (%)	Saturated Resistivity (Caltrans 643) Ohm-cm
BH-3	0 – 5	7.75	120	0.034	540

#### **Sample Storage**

Soil samples presently stored in our laboratory will be discarded 30 days after the date of this report, unless this office receives a specific request to retain the samples for a longer period.

#### **APPENDIX G – CATCH BASIN FILTER INFORMATION**

820 Brevard Avenue • Rockledge, Florida 32955 (321) 638-0808 Fax (321) 638-0978

November 7, 2007

Mr. Henry Happel Suntree Technologies 798 Clearlake Road, Suite 2 Cocoa, FL 32922

Re:

Suspended Soils Retention Testing for

Suntree Curb Inlet Basket and Grate Inlet Skimmer Box

Rockledge, FL

Universal Project No. 34184-004-01

Docs No. 622763

Dear Mr. Happel:

As requested, we have performed testing of a curb inlet and a skimmer box of your design at our laboratory in Rockledge, Florida. The purpose of the test was to determine the percentage of 100 micron grain size particles of OK90 sand that would be retained in the baskets of the devices following a 3 minute wash through the devices.

To perform the test, we recorded certain amounts of dry OK90 sand and washed it though each of the devices using an electric pump with a flow of approximately 1200 gallons per hour for 3 minutes. The sand that passed through the baskets and was retained on the reservoir was then dried and weighed. The percentage of sand that has a grain size larger than 100 microns was determined from the attached sieve analyses and used to calculate the removal efficiencies.

Based on the results of the testing, the Suntree Curb Inlet Basket had a removal efficiency of 93 percent for particle sizes of 100 microns or greater.

Based on the results of the testing, the Suntree Grate Inlet Skimmer Box had a removal efficiency of 86 percent for particle sizes of 100 microns or greater.

We trust that this information is sufficient. Please call if you need any further information.

Sincerely,

Universal Engineering Sciences, Inc.

Richard E. Hoaglin, P.E.

Branch Manager FL Reg. no. 48796

# SITE EVALUATION OF SUNTREE TECHNOLOGIES, INC. GRATE INLET SKIMMER BOXES FOR DEBRIS, SEDIMENT, AND OIL & GREASE REMOVAL

Reedy Creek Improvement District Planning & Engineering Department Eddie Snell, Compliance Specialist

Stormwater is now recognized as the leading source of pollution to our remaining natural water bodies in the United States. Development and urbanization have removed most of the natural filtration and sediment trapping systems provided by the environment. Current development must address this need through the implementation of stormwater treatments systems in the project design. Most of these systems perform reasonably well, if properly designed, constructed, and maintained.

Retrofit of older urban areas lacking these modern stormwater systems is a continually expensive challenge. The Downtown Disney complex, formerly the Lake Buena Vista Shopping Village, has several drainage basins with 1970's stormwater systems. These older systems discharge directly into the adjacent drainage canal with no pollutant treatment. Over time the accumulation of sediments, nutrients, intensive development, and recreational/entertainment pressures are contributing to water quality degradation.

Whenever new development or redevelopment occurs, the stormwater system is brought to current code/permit requirements. In the interim, several areas are in need for rapid, effective, and economical improvement in the quality of its stormwater discharge.

Suntree Technologies Incorporated, located in Cape Canaveral, FL, manufactures stormwater grate inlet skimmer boxes. They are made of a high quality fiberglass frame, with stainless steel filter screens backed by heavy-duty aluminum grating. Each unit is custom made to accommodate various inlet sizes. A hydrocarbon absorption boom is attached to the top of the skimmer box for petroleum, oil, and grease removal.

These devices fit below the grate and catch sediment, debris, and petroleums, oils & greases. Clean-out, maintenance, and performance reporting is provided by Suntree on a scheduled basis.

#### Picture of Grate Inlet Skimmer Box

The Reedy Creek Improvement District (RCID) selected six (6) test sites in the Lake Buena Vista area to evaluate the performance of these units. One unit was placed in a curb inlet along Hotel Plaza Boulevard to trap landscape leaf litter, sediment, and oil & grease from a high use roadway. Three (3) units were placed in the backstage service area of the Rain Forest Cafe. Two (2) units were placed in the backstage service area of the McDonald's restaurant and Legos merchandise shop.

After several field meetings, during which Suntree took extensive measurements, photos, and other documentation of each stormwater drain, the Grate Inlet Skimmer Boxes were manufactured and delivered for installation. All units were installed without mishap approximately two weeks before the 1999 Christmas holiday season. The target time period for particle catchment was one month. Mr. Henry and Tom Happel, Suntree Technologies, visited each site several times during the month to ensure that debris would not fill the units too soon.

On January 25,2000, Suntree serviced the six units. At each site, the material captured in the skimmer boxes was removed, measured, weighed, visually identified, photographed, and recorded. Some units were slightly field modified for optimum performance. All

units performed as expected removing, on average, 20 pounds of debris from each of the six sites. The composition of debris varied considerably.

The Hotel Plaza (roadway) site was 90% leaf litter and 10% sediment. The Rain Forest Cafe sites ran in opposition as you got close to the lake. First inlet was about 50% leaf litter and cigarette butts and 50% sediment. The middle inlet was 60 % sediment and 30 % leaf litter (10% miscellaneous). The inlet closest to the lake was 95% sediment and 5% leaf litter. The two sites at the McDonalds/Legos area were similar to each other. The site closest to the lake was 95% sediment and 5% leaf litter. The site closest to the entrance gate was 98% litter sediment and 2% leaf litter.

This composition is indicative of the human activities and drainage flow patterns of that site. Backstage areas in the Walt Disney World Resort receive an artificial rain event each night during cleaning operations. This washes a continual flow over the impervious site, washing all materials into the stormwater system.

Municipalities in Brevard, Volusia and Dade counties have successfully used inlet skimmers in Florida. RCID partnered with Walt Disney Imagineering (WDI) Research and Development to coordinate some basic chemical sampling for pollutant removal efficiency determination. Mr. Craig Duxbury, WDI, provided technical support and guidance for this. An ingeniously simple device was fabricated by Suntree to allow sampling of the First Flush of water going into the units and ultimately coming out of the skimmer boxes.

Collected samples were processed and analyzed by the RCID Environmental Services Laboratory. Analysis parameter were: Ammonia, Chemical Oxygen Demand, Fecal Coliform (MPN), Nitrite and Nitrate, Total Kjeldahl Nitrogen, Oil and Grease, Total Phosphate, Suspended Solids, and Metals.

Analysis results are presented in the following table:

						Pollutant	%
ANALYSIS	LOCATION	LAB NO.	VALUE	CNITS	SAM-DATE	Change	Chanae
Ammonia, Salicylate	RF-IN	1646	0.38	mg/l	09-Feb-00	0.14	37%
Ammonia, Salicylate	RF-OUT	1646	0.23	mg/l	09-Feb-00		
Ammonla, Salicylate	RF-OUT-	1646	0.25	light.	09-Feb-00		
Chemical Oxygen Demand	RF-IN	1646	2670	mg/	09-Feb-00	1035	
Chemical Oxygen Demand	RF-OUT	1646	1780	∏g⁄⊔	09-Feb-00		
Chemical Oxygen Demand	RF-OUT-I	1646	1490	∥gш	09-Feb-00		
Coliform, Fecal MPN	RF-IN	1646	1600	稚	09-Feb-00	-93400	
Coliform, Fecal MPN	RF-OUT	1646	160,000		09-Feb-00		
Coliform, Fecal MPN	RF-OUT-I	1646	30,000		09-Feb-00		
Nitrate and Nitrite	RF-IN	1646	90.0	₩g/l	09-Feb-00	0.035	
Nitrate and Nitrite	RF-OUT	1646	0.04	Mg/l	09-Feb-00		
Nitrate and Nitrite	RF-OUT-	1646	0.01	mg/l	09-Feb-00		
Nitrogen, Total Kjeldahl	RF-IN	1646	24.3	mg/f	09-Feb-00	13.55	
Nitrogen, Total Kjeldahi	RF-OUT	1646	10.4	mg/l	09-Feb-00		
Nitrogen, Total Kjeldahl	RF-OUT-I	1646	4.1	₽åш	09-Feb-00		
Oil and Grease	RF-IN	1646	526	₩	09-Feb-00	283	

Pollutant removal efficiencies averaged about 50% for all parameters tested. The minimal removal was 37% for Anmonia and the maximum removal was 74% for Suspended Solids.

Coliform bacteria were not effectively removed by the skimmer boxes, although, they are not designed to provide water disinfection. Oil and Grease are a food source for bacteria and reduction of this pollutant should provide some effect on bacterial numbers.

Curb Inlet Basket and Grate Inlet Skimmer Box

Universal Project No. 34184-004-01

Dear Mr. Happel:

Universal Engineering Sciences, Inc. (Universal) is pleased to submit this letter report to Suntree Technologies, Inc. including laboratory analysis and photo documentation of the testing procedures used, as described below.

### SCOPE OF WORK

Universal measured the percentage (by dry weight) of OK-90 calibrated sand provided by the client that was retained in the Curb Inlet Basket and Grate Inlet Skimmer Box. In addition, gradation analyses were performed on the OK-90 sand before it was used in the testing beds and again after it had been used in the testing beds, on both the portions of sand retained in the skimmer box and curb basket, and the portions of sand that passed through the skimmer box and curb basket.

### DESCRIPTION OF TESTING APPARATUS

On November 6, 2007 Suntree Technologies arrived at the Universal branch office located at 820 Brevard Avenue in Rockledge, FL with the Curb Inlet Basket test bed and Grate Inlet Skimmer Box test bed, as shown in **APPENDIX B**. Two 100 pound bags of U.S. Silica OK-90 Unground Silica Sand were previously delivered to the Universal laboratory in preparation for the Suspended Solids Testing.

### Grate Inlet Skimmer Box

The Grate Inlet Skimmer Box test bed consisted of a two-tiered formed fiberglass table and water pumping apparatus designed to simulate a standard storm water catch basin

that would typically be found in a parking lot. The dimensions of the Grate Inlet Skimmer Box test bed are approximately 64" by 45". The top tier is ringed with a 1-inch diameter PVC tube, perforated so as to form water jets at 2 inch intervals once pressurized water is pumped into the tubes. The surface of the top tier is sloped towards the center of the table so that water from the jets will flow towards the center of the top tier, where a 36" by 27" rectangular opening has been cut into the surface. The Grate Inlet Skimmer Box is placed into the opening. Water and/or debris are washed into the Skimmer Box. Debris is retained on the mesh sieves that line the bottom and sides of the Skimmer Box, while water drains freely through the sieves.

Once the water has passed through the Skimmer Box apparatus, it collects in the bottom tier of the table. The bottom tier is separated into two areas by a wall with large openings in it which allows water to pass freely between the two areas. The larger area acts as a reservoir for the recirculation pumps, which are located in the smaller area. A screen has been placed along the face of the wall to prevent debris which has passed through the Skimmer Box and into the reservoir from entering the pump intake area. The recirculation pumps supply water to the PVC tubes located on the top tier.

#### **Curb Inlet Basket**

The Curb Inlet Basket test bed consisted of a basin approximately 48" by 48" and approximately 36" deep. A shelf is located along one side of the basin approximately 15" wide that runs the length of the basin approximately two inches below the top edge of the basin (see photos in **APPENIDX B**). A one-inch diameter PVC tube similar to the one used for the Skimmer Box test bed runs the length of the shelf and is supplied by a single pump located in the reservoir of the test bed. Similarly to the Skimmer Box test bed, the Curb Inlet test bed has a reservoir divided by a wall with screened opening. The Curb Inlet Basket has two hooks on it which are hung through slots that have been cut into the edge of the shelf, which allows the shelf to simulate a standard "D.O.T. Type F" curb. The Basket is hung so that water flows off of the shelf and into the Basket (see photos in **APPENIDX B**).

### OK-90 Unground Silica Sand

Two 100 pound bags of US Silica OK-90 sand were provided by Suntree Technologies to use for suspended solids testing. A gradation analysis (AASHTO T-88) was performed at the Universal office on a representative sample of each bag of the OK-90 sand provided by the client to determine the percentage of OK-90 sand that has a grain size larger than 100 microns for future calculations. The results of the sieve analysis are presented in **APPENDIX A** along with the sieve analysis provided by the manufacturer.

Approximately 60 pounds of the OK-90 sand obtained from Bag 1 was thoroughly mixed and air dried in preparation for the suspended solids testing.

### SKIMMER BOX TESTING PROCEDURE

The testing bed reservoir was filled with water and the pump system was turned on to begin water circulation. Additional water was added to maintain a water level in the reservoir approximately 1.5 inches below the bottom of the Skimmer Box (see photos in **APPENDIX B**).

The Skimmer Box was removed and weighed wet to establish the container weight.

The Skimmer Box was placed back into the testing bed and a bead of RTV (Room Temperature Vulcanizing) silicon approximately ¼-inch wide was applied around the edge of the Skimmer Box to ensure a positive seal between the edge of the Skimmer Box and the test bed (for testing purposes only), preventing any sand from bypassing the Skimmer Box and washing directly into the reservoir (see photos in **APPENDIX B**). The silicon was then allowed to cure for approximately one hour before testing.

A 546 gram sample of the OK-90 sand was taken for moisture content determination (ASTM-D 2216), then a 25.09 pound (wet weight) sample of OK-90 sand was placed around the Skimmer Box in the top of the test bed over a period of six minutes, while the water jets washed the sand into the Skimmer Box, which resulted in a suspended solids introduction rate of approximately 4.2 pounds of sand per minute (see photos in **APPENDIX B**).

The pumps remained on and water was circulated through the test bed for a period of three minutes, washing all of the sand into the Skimmer Box (see photos in **APPENDIX B**).

The pumps were turned off and the Skimmer Box was removed and weighed wet again, with the sand retained inside.

20.88 pounds (dry weight) of the original 24.99 pound (dry weight) sample of sand was retained in the Skimmer Box. A grain size analysis sample was taken from the sand retained inside the Skimmer Box to determine the retained weight of OK-90 sand that was greater than 100 microns in diameter. The results of this test are presented in **APPENDIX A**.

The reservoir in the lower tier of the test bed was carefully drained, so that only a small amount of water and all of the sand that passed through the Skimmer Box was left in the bottom tier of the test bed. The sand that passed through the Skimmer Box was then washed into a container and a grain size analysis was performed on this sample (see photos in **APPENDIX B**). The results of this test are presented in **APPENDIX A**.

The laboratory worksheet results of the Suspended Solids Retention Testing for the Skimmer Box are presented in **APPENDIX A**.

### **CURB INLET TESTING PROCEDURE**

The testing bed reservoir was filled with water and the pump system was turned on to begin water circulation. Additional water was added to maintain a water level in the reservoir approximately 1.5 inches below the bottom of the Curb Inlet (see photos in **APPENDIX B**).

The Curb Inlet was removed and weighed wet to establish the container weight.

A 12.77 pound (wet weight) sample of OK-90 sand was placed approximately midway along the length of the shelf of the Curb Inlet test bed over a period of three minutes, while the water jets washed the sand into the Curb Inlet, which resulted in a suspended solids introduction rate of approximately 4.3 pounds of sand per minute (see photos in **APPENDIX B**).

The pump remained on and water was circulated through the test bed for a period of three minutes, washing all of the sand into the Curb Inlet (see photos in **APPENDIX B**).

The pump was turned off and the Curb Inlet was removed and weighed wet again, with the sand retained inside.

11.70 pounds (dry weight) of the original 12.72 pound (dry weight) sample of sand was retained in the Curb Inlet. A grain size analysis sample was taken from the sand retained inside the Curb Inlet basket. The results of this test are presented in **APPENDIX A**.

The basin of the test bed was carefully drained, so that only a small amount of water and all of the sand that passed through the Curb Inlet was left in the bottom of the test bed. The sand that passed through the Curb Inlet was then washed into a container and a grain size analysis was performed on this sample to determine the retained weight of OK-90 sand that was greater than 100 microns in diameter (see photos in APPENDIX B). The results of this test are presented in APPENDIX A.

The laboratory worksheet results of the Suspended Solids Retention Testing for the Curb Inlet are presented in **APPENDIX A**.

### SUMMARY

The Grate Inlet Skimmer Box by Suntree Technologies, Inc. retained a minimum of 84% of the portion of OK-90 sand in suspension with an average grain size greater than 100 microns (.100 mm).

The Curb Inlet Basket by Suntree Technologies, Inc. retained a minimum of 93% of the portion of OK-90 sand in suspension with an average grain size greater than 100 microns (.100 mm).

Universal appreciates this opportunity to provide testing services to you, and looks forward to working with you on future projects. Please do not hesitate to contact us if you have questions or require any additional information.

Sincerely,

UNIVERSAL ENGINEERING SCIENCES, INC. Certificate of Authorization No. 549

# **Evaluation of the Performance of Four Catch Basin Inserts** in Delaware Urban Applications

Marianne Walch, Randall Cole and Wendy Polasko Delaware Department of Transportation NPDES Program P.O. Box 778, Dover, DE 19930

> Dwight Walters and William Frost KCI Technologies, Inc. Newark, DE 19713

Patrick DiNicola and Ron Gneo RK&K Consulting Engineers Baltimore, MD 21217

#### Introduction

Catch basin inserts are becoming more widely used as stormwater best management practices (BMPs). A variety of commercial devices are available. Most are designed to remove trash, sediments and hydrocarbons to varying degrees from stormwater runoff that enters the catch basins. They are a relatively easy and inexpensive retrofit, particularly for older, existing drainage systems where end-of-pipe treatment technologies may be impractical or prohibitively expensive. However, until recently, few catch basin insert filters have had performance data collected under actual field conditions.

The Delaware Department of Transportation (DelDOT) is investigating the performance of four different types of inlet protection devices in urbanized areas of northern Delaware. We are evaluating and comparing the performance of these inserts with respect to their ability to remove sediment and hydrocarbons from stormwater runoff, as well as their maintenance requirements in different applications. Monitoring will continue year-round over a two- to three-year period, in order to incorporate data from varying seasonal and rainfall conditions.

### **Methods**

The catch basin inserts being tested are

- 1. UltraDrainguard® Oil and Sediment Model (UltraTech International, Inc.) an X-TEX geotextile sock and skirt that fits the size of the inlet opening.
- 2. HydroKleen® (Hydro Compliance Management, Inc.) a two-chambered system consisting of a presettling sediment chamber and a filtration chamber containing one activated carbon and two cellulose filters.
- 3. DrainPac<sup>®</sup> (United Stormwater, Inc.) an HDPE support basket and polypropylene filter liner custom-sized to fit the inlet.
- 4. Flo-Gard+Plus<sup>®</sup> (Kristar Enterprises, Inc.) a support basket and removable polypropylene filter liner, plus a silicate oil-adsorbent filter medium in floatable bags.

The devices were installed in three different locations, with different land use types and varying pollutant loads. These include the service station drainage areas of a rest area on Interstate Rt. 95 near Newark; Drummond North, a residential subdivision in Newark; and a commercial parking area on the Wilmington Riverfront (Table 1). Photographs of each insert are included in Figure 1.

To determine the effectiveness of the catch basin inserts, we are comparing data from wet-weather samples collected at the outfalls of both protected and nearby unprotected (control) runs of inlets. Criteria for a qualifying storm event are a 72-hour dry period preceding and at least 0.1 inch of rainfall during the storm. First flush and flow-weighted composite stormwater samples are analyzed for the following water quality parameters: suspended and dissolved solids, pH, chemical and biological oxygen demand, nutrients, chloride, oil and grease, petroleum hydrocarbons, BTEX, phenolics, PAHs, heavy metals, and indicator bacteria. Only first flush samples are being collected for the Flo-Gard+Plus<sup>®</sup> inserts. In addition, we inspect all of the inserts on a regular basis; when cleaning or replacement occurs, the sediment and other solids collected in the filters are weighed, characterized as to content, and samples are taken for chemical analysis. This allows us to estimate the total sediment and nutrient load removed by the filters.

The inserts were installed at various times during the past year (Table 1). The drainage pipes and catch basins were cleaned before installation of the inserts.

#### Results

At the time of this writing, data were available from six wet weather events for the DrainPac<sup>®</sup> units and one event each for the HydroKleen<sup>®</sup> and Flo-Gard Plus<sup>®</sup> units.

*HydroKleen*<sup>®</sup>: The HydroKleen<sup>®</sup> catch basin inserts were selected for the service plaza site because of their multilayer filter design for removing hydrocarbons and other dissolved organics. Baseline monitoring data collected for the past year from the I-95 service plaza show that metals, petroleum hydrocarbons and PAHs are major stormwater contaminants there.

The single set of data from wet weather samples collected from the HydroKleen<sup>®</sup>-protected run of inlets do not show much protective effect for most of the parameters we measured (Table 2). However, we do not draw any conclusions from this single sampling event, because of the variability of the data. Additional samples collected during the next year or two may clarify this.

The filters were replaced immediately before water quality sampling began, after about nine months of service. The originally white cellulose filters were thoroughly blackened, indicating that the media was saturated with adsorbed hydrocarbons (Figure 2). Little sediment had accumulated in the sedimentation chambers of the inserts; even after nine months most of the chambers had less than an inch of sediment in them. It is not clear whether this is due primarily to a very low sediment and debris load coming from this part of the service plaza or to resuspension and failure to collect the sediment that does enter the units.

DrainPac®: The Drummond North subdivision in which the DrainPac® catch basin inserts were installed lies within the White Clay Creek watershed, an urban area facing TMDL restrictions for nutrients, bacteria, and biology and habitat. This is an older single-family home community, with numerous trees, so the inserts were expected to collect leaves and yard debris, especially during the fall months.

Wet weather data from the DrainPac®-protected catch basins have been highly variable (Table 2). Concentrations of most parameters measured in first flush samples collected from the protected run of inlets were frequently higher than in samples from the untreated control (Table 2). This difference, however, generally was not statistically significant (Wilcoxon signed rank test, p>0.05). Contaminant concentrations in composite samples also were not significantly different between treated and control runs. The lack of difference in this case may be explained by the observation that much of the water flowing into the catch basins appears to bypass the DrainPac® filters. The catch basins in this community, like many in Delaware, are grated curb inlets (Figure 3), and, because in our trial the

DrainPac® units do not extend under the curb opening, water that flows into the curb opening does not get treated. For this type of inlet it is clearly desirable to have a BMP that extends under this opening in order that most of the water is not bypassed.

The DrainPac® units, despite the relatively large size of the filter bag, filled up rapidly in this tree-lined community, particularly during the autumn leaf fall (Figure 4). They were cleaned at two-month intervals. However, in this case the units should probably be cleaned more often to prevent resuspension of the collected debris, which may also have contributed to the lack of observed difference in treated and untreated contaminant concentrations. Stenstrom (1999) also demonstrated that DrainPac inserts bypassed much flow once they had accumulated debris.

UltraDrainguard<sup>®</sup>: UltraDrainguard<sup>®</sup> inserts were installed in both the I-95 service plaza and the Drummond North subdivision (Table 1). These inserts are appealing because of their relatively low initial cost and ease of installation. However, the smaller bag size compared to other inserts may make their maintenance more burdensome in areas with heavy debris or sediment loads. At the service plaza, these units have collected primarily trash, sand (in winter), grass clippings (in summer), and some leaves. They have been able to go for a number of months between cleanings at this site. The UltraDrainguard<sup>®</sup> filters were not installed in the Drummond North community until mid-Winter 2004. At the time this paper was written, no wet weather data had yet been collected.

Flo-Gard Plus<sup>®</sup>: Flo-Gard<sup>®</sup> inserts also were not installed until late Winter 2004. Initial wet weather data suggest that sediment and oils are removed by the units (Table 2), although more storm events will need to be sampled to determine if this difference is significant.

#### **Discussion and Conclusions**

This study was designed to collect stormwater quality data from field installations of catch basin inserts. Thus, the water samples collected represent actual discharge to the stormwater system, including untreated bypass flow. The study will provide information not only on the effectiveness of various inlet protection devices in removing runoff pollutants, but also on their practicality in terms of maintenance issues and cost. Results will help DelDOT in its efforts to select BMPs that are appropriate for particular sites, land uses or stormwater quality problems in the state.

The limited data that we have collected so far on these catch basin inserts point out the variability in wet weather data, as well as in pollutant loads and the effectiveness of the inserts at removing those contaminants. Other studies have also demonstrated considerable variability in field results. DeMaria et al. (2003) have discussed the challenges in acquiring good field data in this type of study. A Navy Environmental Leadership Program study found a 17-95% range of removal efficiencies for DrainPac inserts (NELP, 2002). A study performed by the Interagency Catch Basin Insert Committee found that a variety of catch basin inserts showed little removal of suspended solids, partially due to scouring from relatively small storms (ICBIC, 1995). A recent CalTrans study of highway BMP retrofits included several types of drain inlet inserts. The inserts performed poorly compared to other BMP types, generally providing less than 10% reduction in the concentration of most constitutents. This study concluded that drain inlet inserts are best suited for gross solids removal (Currier et al., 2001; Taylor, 2002).

Lee (2000) and Taylor (2000) claim that storm drain inserts of all kinds generally perform poorly in field tests due to limited contact time between the water and sorptive media, resuspension of material removed by the filters, and requirements for close monitoring and frequent maintenance. They also conclude that inserts do little to remove dissolved contaminants and are bested suited for removing trash and other gross pollutants.

Catch basin inserts are attractive retrofits because of the relative ease and low cost of installation. Ultimately, however, their cost effectiveness is determined by the frequency with which they must be maintained. Our study and others have demonstrated that for many applications a very high frequency of cleaning is necessary to keep the inserts from clogging and bypassing stormwater flows, as well as resuspending captured material. Inserts may not be practical for large drainage areas or for areas with high levels of leaves or debris that can plug them.

### Acknowledgements

We wish to thank the dedicated field staff of KCI Technologies for their hard work performing the wet weather monitoring and maintenance of the catch basin inserts. We also thank the vendors for their assistance and advice.

**Figure 2.** Used cellulose (front) and activated carbon (back) filters removed from HvdroKleen inserts after nine months service.

**Figure 3.** UltraDrainguard-protected inlet showing water flow bypassing the filter and entering the curb opening.

**Figure 4.** Mean percent volume of contents removed from DrainPac filter bags at two different times, showing the preponderance of leaves and other organic debris.
