Introduction

Funding for this Project has been provided in full or in part through an agreement with the State Water Resources Control Board. The contents of this document do not necessarily reflect the views and policies of the State Water Resources Control Board, nor does mention of trade names or commercial products constitute endorsement or recommendation for use. (Government Code 7550, 40 CFR 31.20)

The City of Malibu (the “City”) entered into an agreement (Agreement Number 06-298-550-0) with the State Water Resources Control Board (SWRCB) in July of 2007. The City later entered into an agreement December of 2008 for State Revolving Fund Project No. C-06-6969-110 Agreement No. 08-354-550. The SWRCB provided federal funds for the City of Malibu to upgrade a former 100 gallon per minute (gpm) storm water treatment device, located at the outlet of Ramirez Creek, to reduce bacteria loading to Paradise Cove beach. The new treatment device substantially expanded the treatment capacity, with the goal of reducing bacteria exceedances at Paradise Cove beach during summer and winter dry weather, and wet weather up to the design capacity.

The project’s original Proposition 40 Clean Beach Grant Program allocated \$920,000 to implement the project from design to post construction monitoring. On December 22, 2008, the City was notified by the State Water Board that the Proposition 40 funding for the project had been suspended. At that time, the City had already received reimbursement for \$116,834 of expenses related to professional and consultant services.

On April 7, 2009, the City began working with the SWRCB to apply for supplemental funding from the State Revolving Fund (SRF) financed by the American Recovery and Reinvestment Act of 2009 (ARRA). On August 3, 2009, SRF Agreement No. 08-354-550 was executed dated as of December 18, 2008. The agreement included the remaining balance of \$803,166 from the Proposition 40 grant plus an additional \$13,110 to cover City personnel services to restart the project. The total SRF funding for the project was \$816,276. On January 21, 2010, Amendment No. 1 to SRF Agreement No. 08-354-550 was executed allocating an additional \$3,820 for City personnel services for work associated with Davis Bacon Act requirements. As a result, the total SRF funding for the project was increased to \$820,096. The funding was budgeted as follows:

Personnel Services	\$16,930
Professional & Consultant Services	\$23,166
Equipment	\$370,000
Construction	\$330,000
Monitoring	\$80,000

The total budget allocation for equipment and construction was \$700,000. The project actual construction costs, including equipment, were \$958,452.41. The City paid for the additional expenses with money from its General Fund.

As the City prepared to execute a contract for monitoring services, it was discovered that monitoring in accordance with the QAPP and MP would cost approximately \$35,000 for the year. The City worked with the grant manager to adjust the line items as follows:

Monitoring	\$35,000
Professional & Consultant Services	\$56,011

After this line item adjustment, the total budget allocation for Professional & Consultant Services from both the original Proposition 40 grant and the SRF grant was \$172,845. The City spent a total of \$195,217 for design, permitting, QAPP and MP preparation and construction management services. The City paid for the additional expenses with General Fund. The City anticipates spending all of the grant funds for this project.

Since this project was initiated, the City has pursued and successfully executed funding agreements with the SWRCB for two additional projects. The City was awarded \$540,000 to design and construct the Wildlife Road Stormdrain Treatment and Focused ASBS Outreach Project and \$2,250,000 to design and construct the Broad Beach Road Biofiltration Project.

The following Table 1 includes the list of documents submitted and submittal dates in accordance with the Agreement.

Task 5 of the Agreement required the City to develop a Monitoring & Reporting Plan that achieved the following:

- Identifies the nonpoint source(s) of pollution to be prevented or reduced.
- Describes the baseline water quality or quality of the environment to be addressed.
- Describes the manner that this project will prevent or reduce pollution and demonstrate desired environmental results.
- Describes the monitoring program, including, but not limited to, the methodology, frequency and duration of monitoring.

The City submitted a Monitoring Plan (MP) and Quality assurance Project Plan (QAPP) (collectively referred to herein as the Plan) to the State in accordance with the Agreement and as listed above in Table 1. The approved Plan was implemented over the past year. The agreement also required the City to submit a report that includes information collected by the Recipient in accordance with the Project monitoring and reporting plan, including but not limited to, a determination of the effectiveness of the Project in preventing or reducing pollution and the results of the monitoring program. This report documents the results of the monitoring programs analysis of fecal indicator bacterial (FIB) loading in Ramirez Canyon Creek

both upstream and downstream of the treatment device at the seven spatially distinct sampling locations, as well as flow data and physical observations. This report also discusses the findings regarding the effectiveness of the treatment device to reduce bacterial loads to Paradise Cove Beach.

Project Background

Paradise Cove is a popular public beach located in Malibu, California. Paradise Cove is frequented by locals and visitors who utilize an onsite restaurant, fishing pier, and/or reside in the 250 unit mobile home park (Figure 1). Approximately one million people visit the Paradise Cove Beach Café restaurant and beach each year. Paradise Cove beach experiences frequent exceedances of FIB water quality objectives in the receiving waters for recreational use resulting in beach postings throughout the year. Stormwater and urban runoff, which can carry adulterants including bacteria, flows to the ocean at Paradise Cove beach via Ramirez Canyon Creek. Ongoing monitoring conducted by the Los Angeles County Department of Public Health (DPH) and Heal the Bay's weekly Beach Report Cards indicate that poor beach conditions occur regularly at Paradise Cove Beach during the dry weather.¹

Ramirez Canyon Creek flows year round in the concrete lined reach where it outlets into the ocean at Paradise Cove Beach (Figure 2). Ramirez Canyon Creek is a natural soft bottom creek north of Pacific Coast Highway and becomes a concrete lined channel on the ocean side of Pacific Coast Highway until it empties onto the sand at the beach. Ramirez Canyon Creek carries runoff from a 3,334-acre watershed (Figure 3). The watershed is comprised of 78% undeveloped open space with 2.3 % high density residential development and 18.5% low density residential development focused in the bottom third of the watershed.² Wastewater management and treatment is by individual privately owned onsite wastewater treatment systems (OWTS) and small wastewater package plants.

The definite source of bacterial exceedances at Paradise Cove beach was uncertain at the initiation of the project. However, equestrian facilities and uses adjacent to the creek, other animals in the watershed, decomposing organics including those from illegally disposed landscaping debris, natural background levels (upstream of the coast and along the shore), incidental urban runoff, and faulty or malfunctioning OWTS were considered potential sources. The County of Los Angeles implemented the North Santa Monica Bay Bacteria Source Identification Study with the goal identifying the sources of indicator bacteria to this watershed and Escondido Canyon. The study is being conducted by Southern California Coastal Water Research Project (SCCWRP) in cooperation with local agencies. Another goal of the study was to develop a protocol for identifying the source of FIB that may be applied to other drainage/watersheds. A preliminary report has not yet been published. Due to the variable nature of bacteria in the environment, the lack of late wet season exceedances at the beach, and lack of flow in the creek at some monitoring sites, the source Identification study has thus far been unable to definitively identify the source of FIB. However, results reveal that there are

¹ <http://www.healthebay.org/about-bay/beach-report-card>.

² Los Angeles Regional Water Quality Control Board, January 24, 2002, Santa Monica Bay Beaches Bacteria TMDL-Attachment A to Resolution No. 02-004.

no or very low levels of human specific bacteroides (too low to have an effect on the water quality at the beach) have been present in samples analyzed, indicating humans are unlikely to be a significant source. Furthermore, field observations indicated that decaying vegetative matter is likely a significant source of indicator bacteria. Because the source of indicator bacteria was unknown, the City proposed a treatment device to help eliminate bacteria from natural sources which could not be controlled. In addition, the City committed to continue to investigate sources of bacteria and develop targeted outreach and programs to reduce indicator bacteria levels.

Figure 1. Paradise Cove

Figure 2. Location Aerial- Restaurant & Lined Channel

The Santa Monica Bay Beaches Bacteria (SMBBB) TMDL for Wet and Dry Weather were adopted by the Los Angeles Regional Water Quality Control Board on January 24, 2002; both became effective on July 15, 2003.

SMBBB TMDL mandates that no beach, including Paradise Cove, exceed bacteria water quality standards during the Summer Dry Weather Season (April 1 to October 31). The compliance date for the summer dry weather period was July 15, 2006, three years after the effective date of the TMDL. The SMBBB TMDL for the Winter Dry Weather Season (November 1 through March 31) dictates that after November 1, 2009³ only one day of exceedance of the bacteria water quality standards is allowed at Paradise Cove beach. The SMBBB TMDL for Wet Weather requires improvement of water quality at Paradise Cove beach, so that during rain events bacteria water quality standards are not exceeded on more days than the “reference site.” A reference site is one located in receiving water at the mouth of a watershed with limited anthropogenic influences, and can be considered as close to its natural state as possible. Arroyo Sequit at Leo Carillo State Beach in the North Santa Monica Bay was used as a reference site in establishing this TMDL. The total number of wet weather exceedance days for Jurisdiction 1 (which includes Paradise Cove) is 17 days based on daily compliance monitoring. The wet weather SMBBB TMDL requires full compliance with the bacteria water quality standards within 18 years of the effective date of the TMDL. It is important to note, that as of the draft of this report, the reference site at Leo Carillo beach at the mouth of Arroyo Sequit

³ Los Angeles Regional Water Quality Control Board, December 12, 2002, Santa Monica Bay Beaches Bacteria TMDL- Attachment A to Resolution No. 02-022.

has already experienced at least four dry weather exceedance days. This evidences that FIB levels vary even in a reference watershed, and are likely of natural origin.

The minimum protective bacteriological standards for waters adjacent to public beaches and public water-contact sports areas shall be as follows:⁴

(1) Based on a single sample, the density of bacteria in water from each sampling station at a public beach or public water contact sports area (REC-1) shall not exceed:

(A) Total coliform density shall not exceed 10,000/100 ml;

(B) Fecal coliform density shall not exceed 400/100 ml;

(C) Enterococcus density shall not exceed 104/100 ml; and

(D) Total coliform density shall not exceed 1,000/100 ml, if the ratio of fecal-to-total coliform exceeds 0.1.

(2) Based on the mean of the logarithms of the results of at least five weekly samples during any 30-day sampling period, the density of bacteria in water from any sampling station at a public beach or public water contact sports area, shall not exceed:

(A) Total coliform density shall not exceed 1,000/100 ml;

(B) Fecal coliform density shall not exceed 200/100 ml; and

(C) Enterococcus density shall not exceed 35/100 ml.

⁴ The bacteriological objectives were revised by a Basin Plan amendment adopted by the Regional Board on October 25, 2001, and subsequently approved by the State Water Resources Control Board, the Office of Administrative Law and finally by U.S. EPA on September 25, 2002.

Figure 3. Ramirez Canyon Watershed

Problem Statement

Monitoring data where Ramirez Canyon Creek outlets to Paradise Cove Beach shows a history of exceedances of REC-1 FIB exceedances. At present, the Los Angeles County DPH and the City of Malibu conduct weekly bacteria monitoring of ocean water quality at the interface where Ramirez Creek mixes with the ocean (wave wash). Both of these monitoring programs continue to show occasional single sample exceedances of FIB standards. The standards used to analyze water quality and determine exceedances are based on the water quality objectives set forth by the California Ocean Plan, and the Santa Monica Bay Beaches Bacteria TMDL as listed previously in this plan. The City's and County's data are available and attached in Appendices A and B.

Prior to construction of this project, FIB water quality exceedances at the beach were evaluated between October 1 and September 30 for each year, to coincide with Los Angeles County rainfall data. In 2003/2004 single sample beach FIB water quality standards were violated 11 times on 8 individual days at Paradise Cove beach. In 2004/2005 Paradise Cove beach exceeded these standards 91 times on 45 days. In 2005/2006 Paradise Cove beach exceeded these standards 38 times on 21 individual days. Finally, in 2006/2007 these standards were exceeded 18 times on 11 individual days.

The treatment system constructed by the City to address this problem has a full treatment capacity of 900 gpm (including sediment removal, filtration, and disinfection). This design capacity was exceeded during the near normal rainfall year of 2006 on only 6 days. Four of the days when capacity was exceeded were during the April 1st -October 31st dry season. During 2007 the 900 gpm design capacity was never exceeded. Daily stream flows (as measured by Santa Monica Baykeeper) only exceeded the 900 gpm capacity following rain storms of greater than 1 inch in 2006, and stream flows dropped below 900 gpm approximately 24 hours following the rain events. The new treatment system also has a treatment capacity of 3,600 gpm for gross solids and sediment removal only. It was designed to meet the water quality objectives set forth in the Santa Monica Bay Beaches Bacteria TMDL for summer and winter dry weather, and wet weather periods for all but the wettest of rainfall years. The Plan was implemented to help ascertain the efficacy of the new device, and help guide maintenance and management decisions for the facility.

Environmental Monitoring & Data Analysis Techniques

The facility was constructed toward the outlet of the creek, in an armored channel (installed by the property owner to protect properties from creek flooding). It was constructed within a block wall structure to screen it from view and protect it. All flows within the previously described facility capacity are diverted from the creek into a series of sediment and solids removal devices by way of a sump in the channel. When sufficient volume is captured, the water is pumped from a collection vault/pump station to filters, and then through a ultra-violet disinfection system. The treated water then intermittently discharges from a PVC pipe (separate from the creek/channel) to the beach which was installed at the culvert/overpass on

the beach. Flows from the creek greater than the facility's capacity, bypass the system and discharge out of two large culverts to the beach under the driveway to the parking area. A cement scour pad was installed to prevent erosion and scour to the beach at the point of treated discharge. Figures 4 and 5 show the location and discharge point of the Paradise Cove Stormwater Treatment facility as constructed.

Figure 4. Treatment Facility and Physical Setting- Facing Upstream

Figure 5. Treatment Facility and Physical Setting- Facing Treated Discharge Pipe

The monitoring program was designed to test the bacterial water quality in Ramirez Canyon Creek before it is treated by the new device and at various points along the treatment process to ensure the device is functioning as designed. The monitoring program design also measured and documented any bacterial loading that occurs after the treated water is discharged onto the sand before entering the ocean. The monitoring program sought to measure and document the effectiveness of the newly constructed treatment device to:

- Eliminate summer and winter dry weather bacterial loads to the ocean from Ramirez Creek.
- To reduce the bacteria loads by more than 95% during summer and winter dry weather and wet weather to the Paradise Cove beach surf zone.

The program included monitoring FIB on a weekly basis for a year, and stream flow monitoring of Ramirez Creek for March through June capturing both wet and dry weather data. Monitoring for FIB at seven designated sites (Figures 6-13) included: upstream of the device along channelized Ramirez Canyon Creek, in the sump, in the pump station, from the treated discharge, at the discharge's interface with the beach, and in the wavewash/point zero of the creek. Additionally, a control site was sampled (Site PC-7) located in excess of 100 yards west/upcoast of the Ramirez Canyon Creek interface with the ocean. These seven sampling locations were similar to the same sampling sites used by Santa Monica Baykeeper to monitor the effectiveness of a 100 gpm pilot project treatment system that was previously installed at this location to test the feasibility of a treatment project. The sites were chosen for comparison purposes, but with slight modifications to account for the different design of the current treatment facility. Stream flow was used to gauge the capacity of the treatment device and how effective treatment is during various storm events and different stream flows. This monitoring design provided data and results to quantify creek flow and bacterial load using field measured parameters. The following figures show the monitoring sites used to assess the effectiveness of the treatment facility over the course of this Plan.

Figure 6. Monitoring Sites Map

The sample sites have been revised from the pre-design sample sites designated in the monitoring plan. They have been chosen to best represent the final constructed design. Images and descriptions follow.

Figure 7. Site 1: Ramirez Canyon Creek Upstream of System

Latitude: 34.02089 Longitude: -118.78716

Sample: Upstream of treatment system, midway in cement channel. Access in line with parking area gate arm/end of guardrail.

Figure 8. Site 2: Sump (prior to solids removal)

Latitude: 34.02078 Longitude: -118.78702

Sample: From the sump prior to treatment. Sample should be taken from the flowing water where feasible.

Figure 9. Site 3: Pump Station (post solids removal)

Latitude: 34.02067 Longitude: -118.78708

Sample: From inside the pump station tank, after treatment by sediment removal. Public Works will provide access.

Figure 10. Site 4: Fully Treated Discharge, Directly from Pipe

Latitude: 34.02036 Longitude: -118.78668

Sample: Directly from pipe

Figure 11. Site 5: At interface of treated discharge and the sand

Latitude: 34.02034 Longitude: -118.78664 Sample: Interface where treated water contacts beach sand from the discharge pipe.

Sample: In the flow as the treated discharge runs across the sand (about 3 feet from discharge).

Figure 12. Site 6: Wave wash at point zero

Latitude: 34.02021 Longitude: -118.78658

Sample: Point zero/wavewash from pipe outfall at ankle deep in the ocean where the flows contact the ocean (using a sample pole). This site may vary slightly depending on where the water flows.

Figure 13. Site 7: Wave wash upcoast of the discharge

Latitude: 34.01975 Longitude: -118.78718

Sample: Ankle deep in wave wash in front of lifeguard tower (using a sample pole), upcoast of the creek outfall.

The Plan consisted of FIB water quality samples being taken on a weekly basis for one year following the device's installation at each of the seven monitoring sites. Sampling and analysis was conducted by Aquatic Bioassay and Consulting Laboratory (ABC), a State certified (Environmental Laboratory Accreditation Program) testing lab using standard methods as approved by the Federal EPA. Monitoring began August 10, 2010 and is continuing beyond the first year to ensure continued proper operation of the system. Ongoing monitoring locations and/or frequencies may be revised, however, as need and funding dictates. A sampling day consisted of one grab sample taken from each of the seven sites shown in Figure 6. The frequency was one sample per site per sampling day. Sample depth varied depending on stream flow elevations in the concrete lined channel and along the beach where treated water discharges from the device. From Sites 1 and 2, the sample depth was generally below the stream surface when flows were adequate. The site 3 sample was taken in the pump station prior to filtration and disinfection. The site 4 sample was taken directly from the fully treated discharge flow. The sample for site 5 was taken below the surface flow, on the beach, being careful to prevent sand/sediment from entering the sample. Samples for sites 6 and 7 were taken at ankle deep in the wavewash, set according to TMDL compliance monitoring protocol approved by the Los Angeles Regional Water Quality Control Board. Sample times during the reporting year were recorded on data sheets and chains of custody forms. Additionally, a

selection of physical observations was documented for each of the seven monitoring sites (Appendices C and D).

Samples were collected using sterile vessels, and properly labeled with the site number and collection time. Samples were transported and stored on ice or refrigerator at a temperature of 4 degrees Celsius until analysis in accordance with prescribed holding times. Samples were analyzed using Federal EPA approved standard method. All bacteria samples were analyzed for FIB parameters using the IDEXX reagent system and Quanti-tray/2000 supplies and methods. All bacteria samples were diluted by a factor of 10 making the lowest detection limit of the bacteria tests <10 and the upper limit >24,192 MPN per 100 mL. One laboratory duplicate (split) sample was randomly selected from Sites PC-1 through PC-7 and analyzed on every sampling day, as well as field blanks for quality assurance. Chain-of-custody (COC) sheets were properly maintained.

A HACH Sigma ultra-sonic flow meter and compound weir were installed in the concrete lined box channel approximately 200 feet upstream from the sump (Figures 14 and 15) in February 2011, and data is available from March 17, 2011. The flow meter measured the level of stream flow and flow at five minute intervals. The flow meter was calibrated and certified by the installer. Calibration was accomplished by measuring the water level elevation as it flowed over the weir installed in Ramirez Creek. This water level elevation was compared to the internal measurements taken by the Sigma and adjusted, as necessary. The consultant provided a table of conversions for level to flow rate (Appendix F). Additionally, all debris was removed from, in, and around the weir as needed. The data from the flow meter were uploaded monthly to a portable laptop computer in the field. Stream flow data was integrated into Hach's proprietary database "Insight" for analysis.

Figure 14. Flow Meter

Figure 15. Ultrasonic Probe and Weir for Flow Monitoring

All personnel followed all field and laboratory procedures and protocols dictated by the Quality Assurance Project Plan (QAPP) approved by the SWRCB for this project.

Precision: Precision for bacterial parameters was ensured by having the same analyst complete the procedure for laboratory duplicates of the same sample, and/or duplicates were run on a minimum of 5% of the samples when there were over 20 samples run that day (the contract lab also analyzed samples for another project for the City). The results of the laboratory duplicates were compared to the confidence limits supplied by the manufacturer.

Field Sample Collection: Sampling personnel used a sampling apparatus/extension pole to collect bacteria water quality samples in the ocean, channel, and pump station. Only sterile containers (plastic or glass) were used to collect bacteria samples.

Sample Handling: Identification information for each sample was recorded on the sample container and chain-of-custody (COC) sheet. Each sample container and COC was labeled with the station identification number, date and time of collection for each sample, and the method used to preserve samples (if any). The sampling personnel signed their names on COC sheet

certifying that they followed all QAPP procedures and that all the information recorded on the data sheet is correct.

Data Management: Data was managed and housed in a database and provided to the City on a weekly basis in Excel format for review.

Monitoring Results

Data and observations were collected weekly at the aforementioned monitoring locations. All three FIB regularly exceeded single sample limits in the creek channel monitoring locations PC-1 and PC-2 upstream of the treatment facility. There was a marked increase in areas where there was a pronounced collection of organic/vegetative matter such as leaves, pine needles, algae, and seaweed. It was often observed that the sump had increased bacteria levels; not surprising given that this area was particularly prone to accumulation of organic and inert matter.

Site PC-3 was anticipated to have lower indicator bacteria levels due to the pretreatment by sediment removal. However, that did not often prove to be the case. Site PC-3 often had similar or higher bacteria levels than PC-2. This may be due to possible bacterial growth in the accumulated sediments within the sediment removal devices themselves. Water exiting the devices may pick up additional indicator bacteria or transport it on finer sediments to the pump station. While a less than ideal result, this information serves as a useful management tool. If analyses showed that FIB levels were creeping up, it would provide a strong indicator for when cleanout/maintenance was necessary for the sediment removal devices.

Site PC-4, as hoped, displayed excellent water quality. Nearly all of the data shows results below the detection limit, or at least within acceptable range (far below the standards). On a few rare instances, this site experienced mechanical upsets which led to the discharge of water that did not meet the REC-1 bacterial indicator standards directly from the pipe. However, according to the California Ocean Plan, compliance measurements for a discharger's gross (not net) discharge must be made in the ocean sufficiently within the mixing zone and not at an effluent pipe.

Site PC-5 at the interface of the treated discharge and the sand was regularly above FIB standards. It was clear that once the treated water flowed across the sand and the accumulated kelp wrack, there was a dramatic decline in water quality and bacteria levels had increased. The scientific community is just beginning to fully understand the complexity of the hydrology in the Santa Monica Bay and the effects of the natural environment on water quality. For example, an independent 2009 University of California at Los Angeles (UCLA) study⁵ looking for human bacteria sources in Malibu Creek and Lagoon supports the fact that MS4 discharges are not the only source of pollutants in the water. In another recent study, the USGS⁶ is

⁵ UCLA 2009 Investigation of Spatial and Temporal Distribution of Human-specific Bacteroides marker in Malibu Creek, Lagoon and Surfrider Beach, available at: <http://www.ci.malibu.ca.us/index.cfm/fuseaction/detail/navid/493/cid/15808/>.

⁶ USGS Letter for Task 1 Results dated June 28, 2010 and corresponding Study description, available at: <http://www.ci.malibu.ca.us/index.cfm/fuseaction/detail/navid/493/cid/15777/>.

learning that bacteria in the near shore ocean were associated with tidal fluxes, with highest bacteria concentrations occurring during high tide. The studies have shown that the source, or combination of sources, of bacteria to near-shore ocean water is not precisely known but may also include natural sources either directly deposited by birds and other wildlife, or indirectly mobilized as tides and waves wash beach sands and material accumulated at the high-tide line (wrack line) along surface flow across the beach. Other studies have recently shown that wrack (especially kelp) at marine beaches has the propensity to sustain FIB and may provide organic carbon and other nutrients for cells to persist and/or grow. An additional study conducted by UCLA and Stanford University⁷ found that:

“Wrack collected from the three different zones at central and southern Californian beaches exhibited a fairly consistent trend. FIB were present at the highest concentrations in the dry zone wrack, next highest in the wet zone wrack, and at the lowest levels in the surf zone wrack. The dry zone wrack represents wrack that was stranded on the beach well above the high tide line. This finding supports the hypothesis that wrack harbors FIB. The relatively high levels in dry wrack compared to wet or surf wrack would be consistent with the premise that FIB can grow on wrack and accumulate over time as wrack is stranded on the beach.”

Further, when investigating the effects of seawater on wrack, this study also found:

“Results suggest that FIB in the nearshore of beaches with high levels of wrack suspended in the water column may persist for longer than FIB in the nearshore of beaches where there is no wrack; and thus affect violation of water quality standards.”

Despite these water quality effects, this same study warns:

“It should be noted that wrack plays an important role in the beach ecosystem by providing nutrients to the beach food web. Sea birds, invertebrates and insects all rely on kelp as a food source. Beach grooming to remove stranded kelp has been show to adversely impact the beach ecosystem. Thus a decision to remove wrack from a beach should only be undertaken after careful consideration of both water quality and ecosystem needs.”

Sites PC-6 and PC-7 were regularly within acceptable water quality criteria. PC- 7 seemed neither to be influenced by, nor to influence the down coast monitoring sites. This site will probably be eliminated from the monitoring protocol in the near future. Because PC-6, which is in the ocean receiving farther from the creek, often had some level of bacteria (regularly low, but occasionally above the standards) when PC-4, which is the treated discharge and the only water discharging from the creek/channel, was below detection limit, it is safe to say that the creek is not negatively impacting the compliance monitoring location, nor causing or contributing to the water quality exceedances at this site. The few rare occasions that PC-4 had

⁷ Imamura, Thompson, Jay, and Boehm, February 2011, Wrack Promotes the Persistence of Faecal Indicator Bacteria in Marine Sands and Seawater, February 2011.

elevated bacteria levels may not be statistically significant to justify any corresponding receiving waters elevations.

Flow monitoring over the course of the study showed an overall trend of slight fluctuation over the course of a 24 hour period, but clearly demonstrated that flows were higher at the start of the study in the wet season and flows reduced as expected as storm events ceased, and hotter summer weather progressed. The daily fluctuations showed an unusually strong trend of flows peaking between midnight and four in the morning daily. Upon speaking with engineers familiar with the hydrology and geology of this area of the coast, it was explained that many creeks in the area seem to “dry up” depending on the topography and permeability of the creek bed. When the flow has gone subsurface it is sometimes below and therefore constrained by an impenetrable rock bed which reduces the flow. The creek then builds up enough head to increase the volume of flow once the subsurface geology changes to a more porous substrate once again. Other flow studies currently conducted by the West Basin Municipal Water District under a Prop 50 grant in area drainage gullies adjacent to Ramirez Canyon are also demonstrating this same daily flow phenomenon. Due to the higher volumes of rain this past year, all area creek systems seemed to have higher flows for longer into the summer dry season, where normally they would have dried up or ponded (thus creating a small lagoon at the mouth of the creek at the beach) earlier in the season. Flows in Ramirez canyon Creek were observed to peak around 4,000 GPM, with a couple anomaly peaks around 10,000 gpm or greater (due most likely to large debris fouling the measurements briefly), down to less than 100 gpm. This demonstrates that except during storm events, the facility had sufficient capacity for at least sediment removal, and for a great percent of time it had adequate capacity to also filter and disinfect flows. Very little creek flow bypassed the system except during larger wet weather events and due to operational problems. Staff also made note while inspecting the facility of whether there was any flow beyond the sump, and observed that- the channel was regularly dry with the exception of extreme tides filling the channel, to be discussed further in the following section.

All monitoring (water quality and flow) and observations data collected by or on behalf of the City is following in Appendices C, D, E and G. Additionally, Los Angeles County DPH data for SMB 1-06 has been included for the past year in Appendix B.

Discussion of Project Effectiveness

The treatment facility was constructed upstream of where Ramirez Canyon Creek outlets to the Pacific Ocean on Paradise Cove beach. The project was designed to fully treat all flows up to approximately 900 gpm in Ramirez Canyon Creek by gross solids and sediment removal, filtration, and disinfection. All flows between 900 gpm and 3,600-3,900 gpm have gross solids and sediment removal only. The treated discharge is released directly to the beach (not through the creek/channel), and depending on tide, may occasionally discharge directly to the ocean, thus preventing any flows to encourage re-growth or re-suspend bacteria in the actual culvert pipes from the channel (see figure 5). While it is obvious that the treated water flowing across the sand picked up bacteria from the natural beach environment, it did not seem to

directly correlate results in the wavewash. Thus the treated creek/channel flows within the capacity of the treatment system are not believed to be a source of exceedances at the compliance point in the ocean. Based on review of the flow study data, all flows outside of major storm events, and lower average creek flows (as groundwater was less saturated) were within the range of treatment capacity for the facility. Discharge results proved that the facility reduced and even eliminated fecal bacteria loading from the Ramirez Canyon Creek Watershed to the beach at Paradise Cove, as was an established goal of the project.

Being located in a fairly rural area, presented several management challenges. This creek channel being downstream of a naturalized canyon is subject to large amounts of woody and rocky debris. Furthermore, a fairly dense tree canopy is above the channel and regularly sheds pine needles and leaves. Algal growth within the channel prior to the treatment system is also problematic and increases maintenance issues in the channel.

Due to the upset caused by the volume of large woody and rocky debris, and trash that was carried down the canyon and deposited in the channel during the first flush in October of 2010, the City opted to install stainless steel mesh screens over the inlets to the sediment removal devices. This kept the larger natural debris from damaging or overloading the treatment system. The City then later learned that this site is prone several times a year to extreme tides which cause a reverse flow of ocean water into the channel. It also unfortunately carries large uncontrollable amounts of seaweed and sand to flood the channel and culverts, while also accumulating to a height which blocked the discharge of the PVC treated water discharge pipe. The City has employed a removable rebar-type screen in the channel to try to reduce some of the seaweed from filling the sump (it was actually observed to have gone up the channel beyond the sump), which will require costly, ongoing maintenance of the channel. Other strategies to reduce the affects of the reverse flow will need to be investigated. This appears to be an environment conducive to the overgrowth of algae, and potentially FIB. Therefore, the proliferation of algae in the channel is an issue. With the dense canopy of trees reducing sunlight penetration, a source of vegetative organic matter for nutrients and lower flows of warmer water, algae is thriving and then breaking down in the channel creating a welcoming substrate for bacteria to generate. This is likely primary major source and cause of elevated bacterial indicator levels in the creek and channel.

Another challenge caused by nature and the site in general is the contribution to bacterial contamination by birds. As previously described, Paradise Cove is also home to a recreational fishing pier which attracts large numbers of birds. Seagulls and pelicans in particular are regularly seen roosting on the pier and mingling on the beach. Large deposits of guano cover the pier's railings and the parking lot, and can be clearly seen on the sand over which the treated discharge from the facility flows. The City will be contacting other agencies with similar challenges due to a pier and discussing strategies with the property owners. This project was constructed with the understanding that there were multiple upstream sources of FIB that could not be controlled, and has been effective at eliminating that issue from the discharge of the creek at the beach. However, there are clearly non-stormwater issues from the environment outside of the creek that complicate the water quality conditions at the shore. Overall the stormwater facility is working as intended. With the dry weather creek flows and

most of the stormwater being properly treated, the City and partners can now begin looking at solutions to possibly address other sources of bacteria at Paradise Cove and continue to educate the community about the sources and effects of FIB.

In conclusion, this project is effective and overall a great success. The process from concept through maintenance has been a model in partnerships and collaboration between private property owners, public agencies, consultants and non-governmental organizations. While bacterial indicator levels are sometimes high at certain sites in the area, those sites are above the treated discharge point, and the discharge was near perfect after treatment. So the stormwater in Ramirez Creek is being effectively treated. The project has accomplished the goal of reducing bacterial loading from Ramirez Canyon Creek superbly and was adequately sized to treat all dry weather flows and capture some increased flows resulting from storm events.

APPENDIX A

City of Malibu Water Quality Data for Sites PC 1 – PC 7

Paradise Cove Bacteria Results- ABC

Key on following page

KEY

T - Total coliform per 100 ml

F - Fecal coliform per 100 ml.

E - Enterococcus per 100 ml.

THE FOLLOWING LETTERS AND NUMBERS APPEAR WHEN STATE STANDARDS ARE EXCEEDED

a - Total coliform level exceeds 10,000 organisms per 100 ml.

b - Fecal coliform level exceeds 400 organisms per 100 ml.

c - Enterococcus level exceeds 104 organisms per 100 ml.

- A number appearing in the extreme top right-hand corner indicates the total coliform level is greater than 1,000 organisms per 100 ml. and the fecal/total coliform ratio is greater than 0.1.

X - One or more parameters exceed State standards.

d - The log mean of total coliform levels exceeds 1,000 organisms per 100 ml.

e - The log mean of fecal coliform levels exceeds 200 organisms per 100 ml.

f - The log mean of enterococcus levels exceeds 35 organisms per 100 ml.

Blank entries indicate samples not taken or analyst error.

APPENDIX C

Physical Observations Sheet and Legend

PARADISE COVE OBSERVATION SHEET

Station: _____

Sampler's Name: _____

Sample Date: _____

Sample Time: _____

Observation	Observation Code ^{1.}
Excrement	
Refuse/Litter/ Debris (Unnatural)	
Natural Organic Matter/Ocean Debris	
Seaweed	
Algae	
Dead Marine Animals	
Bathers	
Animals/ Birds	

Observation	Observation Code ^{1.}
Weather	
Tide	
Ocean Conditions	
Storm Drain Culvert Flow	
Reached Surf ^{2.}	
Reverse Flow ^{3.}	

OTHER OBSERVATIONS (red tide, color, foam, oily sheen, etc.):

1. Observation codes are on the back of this worksheet.
2. Does the effluent or culvert (if flowing) reach the surf?
3. Does the tide reach the culvert?

CODE	0	1	2	3	4	5	6	7
Excrement	None	Some	Moderate	Heavy				
Refuse/Litter/Debris Unnatural	None	Some	Moderate	Heavy				
Natural Organic Matter/Ocean Debris	None	Some	Moderate	Heavy				
Seaweed	None	Some	Moderate	Heavy				
Algae	None	Some	Moderate	Heavy				
Dead Marine Animal	None	Fish	Jellyfish	Seal	Dolphin	Bird	Whale	Crab
Animals / Birds or Bathers or People Out of Water (50 yards each direction)	None	1 to 5	5 to 10	10 to 20	20 to 50	50 to 100	>100	
Weather	Clear	Overcast	Ptly Cldy	Thunderstorm	Rain	Drizzle	Cloudy	Fog
Tide	Incoming	Outgoing	at high +/- 30 min	at low +/- 30 min				
Ocean Conditions	Calm	Choppy	Wave					
Storm Drain Culvert Flow	Dry	Low Flow (Garden Hose)	Medium flow (between 1 & 3)	Heavy flow (Fire Hose)	Ponded in front of culvert			
Reached Surf	No	Yes						
Reverse Flow	No	Yes						

Some = 1-2 pieces or 1-2 ft
area covered

Moderate= 3-5 pieces or 3-5 ft area
covered

Heavy= more than 5 pieces or
greater than 5 ft area covered
