Index Period	Collection times are variable throughout the year, and sampling is performed without regard to seasonal influences.	An index period is conceptually recognized, but sampling may take place outside of this period for convenience or to match existing programs; sampling outside of the index is not adjusted for seasonal influences.	A well-documented seasonal index period(s) is calibrated with data for reference conditions, but sampling may take place outside of this period for convenience or to match existing programs; sampling outside of the index is adjusted for seasonal influences. Index periods are selected based on known ecology to minimize natural variability, maximize gear efficiency, and maximize the information gained about the assemblage.	Same as Level 3, but administrative needs and index periods fully reconciled. Scientific basis of temporal sampling influences management decision framework.	April-October seasonal index period that "slides" from south to north: SoCal – April to early June; NoCal – August to September; most regional boards adhere to this, but some do not to accommodate program support needs. **Points** **Statewide: 4.5** **Regional: 4.0**

Element 2	**(Lowest) 1.5**	**2.0 2.5**	**3.0 3.5**	**4.0 4.5 (Highest)**	**Comments**
Spatial Coverage	An individual site is used for assessment of watershed condition; simple upstream/ downstream and fixed station designs prevail; assessments at local scale.	Multiple sites are used for watershed assessment; spatial coverage only for questions of general status or locally specific problem areas; synoptic (non-random) design at coarse scale (e.g., 8-digit HUC common); spatial extrapolation is based on "rules of thumb"; may be supplemented by simple upstream/downstream assessments.	Spatial network suitable for status assessments; statewide spatial design using rotating basins with single purpose design at coarse scale (e.g., 8 digit HUC); may be supplemented by occasional intensive surveys.	Comprehensive spatial network suitable for reliable watershed assessments in support of multiple water quality management programs at more detailed scale (e.g., 11-14 digit HUC); statewide rotating basin approach or similar scheme to complete statewide monitoring in a specified period of time; multiple spatial designs appropriate for multiple issues.	Statewide probability design (WEMAP) and "pour point" integrator sites at 8 digit HUC scale; Regional boards employ watershed scale intensive survey designs at HUC 11 scale (currently in 4 of 9 regions). **Points** **Statewide: 3.5** **Regional: 4.0** **Combined: 4.0**

Appendix Table 2. (continued)

Element 3	(Lowest) 2.0	2.5 3.0	3.5 4.0	4.5 5.0 (Highest)	Comments
Natural Classification	No partitioning of natural variability in aquatic ecosystems. Minimal classification limited to individual watersheds or basins with generalized stratification on a regional basis; does not incorporate differences in stream characteristics such as size, gradient.	Classification recognizes one stratum, usually a geographical or other similar organization such as fishery based cold or warmwater, and is applied statewide; lacks other intra-regional strata such as watershed size, gradient, elevation, temperature, etc.	Classification is based on a combination of landscape features and physical habitat structure (inter-regional); achieves highest level of classification possible by considering all relevant intra-regional strata and subcategories of specific stream types.	Fully partitioned and stratified classification scheme based on a true regional approach that transcends jurisdictional (i.e., State) boundaries to strengthen inter-regional classification and recognizes zoogeographical aspects of assemblages.	Classification includes intra-regional factors such as watershed size, elevation, and other stratifying factors; not yet developed for all bioregions. **Points** **Statewide: 3.5** **Regional: na**

Element 4	(Lowest) 2.0	2.5 3.0	3.5 4.0	4.5 5.0 (Highest)	Comments
Criteria for Reference Sites	No criteria, except informal BPJ selection of control sites. May be little documentation and supporting rationale.	Based on "best biology", i.e., BPJ on what the best biology is in the best waterbody; minimal non-biological data used.	Non-biological criteria supported by narrative descriptors only; combine BPJ with narrative description of land use and site characteristics; may use chemical and physical data thresholds as primary filters.	Quantitative descriptors used to support non-biological criteria; characteristics of sites are such that the best biological organization expected to be supported; chemical and physical characteristics of sites used only as secondary and tertiary filters to avoid circularity in other criteria.	A quantitative procedure for screening reference sites is used; **Points** **Statewide: 5.0** **Regional: na**

Appendix Table 2. (continued)

Element 5	(Lowest) 1.0 / 1.5	2.0 / 2.5	3.0 / 3.5	4.0 (Highest)	Comments
Reference Conditions	No reference condition; presence and absence of key taxa or best professional judgment. rather than established reference conditions may constitute the basis for assessment.	Reference condition based on biology of a 'best' site or waterbody; a site-specific control or paired watershed approach may be used for assessment; regional reference sites lacking.	Reference conditions based on site-specific data, but are used in watershed scale assessments; regional reference sites are conceptually recognized, but are too few in number and/or spatial density to support the deviation of biocriteria.	Applicable regional reference conditions are established within the applicable waterbody ecotypes and aquatic resource classes; consist of multiple sites that either represent reference or are along the BCG in such a manner to allow extrapolation of expected conditions for assessing and monitoring within waterbody ecotype. Re-sampling of reference sites done systematically over a period of years.	Development of regional reference condition is in progress – not yet completed for all regions. **Points** **Statewide: 3.5** **Regional: na**

Element 6	(Lowest) 2.0 / 2.5	3.0 / 3.5	4.0 / 4.5	5.0 (Highest)	Comments
Taxonomic Resolution	Gross observation of biota; single assemblage only; very low taxonomic resolution (e.g., order/family level for macro-invertebrates.; family for fish by non-biologists).	Single assemblage (usually macroinvertebrates); low taxonomic resolution (e.g., family level) by experienced biologists.	Single assemblage with high taxonomic resolution (e.g., "lowest practical" i.e., genus/species); if multiple assemblages, others are lower resolution or infrequently used.	Two or more assemblages with high taxonomic resolution (e.g., "lowest practical" i.e., genus/species); capacity to use each assemblage concurrently is maintained; practitioners are certified in accordance with available offerings (e.g., NABS, state credible data provisions).	Statewide program employs lowest practicable taxonomy (usually genus/species); SoCal employs genus level; second assemblage (periphyton) is under development; fish may be used regionally. **Points** **Statewide: 4.5** **Regional: 4.5**

Appendix Table 2. (continued)

Element 7	(Lowest) 2.0	2.5	3.0	3.5	4.0	4.5	5.0 (Highest)	Comments
Sample Collection	Approach is cursory and relies on operator skill and BPJ, producing highly variable and less comparable results; Training limited to that which is conducted annually for non-biologists who compose the majority of the sampling crew. Documentation of methods more as an overview.		Textbook methods are used rather than in-house development of detail of SOPs to specify methods; a QA/QC document may have been prepared; training consists of short courses (1-2 days) and is provided for new staff and periodically for all staff.		Methods are evaluated and refined (if needed) for State purposes; detailed and well documented; SOPs are updated periodically and supported by in-house testing and development; a formal QA/QC program is in place with field replication taken; rigorous training is for all professional staff, regardless of skill mix to raise skill levels and enhance interaction and consistency.		Same as Level 3, but methods cover multiple assemblages.	Sample collection methods are fully developed for two assemblages (macroinvertebrates, periphyton); fish methods also exist in other agencies. **Points** **Statewide: 5.0** **Regional: 5.0**

Element 8	(Lowest) 2.0	2.5	3.0	3.5	4.0	4.5	5.0 (Highest)	Comments
Sample Processing	Biological samples are processed in the field using visual guides; sorting and identification are dependent on operator skill and effort.		Organisms are identified and enumerated primarily in the field prohibiting ample QC but done by trained staff; for fish cursory examination of presence and absence only; no in-house development of SOPs.		Laboratory processing of all samples (except for fish); A formal QA/QC program is in place; rigorous training is provided; vouchering of organisms done for ID verification.		Same as Level 3, but is applicable to multiple assemblages; subsampling level tested. Notations made on fish as to diseased, erosion, lesion, tumors.	Sample processing fully developed for statewide program and for two assemblages; some regional programs are not as well developed. **Points** **Statewide: 5.0** **Regional: 4.0**

Appendix Table 2. (continued)

Element 9	(Lowest) 2.0	2.5 / 3.0	3.5 / 4.0	4.5 / 5.0 (Highest)	Comments
Data Management	Sampling event data organized in a series of spreadsheets e.g., (by year, by data-type, etc); QC cursory and mostly for transcription errors.	Separate quasi-databases for physical-chemical and biological data (Excel, Access, dBase, etc) with separate GIS shape files of monitoring stations; data-handling methods manuals available; QC for data entry, value ranges, and site locations.	True relational database containing biological and sampled site info (Oracle, etc); fully documented and implemented data QAPP.	Relational database of bioassessment data (including indices and biocriteria) with real-time connection to spatial data coverage showing monitored sites in relation to other relevant spatial data layers (population density; impervious surfaces; vegetation coverage, low-flight photos, nutrient concentrations, ecoregion, etc); fully documented and implemented data QAPP; data available from multiple assemblages to enable integrated analysis.	**Points** **Statewide: 4.5** **Regional: 3.0**

Element 10	(Lowest) 1.5	2.0 / 2.5	3.0 / 3.5	4.0 / 4.5 (Highest)	Comments
Ecological Attributes	Linkage to the BCG or adherence to the basic ecological attributes as a foundation is lacking; simple measures of presence/absence.	Only inferences can be made for a few of the comparatively simple ecological attributes, e.g., sensitive/tolerant taxa of a ubiquitous nature; single dimension measures used.	Ecological attributes used as a foundation for bioassessment, but may not be fully developed, or may be lacking. BCG incorporated into conceptual underpinnings.	The ecological attributes of the BCG form the conceptual foundation; level of rigor represents or extends to all underpinnings of the ecological attributes.	Statewide O/E model and 3 regional MMIs have been developed; periphyton index under development. **Points** **Statewide: 4.0** **Regional: na**

Appendix Table 2. (continued)

Element 11	(Lowest) 1.0	1.5	2.0	2.5	3.0	3.5	4.0 (Highest)	Comments
Biological Endpoints and Thresholds	Assessment may be based only on presence or absence of targeted or key species; (Some citizen monitoring groups use this level); attainment thresholds not specified; this approach may be sufficient for Coarse problem identification. Coarse method (low signal) and detects only high and low values.		A biological index or endpoint is established for specific water bodies, but is likely not calibrated to waterbody classes or statewide application; index is probably relevant only to a single assemblage; presence/absence based on all taxa; BPJ thresholds based on single dimension attributes. Limited to pass/fail determinations of attainment status that does not reflect incremental measurement along the BCG.		A biological index, or model, has been developed and calibrated for use throughout the State or region for the various classes of a given waterbody type; the index is relevant to a single assemblage; attainment thresholds are based on discriminant model or distribution of candidate reference sites, or some means of quantifying reference condition. Can distinguish 3-4 increments along the BCG; supports narrative evaluations based on multimetric or multivariate analysis that are relevant to the BCG.		Biological index(es), or model(s) for multiple assemblages is (are) developed and calibrated for use throughout the State or region and corresponds to the BCG; integrated assessments using the multiple assemblages are possible, thus improving both the assessment and diagnostic aspects of the process; multiple parameters for evaluation, based on integrated data calibrated to regional reference condition. Able to detect status (integrated signal) on a continuous scale along the BCG; power to detect at least 5-6 categories of condition.	O/E model is statewide; MMI developed for selected regions; periphyton in development. **Points** **Statewide: 3.5** **Regional: na**

Element 12	(Lowest) 1.0	1.5	2.0	2.5	3.0	3.5	4.0 (Highest)	Comments
Diagnostic Capability	Diagnostic capability lacking.		Coarse indications of response via assemblage attributes at gross level, i.e., general indicator groups (e.g., EPT taxa); Supporting analysis across spatial and temporal scales limited.		More detailed development of indicator guilds and other aggregations to distinguish and support causal associations; usually involves refined taxonomy (at least genus level); supported by analysis of larger datasets and/or extensive case studies; patterns repeatable across different sources; developed for a single assemblage only.		Response patterns are most fully developed and supported by organized and extensive research and case studies across spatial and temporal scales; results are actively used in biological assessment and in assigning associated causes and sources for program support purposes; involves refined taxonomy; accomplished for two assemblage groups.	Baseline research to support diagnosis has not been completed; baseline database is being developed – need to assure full range of stress:response in statewide and regional datasets. **Points** **Statewide: 2.5** **Regional: na**

Appendix Table 2. (continued)

Element 13	(Lowest) 1.5	2.0 2.5	3.0 3.5 4.0	4.5 (Highest)	Comments
Professional Review and Documentation	Review limited to editorial aspects.	Internal scientific review only, Outside review for objectivity left for higher levels.	Outside review of documentation and reports conducted. However, selection of peer review can be subjective.	Formal process for technical review to include multiple reference and documented system for reconciliation of comments and issues. Process results in methods and reporting improvements. Can include peer-reviewed journal publications.	A formal process is in place and is used; methods and protocols are in the process of being published in journals. **Points** **Statewide: 4.5** **Regional: na**

Statewide CE Score = 53 (Regional = 50.5)
Statewide CE % = 88.3% (Regional = 84.2%)
Statewide Level = L3 [85-95%] (Regional Level = L2 [70-85%])

Appendix Table 3. Summary of the critical technical elements evaluation for the California WRCB statewide bioassessment program conducted January 23-25, 2008.

Element	Comment
Element 1: Index Period Maximum score = 4.5 Statewide = 4.5 Regional = 4.0	The statewide program adheres to a standardized index period that slides from north to south. The regional board score will improve to 4.5 once the standard permit boilerplate language developed by the Lahontan Region is standardized statewide.
Element 2: Spatial Coverage Maximum score = 4.5 Statewide = 3.5 Regional = 4.0 Combined = 4.0	The current score of 3.5 for the statewide program reflects the statewide probabilistic design and "pour point" design for integrator sites. Regional boards apply watershed scale designs that include a resolution at an 8-11 digit HUC spatial scale and other designs such as upstream/downstream sampling. The regional board score of 4.0 reflects the watershed design and rotating subbasin approach applied by some, but not all boards. The combined score of 4.0 reflects the practical integration of the statewide and regional board programs as a reflection of the overall WRCB effort. Attaining a score of 4.5 will be realized when the watershed design is applied by all of the regional boards.
Element 3: Natural Classification Maximum score = 5.0 Statewide = 3.5 Regional = na	The CE score of 3.5 will be elevated to 5.0 with the developments that are already underway including the inclusion of other bioregions (the na score for the regional boards reflects the relevancy of this element to a statewide setting).
Element 4: Criteria for Reference Sites Maximum score = 5.0 Statewide = 5.0 Regional = na	The score of 5.0 for the statewide program reflects the high degree of development of reference site selection criteria and procedures (the na score for the regional boards reflects the relevancy of this element to a statewide setting).
Element 5: Reference Conditions Maximum score = 4.0 Statewide = 3.5 Regional = na	The CE score of 3.5 should improve to 4.0 with the addition of regional reference sites that are being established as part of the ongoing improvements described for elements 3 and 4 (the na score for the regional boards reflects the relevancy of this element to a statewide setting).

Appendix Table 3. (continued).

Element	Comment
Element 6: Taxonomic Resolution Maximum score = 5.0 Statewide = 4.5 Regional = 4.5	The CE score of 4.5 reflects the full development of the macroinvertebrate assemblage and the in progress development of a periphyton indicator. Fish may be applicable in certain regions pending developments by USGS. Reaching the CE score of 5.0 is contingent on the full development and use of a second assemblage.
Element 7: Sample Collection Maximum score = 5.0 Statewide = 5.0 Regional = 5.0	The CE score of 5.0 reflects the full development of the macroinvertebrate and periphyton assemblage methodologies for the statewide and regional programs. Fish methods also exist n other agencies.
Element 8: Sample Processing Maximum score = 5.0 Statewide = 5.0 Regional = 4.0	The CE score of 5.0 for the statewide program reflects the full development of the macroinvertebrate and periphyton assemblage sample processing methods. The regional boards have the capacity to apply the macroinvertebrate assemblage. Reaching the CE score of 5.0 is contingent on the full use of a second assemblage by the regional boards.
Element 9: Data Management Maximum score = 5.0 Statewide = 4.5 Regional = 3.0	The CE score of 4.5 for the statewide program can be improved to 5.0 once the current data management system includes all reporting fields and calculation routines. The regional board score should likewise improve when their data is routinely uploaded to the statewide data management system.
Element 10: Ecological Attributes Maximum score = 4.5 Statewide = 4.0 Regional = na	The CE score of 4.0 should increase with the development of the macroinvertebrate MMI and O/E model for all bioregions and the addition of a second assemblage (the na score for the regional boards reflects the relevancy of this element to a statewide setting).
Element 11: Biological Endpoints & Thresholds Maximum score = 4.0 Statewide = 3.5 Regional = na	The CE score of 3.5 will improve with the full development of the macroinvertebrate MMI and O/E models, a second assemblage, and the derivation of appropriately detailed numeric biocriteria (the na score for the regional boards reflects the relevancy of this element to a statewide setting).

Appendix Table 3. (continued).

Element	Comment
Element 12: Diagnostic Capability Maximum score = 4.0 Statewide = 2.5 Regional = na	The comparatively low CE score of 2.5 is a common characteristic of bioassessment programs that are in development and/or which have singularly been focused on status assessments. Improving the score for this element will occur as a result of addressing preceding elements 2, 3, 6, 10, and 11 and gaining a familiarity with how diagnostic capacity is developed; a familiarity with the concepts involved is encouraging. This will require some dedication to exploratory analyses in which the response of the biological assemblages is evaluated along the stressor axis of the BCG.
Element 13: Professional Review Maximum score = 4.5 Statewide = 4.5 Regional = na	The CE score of 4.5 reflects a thorough and complete peer review process. Statewide methods and procedures are in the process of being published in refereed journals.

Program update

Overview of a redesigned survey

In 2015, the SMC initiated the first year of its redesigned stream bioassessment survey, sampling 102 sites and implementing several major changes to address information gaps identified in the initial five-year survey, including:

- Inclusion of nonperennial streams in the survey. Whereas nonperennial streams were previously excluded from sampling, we now attempt to include them among the 55 “condition” sites (i.e., sites selected in a probabilistic way to represent the typical condition of streams in the region) where bioassessment occurs. By shifting the sampling period earlier in the season (starting as early as March), intermittent streams that dry up before May are more likely to be represented in the survey.
- Improved trend detection through site revisits. A total of 47 “trend” sites that were sampled in the first cycle of the survey were revisited in 2015. With a sufficient number of revisits, the survey will be able to determine the extent of stream-miles that are improving or degrading over time, and identify factors that are associated with these trends.
- A change in analytes and indicators measured at each site. In order to focus on new priorities and concerns, SMC participants sampled a number of new indicators (highlighted elsewhere in this report), such as hydromodification impact potential, aquatic invasive vertebrate occurrences, hydrologic state, cellular bioassays, and non-target analysis of chemicals of emerging concern. Assessment of sediment contamination, although part of the updated survey workplan, was deferred so that a pilot study in limited areas could be completed in 2016.

What is the Stormwater Monitoring Coalition (SMC)?

The SMC is a coalition of multiple state, federal, and local agencies that works collaboratively to improve the management of stormwater in Southern California. SMC members include regulatory agencies, flood control districts, and research agencies: County of Los Angeles Department of Public Works, County of Orange Public Works, County of San Diego Department of Public Works, Riverside County Flood Control and Water Conservation District, San Bernardino County Flood Control District, Ventura County Watershed Protection District, City of Long Beach Public Works Department, City of Los Angeles Department of Public Works, California Regional Water Quality Control Board—Santa Ana Region, Los Angeles Region, and San Diego Region, State Water Resources Control Boards, California Department of Transportation, Southern California Coastal Water Research Project (SCCWRP). In addition, the SMC collaborates with the U.S. Environmental Protection Agency Office of Research and Development. For more information, visit the SMC webpage at www.socalsmc.org.

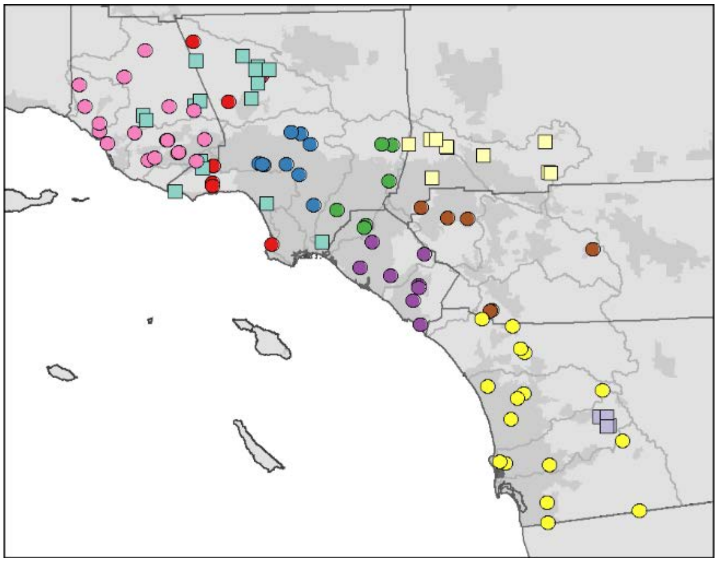
The SMC has conducted a probabilistic survey of streams in the South Coast region since 2009. The goals of this survey are to provide the technical foundation for scientifically sound management of stormwater by answering three questions:

1. What is the biological condition of streams in the South Coast region?
2. What stressors are associated with streams in poor condition?
3. Are the conditions of streams changing over time?

The first five-year cycle of survey took place between 2009 and 2013. The results of the first cycle are summarized in a report available on SCCWRP’s website. The survey continues with a new cycle that spans from 2015 to 2019, evolving to address new questions. This report summarizes the current status of the survey and describes major developments and accomplishments that occurred in 2015. A comprehensive report will be released after completion of the fifth year of the current cycle.

B357

Changes in cost from the first cycle were minimized, as certain indicators (i.e., toxicity, metals, and pyrethroids in the water column) were dropped based on recommendations by the SMC workgroup. Priority indicators that were retained, such as benthic macroinvertebrates, algae, riparian wetlands (i.e., CRAM), physical habitat, nutrients, and major ions, were sampled at every site.



Sampling effort in 2015 by agency.

Stormwater agencies	**Condition (□ sites)**	**Trend (□ sites)**	**Total (□ sites)**
Ventura County	10	8	18
Los Angeles County	5	2	7
Los Angeles WMP	3	6	9
San Gabriel RMP	2	4	6
Orange County	5	3	8
Riverside County	3	3	6
San Diego WMAs	12	4	16
Water boards			
RB4	9	7	16
RB8	4	6	10
RB9	2	4	6
Total	55	47	102

San Diego Watershed Management Areas (black text) nested within SMC watersheds (brown text). Local jurisdictions take the lead in monitoring each WMA and setting management priorities, contributing to and making use of the SMC's regional survey.

New watershed-based permits enhance interactions with multiple agencies in San Diego County

Marking a major transition in the implementation of the SMC survey in San Diego County, smaller municipalities (including the cities of Oceanside, Encinitas, San Diego, and Imperial Beach) are now working directly alongside SMC member agencies to collect data for the survey, as opposed to working indirectly through San Diego County Public Works as a lead agency. This transition is intended to increase interaction between stormwater co-permittees and the San Diego Regional Water Quality Control Board, while also making the survey more useful to local managers. These municipalities contribute to the survey through coalitions focused within Watershed Management Areas (WMAs). The WMAs have the effect of spreading responsibility among the individual municipalities to fulfill the permit obligations. As a result, more municipalities are engaged with the regional monitoring program in supporting their management and regulatory needs.

The formation of WMAs began when the San Diego Regional Water Board consolidated municipal stormwater permits into a single regional stormwater permit. Whereas previously, all monitoring in San Diego County was coordinated through a single agency (i.e., the County of San Diego), each WMA coalition is now tasked with collecting data and identifying management priorities for its own WMAs. Survey data are used to develop a Water Quality Improvement Plan, or WQIP (see article on the San Juan WQIP below) for each WMA, with stakeholders responsible for identifying priority issues and associated stressors that each coalition should address. For watersheds that cross county borders (e.g., Santa Margarita), the WMAs facilitate cooperation among municipalities in the different jurisdictions.

Not only do the WMAs help the partners outside the SMC with the survey, but they also carry forward the SMC's vision of collaborative monitoring to the local level. Through minor adjustments to the SMC's sampling plan (e.g., allocating trend sites by watershed rather than by land use), combined with enhanced dialogue between permittees and the Regional Board, the new partners were able to acquire data for their own needs, as well as contribute to the regional assessment goals of the SMC survey.

What are the biological conditions in engineered channels?

The SMC survey helps managers evaluate biological conditions in engineered channels and understand the potential policy implications.

Key Points

- Engineered channels surveyed to date are, generally speaking, in worse ecological health than natural channels based on biological indicators based on benthic macroinvertebrate and algae assemblages. These preliminary results suggest that tradeoffs between ecological health and flood protection may be unavoidable.
- While engineered channels invariably have poor scores for the California Stream Condition Index (CSCI) based on benthic macroinvertebrates, algal indices occasionally indicated better biological conditions—sometimes similar to reference condition. This wide range in index scores suggest that some engineered channels support more ecosystem functions than others.
- Within engineered channels, design and construction characteristics (e.g., armoring material or presence of low-flow features) did not influence index scores or other measures of ecological condition
- Within engineered channels, algal indices may reflect water quality conditions better than the macroinvertebrate index. For example, lower specific conductivity was associated with higher diatom index scores, but not CSCI scores. However, both types of indices have some capacity to respond to stressor gradients in these systems.
- Targeted sampling (particularly from hardened channels with good water quality, or engineered channels with high bioassessment index scores) and experimental studies may clarify the factors that support better ecological conditions.
- Survey data can provide a context for evaluating the biological condition of streams in engineered channels, thereby helping managers recognize factors, such as water quality or stream temperature, that may lead to better conditions.

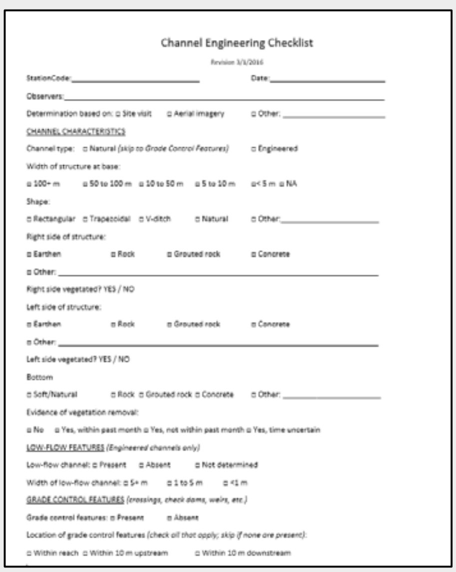
Engineered channels are common features in urban stormwater systems, protecting surrounding neighborhoods from floods that could damage property or endanger lives. However, this service often comes at a cost, as engineered channels do not provide the same quality habitat that natural stream channels provide. Additionally, engineered channels may reduce groundwater recharge, or degrade water quality through alterations of biochemical processes. Consequently, engineered channels often fail to support designated beneficial uses related to ecosystem health, such as those related to aquatic life or wildlife. Faced with these tradeoffs between competing uses, stormwater agencies and regulators encounter questions from stakeholders, such as what range of ecological conditions are possible in engineered channels? And what factors can be managed to support better conditions? The SMC stream survey provides a rich source of data to answer these questions. By developing methods to characterize engineered channels, analyzing bioassessment scores in different channel types, and exploring responses to water chemistry gradients, the SMC stream survey offers preliminary answers to these questions.

Bioassessment indices, such as the California Stream Condition Index (CSCI, based on benthic macroinvertebrate communities) and the Southern California algal Indices of Biotic Integrity (IBIs), are the key indicators used by the State and Regional Water Boards to assess attainment of aquatic life beneficial uses in streams. These indices will have a central role in the implementation of the State's bio-integrity policies; it is therefore necessary that stormwater managers understand how these indices work in engineered channels. Aquatic organisms have diverse life history traits with sensitivities to a wide range of stressors. As a result, bioassessment indices provide a holistic measure of the combined impacts of poor water quality, habitat alteration, hydrologic modification, and other disturbances. This integration allows assessment of cumulative and diverse impacts on ecosystem health. Three indices are sampled in the SMC program: the CSCI, a diatom index, and a soft algal index; each of these three indices provide an independent measure of a stream's ability to support aquatic life.

To assess the range of biological conditions in engineered channels, the SMC took advantage of the extensive bioassessment data collected by the survey since its inception in 2009. In prior years, the SMC collected benthic macroinvertebrates and algae samples at hundreds of sampling reaches across Southern California, many of which were in engineered channels. In order to make the use of these data, the SMC bioassessment workgroup developed a simple procedure for characterizing and classifying the different types of channels found in the region (Sidebar 1). The protocol was designed for rapid application in the field or in the office (if aerial imagery or other data are available). This ease of use meant that the SMC could generate a large data set from recent and older data that would support robust analyses on the features of engineered channels associated with variability in bioassessment scores. Elements of this protocol have been adopted by the Surface Water Ambient Monitoring Program (SWAMP), and resource managers throughout the state are looking to the SMC to provide guidance on how to evaluate engineered channels in their regions. These data will also be used in mapping and modeling efforts to determine locations of engineered channels in the landscape.

Characterizing engineered channels

Modification of stream channels takes many forms, exhibiting a variety of designs and constructions. To characterize the diversity of engineered channels, the SMC developed simple forms to record key features, like shape, material, size, and presence of low-flow channels. These forms were filled out during site visits for the 2015 sampling season, as well as for sites visited in earlier years (relying on aerial imagery, photographs, data from earlier field visits, and other sources of information). Elements of the SMC's approach for characterizing engineered channels have been incorporated into SWAMP's standard bioassessment protocols.



Channel Engineering Checklist

Revision 3/1/2016

StationCode:______________ Date:______________

Observers:______________

Determination based on: □ Site visit □ Aerial imagery □ Other: ______________

CHANNEL CHARACTERISTICS

Channel type: □ Natural *(skip to Grade Control Features)* □ Engineered

Width of structure at base:

□ 100+ m □ 50 to 100 m □ 10 to 50 m □ 5 to 10 m □< 5 m □ NA

Shape:

□ Rectangular □ Trapezoidal □ V-ditch □ Natural □ Other:______________

Right side of structure:

□ Earthen □ Rock □ Grouted rock □ Concrete

□ Other: ______________

Right side vegetated? YES / NO

Left side of structure:

□ Earthen □ Rock □ Grouted rock □ Concrete

□ Other: ______________

Left side vegetated? YES / NO

Bottom

□ Soft/Natural □ Rock □ Grouted rock □ Concrete □ Other: ______________

Evidence of vegetation removal:

□ No □ Yes, within past month □ Yes, not within past month □ Yes, time uncertain

LOW-FLOW FEATURES *(Engineered channels only)*

Low-flow channel: □ Present □ Absent □ Not determined

Width of low-flow channel: □ 5+ m □ 1 to 5 m □ <1 m

GRADE CONTROL FEATURES *(crossings, check dams, weirs, etc.)*

Grade control features: □ Present □ Absent

Location of grade control features *(check all that apply; skip if none are present)*:

□ Within reach □ Within 10 m upstream □ Within 10 m downstream

Forms developed by the SMC to characterize engineered channels are simple enough to complete within minutes during field visits, or from the office if aerial imagery and other data are available.

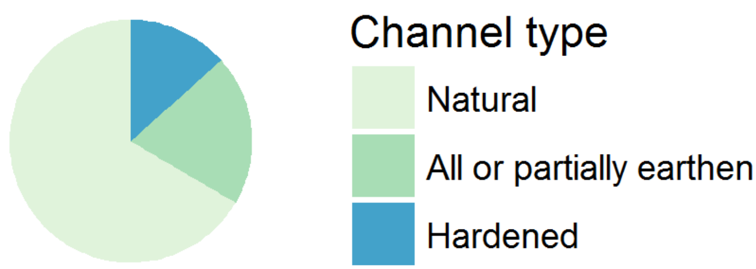


Figure 1. Proportion of stream types observed in the study

Armed with this protocol, the SMC bioassessment workgroup evaluated 724 unique bioassessment sites, with about 20% of these evaluations being made in the field. About two-thirds of the sites were natural, lacking any evident armoring, artificial structures (apart from road or bridge crossings), or straightening (Figure 1). Ninety-seven sites were entirely hardened, with concrete or grouted rock banks and a hardened bottom. The remaining 145 sites retained some earthen elements—typically a natural bottom, with earthen or partially armored banks. Because CSCI and algae IBI scores had already been calculated for these sites from the previous survey cycle, and because water chemistry and habitat quality measurements were also available, the data set was a good starting point for analyzing biological conditions in engineered channels.

Engineered channels are largely in poor condition, but some are in better condition than others

Nearly all engineered channels were in poor health, as measured by both the CSCI and the algal IBIs (Figure 2). Although a wide range of invertebrate CSCI scores was evident in engineered channels (inter-quartile range: 0.44 to 0.66), they rarely exceeded 0.79 (the threshold used in previous SMC reports to identify healthy streams similar to reference conditions). None of the entirely hardened channels met this benchmark, and only 14% of the earthen or partially hardened engineered channels did so. In contrast, 63% of the natural channels in the analysis met the healthy stream benchmark. Aquatic insect communities appear to be strongly affected by partial or complete channel hardening (see Sidebar 2).

Algal indices, however, provided different insights into stream condition. While the diatom and soft algae IBIs, like the CSCI, showed that engineered channels were generally in worse condition than natural channels, high algal IBI scores indicative of healthy (i.e., similar to reference) conditions were not uncommon. In fact, 43% of hardened channels had diatom IBI scores above the reference threshold, and 20% had high soft algae IBI scores. Whereas the CSCI indicated almost exclusively poor conditions in engineered channels, algal indicators suggest that engineered channels can support healthy streams under conducive conditions (such as good water quality).

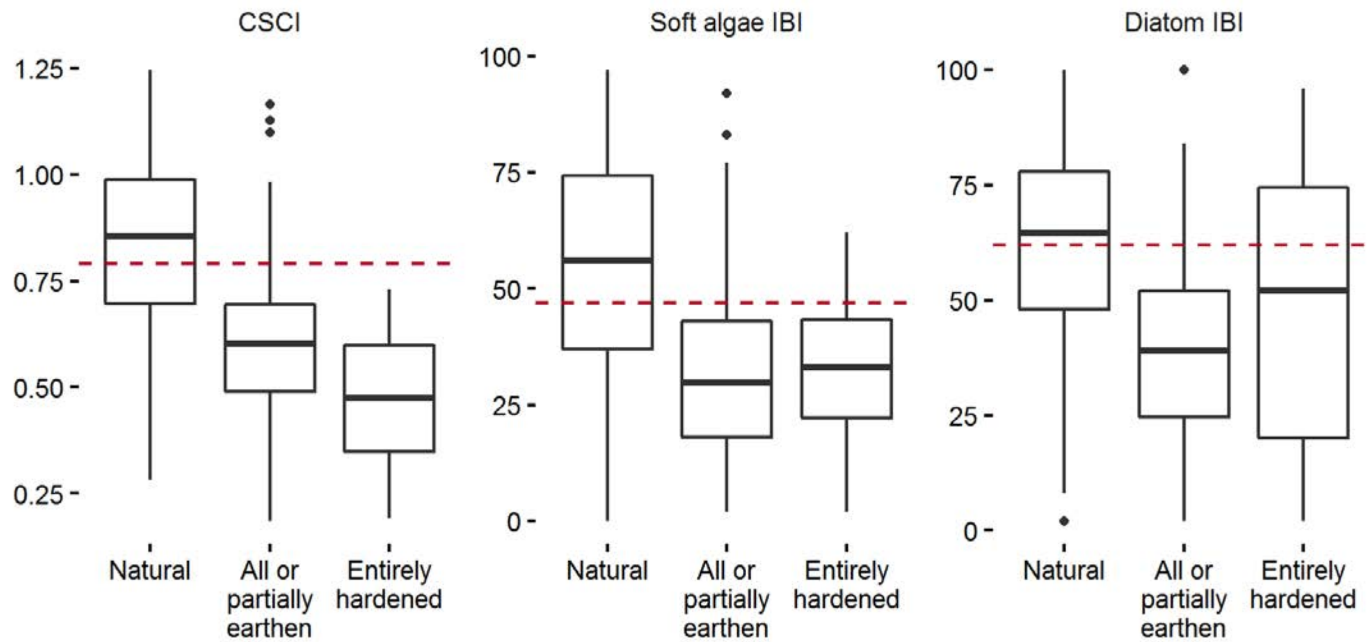

Figure 2. Bioassessment scores were typically higher in natural channels than in engineered channels. However, high scores for the algal indices were sometimes observed in engineered channels, occasionally exceeding the threshold for identifying sites in reference condition (red dashed line).

What kind of organisms are found in engineered channels?

Despite the poor in-stream ecological condition noted in this study, engineered channels do, in fact, support aquatic life, as well as terrestrial wildlife that depend on streams and rivers. Because of their accessibility and proximity to populated areas, engineered channels are frequently enjoyed for their wildlife-viewing opportunities, particularly for waterfowl and wading birds that forage in shallow areas. Although fish and amphibians are sometimes observed as well, these are almost exclusively non-native species, such as carp (*Cyprinus carpio*), tilapia (Cichlidae), bullhead (*Ameiurus*), and mosquito fish (*Gambusia affinis*).

Great blue herons and black-necked stilts forage on the concrete banks of the San Gabriel River.

Photo courtesy of Kerry Matz

***Dasyhelea*, a fly in the family of biting midges (*Ceratopogonidae*), are particularly common in hardened channels.**

The benthic macroinvertebrates found in engineered channels are only a small subset of the diversity of species found in the natural channels, typically with life history adaptations that provide resilience to disturbance (for example, rapid life-cycles with multiple generations per year, or tolerance to temperature extremes). A few invertebrate species show a particular affinity for engineered channels: Biting midges (*Dasyhelea*), soldier flies (*Euparyphus*), minnow mayflies (*Fallceon*), snails (*Physa*), worms (Oligochaeta), flatworms (Turbellaria), and seed shrimp (Ostracoda) were all more common than expected within hardened channels. Species that require complex substrates, such as those that burrow in the substrate (e.g., midges in the subfamily Tanypodinae) were less common than might be expected in a natural channel. Most sensitive and moderately tolerant species (e.g., net-spinning caddisflies, like *Hydropsyche*) were entirely eliminated. The abundance of tolerant species, and rarity of sensitive species, is reflected in the lower CSCI scores observed in engineered channels.

As with macroinvertebrates, algal assemblages within engineered channels contained subsets of species found in natural channels. Many planktonic diatoms, such as species in the *Scenedesmus* genus, were common, as well as the green filamentous algae *Cladophera glomerata*, found at nearly all concrete channels. These species are sometimes a concern. For example, *C. glomerata* form large, unsightly mats that trap debris, smother streambeds, and create odor problems.

The green alga *Cladophora glomerata* often proliferates in engineered channels, particularly if nutrient inputs are high and shading has been reduced.

What factors support higher bioassessment scores in engineered channels?

Why do some engineered channels score better than others? And why are high scores more common for algal IBIs than for the invertebrate CSCI? Design features (such as construction material or presence of a low-flow channel) had no discernible impact on either CSCI or algal IBI scores, so perhaps water quality or other habitat features were more important. That is, relatively high scores in engineered channels may indicate better water or habitat quality than lower scores.

Analyses of the data provide some support for this hypothesis. The diatom index responded to a range of water quality conditions, even within concrete channels (Figure 3, Table 1). For example, the diatom IBI declined with increasing specific conductivity in all channel types, whereas scores for the soft algae index and the CSCI exhibited responses within natural or partially earthen channels. The hypothesis that the constraints within engineered channels overwhelm the ability of bioassessment indicators to respond to stress is not well supported for diatoms.

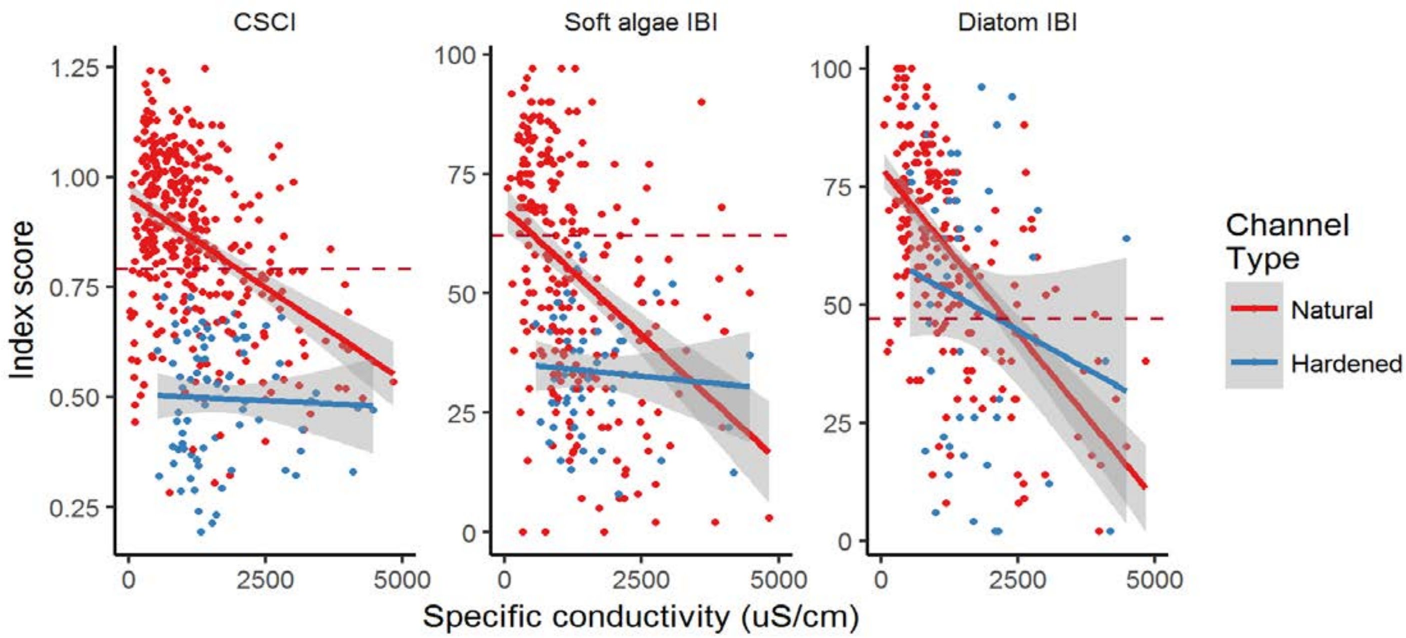

Figure 3. Specific conductivity versus bioassessment index scores in hardened and natural channels. The red dashed line is the threshold for sites in reference condition. For clarity, earthen and partially hardened channels are excluded from this plot.

Factors related to habitat showed a similar pattern of responses. For example, high levels of sands and fines in the streambed were associated with lower scores for all indices, but the relationships within hardened channels were strongest for the diatom index (Figure 4). Although the CSCI did not respond to many water chemistry and physical habitat gradients within hardened channels, shading and temperature appears to be important for this index, with higher scores observed in hardened channels where shading was high (Figure 5). Stream-side vegetation, which is often removed for flood control purposes, may provide the conditions that improve CSCI scores. However, shading had the opposite relationship with diatom IBI scores, and no relationship with soft algae IBI scores.

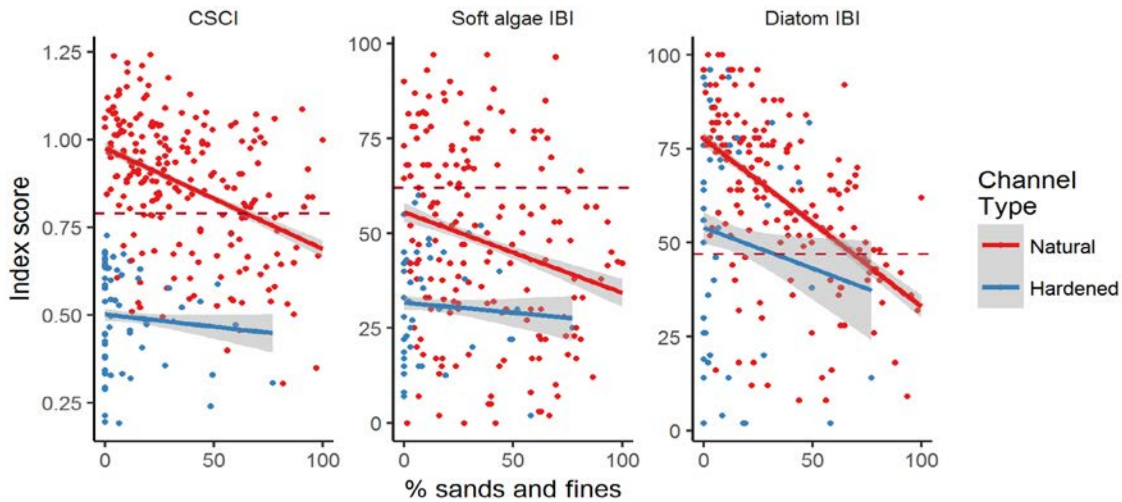

Figure 4. Percent sands and fines in the streambed versus bioassessment index scores in hardened and natural channels. The red dashed line is the threshold for sites in reference condition. For clarity, earthen and partially hardened channels are excluded from this plot.

Little Dalton Wash: An example of a high-scoring engineered channel

Figure 6. Little Dalton Wash.

Perhaps the most valuable insight provided by the SMC's study of engineered channels is that it helps managers identify examples of high-scoring sites, providing a target for managing streams in poorer condition. One such site is Little Dalton Wash, part of the San Gabriel River watershed in Azusa (Figure 6). Although the CSCI score of 0.73 was somewhat lower than the threshold of 0.79 for identifying sites in reference condition, it was higher than nearly all other hardened channels in the data set. Moreover, the diatom IBI score of 92 was well above the threshold of 62, although the soft algae IBI score was low (23). When compared to other hardened channels in the SMC survey, the unusually high scores at Little Dalton Wash are evident (Table 2).

Index	Score	Percentile of reference	Percentile of hardened channels
CSCI	0.73	3	92
Diatom IBI	92	84	92
Soft algae IBI	23	0	15

Table 2. Index scores at Little Dalton Wash compared to reference sites and to other hardened channels. Percentiles calculated through a normal approximation.

The field conditions at Little Dalton Wash are not different from other hardened channels in any obvious way. The sampled reach is in a rectangular concrete box that lacks low-flow features. Located in the midst of a heavily developed area, it receives drainage from a 27-km^2 watershed that is more than one-third urbanized. However, comparison with survey data from other hardened channels suggest a few possibilities. Several water quality analytes, as well as physical habitat metrics, were better at Little Dalton Wash than at lower-scoring hardened channels, including chloride, total nitrogen, temperature, and specific conductivity (Figure 7). The diversity of flow microhabitats (e.g., riffles and glides) was high as well. These factors may explain the higher scores observed at this site.

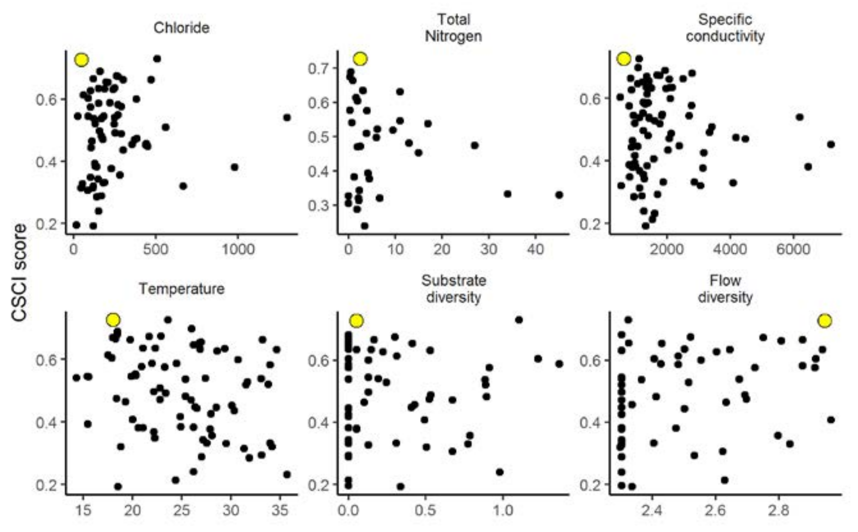

Figure 7. CSCI scores versus water quality and habitat metrics in hardened channels. The large yellow symbol represents Little Dalton Wash.

Conclusions

These preliminary results suggest that, although ecological health is clearly degraded in hardened channels, higher bioassessment index scores could be supported in certain reaches if water quality and in-stream habitat conditions are good. The ranges of observed index scores provide a starting point for managers, regulators, and stakeholders to discuss which types of actions are needed to achieve the desired level of health in modified channels, or in downstream receiving waters.

The SMC survey has cleared up a few major questions about engineered channels. It demonstrated that, although conditions in engineered channels are generally poor, some channels support better conditions than others. Additionally, this analysis underscores the value of a multi-indicator approach to ecological health assessment, as each assemblage adds to a more well-rounded view of the condition of engineered channels. Additional data may help further identify the factors that lead to better ecosystem health in engineered channels, including targeted sampling of concrete channels with good water quality, monitoring after the removal of concrete features from a channel (see Sidebar 3), and tracking water quality improvements following the implementation of best management practices that remove pollutants. Although this opportunistic analysis of available SMC survey data suggests that an engineered channel may not be able to support aquatic life as well as natural streams can, and tradeoffs between flood protection and ecological condition may be unavoidable, it shows that a range of conditions is possible, and that better conditions may be possible through management of water quality and habitat.

Restoration of engineered channels

Restoring natural features in engineered channels is sometimes proposed as a way to improve ecological conditions, as well as create amenities like improved flood control and enhanced recreational opportunities. In the County of San Diego, concrete walls and bank armoring were removed from a 1.2-mile segment of Forester Creek in 2006 at a cost of $36 million, returning the channel to a more naturalistic, vegetated form. Some water quality impairments improved following restoration (e.g., pH), while others did not (e.g., total dissolved solids). Bioassessment scores (measured with the Southern California IBI, which preceded the CSCI) increased from 25 to 40 points, although too few samples have been collected to see if this difference is statistically significant.

Left: Forester Creek upstream of the restoration site. Right: The restored portion of Forester Creek.

The Los Angeles River provides a much larger-scale example. The revitalization master plan for the Los Angeles River calls for the removal of concrete walls from up to 32 miles of the river, wherever it is safe and feasible to do so. This project may be one of the largest urban river restoration efforts undertaken in the country. With a cost that will exceed $1 billion, the impact on the river's ability to support aquatic life are not clear. Fortunately, the SMC stream survey provides abundant data, both from the Los Angeles River itself, as well as from comparable hardened and restored rivers, to provide benchmarks that enable the success of this effort to be evaluated.

Updates on new indicators

Cell bioassays evaluate the potential for harm from chemicals of emerging concern

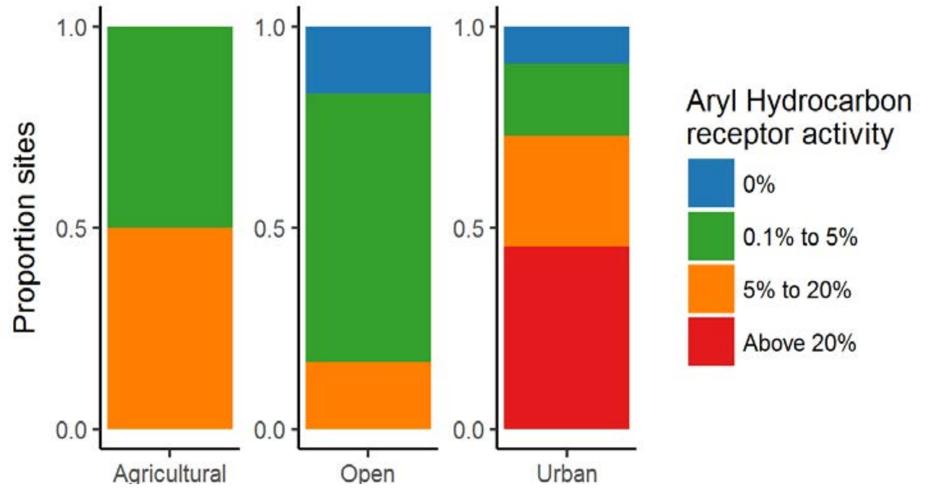

Figure 1. Aryl hydrocarbon receptor (AhR) responses were measured at sites representing different land uses within the SMC stream survey area.

Chemicals of emerging concern (CECs) have the potential to degrade ecological condition and harm human health through endocrine disruption and other physiological pathways. Comprising over 10,000 distinct chemical compounds, CECs come from pharmaceuticals, personal care products, and other sources. Many of them are biologically active, with the potential to disrupt hormonal pathways of organisms. With hundreds of new compounds being added to commercial markets every year, most without disclosure of their composition, measuring the extent and impact of CECs in the environment through traditional (i.e., single-compound) approaches is unrealistic.

The SMC survey tested an alternative approach that promises to be more effective and less expensive than traditional methods. First, samples are used in bioassays to detect cellular-level responses, followed by a non-target (i.e., multiple-compound) analysis to identify the compounds that could cause the observed response. This screening approach provides new information about potential risks of contaminant exposure to humans, aquatic life, and wildlife. For example, estrogen receptor (ER) assays can help detect the presence of hormone-mimicking chemicals that affect growth, development, and reproduction. The SMC screened 31 samples collected in 2015—one of the first applications of this new technology to a stream biomonitoring program.

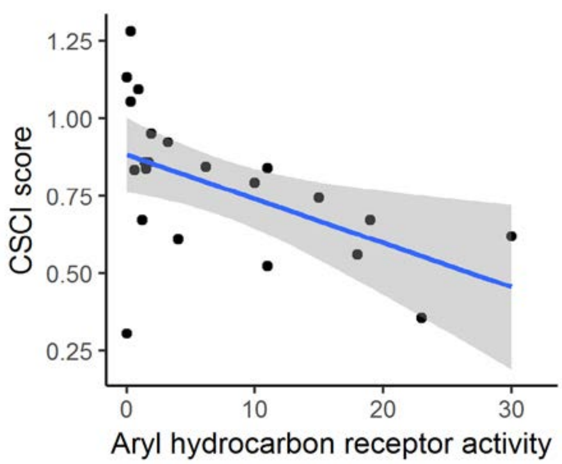

Figure 2. Aryl hydrocarbon receptor response versus CSCI scores

Responses for receptors of steroid hormones, such as glucocorticoid and estrogen, were rare, affecting only 2 and 8 sites respectively. In contrast, aryl hydrocarbon receptor (AhR) responses were widespread, affecting 28 of the 31 sites; furthermore, AhR responses were stronger at urban sites than at undeveloped sites (Figure 1). The AhR receptor is thought to play a role in mediating environmental toxicity and immune response, as well as supporting normal vascular development. Dioxins and other pollutants are known to provoke AhR responses.

Bioassay responses may explain why some sites are in poor biological condition. For example, AhR activity was negatively correlated with CSCI scores (r = -0.84, Figure 2), suggesting that contaminants known to cause AhR responses (e.g., polycyclic aromatic hydrocarbons, commonly associated with runoff from asphalt or combustion) may alter benthic macroinvertebrate assemblages (Figure 2). Follow-up targeted chemical analyses found sunscreen ingredients at sites with ER activity and flame retardants at sites with AhR activity, although concentrations were generally too low to explain the observed responses, meaning that other, unmeasured compounds are responsible. Field blanks were clean, meaning that contamination of the samples was not a likely cause of the response. Non-targeted analyses to identify these unknown chemicals are underway.

Assessing the ability of streams in southern California to support aquatic vertebrates

Figure 1. California tree frog (*Pseudacris cadaverina*), one of the more common native species of vertebrate found in Southern California streams.

Although the initial SMC stream survey provided a great quantity of data about stream condition based on benthic macroinvertebrates and algae, a lingering question remained about what our findings meant for higher trophic levels, such as fish, amphibians, and other vertebrates (Figure 1). Although a thorough investigation of this question is beyond the scope of the current regional monitoring program, the SMC found a way to get some answers, and at remarkably low costs.

In 2015, SMC field crews received training in identifying common aquatic vertebrates in the region, and began reporting observations of species they encountered during normal bioassessment sampling (that is, no additional time was spent trying to observe vertebrates). This effort began as a collaborative venture initiated by the SMC, the US Geological Survey (USGS), the US Fish and Wildlife Service (USFWS), and SWAMP, all of whom were hoping to improve their understanding of the spatial distributions of both native and non-native vertebrates in the region. The survey provided a concrete example of how the core regional monitoring program can be used to opportunistically collect data to answer important management questions. The resources necessary to successfully complete the survey were relatively trivial for several reasons: the SMC field teams were already visiting the sites; the teams already included biologists easily trained to identify stream vertebrates; and the sampling design was based on a time-saving casual observation approach, instead of a more traditional rigorous search at each site.

Despite the low costs, this survey provided a great deal of new and valuable data on vertebrates in the region’s streams, with observations attempted at a total of 95 sites (Figure 2). Vertebrates were seen at 46% of the sites, and surprisingly, the distributions of native frogs were fairly widespread across urban, agricultural and open land use types. These native amphibians were unexpectedly tolerant to the presence of non-native fish, frogs or crayfish. In contrast, native fish species were only observed at five mountainous sites. Mosquito fish (*Gambusia affinis*) were observed at 21 sites and were the most common non-native fish species, likely as a result of deliberate introduction as a vector-control measure.

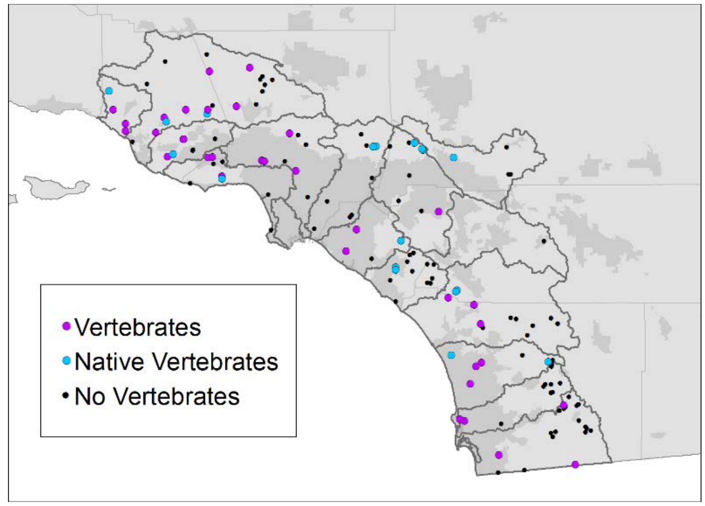

Figure 2. Location of vertebrate observations conducted in 2015.

Of the sites located on agricultural land, 68% supported vertebrates, although the many of these were non-natives (47%). In contrast, 49% of open land sites supported vertebrates, but only 17% of these were non-natives. It is important to note that these numbers likely underestimate the actual distribution of vertebrates because the field crews did not conduct exhaustive surveys of each site.

The addition of vertebrate observations to the survey yielded detailed information regarding the distributions of vertebrates throughout the southern California region, despite the limited amount of resources and training required to successfully implement it. Although more intensive efforts may have detected more species (especially nocturnal or cryptic species), opportunistic sampling was sufficient to improve our understanding of the ability of Southern California streams to support wildlife. Future work for this program might focus on the environmental and habitat factors that contribute to the presence or absence of vertebrates on agricultural, urban and open land use types; investigation of the relationships among vertebrates and other biological condition indicators including the CSCI, CRAM and Southern California algal IBIs; and improving our understanding of the spatial distribution of these important taxa by combining the SMC vertebrate dataset with those from iNaturalist, regional fish surveys, the USFWS, the USGS, and the California Department of Fish and Wildlife.

Applications of survey data

A water-quality improvement plan supported by survey data

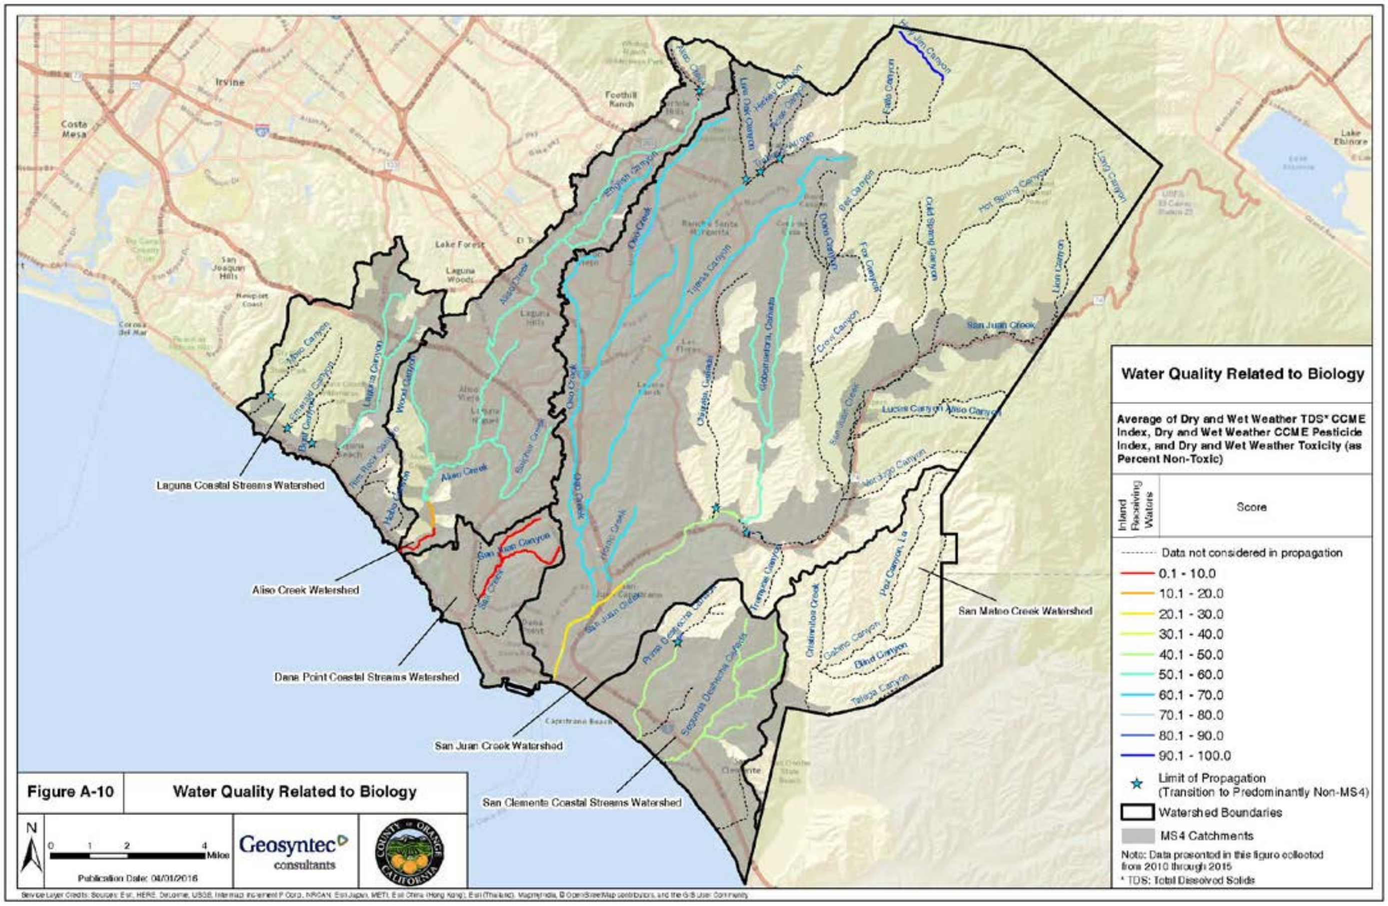

Figure 1. Excerpt from the San Juan Water Quality Improvement Plan shows how the County of Orange used SMC bioassessment and water quality data to prioritize problem areas in the watershed. Red, orange, and yellow stream segments have low-scoring bioassessment sites, in conjunction with measures of poor water quality. A separate analysis identifies stream reaches where low-scoring bioassessment occur in conjunction with geomorphic alteration.

A key objective of the SMC stream survey is to provide participants with data that helps them manage watersheds. One recent notable example is Orange County's Water Quality Improvement Plan (WQIP) for the San Juan Hydrologic Unit, which prioritizes problems in the watershed based on SMC data, emphasizing biological indicators like benthic macroinvertebrates and algae. The goal of the WQIP is to 1) determine high-priority water-quality problems; 2) identify goals, strategies, and schedules to address them; and 3) propose an approach to monitor and assess progress. In all three elements, the SMC survey provides the foundation and the framework for implementing these goals.

The WQIP identified three priority problems, and two of them were determined through bioassessment data: geomorphic alteration, and unnatural flow regimes. These problems were identified by the association of stressors related to these problems (e.g., hydromodification and habitat degradation), and their relationships with poor bioassessment index scores (Figure 1). Best management practices to mitigate these stressors will be identified, and their success will be partly determined in terms of improvements in biological condition. The monitoring and assessment component of the WQIP is currently under preparation, and it is expected that biological monitoring through the SMC stream survey will play a crucial role in this component.

Regional flow targets to support biological integrity

The SMC stream survey data provides a strong foundation to explore the problems affecting streams in the region, such as hydrologic alteration, which previous surveys suggested is a major factor affecting biological condition. Hydrologic alteration results from water diversions, inter-basin transfers, and increased imperviousness that alter the natural flow regime in a stream. Taking advantage of a new ensemble-modeling approach to estimate current and historic flows at ungauged streams, hydrologic alteration was estimated at 572 bioassessment sites, most of which are part of the SMC stream survey. The ensemble was built by calibrating simple rainfall-runoff models at 26 stream gauges in Southern California, then assigning one model to ungauged sites with similar catchment properties. Biological responses (e.g., California Stream Condition Index [CSCI] scores) were modeled against metrics reflecting hydrologic alteration, thresholds of biological response were established for multiple flow metrics, and metrics were combined into an overall index of hydrologic alteration with scores ranging from 0 (no alteration) to 14 (all metrics severely altered).

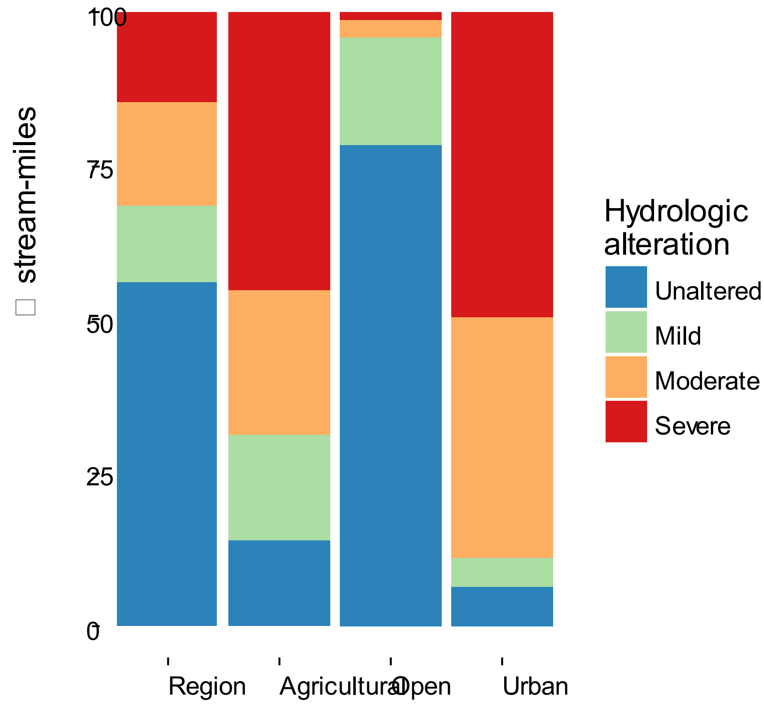

Figure 1. Extent of hydrologically altered streams in the region, as well as within three land-use classes.

Because this index was applied to survey data, it allowed the first-ever estimate of the extent of hydrologic alteration in the region. Approximately 34% of stream-miles in Southern California were estimated to be moderately or severely hydrologically altered, and alteration was more pervasive in urban (91% stream-miles altered) and agricultural (80%) than undeveloped (11%) streams (Figure 1).

The index also allowed rapid setting of management priorities and causal assessment screenings (Table 1, Figure 2). Among the biologically healthy sites (i.e., CSCI scores > 0.79), hydrologically unaltered sites (52% of total stream-miles) were prioritized for protection, and hydrologically altered sites (4%) were prioritized for monitoring. Among the biologically degraded sites, 30% were hydrologically altered, and prioritized for evaluation of flow management (such as increased stormwater detention or groundwater infiltration). Evaluation of other stressors was prioritized at the remaining 14% of stream-miles.

Table 1: Management action priorities based on measures of biological condition and hydrologic alteration.

	Unhealthy biology	Healthy biology
Altered hydrology	Evaluate flow management: 30	Monitor: 4
Unaltered hydrology	Evaluate other stressors: 14	Protect: 52

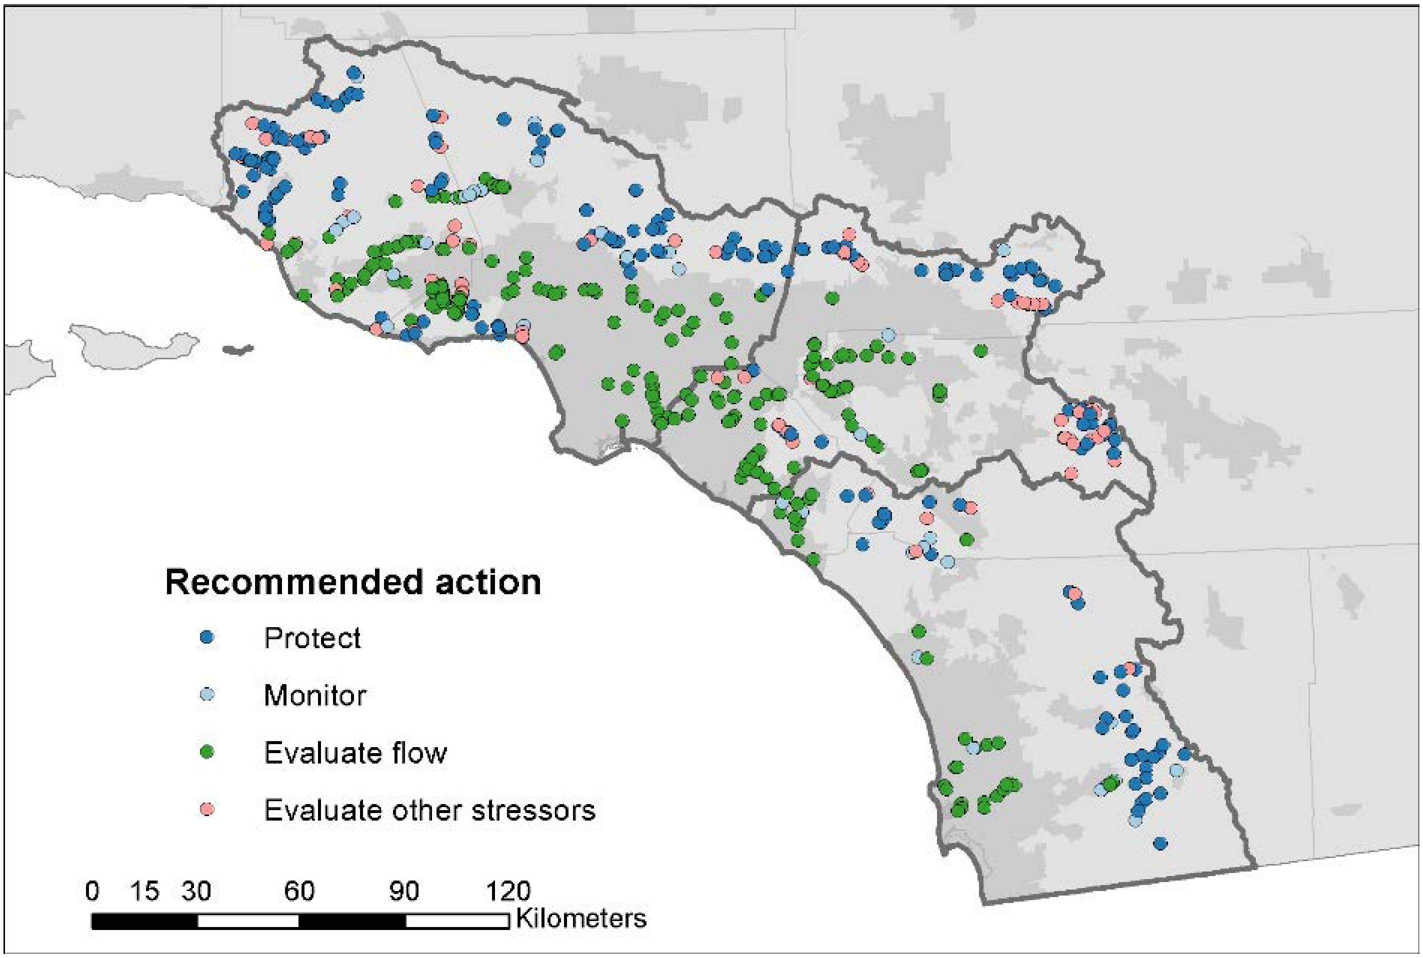

Figure 2. Management priorities for streams in the SMC region, based on estimates of hydrologic alteration and biological condition.

Regionally derived, biologically based targets for flow allow watershed managers to rapidly prioritize activities and conduct screenings for causal assessments at many sites across large spatial scales. Furthermore, regional tools pave the way for incorporation of hydrologic management in policies and watershed planning designed to support or enhance biological integrity in streams. Development of regional tools should be a priority in regions where hydrologic alteration is pervasive or expected to increase in response to climate change.

ACKNOWLEDGEMENTS

We thank the stakeholder workgroup for their participation and dedication to completing this demonstration project. The proof of concept and lessons learned would not have been possible without their engagement and support. We also thank Drs. Derek Booth and Brian Bledsoe for their review of draft manuscripts. Their critical reviews greatly improved the quality of the final product. This work was funded by the State Water Resources Control Board under Grant Agreement #12-430-550 for "Development of Numeric Flow Criteria to Support Freshwater Bio-Objectives, Hydromodification Management, and Nutrient Numeric Endpoints."

TABLE OF CONTENTS

EXECUTIVE SUMMARY

Changes to instream flow are known to be one of the major factors that affect the health of biological communities. Regulatory, monitoring, and management programs are increasingly using biological community composition, particularly benthic invertebrates, as one measure of instream conditions, stormwater project performance, or regulatory compliance. Understanding the relationship between changes in flow and changes in benthic invertebrate communities is, therefore, critical to informing decisions about ecosystem vulnerability, causes of stream and watershed degradation, and priorities for future watershed management.

Taking advantage of large, robust regional monitoring data sets and recently completed regional watershed models, the Southern California Coastal Water Research Project (SCCWRP) has developed a set of "flow–ecology" relationships for southern California that relate changes in specific flow metrics to changes in benthic invertebrate indices that have been shown to be indicative of stream health. These relationships are based on the Ecological Limits of Hydrologic Alteration (ELOHA) framework, which uses a variety of hydrologic and biologic tools to determine and implement environmental flows at the regional scale. Results of the ELOHA analysis can inform management decisions, such as release rates from dams, reservoirs or basins; diversion volumes for irrigation or water re-use, or flows associated with stream restoration.

The goal of this project is to demonstrate how regionally derived flow–ecology relationships can be implemented at a watershed scale to inform management decisions. Regional relationships allow us to describe general patterns of response in biological communities to changes in hydrology. Local case studies are critical to determine how these relationships can be applied to site-specific decisions, and to identify areas where the regional relationships may need to be refined to better support local application.

Our case study focused on the San Diego River Watershed in southern California, where the potential effects of urban growth and water/runoff management on stream flow and biological condition are currently being considered. We worked with a group of local watershed stakeholders to identify three questions that that would both inform local management decisions (along with other planning considerations) and demonstrate the utility of the regional flow–ecology relationships. Close coordination with the stakeholder group enhanced the relevancy of the analysis and helps to determine how the technical approach to establishing targets may be applied in other areas. The case study focused on the following management questions:

1. How will future land use changes affect flow conditions and impact biological endpoints in the San Diego River watershed? This involves a comparison of the current hydrologic conditions to modeled conditions based on San Diego County's 2050 land use projection. Future scenarios did not include any assumptions about best management practices, low impact development or hydromodification, which would be expected to reduce potential effects of future hydrologic alteration.

2. How can we use our understanding of current and expected future hydrologic conditions along with the regional flow–ecology relationships to prioritize regions of the watershed where flow management may be most critical to maintain or improve future stream health?

3. What are the biological implications of two future management decisions that will affect in-stream flow conditions:

4. What would be the effects of reduced discharge from Santee Lakes Reservoir due to increased capture and storage to meet demand for reclaimed water?

5. What would be the effect of disconnecting imperviousness and implementing stormwater capture strategies in a currently developed portion of the watershed?

These local management questions were addressed using regional flow-ecology relationships that relate changes in stream health to changes in hydrology. Stream health was assessed using the California Stream Condition Index (CSCI), a statewide index of benthic macroinvertebrates community composition. Hydrologic alteration was assessed based on the following hydrologic metrics, which were shown to have strong statistical and ecological relationships with the CSCI (Table ES-1; See Mazor et al. in review). Metrics were also selected to ensure representation of different components of the flow regime (e.g. duration, magnitude, etc.) and different climate conditions (e.g. wet vs. dry vs. average years).

Table ES-1. Priority hydrologic metrics used in the regional flow-ecology relationships. Metrics are grouped by the hydrograph component they represent. Metric effects on biology were typically strongest during either average, wet, or dry rainfall years, or all years combined (overall).

Hydrograph Component	Metric	Metric Definition	Critical precipitation condition
Duration	NoDisturb (days)	median annual longest number of consecutive days that flow is between the low and high flow threshold	Average
	HighDur (days/event)	median annual longest number of consecutive days that flow was greater than the high flow threshold	Wet
Magnitude	MaxMonthQ (m3/s)	Maximum mean monthly streamflow	Wet
	Q99 (m3/s)	streamflow exceeded 99% of the time	Wet
Variability	RBI (unitless)	Richards-Baker index of stream flashiness	Dry
	QmaxIDR (m3/s)	interdecile range of flow	Overall
Frequency	HighNum (events/year)	median annual number of events that flow was greater than high flow threshold	Dry

Effect of future land use change

Under current land use conditions, 44% of the catchments in the watershed were considered hydrologically altered based on the metrics shown in Table ES-1. There is a broad spatial gradient of hydrologic degradation in the watershed, with the most hydrologically intact areas in the upper watershed, moderately altered catchments in the middle watershed, and the most hydrologically altered catchments in the lower watershed (Figure ES-1). Hydrologic alteration is largely correlated with total impervious cover, with hydrologic alteration generally becoming measurable as the impervious cover reaches and exceeds 5%. Given this pattern, hydrologic conditions are expected to degrade under San Diego County's projected 2050 land use for the watershed (Figure ES-1). The majority of new impacts are expected to occur in the upper watershed where current open space may convert to low-density residential land use and exceed the 5% impervious cover level. Based on the regional flow-ecology relationships, we expect that future hydrologic changes will also manifest as declines in benthic invertebrate communities, reflecting an overall impairment of biological conditions. Efforts to reduce *effective impervious cover* through low impact development or hydromodification control (which act to disconnect total imperviousness from streams) would be expected to reduce future impacts.

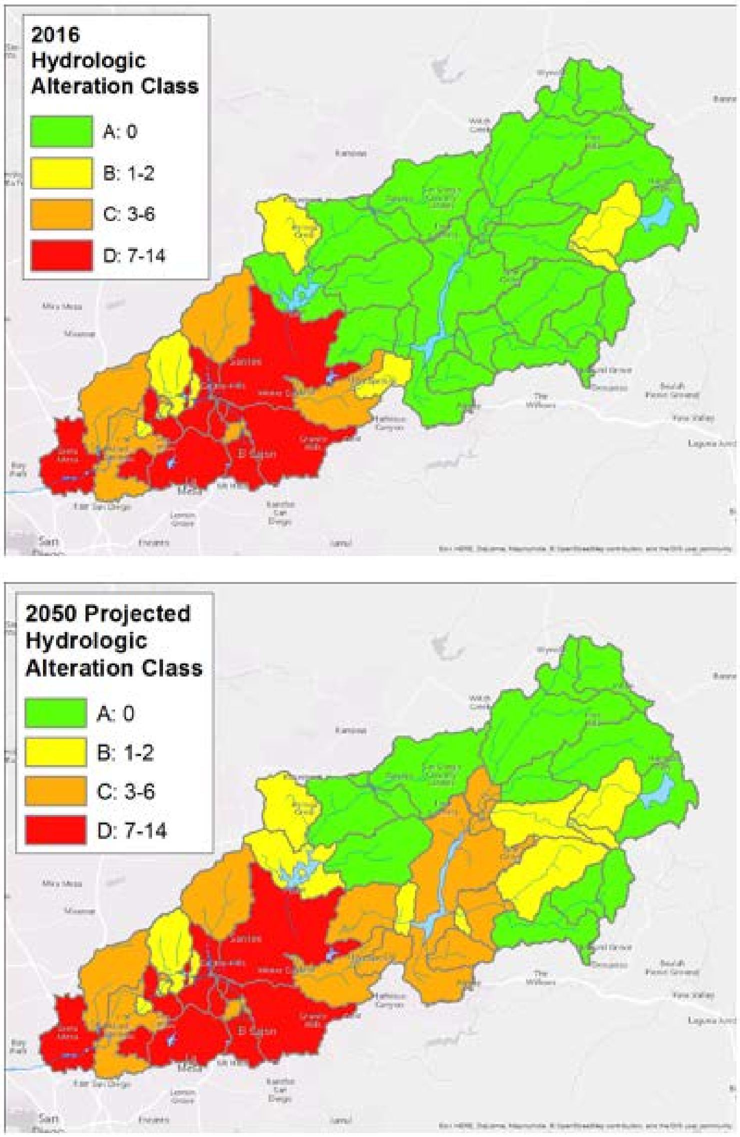

Figure ES-1. Hydrologic alteration under current (top) and 2050 projected (bottom) land use.

Prioritization of areas for various management actions

We prioritized areas of the watershed for various management actions using a combination of hydrologic alteration (see Figure ES-1) and biological condition based on existing bioassessment data (using the CSCI). The majority of upper watershed sites were considered intact and thus a high priority for preservation or protection (Figure ES-2). Two sites in the middle watershed had altered hydrology, but healthy biological communities. This suggests that the communities are either resilient or have not yet responded to the hydrologic alteration. Therefore, these sites should be monitored for potential future degradation. The lower watershed largely expressed both poor biological condition and altered hydrology. For sites in the lower watershed where both hydrology and biology were in altered, we examined available data on water quality and channel condition to better understand the relative contribution of flow alteration vs. other stressors to reduced biological health. This analysis allowed us to provide preliminary management recommendations that can be prioritized for each location (Figure ES-2). We estimate that flow alteration alone is the principle factor affecting biology at only 3 of the 13 biologically degraded sites in the lower watershed. At all other sites, flow management should be coupled with habitat or water quality remediation in order to improve biological conditions.

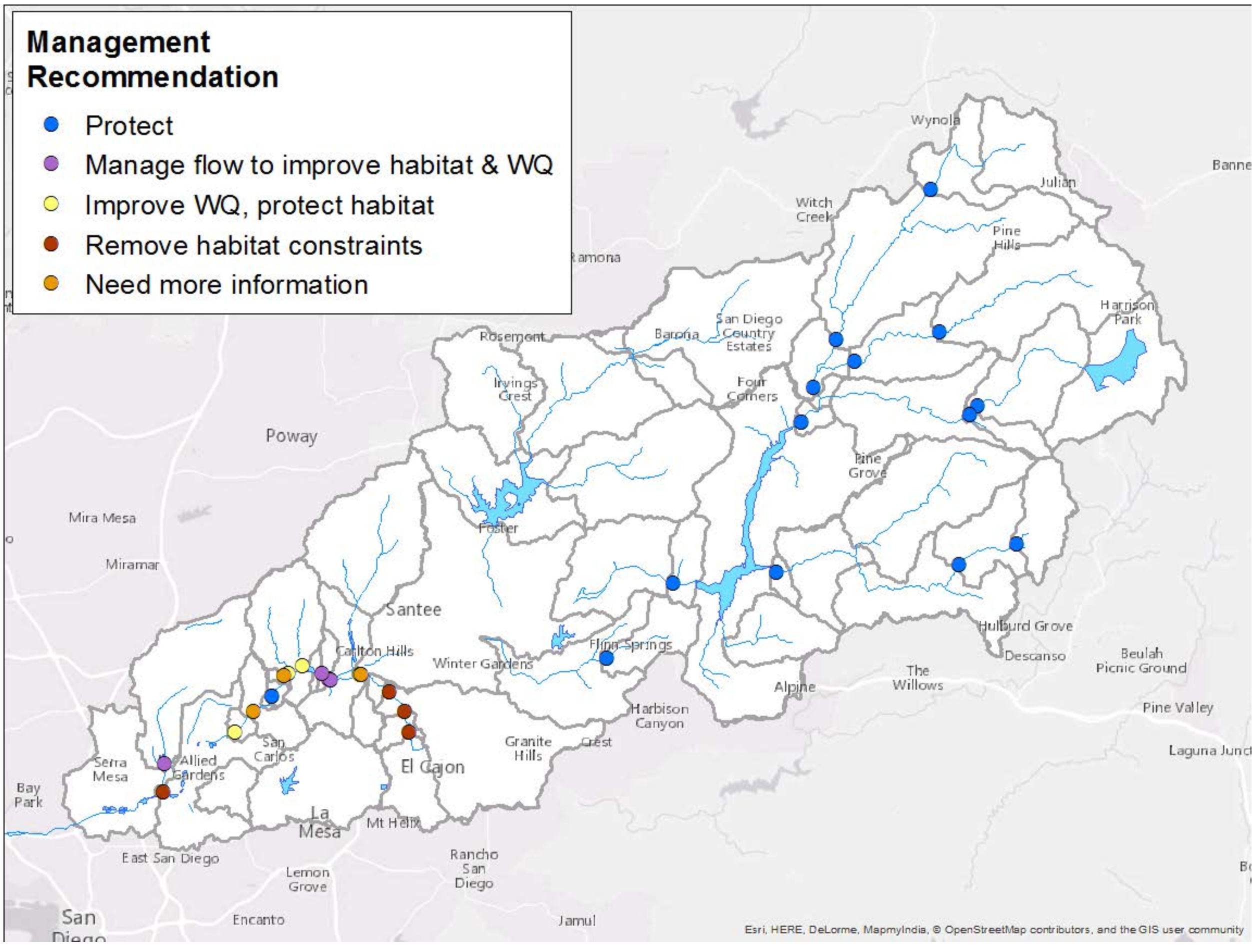

Figure ES-2. Recommended management actions for all sites based on a combination of hydrologic and biological condition. Recommendations are based on both flow-ecology information and available data on habitat and water quality obtained through the local regional monitoring program. Only sites with existing bioassessment data are included.

Evaluation of management scenarios

We demonstrated application of the flow–ecology tools to evaluate both a reservoir management scenario and an urban runoff management scenario. The reservoir management scenario involves eliminating discharge of treated wastewater into the Santee Lakes Reservoir and redirecting it for reuse to help meet increased demands for recycled water. This would reduce reservoir outflow and change hydrology of the downstream Sycamore Creek. Our analysis showed that modifying reservoir management would reduce several flow metrics closer to reference conditions; however, they will probably not fully return to reference condition due to the ongoing contribution of urban runoff. Overall, certain components of the hydrograph (usually under high flow conditions) in Sycamore Creek will improve, but is likely to remain in degraded hydrologic and biological condition, even if discharges from Santee Lakes Reservoir are eliminated following the proposed management scenario.

We modeled two urban runoff management scenarios: 1) disconnecting impervious areas from discharging to streams (i.e. reducing impervious cover), and 2) implementing stormwater retention facilities that can capture 85th percentile of a 24-hour rain event. Disconnecting imperviousness decreases the extent of hydrologic alteration in the downstream reaches. However, flow metrics do not return to levels associated with healthy biological communities until the total imperviousness is at or below 5%. Analysis shows that for most metrics, there is a 66% likelihood of meeting flow targets at 5% total impervious cover and an 80% likelihood of meeting flow targets at 2% total impervious cover (i.e. with stormwater control measures installed). The sensitivity of the creek to relatively low levels of impervious cover is consistent with past studies from southern California. In contrast, retention of the 85% storm event (as is currently required through the local stormwater permit) resulted in flow metrics that met all target values.

Utility of the ELOHA approach for establishing flow-ecology relationships

A major objective of this case study was to evaluate the ability to apply the flow–ecology relationships derived from the regional ELOHA analysis to inform local watershed-scale decisions. Our results illustrate that several of the stated advantages of the ELOHA approach do aid in such watershed-scale application. The ability to apply regionally derived flow targets to inform local decisions is a major advantage of the ELOHA approach. This eliminates the need to develop local flow–ecology relationships for every stream of interest, as is the case in more traditional instream flow methods. The tools developed through the regional analysis provided readily transferable tools for local stakeholders to produce measures of hydrologic change for any location of interest and to explore how those values would change under different land-use or management scenarios. This had the dual benefit of allowing for robust analysis and providing a vehicle for stakeholder engagement in setting management priorities related to instream flow. A potential downside of the ELOHA approach is that the regionally established flow targets may not fully address all concerns or considerations at a specific project location in the same manner as a site-specific analysis would. Ultimate policy decisions about how streams are managed must balance many competing needs. This case study shows how regional flow-ecology relationships can help inform these decisions.

Lessons learned for future implementation of regional flow-ecology relationships

Future efforts can build on the experiences from this case study and continue to refine an iterative process of developing flow targets that are scientifically defensible, practical (i.e., can lead to management actions), and consistent with local stakeholder needs. Key lessons learned from this effort include:

1. Include a broad set of engaged stakeholders, including regulatory agencies, municipalities, water agencies, non-governmental organizations, and researchers. This ensures a broad perspective in the deliberations and increases the likelihood of developing balanced recommendations.

2. Invest in educating the stakeholders early in the process on the underlying science and the rationale behind how regional flow targets were developed. This promotes engagement and fosters creative solutions to the complex challenges of flow management.

3. Invest the time to compile high quality local data sources and show how local data can be used in the evaluation process. Identify the areas were future data collection can most improve outputs of

the flow–ecology analysis (e.g., local rainfall data, more refined land use, water quality data). This can inform future monitoring.

4. Develop documentation that clearly illustrates how the products of the flow–ecology analysis can be used in the context of existing regulatory or management programs.

The San Diego River implementation case study also produced several technical recommendations that can improve our ability to apply flow-ecology relationships to manage southern California streams:

1. Several flow metrics, particularly those associated with flow duration, may require modification for use in streams where the natural condition is intermittent or ephemeral. Application of regionally derived flow thresholds to specific streams that may have been naturally intermittent can lead to erroneous results.

2. Metrics associated with flow durations should be calculated on a single threshold value based on reference conditions. Estimating hydrologic change based on a moving threshold estimated separately for current and reference conditions may produce erroneous results.

3. Need to improve the representation of the drainage system to provide a more accurate hydrologic foundation for analysis. This would ultimately include improved mapping of discharges, diversions, stormwater control facilities, low impact development (LID), etc. for incorporation into modeling scenarios and effects.

4. Consider expanding the analysis to include additional elements in future case studies
    a. Include other stream or water body types
    b. Include other indicators (e.g. algae)
    c. Explore how consistent/transferable findings are from one watershed to another
    d. Explore application in watersheds that cross jurisdictional boundaries

INTRODUCTION

Flow regime has been shown to affect a broad suite of ecological processes and biological communities (Bunn and Arthington 2002, Naiman et al. 2002, Poff et al. 1997, Poff and Zimmerman 2010, Novak et al. 2015). Many studies have demonstrated that alterations of flow regime can be associated with changes in macroinvertebrate assemblages, which are used as key bioindicators for many regulatory and management programs globally (Pringle et al. 2000, Miller et al. 2007, DeGasperi et al. 2009, Poff & Zimmerman 2010). Although a basic understanding of the relationship between flow alteration and ecological response exists (Poff et al. 2010), few studies have demonstrated how to develop regulatory or management objectives (or targets) based on these relationships. Establishing quantitative and predictive relationships between change in flow and change in biological community composition is a critical step in using bioassessment indicators to establish measures of project performance or regulatory compliance.

Various approaches have been used to develop relationships between flow characteristics and biological response. Examples include use of habitat suitability models that relate flow change to requisite habitats for target taxa (e.g., MesoHABSIM, Parasiewicz 2009; and PHABSIM, Beecher et al. 2010); establishment of functional flow regimes to support species of management concern (McClain et al. 2014, Yarnell et al. 2015); and use of statistical ranges of sustainability based on unaltered hydrographs (Richter et al. 2011). Concepts from several of these approaches have been organized into the Ecological Limits of Hydrologic Alteration (ELOHA) framework (Poff et al. 2010). The ELOHA framework uses a variety of hydrologic and biologic tools to determine and implement environmental flows at the regional scale. Results of the ELOHA analysis can inform management decisions, such as release rates from dams, reservoirs or basins, diversion volumes for irrigation or water re-use, or flows associated with stream restoration. Because the ELOHA framework provides a way to assess the effect of flow alteration on the condition of biological communities (vs. individual taxa) on a regional basis, it is a useful approach for setting targets across a wide range of geographies and stream types where comprehensive detailed site-specific investigations are not practical. The ELOHA framework includes elements of stream classification, estimation of flow alternation (termed "delta H") and development of flow ecology relationships based on the relationship between delta H and changes in the biological community ("delta B").

There have been several recent applications of the ELOHA framework to develop flow targets for benthic invertebrates, fish, mussels, amphibians, and aquatic and riparian vegetation. Buchanan et al. (2013) completed the ELOHA approach in the mid-Atlantic region of the U.S. and was able to show clear relationships between changes in a subset of six flow metrics and six benthic invertebrate endpoints. This allowed the authors to recommend specific metrics that could be used for monitoring and assessment. McManamay et al (2013) applied ELOHA through a case study in North Carolina to assess the effect of a stream restoration on fish and riparian communities. Although the ELOHA framework worked well at documenting effects of the restoration projects, confounding factors (e.g., associations between delta H and water chemistry alteration) produced equivocal relationships between flow alteration and response of the fish community. The Nature Conservancy has developed ecosystem flow recommendations for the Susquehanna River Basin (DePhilip and Moberg 2010) and the upper Ohio River Basin (DePhilip and Moberg 2013) that provide seasonally differentiated targets for different stream classes and multiple biological endpoints (e.g., fish, mussels, amphibians, vegetation). Solans and Jalon (2016) used a series of flow alteration-ecological response curves to develop environmental flow standards for the Ebro River Basin in the Iberian Peninsula. Most recently, Mazor et al. (in review) capitalized on extensive regional biomonitoring data and a set of regional hydrologic models developed by Sengupta et al. (in review) to develop flow-ecology relationships for southern California based on benthic macroinvertebrate communities as a measure of stream health.

Previous studies have demonstrated the utility of the ELOHA framework for establishing flow targets and thresholds using relationships between changes in flow and changes in biological condition. Broad scale application of ecologically derived flow targets (or thresholds) can be informed by case studies that demonstrate how flow-ecology relationships can be used to inform actual management decisions. In addition to the study by McManamay et al (2013), the main place where flow-targets have been implemented to inform management actions is in the Juanita Creek Watershed in Washington State, USA (King County 2012). The Juanita Creek study evaluated the effectiveness of seven potential stormwater mitigation scenarios at achieving biologically relevant flow targets using a calibrated Hydrological Simulation Program-Fortran (HSPF) model; a single scenario was identified which would accomplish the stated watershed goals. To our knowledge, none of the previous cases studies attempted to apply regionally-derived flow-ecology relationships (such as those developed for southern California) to inform decisions at the watershed scale. Additional case studies that demonstrate this application can provide a template for future applications of flow-ecology based targets, and allow for consideration of lessons learned to refine these future applications. Such case studies are also important because they provide an opportunity to work with local watershed stakeholders to identify management needs and apply ecohydrology analyses to inform decisions in a way that balances consideration of ecological endpoints with other needs (e.g., water supply management, new infrastructure and development, flood control).

The goal of this project is to demonstrate how the regionally derived flow–ecology relationships developed by Mazor et al. (in review) can be implemented at a watershed scale to guide management targets/decisions. Regional relationships allow us to describe general patterns of response in biological communities to changes in hydrology. Local case studies are critical to determine how these relationships can be applied to site-specific decisions, and to identify areas where the regional relationships may need to be refined to better support local application.

METHODS

Study area

We conducted the demonstration in the San Diego River watershed, in San Diego County, California, where the potential effects of urban growth and water/runoff management on stream flow and biological condition are currently being considered (Figure 1). At 440 square miles (1,140 square km), it is among the largest watersheds in San Diego County and also has the highest population (~475,000), containing portions of five cities and several unincorporated communities. Important hydrologic resources in the watershed include five water storage reservoirs, a large groundwater aquifer, extensive riparian habitat, and coastal wetlands. Approximately 58% of the San Diego River watershed is currently undeveloped. The majority of this undeveloped land is in the upper, eastern portion of the watershed, while the lower reaches are more highly urbanized. The San Diego River watershed is a valuable case study because it includes a range of stream types, including reference (as defined by Ode et al. 2016) and highly impacted reaches; it is affected by several types of hydrologic alteration, including urban runoff, flood control, and reservoir management; it is relatively data-rich, benefiting from years of ambient and targeted monitoring programs (e.g., Mazor 2015); and there is an active and engaged watershed workgroup that is willing to participate in the demonstration project.

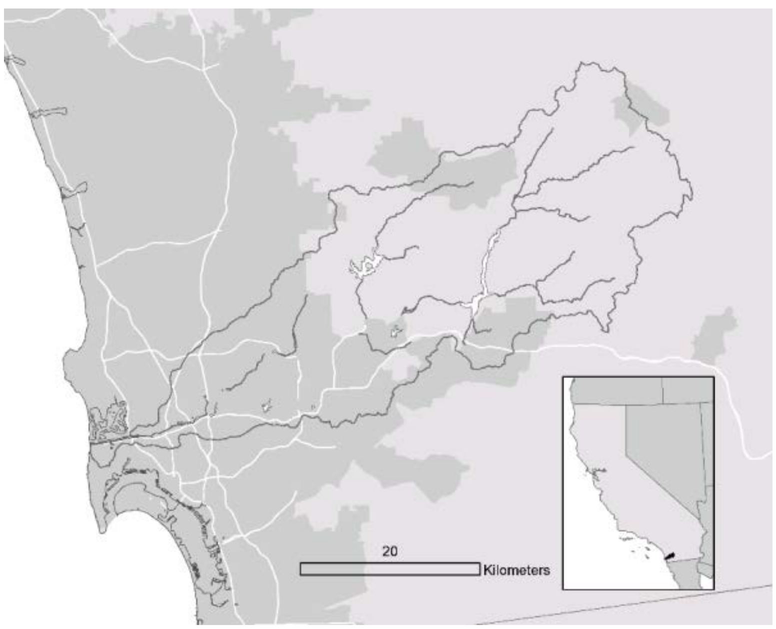

Figure 1. San Diego River Watershed

Stakeholder Process

Active stakeholder participation is integral to a successful demonstration case study because the stakeholders must identify the issues and interpret the utility of the recommendations resulting from the analysis. Stakeholders for the San Diego River case study included local municipalities, water districts, a land conservancy, a non-governmental organization, water quality regulatory agencies, the U.S. Forest Service as the upper watershed landowner and a local consulting firm (Table 1).

The stakeholder workgroup met monthly over an eight-month period and was facilitated by technical staff from the Southern California Coastal Water Research Project (SCCWRP), who had recently completed a regional ELOHA analysis (Mazor et al. in review). The workgroup was engaged in all aspects of the project including detailed scoping, assisting in modeling and analysis, and interpretation and refinement of findings. This intimate participation was key to developing products that would be acceptable for incorporation into future management decisions. A list of workgroup participants and topics for each workgroup meeting are provided in Appendix B.

Table 1. Stakeholders who participated in the San Diego River case study

- City of San Diego
- U.S. Forest Service
- Helix Water District
- Padre Dam Municipal Water District
- San Diego County
- Southern California Coastal Water Research Project
- San Diego River Conservancy
- The San Diego River Park Foundation
- San Diego Regional Water Quality Control Board
- San Diego State University
- AMEC Environmental

The stakeholder workgroup identified three questions that would both demonstrate the utility of the regional flow–ecology relationships and inform local management decisions.

1. How will future land use changes affect flow conditions and impact biological endpoints in the San Diego River watershed? This involves a comparison of the current hydrologic conditions to those that would be expected under a 2050 land use scenario.

2. How can flow–ecology relationships be used to prioritize regions of the watershed into various flow management classes that can inform future planning decisions?

3. What are the biological implications of two future management decisions that will affect in-stream flow conditions?
    a. reduced discharge from Santee Lakes Reservoir due to increased capture and storage to meet demand for reclaimed water
    b. disconnecting imperviousness, and implementing stormwater capture strategies in a currently developed portion of the watershed

Regional ELOHA (flow-ecology) analysis

The local management questions were addressed using regional flow-ecology relationships conducted for southern California that relates changes in stream health to changes in hydrology. Stream health was assessed using the California Stream Condition Index (CSCI), a statewide index of benthic macroinvertebrates community composition. Hydrologic alteration was assessed based on a series of hydrologic metrics, which were shown to have strong statistical and ecological relationships with the CSCI (Mazor et al. in review). Metrics were also selected to ensure representation of different components of the flow regime (e.g. duration, magnitude, etc.) and different climate conditions (e.g. wet vs. dry vs. average years). Because we lack measured flow data for both current and historic conditions at most bioassessment sites, both were estimated using watershed models.

Regional benthic macroinvertebrate data were obtained from the southern California regional bioassessment program (Figure 2, Mazor 2015). A total of 799 wadeable stream sites were sampled between 2008 and 2014 using a probabilistic sample design. Sites were randomly distributed across the entire stream network using a spatially balanced generalized random-tessellation design that ensured representation across all natural and anthropogenic gradients in the region (Stevens and Olsen 2004).

Benthic macroinvertebrates were collected using protocols described by Ode (2007). At each transect established for physical habitat sampling, a sample was collected using a D-frame kicknet at 25, 50, or 75% of the stream width. A total of 11 ft2 (~1.0 m2) of streambed was sampled. This method was identical to the Reach-Wide Benthos method used by EMAP (Peck et al. 2006). However, in low-gradient streams (i.e., gradient <1%), sampling locations were adjusted to 0, 50, and 100% of the stream width, because traditional sampling methods fail to capture sufficient organisms for bioassessment indices in these types of streams (Mazor et al. 2010). Benthic macroinvertebrates were collected and preserved in 70% ethanol, and sent to one of five labs for identification. At all labs, a target number of at least 600 organisms were removed from each sample and identified to the highest taxonomic resolution that could be consistently achieved (i.e., SAFIT Level 2 in Richards and Rogers 2006); in general, most taxa were identified to species and Chironomidae were identified to genus.

Figure 2. Locations of bioassessment sites used to support the regional flow-ecology analysis

Benthic macroinvertebrate data was used to calculate the California Stream Condition Index (CSCI; Mazor et al. 2016). The CSCI is a predictive index that compares observed taxa and metrics to values expected under reference conditions based on site-specific landscape-scale environmental variables, such as watershed area, geology, and climate. It includes two components: a ratio of observed-to-expected taxa (O/E) and a predictive multi-metric index (MMI) made up of 6 metrics related to ecological structure and function of the benthic macroinvertebrate assemblage. Because the CSCI and all of its components are based on site-specific reference expectations, scores are minimally influenced by major natural gradients. Therefore, CSCI scores, by definition, compare existing to reference conditions and can be used as a measure of biological alteration (delta B) under anthropogenic stress. CSCI scores and all components were classified as indicating "intact" or "altered" condition, using the normal approximation of the 10^{th} percentile of CSCI reference calibration scores as a threshold (Mazor et al. 2016). For the CSCI, this equates to a score of 0.79 (where 1 is the reference expectation) as the threshold between biologically intact and altered.

Hydrologic alteration was modeled at 584 of the 799 bioassessment sites using HEC-HMS (ACOE 2000). The remaining 215 bioassessment sites were dropped from the analysis because the rainfall data at those locations was insufficient or did not meet quality control criteria for use in model development. Past studies have assessed hydrologic alteration based on empirical observations, often using a space for time substitution (i.e. comparing distinct hydrologically intact vs. altered locations instead of comparing hydrologic change over time). Modeling provides a mechanism to estimate hydrologic alteration at any location where biological data is available, thereby allowing larger data sets to be included in flow-ecology analysis (DeGasperi et al. 2009). Given the size of the southern California data set (584 sites), there was a need to balance the desire to model hydrologic alteration with the practical considerations of needing a tool that could be readily applied to a high number of sites (Sengupta et al. in review). HEC-HMS provides the ability to produce a continuous time series of estimated flow through parameterization of relatively small number of variables in the model (HEC-HMS manual version 4.1, Xuefeng and Steinman 2009).

A set of 26 HEC-HMS models was developed as part of the regional flow-ecology analysis to represent the range of watershed conditions present in the region. Therefore, one of the 26 models can be applied to produce a daily flow time series for every bioassessment site based on basin properties draining to that site. This obviates the need to develop a unique model for every site. Inputs used to develop and parameterize the models are grouped in three categories (Table 2): 1) watershed-specific data (e.g., area, and imperviousness), 2) site-specific data (e.g., observed flow, precipitation) and 3) model-specific parameters (e.g., initial loss, number of reservoirs).

Table 2. Parameters used to develop HEC-HMS models for application to the regional bioassessment sampling sites. Parameters in bold were adjusted during simulation of natural conditions at each site.

	HEC-HMS Method	Parameters
Watershed Specific		Area **Imperviousness** **Time of concentration**
Site Specific		Observed flow Observed precipitation
Model Specific	Simple Canopy	Maximum Storage (in) Initial Storage (□)
	Simple Surface	Maximum Storage (in) Initial Storage (□)
	Deficit and Constant (Loss)	Initial Deficit (in) Maximum Deficit (in) Constant Rate (in□hr)
	Clark Unit Hydrograph (Transform)	**Time of Concentration (hr)** **Storage Coefficient (hr)**
	Linear Reservoir (Baseflow)	Ground Water (GW) 1 Initial Discharge (cfs) GW 1 Storage Coefficient (hr) □ of GW 1 Reservoirs GW 2 Initial Discharge (cfs) GW 2 Storage Coefficient (in) □ of GW 2 Reservoirs

Each model was sequentially calibrated for four criteria: visual hydrograph match, Nash-Sutcliffe efficiency (NSE), percent low flow days, and Richard-Baker Index of flashiness. These calibration endpoints were selected based on relevance for supporting the instream biological communities (Konrad and Booth 2005, Morley and Karr 2002). Calibrating to all four measures produced models tuned to simulate flow conditions relevant for supporting in-stream biological communities. Models were calibrated for a 3-year period and were then validated for temporal and spatial performance. For temporal validation, the calibrated models were run for years outside of the calibration period and matched with the observed flow data. In all cases, model performance (as measured by NSE) during the validation period was within 15% of performance during the calibration period.

To evaluate spatial performance, we applied statistical 'jackknifing' to all calibrated gages. In this analysis, each modeled gage is treated as an 'ungaged' site, and the remaining 25 models are used to predict flows at that site. The models were fitted to the 'ungaged' site by inputting watershed-specific data and model-specific parameters, but without changes to the model-specific parameters. These simulations were run for the 3-year calibration period. Approximately 75% of the sites had an acceptable NSE value higher than 0.5 (Moriasi et al. 2007). A final validation was performed by comparing modeled output to measured flow at 16 bioassessment sites with nearby flow gages (but not included in the model development). At 11 of the sites, the R^2 values averaged 0.61; the range varied from 0.20 to 0.95. Further details on the model validation for accuracy and bias are found in Sengupta et al. (in review).

One of the 26 validated models was assigned to each of 584 bioassessment sites with adequate rainfall data in the southern California region based on similarity of watershed characteristics that were associated with observed hydrology. The assignment was done with a model-selection tool built by 1) classifying the models into 8 clusters based on observed flow metrics; 2) creating a random forest model to predict cluster membership based on watershed characteristics (i.e., elevation maximum and range, mean annual temperature, watershed area, mean catchment-wide summer precipitation, and soil erodibility factor); and 3) calculating proximity values (i.e., the frequency that a site and a model are predicted to be in the same cluster) between novel sites and each of the 26 models. For each bioassessment site, the model with the highest proximity value was selected for further analysis. Details about the development of the model-selection tool, and its performance, are provided in Sengupta et al. (in review).

The watershed models were used to produce an hourly time series of flow for a period of 23 years (1990 - 2013) for the 584 bioassessment sites. A subset of 6 years was selected for each site to calculate specific flow metrics. The six years were chosen to include two wet, two dry, and two average rainfall years based on long-term climate records. The six years were also selected based on the availability of high quality, complete rainfall records (i.e. no missing values or apparent anomalies). A challenge of the ELOHA approach is the need to compare current hydrologic conditions to reference in order to estimate hydrologic change (delta H). Because we seldom have data on historical flows, we rely on modeling to estimate reference conditions. Hourly hydrographs were estimated for both current and reference conditions at each site following Sengupta et al. (in review). Hourly hydrographs were aggregated to daily discharge, and a suite of flow metrics that represent different aspects of flow were calculated for both current and reference conditions (Table 3) Metrics were calculated for wet, dry, and average precipitation conditions, as well as for all 6 years combined. Metric-precipitation combinations that validated poorly (i.e., $r^2 < 0.25$) with observed flow were excluded from further analysis. This resulted in a total of 116 metric–precipitation combinations for analysis. For each metric–precipitation combination, hydrologic alteration (delta H) was characterized as differences between simulated current and reference conditions. "Reference condition" was estimated by adjusting model parameters to reflect undeveloped watershed conditions. Delta H for magnitude metrics was normalized by reference condition or 0.0283 cms (whichever was larger) to account for the effect of catchment size on discharge magnitude. Details on the hydrological analysis and modeling approach can be found in Appendix A.

Table 3. Flow metrics sorted by metric type and period of evaluation. O=overall, W=wet years, A=average years, D=dry years. Unless otherwise noted, metrics are from Konrad et al. (2008), Konrad, personal communication, Colwell (1974), or Bledsoe (personal communication).

Metric			Description	O	W	A	D
Duration							
	LowDur	days/event	Median annual longest number of consecutive days that flow was less than or equal to the low flow threshold	•		•	•
	HighDur	days/event	Median annual longest number of consecutive days that flow was greater than the high flow threshold		•		•
	NoDisturb	days/year	Median annual longest number of consecutive days that flow between the low and high flow threshold	•	•	•	•
	Hydroperiod	proportion	Fraction of period of analysis with flows	•		•	•
	Per□LowFlow	proportion	Percent of time with flow below 0.0283 cms	•	•	•	•
Frequency							
	HighNum	events/year	Median annual number of events that flow was greater than high flow threshold, an event is a continuous period when daily flow exceeds the threshold	•	•	•	•
	FracYearsNoFlow	proportion	Fraction of years with at least one no-flow day	•			
	MedianNoFlowDays	days/year	Median annual number of no-flow days	•	•	•	•
Magnitude							
	MaxMonthQ	cms	Maximum mean monthly streamflow	•	•	•	•
	MinMonthQ	cms	Minimum mean monthly streamflow	•	•	•	•
	Q01	cms	1st percentile of daily streamflow	•	•	•	•
	Q05	cms	5th percentile of daily streamflow	•	•	•	•
	Q10	cms	10th percentile of daily streamflow	•	•	•	•
	Q25	cms	25th precentile of daily streamflow	•	•	•	•
	Q50	cms	50th percentile of daily streamflow	•	•	•	•
	Q75	cms	75th precentile of daily streamflow	•	•	•	•
	Q90	cms	90th precentile of daily streamflow	•	•	•	•
	Q95	cms	95th precentile of daily streamflow	•	•	•	•
	Q99	cms	99th precentile of daily streamflow	•	•	•	•
	Qmax	cms	Median annual maximum daily streamflow	•	•	•	•
	Qmean	cms	Mean streamflow for the period of analysis	•	•	•	•
	QmeanMEDIAN	cms	Median annual mean streamflow	•	•	•	•
	Qmed	cms	Median daily streamflow	•	•	•	•
	Qmin	cms	Median annual minimum daily streamflow	•	•	•	•
Timing							
	C□C	ratio	Colwell's constancy (C) a measure of flow uniformity.	•	•	•	•
	C□CP	ratio	Colwell's maximized constancy (C/P). Likelihood that flow is constant through the year	•	•	•	•

Metric			Duration					
	C□M	ratio	Colwell's contingency (M). Repeatability of seasonal patterns.		•	•	•	•
	C□MP	ratio	Colwell's maximized contingency (M□P). Likelihood that the pattern of high and low flow events is repeated across years.		•	•	•	•
	C□P	ratio	Colwell's predictability (P□C□M). Likelihood of being able to predict high and low flow events		•	•	•	•
	MinMonth	month	Month of minimum mean monthly streamflow				•	•
	MaxMonth	month	Month of maximum mean monthly streamflow			•		
Variability								
	RBI	Unitless	Richard Baker Index (flashiness)		•	•		•
	SFR	proportion	90th percentile of percent daily change in streamflow on days when streamflow is receding (storm-flow recession)				•	
	QminIDR	cms	Interdecile range of annual minima		•			
	QmeanIDR	cms	Interdecile range of annual means		•			
	QmaxIDR	cms	Interdecile range of annual maxima		•			

Hydrologic thresholds that result in biological response were evaluated for each flow metric-precipitation condition combination, based on nine biological response variables (i.e. the CSCI and its component metrics). Hydrologic metrics were evaluated for overall climatic conditions, as well as for wet, dry, or average precipitation years. The 116 metric-precipitation condition combinations were used to predict each of the nine biological response variables in boosted regression tree models using the gbm package in R (Ridgeway 2015, R Core Team 2016), and the importance of each predictor was ranked (Friedman 2001). Ranks were averaged across all models, and the best ranked precipitation condition within each metric was selected for further analysis. Ecologically derived targets were then established for each flow metric. Further detail about modeling biological responses to hydrologic alteration can be found in Mazor et al. (in review).

In order to set targets for hydrologic metrics based on biological response, we developed logistic regression models of the probability of healthy biological condition as a function of different levels of hydrologic alteration. Targets were set at the level of hydrologic alteration where the probability of healthy biological condition was 50% of the probability at hydrologically unaltered sites. It is important to note that these targets do not represent reference conditions. Increasing and decreasing gradients of hydrologic alteration were analyzed independently against each biological response variable. Across all biological response variables, the most conservative target was selected for further analysis. Logistic regression models were created using the glm function in R with a binomial error distribution and a logit link function (R Core Team, 2016). Metrics were scored 0 if they met targets, 1 if they failed targets, and 2 if they failed targets by more than twice the target value (Figure 3).

Metric	100% above UT	Upper Threshold (UT)	Within Threshold	Lower Threshold (LT)	100% below LT
Flow (Q min cfs)	0.04	0.02		-0.02	-0.04
Value	1.2	0.03	0.01	-0.025	-0.6
Score	**2**	**1**	**0**	**-1**	**-2**

Figure 3. Example scale for assigning hydrologic alteration scores

An objective of the regional flow-ecology analysis was to identify a subset of priority flow metrics that can be used to inform management actions. Metrics were prioritized based on the following criteria (Mazor et al. in review):

- Differentiate hydrologic condition at reference sites vs. altered sites
- Have the strongest relationship to biological condition based on boosted regression tree analysis and can produce a hypothesized ecological response
- Can be modeled under both current and reference conditions with a high level of confidence
- Are amenable to management actions and are expected to respond in predictable ways to deliberate changes in flow conditions
- Have minimal redundancy with other metrics; the goal is to select metrics that represent different components of the hydrograph (e.g. magnitude vs. duration)

Based on these criteria and the logistic regression analysis described above, Mazor et al. (in review) identified seven priority flow metrics and associated thresholds of biological response (Table 4). The importance of the seven priority flow metrics varied by climatic condition, with some metrics only being important during certain precipitation conditions (Table 4). Using a subset of metrics has the advantage of allowing management actions to focus on controlling a reasonable set of flow properties that will have the greatest biological effects, as opposed to trying to manage for all 116 metric-precipitation combinations.

Table 4. Priority hydrologic metrics and associated thresholds used in the regional flow-ecology relationships. Metrics are grouped by the hydrograph component they represent. Thresholds are expressed as the change in metric value (delta H) associated with poor biological condition (CSCI <0.79). Metric effects on biology were typically strongest during either average, wet, or dry rainfall years, or all years combined (overall). NT = no threshold established.

Hydrograph Component	Metric	Metric Definition	Critical precipitation condition	Decreasing Threshold	Increasing Threshold
Duration	NoDisturb (days)	median annual longest number of consecutive days that flow is between the low and high flow threshold	Average	-64	NT
	HighDur (days/event)	median annual longest number of consecutive days that flow was greater than the high flow threshold	Wet	-3	24
Magnitude	MaxMonthQ (m3/s)	Maximum mean monthly streamflow	Wet	NT	1.5
	Q99 (m3/s)	streamflow exceeded 99% of the time	Wet	-0.01	32
Variability	RBI (unitless)	Richards-Baker index of stream flashiness	Dry	NT	0.25

Application of regional flow-ecology (ELOHA) relationships to guide watershed management actions

Current and future watershed hydrologic condition was evaluated for 52 distinct catchments defined by major stream nodes (Figure 4). For each catchment, we simulated current and reference hydrology using the most appropriate of the regional HEC-HMS models. Hydrologic alteration (delta H) was calculated for the seven priority flow metrics shown in Table 4, and each metric was scored based on its distance above or below the established threshold (Figure 3). To provide an easy way to convey general hydrologic condition, an overall composite hydrologic condition score was developed by adding the absolute values of the score for each individual metric. The hydrologic condition score ranged from 0-14 because each of the metrics can receive a score between zero and two depending on how far the score is from the threshold (see Table 3). This approach assumes that each metric is of equal importance and that positive or negative changes in metric values have comparable effects. Scores were binned into four categories as shown in Table 5 and each of the 52 catchments was assigned an A – D designation, representing its overall hydrologic condition.

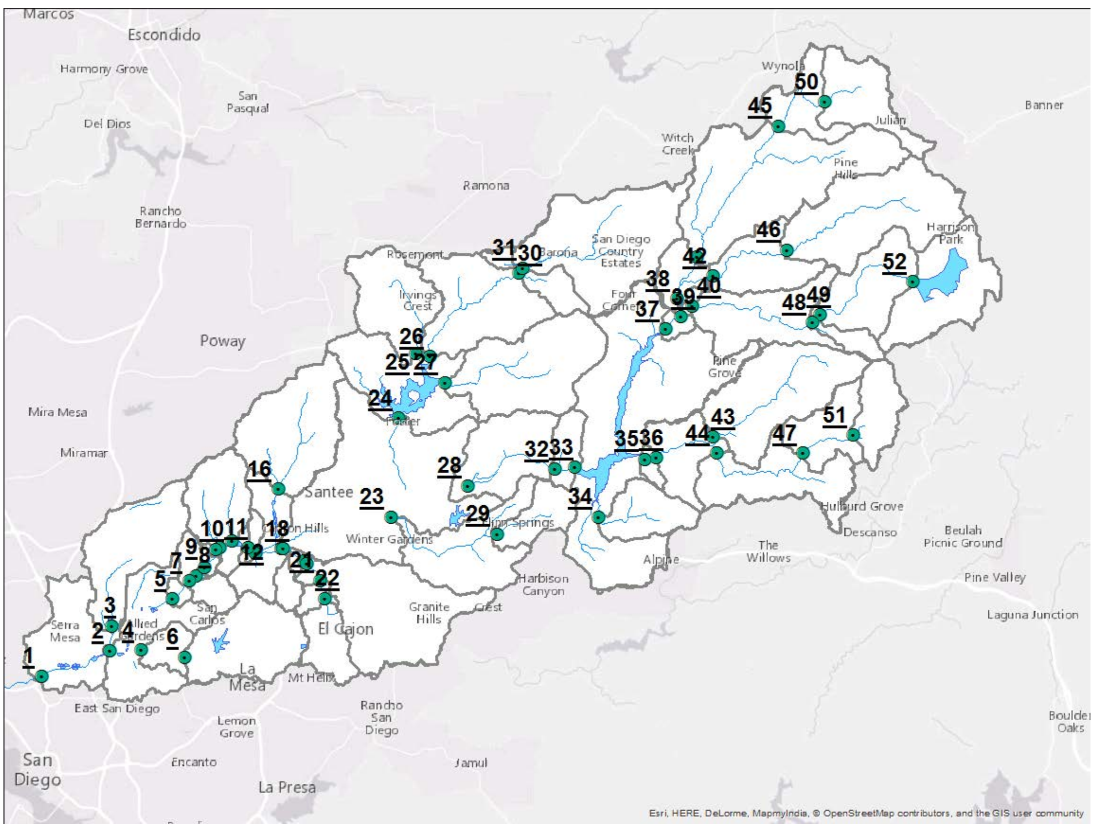

Figure 4. Individual catchments used for watershed analysis

Table 5. Definition of hydrologic condition score (0-14) based on how far each of the priority metrics is from its threshold value. See Figure 3 for explanation of scoring.

Overall Hydrologic Condition Score	Ranges of Metrics Above or Below Threshold
A	0
B	1-2
C	3-6
D	7-14

Flow management classes were assigned to each of the 29 locations where previous bioassessments had been completed. Sites were assigned to one of four classes based on their biological and hydrological status. Biological status was inferred using CSCI scores: Sites with scores greater than 0.79 were designated as biologically intact, and sites with lower scores were designated as biologically altered (Mazor et al. 2016). Hydrological status was assigned using the composite hydrologic condition score described above. Classes A and B were considered hydrologically unaltered when assigning sites to different management classes.

Hydrologically unaltered and biologically unaltered sites were put into a “protection” class; the good conditions at these sites should be protected from further designations. Hydrologically altered and biologically unaltered sites were put into a “monitoring” class; these sites may be resilient to stressors related to hydrologic alteration, but factors related to this apparent resiliency should be monitored to ensure that they continue to support biological health. Hydrologically altered and biologically altered sites were put into a “flow management” class; these sites should undergo a causal assessment to determine if flow management is likely to improve biological condition or if other constraints (e.g., channelization) may limit the ability of a stream to respond to improved flows. Hydrologically unaltered and biologically altered sites were put into an “other management” class; these sites should also undergo causal assessments, but other management options should be prioritized over flow management, such as habitat or water quality improvements (Table 6). Potential additional causes of biological alteration were evaluated for all locations where the CSCI was less than 0.79 based on additional stressor data such as water chemistry and physical habitat assessments that are routinely collected as part of the regional ambient monitoring programs (Mazor 2015).

Table 6. Management categories defined based on combination of hydrologic and biologic alteration

	Poor hydrologic condition	Good hydrologic condition
Poor biology (CSCI □0.79)	***Flow Management***: Evaluate hydrologic alteration among other stressors. Determine relative importance of flow management for improving biological condition, relative to other stressors.	***Other Management/Causal Assessment***: Evaluate other stressors to determine cause of poor biology. Evaluation of flow management not recommended.
Good biology (CSCI □0.79)	***Monitor***: Communities may be resilient to flow alteration. Continue to monitor for factors that may reduce resilience.	***Protect****:* Intact area. Target for preservation. Explore factors that may contribute to resilience or vulnerability.

Following the watershed mapping, the stakeholders prioritized management questions and scenarios for setting flow targets aimed at protecting (or recovering) instream biological health (as measured by CSCI). The scenarios retained for detailed analysis were selected based on consensus of the workgroup and represented a range of different management situations (e.g. reservoir operation, effluent recycling, and stormwater management). The most appropriate model was selected for each priority scenario using the model selection tool (described above) and was used to simulate both current hydrology and future hydrology based on the proposed management action. Future conditions largely consisted of changes in reservoir discharge, runoff capture, or reduction in impervious cover (i.e. low impact development). The subset of seven priority flow metrics based on the regional flow ecology analysis was calculated for each scenario (see Table 4). The projected delta H for each scenario (and each alternative within a scenario) was evaluated relative to the flow–ecology relationships and thresholds developed by the regional analysis. To aid in management interpretation of the results of the scenario analysis, the regional thresholds, which are expressed as *change in the metric value* were converted to the actual target values specific for the situation of the case study. The results of this analysis were used to develop flow management recommendations for each scenario. Ultimately, these flow recommendations should be considered in concert with other management needs for the watershed.

RESULTS AND DISCUSSION

Effect of future land-use change on hydrologic condition

To address the question, "***how will future land-use changes affect flow conditions and impact biological endpoints in the San Diego River watershed?"*** we compared the current overall hydrologic condition to the expected future condition based on 2050 SanGIS land-use projections, assuming no installation of stormwater control device or low impact development features.

Under current conditions, 17 of the 52 catchments (33%) scored in the worst two categories of hydrologic alteration, while 35 of 52 (67%) scored in the least hydrologically altered category (Table 7). There appears to be a spatial gradient of hydrologic condition in the watershed, with the most hydrologically intact areas are in the upper watershed, where much of the land is in public ownership and/or there is currently little urban development. Catchments in the poorest hydrologic condition are concentrated in the lower watershed where most of the current development exists. These areas are also downstream of all the reservoirs in the watershed (Figure 5).

Table 7. Distribution of hydrologic alteration scores under current conditions (□A□is least altered, □D□is most altered).

Category	□of catchments	Proportion of catchments
A	25	48□
B	10	19□
C	6	12□
D	11	21□

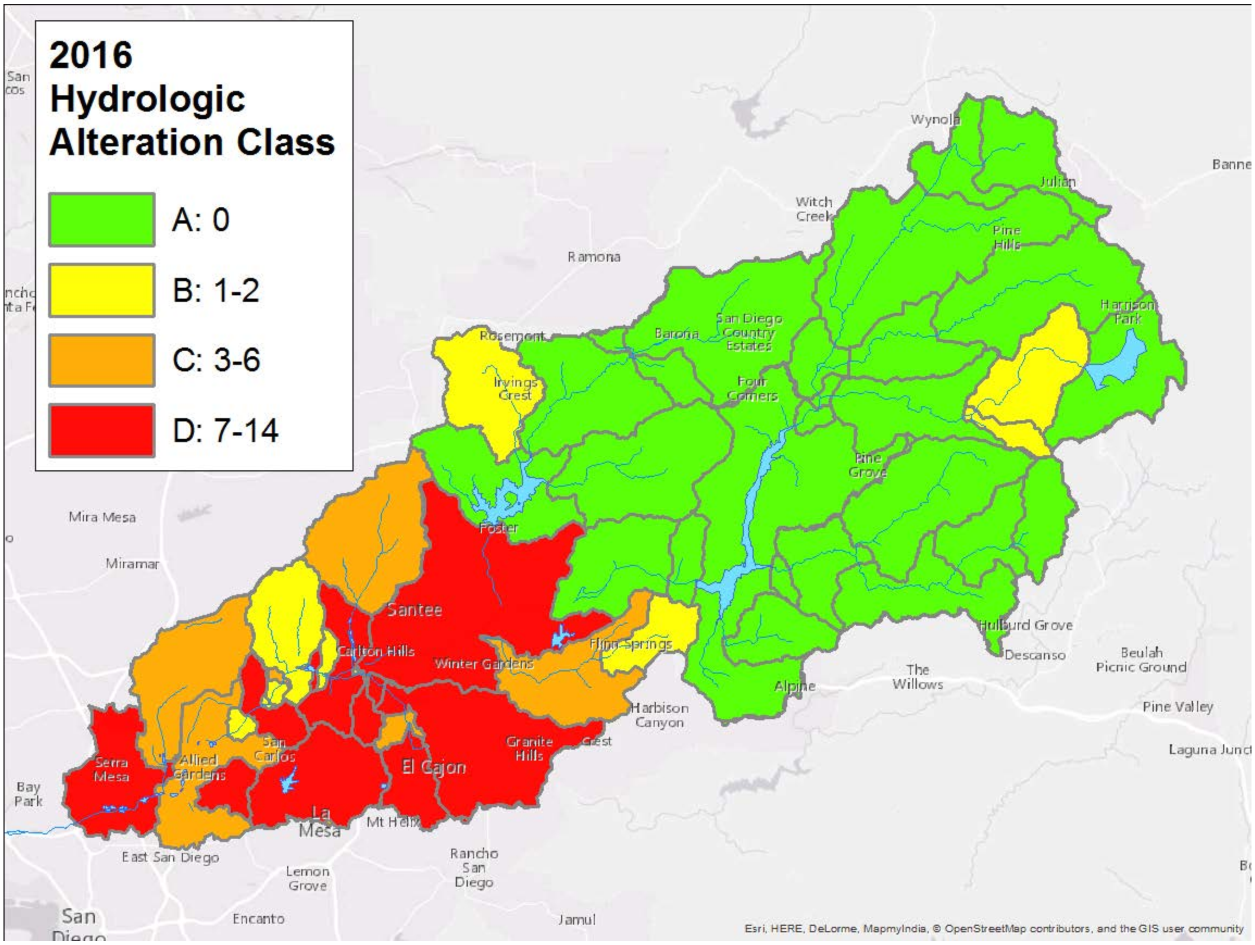

Figure 5. Hydrologic condition of each of the 52 catchments in the watershed. Numbers indicate the number of metrics that failed to meet the designated threshold.

We evaluated all 35 flow metrics in order to provide additional information about the type of hydrologic alteration occurring in each catchment (Figure 6). Catchments that are hydrologically unaltered (Classes A and B in Figure 6) generally "failed" less than 10% of the overall set of 35 metrics. This suggests that the targeted set of metrics used in Figure 5 (based on our screening filters described above) is representative of overall hydrologic condition. The most commonly exceeded metrics range across nearly all categories: duration metrics (e.g. high duration), magnitude metrics (e.g. Q95), frequency metrics (e.g. HighNum), and variability metrics (e.g. RBI). This suggests that when hydrologic alteration occurs, it tends to affect most aspects of runoff hydrographs rather than preferentially influencing certain hydrologic elements.

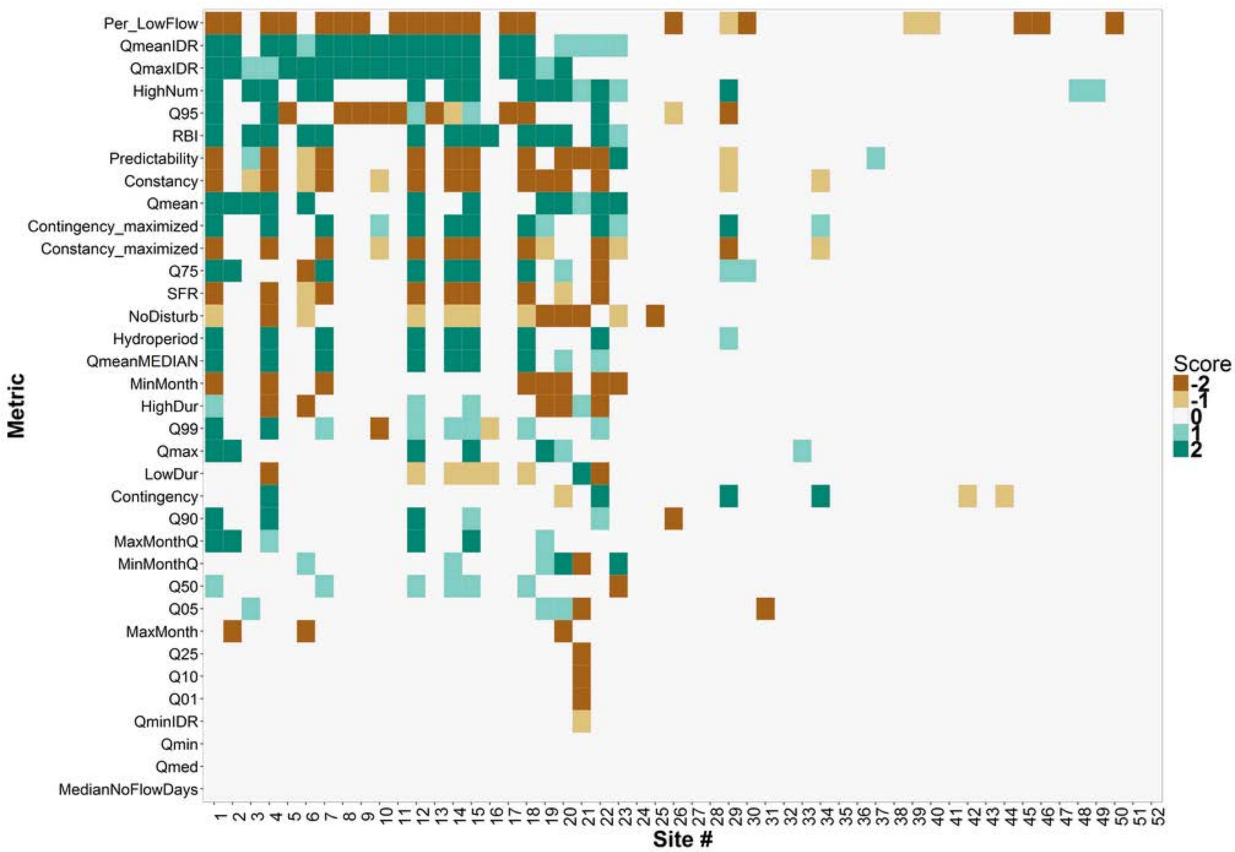

Figure 6. Heatmap showing hydrologic metric scores for all catchments and all metrics. Catchment numbers positions on the x-axis are based on the catchment positions shown in Figure 4.

Hydrologic condition was generally related to catchment imperviousness (Figure 7). In most cases, severe hydrologic alteration was associated with total impervious cover greater than 5%. In all cases, hydrologically unaltered catchments (Classes A and B) had less than 5% total impervious cover, often only 1-2%. This is consistent with past studies that have shown hydrologic and geomorphic responses associated with modest increases in total impervious cover (Hawley and Bledsoe 2011, Vietz et al. 2016).

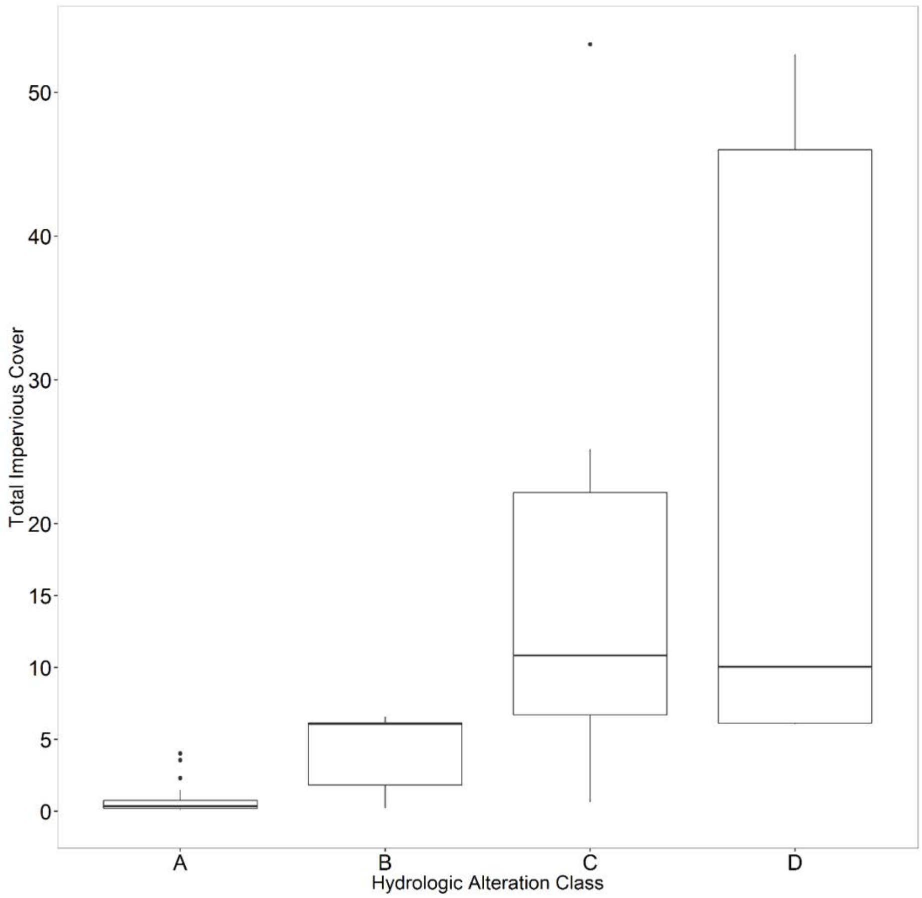

Figure 7. Relationship of hydrologic condition class and percent total impervious cover in the contributing catchment.

Under 2050 land use projections, hydrologic conditions of the watershed are expected to degrade, mainly in the middle portion of the watershed (Figure 8). Mid watershed catchments, around existing reservoirs, are expected to degrade the most in association with future land use changes, with several catchments going from Class A to Class C. Little change is expected in the upper watershed since many of the catchments in the upper watershed are hydrologically unaltered, in public ownership and hydrologic conditions are expected to remain unaltered into the future. Most of the lower watershed is already in poor hydrologic condition and is expected to remain that way in 2050, unless substantial hydrological management and/or remediation measures are implemented. It is important to note that future conditions were modeled using the same precipitation values as the current and historical scenarios since reliable downscaled future precipitation values are not available. Furthermore, the future conditions assumed no stormwater control devices, low impact development or hydromodification management, since we have no information on where/how these will be installed in the future. Therefore, the results of the 2050 analysis should be considered a worst-case scenario.

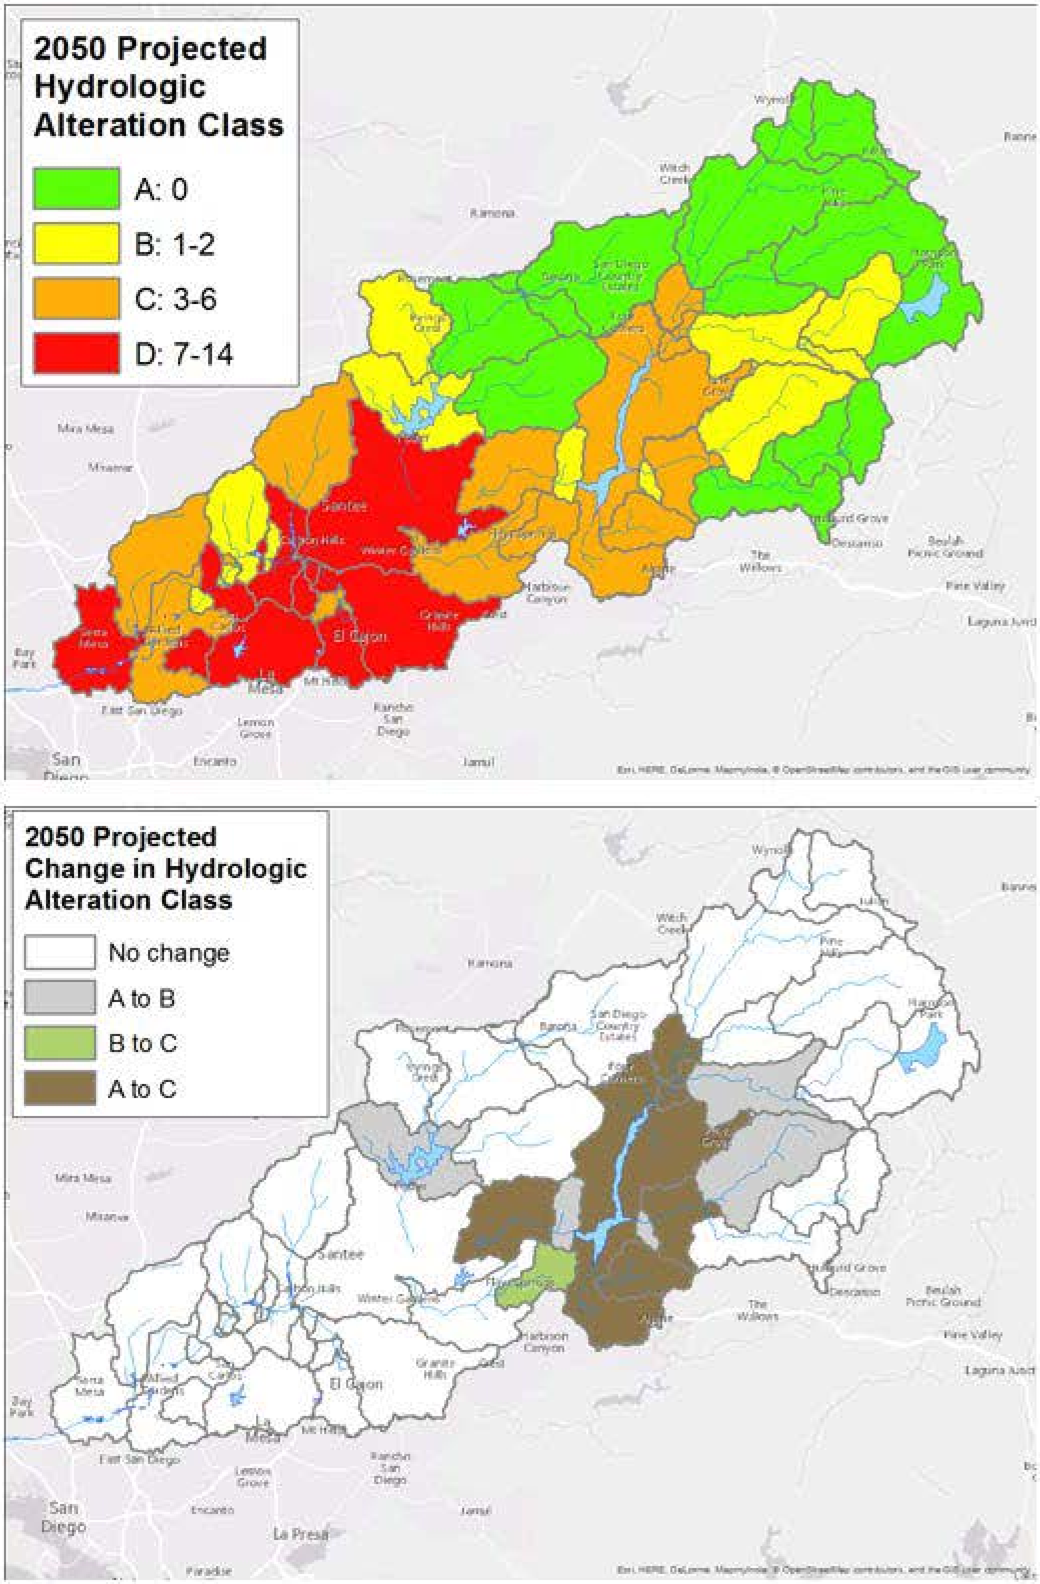

Figure 8. Overall hydrologic condition under 2050 projected land use (top) and change in hydrological condition between 2015 and 2050 (bottom). Categories are defined as in Figure 5.

Future land use changes were associated with sufficient hydrologic alteration to affect all seven metrics that contribute to the overall hydrologic rating. Of the seven metrics, QmaxIDR (a measure of flow variability), Q99 (a measure of high flow magnitude), and HighNum (a measure of the frequency of high flow events) were affected in the greatest number of catchments, and therefore most responsible for the predicted changes in overall hydrologic condition. Changes in these hydrologic metrics are associated with changes in biological condition; this suggests that future hydrologic changes are likely to result in declines in the condition of instream biological communities.

Prioritization of areas for various management actions

To address the question, "***How can flow–ecology relationships be used to prioritize regions of the watershed into various flow management classes that can inform future planning decisions***?" we compared the overall hydrologic condition scores to the CSCI scores at the 29 locations in the watershed where bioassessment has previously occurred.

The majority of upper watershed sites were considered intact, with unaltered hydrology, and therefore a high priority for protection (Figure 9). Candidate areas for flow management were focused in the lower portion of the watershed where both hydrology and biological condition were altered.

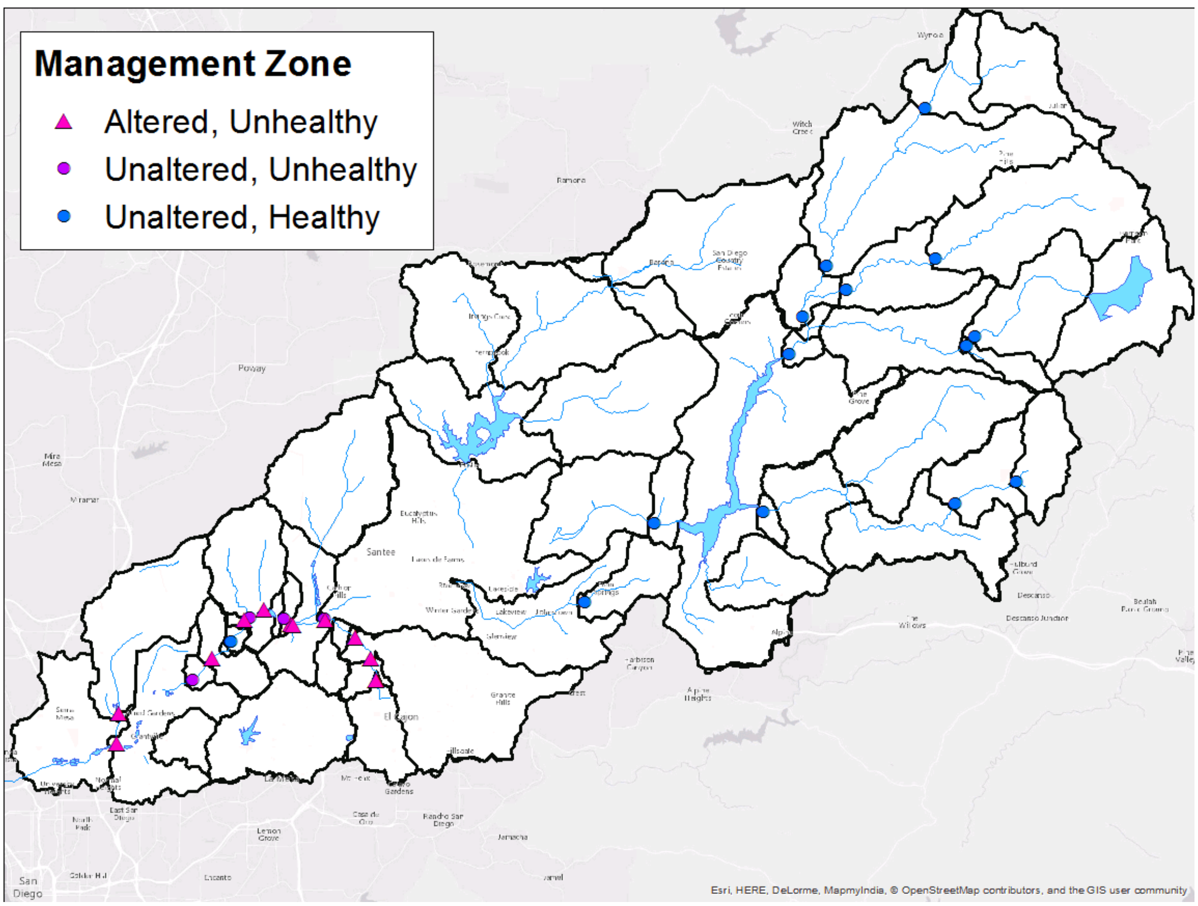

Figure 9. Management categories for bioassessment sites based on combinations of hydrologic and biologic alteration. Only three of the four possible management categories were present in the San Diego River watershed. There were no sites with altered hydrology and healthy biological communities.

Considering both the flow management zones and information available on water quality, habitat, and channel condition from ambient survey data allows us to provide specific management recommendations that can be prioritized for each location (Figure 10). We estimate that flow alteration is the primary factor affecting biology at only 3 of the 13 biologically degraded sites in the lower watershed. At all other sites, flow management should be coupled with habitat or water quality remediation in order to improve biological conditions. The lower watershed was largely in poor biological condition with altered hydrology, making flow management a good option to consider for improving watershed health. However, many of the sites in this category had highly developed floodplains or concrete-lined channels, and all lower watershed sites had poor water quality, as indicated by low scores on the diatom (D18) or soft algae (S2) indices of biotic integrity (Table 8). Therefore, flow management should always be considered in conjunction with other forms of management that address water-quality impacts and alterations to physical habitat. Flow management alone is most likely to improve biological health at sites where habitat is in poor condition, but the channel is unlined and the immediate floodplain is undeveloped. At such sites, the stream form has good capacity to respond to changes in flow, creating the microhabitat structure that supports diverse benthic macroinvertebrate assemblages. In contrast, flow management alone is unlikely to improve sites with armored banks, or where floodplain development limits the capacity of the stream form to respond. In these cases, flow management should be considered in conjunction with habitat restoration efforts that remove these constraints. At lower watershed sites with relatively good condition habitat, other stressors, such as poor water quality, may be responsible for poor biological condition; at these sites, flow management may improve water quality, but care should be taken to maintain good habitat that can support healthy instream biological communities. Finally, in one instance, two sites in close proximity were assigned to different management classes based on different models used to estimate hydrologic alternation. In this instance, we assumed the two sites were in similar condition and assigned the more conservative management class.

Table 8. Relationship of biologically unhealthy sites to water quality and physical habitat stressors.

Recommendation	Sites	Habitat quality	Bank armoring	Response capacity
Manage flows to improve habitat and water quality	3	Poor	Earthen	Moderate or good. Limited development in floodplain.
	13 and 14	Poor	None	Moderate or good. Limited development in floodplain.
Improve water quality	5, 11, 12, and 15	Good	None	Moderate or good. Limited development in floodplain. No channel armoring.
Remove habitat constraints	20, 21, 22	Poor	Concrete	Limited. Stream cut off from floodplain.
	2	Poor	Earthen	Limited. Stream cut off from floodplain.

Figure 10. Recommended management actions for all sites where bioassessment has occurred. Recommendations are based on both flow-ecology information and available data on habitat and water quality obtained through the local regional monitoring program.

Evaluation of management scenarios

The stakeholder workgroup prioritized two future management scenarios for evaluation. Each of them represents potential actions that will affect in-stream flow conditions, and in turn may affect biological condition.

1. lower discharge from Santee Lakes Reservoir due to increased capture and storage to meet demand for reclaimed water
2. disconnecting imperviousness, and implementing stormwater capture strategies in a currently developed portion of the watershed

Results from each of the scenarios are described below:

Scenario 1. Lower discharge from Santee Lakes Reservoir

The Santee Lakes Reservoir receives treated wastewater from Padre Dam Municipal Water District's Ray Stoyer Water Recycling Facility (WRF). The lake releases the treated effluent to Sycamore Creek (which also receives water from a small rain-fed discharge from the lake). Future management scenario involves eliminating discharge of treated wastewater into the lakes and diverting it for reuse to help meet increased demands for recycled water. This will be associated with a proportional decrease in discharge from Santee Lakes Reservoir to Sycamore Creek (because there is less need to create capacity in the lakes); the rain-fed discharge will continue to be released to the creek (Table 9).

Table 9. Inflow into Santee Lakes Reservoir due to wastewater effluent and rainfall runoff. Values are total monthly discharge into the reservoir.

	Average Effluent Flow (Mgal)	Rain-Fed Discharge (Mgal)
January	43.00	2.30
February	33.08	2.73
March	37.60	1.76
April	22.65	1.56
May	12.88	1.31
June	4.91	0.00
July	3.13	2.27
August	2.88	0.00
September	11.25	1.51
October	17.09	0.71
November	28.92	2.79
December	42.24	4.17

Simulations of future scenarios using HEC-HMS indicate that the flow regime will continue to have natural variability, with lower magnitude of flows under the future management scenario relative to current conditions (Figure 11).

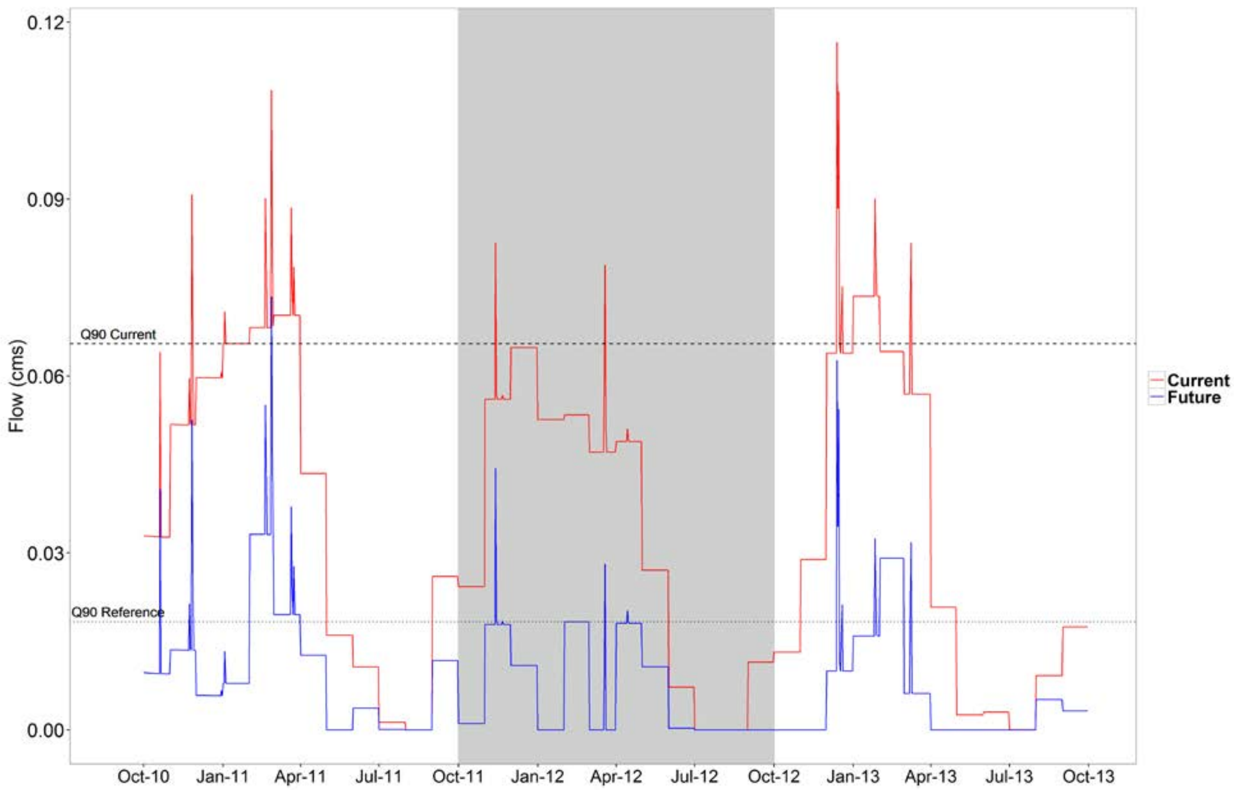

Figure 11: Modeled daily discharge under current and future scenarios at Sycamore Creek. The blue line represents the current scenario (which includes effluent discharge), and the orange line represents a future scenario where effluent is reused and not discharged into the creek.

Current conditions at Sycamore Creek are altered mainly in terms of the duration of high flow conditions (e.g. HighDur and NoDisturb). This reflects discharge from Santee Reservoir that elevates downstream high flow conditions. The balance of the priority flow metrics are currently meeting targets (Table 10). Under future scenarios, many high flow metrics are expected to improve in response to the removal of discharges from the reservoir. In contrast, the remaining metrics will remain at or slightly below the targets associated with healthy biological conditions. Failure to achieve these targets under future conditions likely reflects the effects of ongoing urban runoff, which will not be affected by changes in the reservoir operation. Overall the hydrologic condition in Sycamore Creek will improve under high flow conditions, but is likely to remain in degraded hydrologic and biological condition, even if discharges from Santee Lakes are eliminated following the proposed management scenario.

Providing clear objectives can aid in future desires to manage runoff and reservoir discharge in a manner that promotes healthy downstream biological communities. To assist in future management decisions, we developed the following specific management statements for the Santee Reservoir/Sycamore Creek scenario:

- NoDisturb = Maintain an average low flow between 0 and 0.02 cms (0.7 cfs) for a minimum of 119 days during the dry season

- HighDur = Maintain flow greater than 0.02 cms (0.7 cfs) for between 25 and 52 days per year
- MaxMonthQ = Maintain mean monthly flows below 0.1 cms (3.5 cfs).
- Q99 = Storm flows (or high flow events) should be between 0.03 cms (1 cfs) and 1.1 cms (39 cfs)
- HighNum = Ensure less than 4 high flow events per year with a flow greater than 0.02 cms (0.7 cfs)

Variability metrics do not lend themselves to directed management actions; therefore, we have not provided objectives for RBI or QmaxIDR. Instead these flow metrics should be used to evaluate the effectiveness of actions taken in response to the other metrics.

Table 10. Current and expected future hydrologic metric values in Sycamore Creek (SC) downstream of Santee Reservoir. The table presents site-specific targets that have been calculated based on the regional threshold values. Green cells represent conditions where flow targets would be met; yellow cells represent conditions where flow would be the same as the target value. NT no target assigned.

Metric	Unit	Value		Target	
		Current	Future	Lower	Higher
NoDisturb	days	31	122	119	NT
HighDur	days event	212	28	25.1	52.2
MaxMonthQ	cms	0.1	0.0	NT	0.1
Q99	cms	0.1	0.0	0.0	1.1
HighNum	events year	1	4	NT	4
RBI	unitless	0.0	0.9	NT	0.3

Scenario 2. Impact of disconnecting imperviousness and implementing stormwater retention facilities in an urbanized catchment

Alvarado Creek catchment is located in the downstream portion of the San Diego River watershed. At an area of 14 sq. mi., and 50% total imperviousness cover, it is a heavily urbanized and hydrologically altered reach. We tested **two** scenarios in this sub-catchment: 1) effect of disconnecting imperviousness (modeled as a decrease in total imperviousness in the catchment), and 2) implementing stormwater retention facilities that can capture 85th percentile of a 24-hour rain event.

Disconnecting imperviousness decreases the extent of hydrologic alteration in the creek. However, flow metrics do not drop below levels associated with healthy biological communities until the total imperviousness is at or below 5% (Table 12). Analysis shows that for most metrics, there is a 50%

likelihood of meeting flow targets at 10% impervious cover, 66% likelihood at 5% impervious cover and finally an 80% likelihood of meeting flow targets at 2% impervious cover. Above 10% impervious cover, the likelihood of achieving flow targets declines by 15%. This is consistent with previous results that 5% impervious cover appears to be an important level or maintaining biologically protective levels of flow.

For the 85th percentile of a 24-hour storm event, based on a precipitation isohyetal developed for San Diego River watershed, any storm event with less than or equal to 0.75 inches (1.9 cm) is assumed to be 100 percent captured by the retention structures, resulting in no runoff (Table 11).

Providing clear objectives can aid in future desires to manage runoff and reservoir discharge in a manner that promotes healthy downstream biological communities. To assist in future management decisions, we developed the following specific management statements for the Alvarado Creek scenario.

- NoDisturb = Maintain an average low flow between 0 cms and 0.01 cms (0.4 cfs) for a minimum of 119 days during the dry season
- HighDur = Maintain flow greater than 0.01 cms (0.4 cfs) for between 27 and 56 days per year
- MaxMonthQ = Maintain mean monthly flows below 0.66 cms.(23 cfs)
- Q99 = Storm flows (or high flow events) should be between 0.2 (7 cfs) and 0.66 cms (23 cfs)
- HighNum = Ensure less than 4 high flow events per year with a flow greater than 0.01 cms (4 cfs)

As stated above, variability metrics do not lend themselves to directed management actions. Instead they should be used to evaluate the effectiveness of actions informed by the other metrics.

Table 11. Response of key metrics to changes in total impervious cover and 85□ runoff capture. The table presents site-specific targets that have been calculated based on the regional threshold values. Green cells represent conditions where flow targets would be met. NT □no target assigned

IMPLICATIONS AND RECOMMENDATIONS

The goal of this project was to demonstrate how regional flow-ecology relationships can be used to inform instream environmental flow properties necessary to meet ecological benchmarks as defined by measures of benthic macroinvertebrate community composition and structure. These target flows can be used to help establish goals for use in hydromodification management, nutrient numeric endpoints, and freshwater bioobjectives. They can also be used to develop performance targets for management actions, BMPs, etc. This case study allowed us to develop a framework for implementing regionally derived flow–ecology relationships to inform local management decisions. The stakeholder-focused process allowed us to identify technical and practical benefits and challenges associated with the approach that can inform future implementation efforts.

Utility of the regional flow-ecology approach based on the ELOHA framework

A major objective of this case study was to evaluate the ability to apply the flow–ecology relationships derived from the regional analysis to inform local watershed-scale decisions. Our results illustrate that several of the stated advantages of the ELOHA approach aid in such watershed-scale application. The ability to apply regionally derived flow thresholds to inform local decisions is a major advantage of the ELOHA approach. This eliminates the need to develop local flow–ecology relationships for every stream of interest, as is the case in more traditional instream flow methods (Beecher et al. 2010, McClain et al. 2014). The tools developed through the regional analysis provided readily transferable tools for local stakeholders to produce measures of hydrologic change (i.e., delta H) for any location of interest and to explore how those values would change under different land use or management scenarios. This had the dual benefit of allowing for robust analysis and providing a vehicle for stakeholder engagement in setting management priorities related to instream flow, an important cornerstone of the ELOHA approach.

Use of the predictive CSCI index in our regional flow-ecology analysis took advantage of the available bioassessment data and provided an easy way to provide measures of biological change (delta B), which has been a challenge for past ELOHA applications (e.g., McManamay et al. 2013). Developing the regional flow–ecology relationships and applying them at the local scale would not have been possible without the regional bioassessment data and the existence of the predictive scoring tool (Mazor et al. 2016). Large regional data sets provide sufficient sample size to develop statistically meaningful flow-ecology relationships in spite of the inherent "noise" in the data associated with other co-occurring factors that interact with flow to affect biological community condition (Solans and Jalon 2016). The predictive scoring tool is a measure of biological condition relative to expected reference conditions and thus provides a readily available measure of biological change (delta B) at every site. The availability of similar data and tools should be a major consideration for other efforts interested in developing similar regional approaches.

Other important elements of the ELOHA approach are the inclusion of a broad suite of hydrologic metrics that relate to ecologically relevant biological metrics through hypothesized flow–ecology relationships. Our seven priority flow metrics included two measures of magnitude, two of duration, two measures of variability, and one of frequency. This combination ensures that all elements of the hydrograph will be addressed through flow management. The selected metrics have hypothesized relationships that affect macroinvertebrate communities, allowing us to communicate their ecological relevance to managers and local stakeholders (Table 12). They are also amenable to management and minimize redundancy between metrics (Table 13). Interestingly, our metrics are similar to those identified by DeGasperi et al. (2009) who found that decreases in macroinvertebrate indices in urbanizing watersheds in the Puget Sound area of Washington were associated with changes to the number and duration of high and low flow events, and flow flashiness. It is important to note, however, that hypothesized relationships for both this study and other similar studies were derived through statistical analysis of regional bioassessment data sets. Additional mechanistic studies will be important to validate these relationships and confirm their ecological relevancy. As such studies are completed, they can be used to refine flow management targets based on improved understanding of the flow–ecology relationships.

Table 12. Hypothetical biological responses to alterations in six selected flow metrics

NoDisturb:

- Decrease: Times between spates and droughts are too short to support the expected abundance and diversity of long-lived taxa (e.g., semivoltine insects). Flood-dependent reproducers (e.g., cottonwoods) have fewer opportunities to establish. Good recolonists (drifters, strong fliers, exiters) will flourish.
- Increase: Long-lived taxa are able to out-compete taxa that reproduce quickly or recolonize.

HighDur:

- Decrease: Reduced time with floodplain access, reducing floodplain subsidies to fish and inverts, and diminishing time for riparian seedlings to establish.
- Increase: Desiccation resistance is less useful. More opportunities for aerial colonization (good fliers)

HighNum:

- Decrease: Fewer flushing flows. Allows more clogging of substrate and encroachment of macrophytes. Reduction of spawning gravels for fish. Deposition will fill pools. Greater accumulation of algae may lead to increased grazing.
- Increase: More scouring flows. More incision and bank erosion, leading to mortality of riparian vegetation. Direct mortality of long-lived organisms may eliminate semivoltine taxa.

Q99 and MaxMonthQ:

- Decrease: Reduces size of flushing flows, allowing more clogging of substrate and encroachment of macrophytes. Reduction of spawning gravels for fish. Deposition will fill pools. Greater accumulation of algae may lead to increased grazing. More desiccation-resistant taxa. More predation, and more predation-resistant (armored, or quick reproducers) taxa.
- Increase: Greater scour, leading to incision and bank erosion. Riparian vegetation mortality will increase, both through bank failure and lowering of the water table. Greater flushing of leaf litter will lead to a decline in shredders.

QmaxIDR:

- Decrease: Greater similarity between high and low flows will result in more stable channel morphology, with less bank erosion, leading to a reduction of large woody debris entering the stream. Access to the floodplain will be reduced, limiting growth of fish and amphibians that take advantage of this resource.
- Increase: Increased differences between high and low flows may destabilize channels, leading to greater bank erosion or incision, affecting the growth or survival of riparian vegetation. The consequent loss of riparian vegetation may decrease shading and leaf-litter input to the stream, shifting the trophic structure from an allochthonous system to an autochthonous one.

RBI

- Decrease: Reduced flashiness decreases the frequency of mortality events, allowing the proliferation of long-lived semivoltine taxa.
- Increase: Increased flashiness favors short-lived, multi-voltine taxa and good dispersers that can recover quickly after frequent flooding events.

Table 13. Description and management implications of priority flow metrics

- NoDisturb (days), is the median annual longest number of consecutive days that flow is between the low (Q10) and the high flow (Q90) threshold. Disturbance changes the bed shear stress and effects sediment transport. While an increase in the number of no-disturbance days does not have a high negative impact on the stream health, a decrease in the number of days is significant. Under urbanization scenarios we usually see a decrease in the number of no-disturbance days.

- HighDur, is the median annual longest number of days the flows were greater than upper threshold (Q90). This metric only has a lower threshold and a corresponding lower target. In terms of management, as long as the metric value is higher than the lower target, the stream is not failing the metric. Both the duration metrics require several years of data.

- MaxMonthQ (cms) is the maximum mean of the monthly flows. The MaxMonthQ has an upper threshold and associated target but no lower target. The management goal is to ensure that the metric values are below the upper target value. In cases of urbanization, we see a rapid increase in the MaxMonthQ.

- Q99 (cms) is a high flow threshold, or the top 1□ of the flow and has upper and lower bound targets in cms. The management goal is to maintain the metric values within this range. In cases of urbanization, we see a rapid increase in the Q99 values.

- RBI describes the oscillation in flows (or discharge) relative to the total flows (Baker et al 2004). This flashiness metric usually increases with urbanization which impacts the runoff patterns. However, the flashiness might decrease in case there are dams or steady controlled releases from reservoirs which dampen the natural flashiness of the hydrograph. The metric has an upper target, which implies that an extreme flashy stream is unhealthy for the biological communities, and the management goals should focus on keeping the RBI scores below the upper target value.

- Qmax IDR measures variability as the difference between the high flow threshold (Q90) and low flow threshold (Q10) divided by the 50th percentile flow (Q50). A higher value implies increasing variability, which is typically the case in streams without hydrologic regulation.

- HighNum is the frequency metric which estimates the number of events where the flow is higher than Q90 threshold. This metric has an upper target which implies that the management should focus on maintaining high flow events to a number less than the upper target.

We did not stratify streams in the San Diego case study, as is suggested for the general ELOHA approach. The San Diego watershed includes three stream classes from the statewide classification (Pyne et al. in press), with 60% of the streams being in one class and the remaining 40% being equally divided between two other classes. However, our analysis did not result in substantial differences in the local flow–ecology relationships as result of stream class. Instead climate (wet, dry, average rainfall) was a more important predictor. Therefore, we classified relationships by climatic period vs. stream type.

Challenges of the ELOHA approach

The main challenges associated with local implementation of the regional flow-ecology relationships relate to availability of high-quality input data, applicability of some metrics to site-specific simulation of reference conditions, and limitations on the interpretation of the output relative to other considerations and potentially confounding factors. Quality of rainfall data was one of the most critical factors affecting confidence in the regional flow–ecology relationships (Sengupta et al. in review). Similarly, in the San Diego River watershed the uneven availability of high-quality hourly rainfall data that encompassed all climatic conditions affected our ability to apply the hydrologic models equally across the entire watershed. In some cases, we had to drop data from the nearest gages due to gaps or obvious errors and substitute with less proximate gages, but that provided better or more complete rainfall data. This spatial offset introduced some additional uncertainty that must be accounted for in interpreting the model output.

Application of the regional flow-ecology relationships to local management scenarios revealed several complications associated with the formulations of certain metrics commonly used in applications of the ELOHA framework (e.g., Solans and Jalon 2016). The first complication involves many duration metrics that are calculated based on frequency or duration of flows above or below a benchmark derived from a long-term flow record. For example, the HighNum metric is calculated as the number of flow events over the 90th percentile of daily flow. This formulation may not be suitable for evaluating hydrologic change, because the benchmark may shift along with other parts of the hydrograph, thereby obscuring hydrologic impacts. Figure 12 shows the current and reference hydrographs of a site that has experienced dramatically increased flows. If the current flows are compared to a benchmark derived from the historic hydrograph, it is clear that the site experiences one very extended high flow event every year; in contrast, the historic flows experienced several, short-duration high-flow events each year. However, if the current flows are compared to a benchmark derived from the current hydrograph (as is commonly done), the site appears to experience only a few short high-flow events each year. Thus, the hydrologic alterations from historic conditions are obscured when shifting benchmarks are used to calculate certain metrics. This problem is not easily apparent in regional analyses due to the large sample size, and is most clear when applied to a specific site, as in the present study. We recommend that future analysis use a constant, unshifting benchmark based on historical conditions when estimating thresholds for duration metrics based on thresholds of high- or low-flow events.

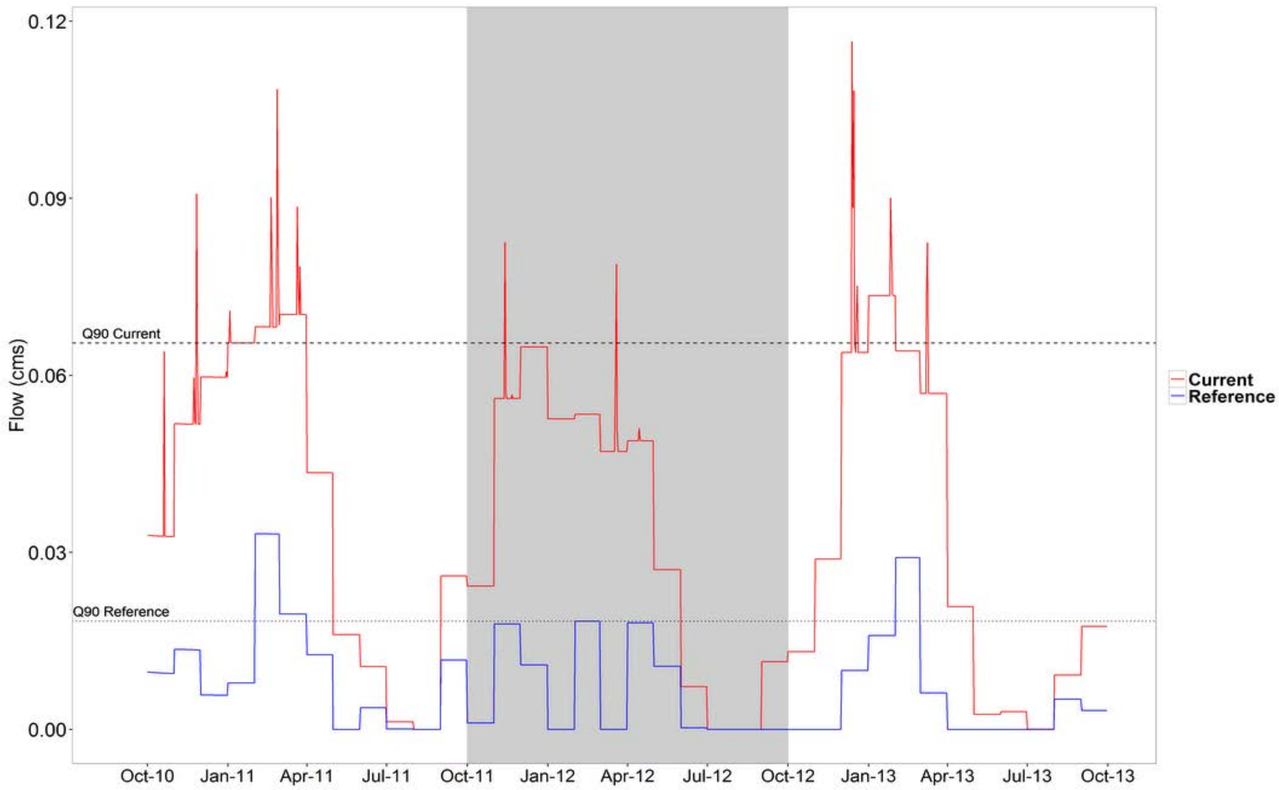

Figure 12. Comparison of current and reference flow for a sample bioassessment site showing the effect of the use of different thresholds. Conclusions about changes in duration of high flow events would vary dramatically if only a single threshold based on reference is issued vs. different thresholds were used for current and reference conditions.

The second issue associated with metric calculation relates to anomalous results that may occur when reference conditions are expected to represent intermittent streams with long periods of zero-flow days. This may result in reference flows for many of the magnitude metrics being extremely low (or zero), making it virtually impossible for management scenarios to achieve targets for certain metrics. This computational issue is confounded by the real challenge that it may not be possible to reduce runoff back to natural conditions, even with full implementation of stormwater runoff controls (DeGasperi et al. 2009). New or modified metrics may need to be developed to accommodate establishing flow management targets appropriate for naturally intermittent or ephemeral streams.

The use of HEC-HMS to produce the delta H values was a tradeoff between ease of use and model precision. HEC-HMS is arguably not optimal for evaluating BMP and other non-point source runoff management measures. We chose this model to develop the regional flow-ecology relationships because of its simplicity, availability, ability to perform long term continuous simulations of streamflow. Its status as an industry standard model developed by the US Army Corps of Engineers makes it practical for application to the hundreds of catchments evaluated during the regional analysis. Similarly, its familiarity and accessibility make it ideal for involving local stakeholders in the analysis and decision-making process. However, other lumped parameter hydrologic models that are also widely used to perform continuous simulations, such as HSPF or SWMM, may be more appropriate. SWMM is more robust in terms of modeling storm sewers and various stormwater control measures including low impact development practices. At the expense of more complexity and model parameters, HSPF includes additional details on soil moisture and subsurface processes that can enhance modeling of baseflow and groundwater behavior. These features would likely provide more precise estimates of how future management interventions could affect runoff and, consequently, stream flow metrics. We did not investigate whether/how use of an alternative or more sophisticated model would affect the output of our scenario analyses, but this should be investigated in the future.

Our reliance on developing flow targets based on the response of a single community assumes that the macroinvertebrate community reflects overall ecological condition. Although this is not a totally unreasonable assumption, we recognize that different components of the stream ecosystem may be affected differently by changes in various components of the hydrograph. Other ELOHA efforts have attempted to address this issue by developing flow–ecology relationships for multiple communities (e.g. fish, vegetation, mussels) and recommending targets around protection of each (DePhilip and Moberg 2013). This approach is more robust, but complicates development of management measures that can address all biological endpoints. Ultimately, such an approach is likely less parsimonious for regulatory applications.

Spatial and temporal factors must also be considered when applying flow–ecology relationships. Our analysis focused on catchment-scale responses. However, benthic invertebrates may also respond to local scale factors such as duration of wetting of bars and localized velocity zones (Kath et al. 2016, Kennedy et al. 2016). Hydrologic change at the local (small) scale may be ecologically important but is likely not affected by managing for the flow metrics we identified, and may be difficult to address through any regionally derived flow management framework. Although our regional flow criteria were developed in consideration of wet, dry and average climatic cycles, they likely do not account for longer term climate patterns and extreme episodic events that may be important for establishing and maintaining resilient instream habitats. This deficiency was highlighted by McManamay et al. (2013), who found that results of ELOHA analysis cannot necessarily be used in a predictive manner because biological communities may respond to other factors not included in the flow–ecology analysis, such as changes in substrate associated with infrequent events, such as catastrophic floods or fires. Moreover, they note that temporal resolution of most case studies does not coincide with the temporal period of data underlying ELOHA relationships. For example, streams may respond to episodic events and patterns operating on decadal time scales. We currently lack flow metrics that capture these interannual and longer term hydrologic patterns. Finally, as we noted in our analysis confounding factors such as changes in water chemistry typically co-occur with hydrologic changes and may contribute to biological community health in ways not captured by flow management.

These issues reinforce the concept that flow-ecology relationships should be used as one line of evidence in coordination with other factors/considerations when establishing stream management prescriptions and targets. In particular, many watersheds are subject to complex regulatory and management systems that involve combinations of new and retrofit facilities aimed at reducing runoff and retaining flows for infiltration and reuse. The regional flow targets established by Mazor et al. (in review) and applied in this case study can be an important consideration in designing and implementing integrated watershed management plans aimed at meeting both short and lon objectives.

Framework for development of local flow targets

We found the case study process to be productive because it provided a framework for considering hydrologic management in the context of watershed planning. It also provided the first opportunity in the region to develop quantitative flow targets that could be used to inform actionable management decisions. The regional flow–ecology relationships provided flexibility in establishing targets based on desired levels of confidence that those targets would be associated with healthy biological communities. Regionally derived targets took advantage of the robust regional monitoring data set and a broad set of hydrologic conditions. This improved relevance to local conditions was an important consideration for the watershed stakeholders. Given the utility of the process, we used the case study to develop a stepwise process that can serve as a framework for future implementation in other watersheds. This stepwise process is based on an adaptation of the ELOHA framework (Figure 13).

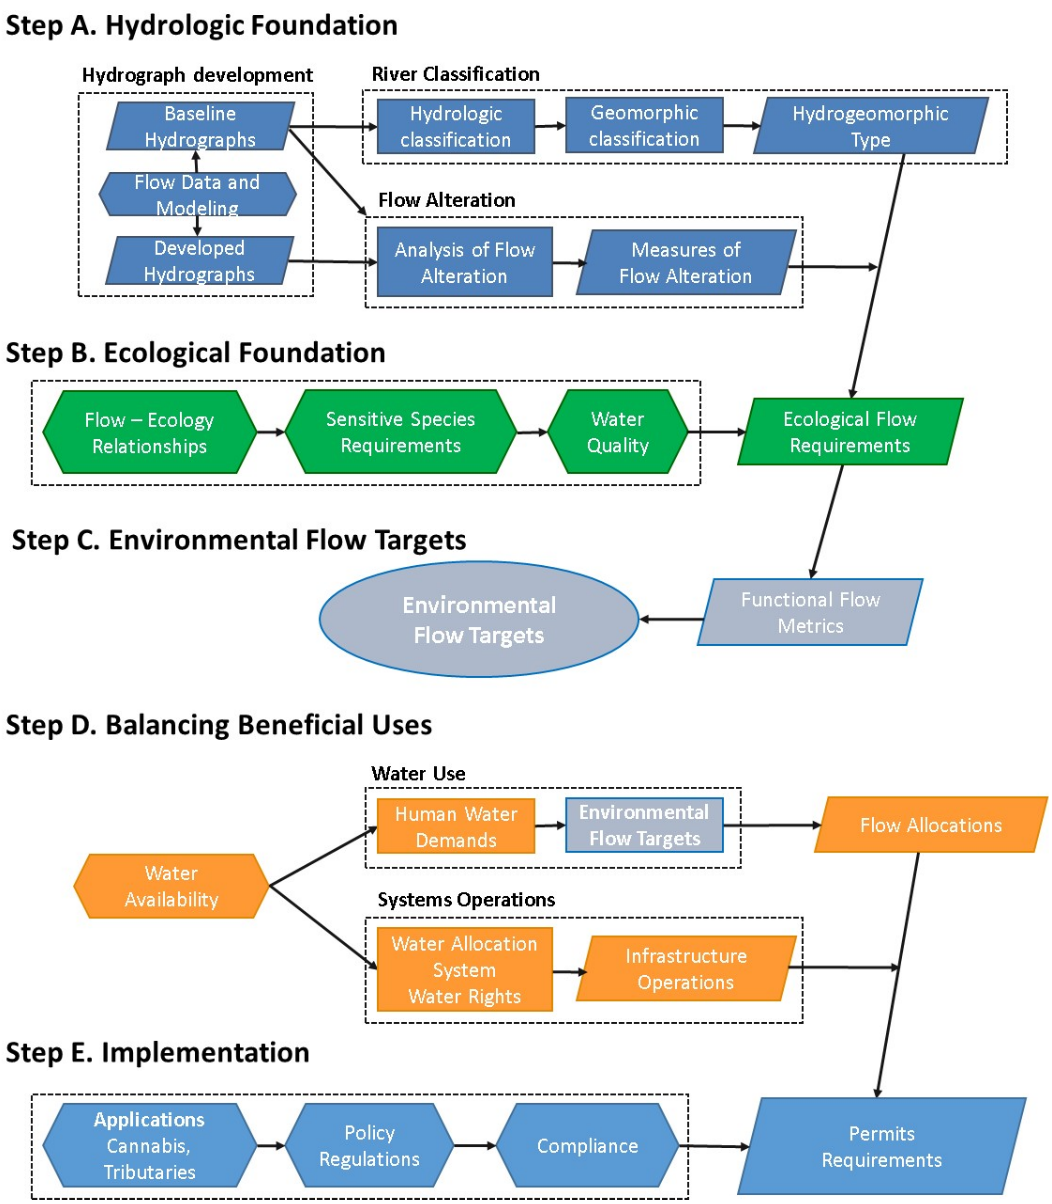

Figure 13. Process for development and implementation of instream flow targets, modified from the ELOHA framework (Poff et al. 2010).

Based on the framework in Figure 13, we identified the following steps that can be followed if other groups wish to pursue similar efforts to develop flow management recommendations:

Step 1: Determine what hydrologic class the stream of interest is in

Step 2: Identify management needs, regulatory objectives, or other targets

Step 3: Compile local data

- Contemporary and proposed future land use
- Information on contemporary and proposed water capture, storage, diversion, discharge, and other water management
- Local rainfall data at hourly time intervals (data must be checked to ensure sufficient quality and duration, at least ten years that encompass wet, dry, average rainfall conditions)

Step 4: Divide watershed in subbasins for analysis based on hydrology and management needs

Step 5: Select appropriate model(s) for catchments of interest using regional model selection tool

Step 6: Model both contemporary and natural hydrology for each catchment

Step 7: Calculate delta H metrics for each reach/node

Step 8: Select priority metrics and targets based on the following:

- Recommendations from the regional ELOHA analysis
- Relevance to local management needs
- Ability to influence through management measures

Step 9: Determine temporal factors associated with the targets

- Seasonality
- Persistence/duration
- Frequency (e.g. always, every X years)

Step 10: Evaluate various management scenarios relative to targets identified in Step 8

Step 11: Explore potential related or confounding factors (e.g. water quality, substrate)

Step 12: Develop recommended actions to achieve flow targets

- Relate actions to specific hydrologic modifications, e.g. diversion rates

Step 13: Relate flow metrics and targets to monitoring design, locations, and indicators

Step 14: Determine adaptive management actions that will be triggered if targets are not met

Informing management decisions

Stakeholder participation was critical in identifying scenarios and interpreting how the results of the analysis can be used to inform management action. Stakeholders identified the following desired applications for flow targets, which helped define our analysis:

- Identify priority management sites based on biological and hydrologic condition
- Use results to inform BMP/LID selection
- Identify areas were flow management has potential to improve CSCI scores
- Explore implication of future management of reservoirs for multiple benefits, e.g. water quality and water supply

These desired uses shaped our ultimate products. For example, we developed the overall composite index of hydrologic alteration in direct response to stakeholder desire to holistically assess the watershed for areas most vulnerable to future hydrologic alteration. Not surprisingly, the degree of hydrologic modification was correlated with impervious cover. We found that hydrologic alteration generally occurred in catchments with greater than 5% total impervious cover, which is similar to other studies that have shown that channel degradation to due to hydromodification occurs at relatively low levels of imperviousness (Hawley et al. 2012, Vietz et al. 2016). Similarly, the map of hydrologic management categories was identified as one of the most useful products for planning purposes because it allows stakeholders to prioritize areas for protection and for flow management.

We were able to demonstrate the utility of applying the flow-ecology relationships to inform management for both point source and non-point source management scenarios. For both the reservoir management scenario and the urban runoff management scenario, we were able to determine a range at which hydrologic management may facilitate recovery of impacted biological communities.

Lessons learned for future implementation

Future efforts can built on the experiences from this case study and continue to refine an iterative process of developing flow targets that are scientifically defensible, practical (i.e., can lead to management actions), and consistent with local stakeholder needs. Key lessons learned from this effort include:

1. Include a broad set of engaged stakeholders, including regulatory agencies, municipalities, water agencies, non-governmental organizations, and researchers. This ensures a broad perspective in the deliberations and increases the likelihood of developing balanced recommendations.
2. Invest in educating the stakeholders early in the process on the underlying science and the rationale behind how regional flow targets were developed. This promotes engagement and fosters creative solutions to the complex challenges of flow management.
3. Invest the time to compile high quality local data sources and show how local data can be used in the evaluation process. Identify the areas were future data collection can most improve outputs of the flow–ecology analysis (e.g., local rainfall data, more refined land use, water quality data). This can inform future monitoring.
4. Develop documentation that clearly illustrates how the products of the flow–ecology analysis can be used in the context of existing regulatory or management programs.

The San Diego River implementation case study also produced several technical recommendations that can improve our ability to apply flow-ecology relationships to manage southern California streams:

1. Several flow metrics, particularly those associated with flow duration, may require modification for use in streams where the natural condition is intermittent or ephemeral.

Natural intermittency poses fewer issues when developing regional flow-ecology relationships based on hundreds of sites. However, application of the resultant thresholds to specific streams that may have been naturally intermittent can lead to erroneous results.

2. Metrics associated with flow durations should be calculated on a single threshold value based on reference conditions. Estimating change in flow durations based on a moving threshold estimated separately for current and reference conditions may produce erroneous results.

3. Need to improve the representation of the drainage system to provide a more accurate hydrologic foundation for analysis. This would ultimately include improved mapping of discharges, diversions, stormwater control facilities, LID, etc. for incorporation into modeling scenarios and effects.

4. Consider expanding the analysis to include additional elements in future case studies

    - Include other stream or water body types
    - Include other indicators (e.g. algae)
    - Explore how consistent/transferable findings are from one watershed to another
    - Explore application in watersheds that cross jurisdictional boundaries

The original authors of the ELOHA framework promote the idea that flow targets derived by statistical analysis are a starting point. Targets should be iteratively refined using additional monitoring data, professional judgement and consideration of all complementary and competing factors necessary to develop flow standards that can address often divergent interests. The San Diego River case study provides an illustration of how watershed stakeholders are critical partners in the process. Resultant flow standards provide a starting point for developing agreed upon, adaptive flow management programs that can protect intact waterbodies and restore those that are currently impacted.

APPENDIX A DETAILED PROCEDURES FOR HYDROLOGIC ANALYSIS

Directions to run HEC-HMS Modeling packages developed for flow ecology analysis

To be able to run these modules

- Basic idea of catchments, watersheds, and delineated areas

- Moderate skills in R programming (scripts provided)

- Basic understanding of watershed modeling

Software needed:

- Streamstats (online, no download necessary)

  http://streamstatsags.cr.usgs.gov/v3_beta/

- R and Rstudio (installation needed for both, install R before installing R studio)

  https://cran.cnr.berkeley.edu/

  https://www.rstudio.com/products/rstudio2/

- HEC-HMS (install)

  http://www.hec.usace.army.mil/software/hec-hms/downloads.asp

Notes for running R scripts:

- setwd("../Desktop/") sets up each script to automatically read files in the folder Modeling Workshop, as long it is located on your desktop

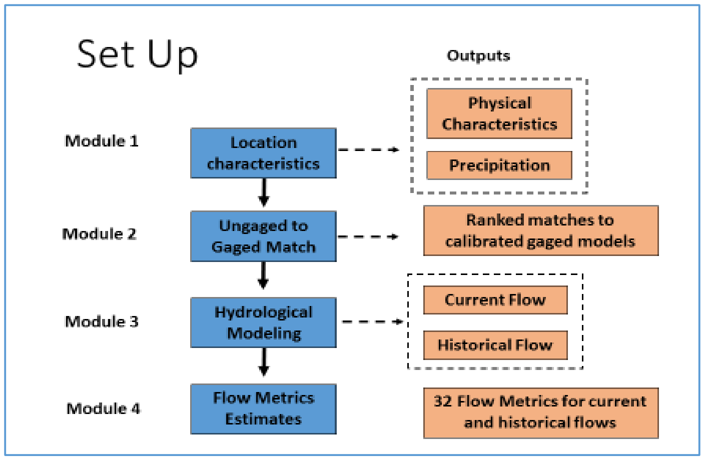
- Mac users will need to change the ".." in "../Desktop/" to "~" (tilde)

- Each script must be opened from within R-Studio in order to correctly use setwd("../Desktop/")

- If you get an error that says you cannot change the working directory, then close the script in R-Studio, close R-Studio, re-open R-Studio, then open the script from within R-Studio

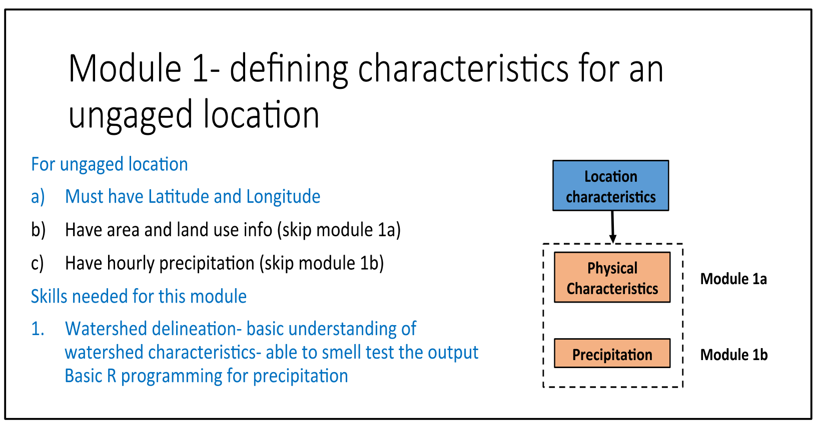
Introduction

The modeling tool has four modules. The modules should be run sequentially to get the flow metrics. Described below are four modules and their outputs.



Module 1.

Module 1 allows the users to delineate the watershed area for an ungaged site, and estimate hourly precipitation (1990-2013).



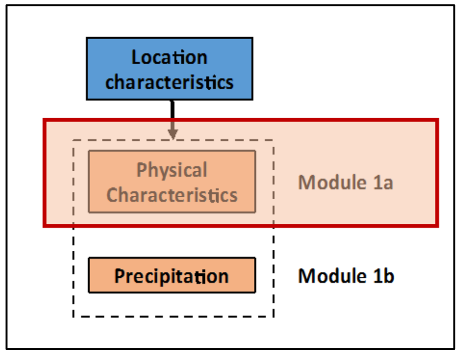
Limitations:

1. For some locations, the Streamstats outputs a square delineated catchment area. Always check the visual output, in case it looks incorrect, move the location slightly to obtain the watershed characteristics.

2. The precipitation raw data from the gages is limited to 1990-2013. The script is enabled for any period, to produce output for periods outside of 1990-2013, hourly gaged precipitation data is required.

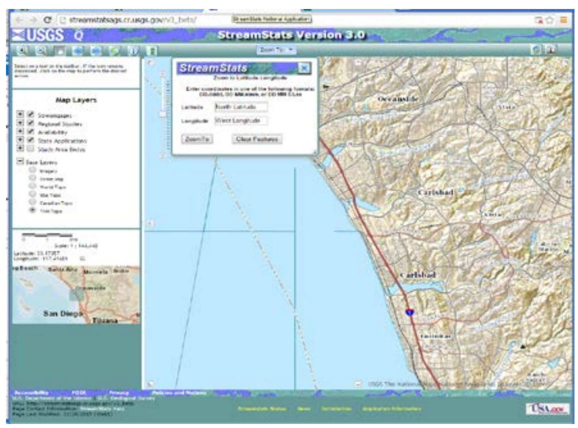
Instructions to run the modules

Delineate the subcatchment/watershed area for ungaged location

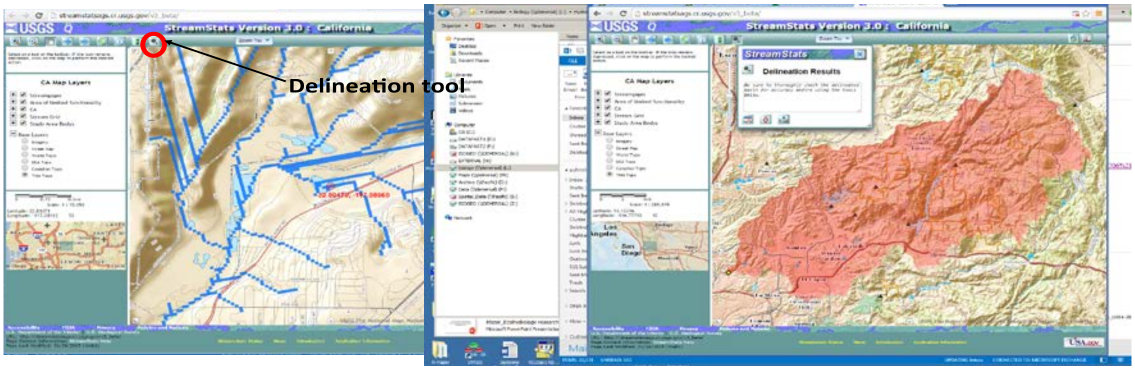


We will use Streamstats to delineate area and land use. URL provided below.

1. http://streamstatsags.cr.usgs.gov/v3_beta/
2. Press the 'zoom to' button highlighted in figure 4, and enter the latitude and longitude.

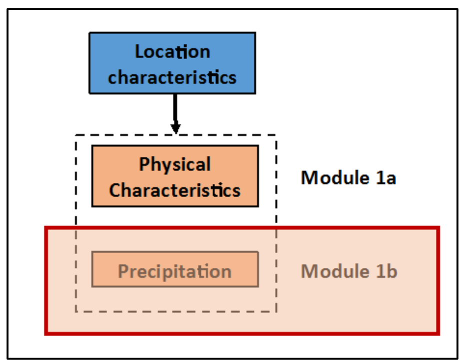


3. Zoom till you see the delineation tool (highlighted below). Select first tab in the pop out window (in figure 5b).



4. Select area and imperviousness, and compute

Module 1b. Estimating hourly precipitation



Input files: Modeling Workshop\Inverse Distance\Data*Precip_(YEAR).csv*, *AssessmentSiteCoord.csv*, *PrecipStationCoord.csv*

Output file: Modeling Workshop\Inverse Distance\Data*Assess_(YEAR).csv*

1. We use R Studio to estimate hourly precipitation.
2. To predict flows at the gages, we need hourly precipitation data
3. Daily data is available on PRISM website
4. For better flow predictions, we estimated hourly flow using precipitation data from >200 sites
5. You can use the script for 1990-2013 (and will require raw precipitation data outside this range)
6. Open the file *AssessmentSiteCoord.csv*, delete the current data in the spreadsheet and enter the data for your site ID, latitude and longitude in the appropriate columns

7. From within RStudio, open Modeling Workshop\Inverse Distance*InvDist_calc_02_SelectYears.R*
8. Run the line install.packages(…), then add a # at the beginning of the line
9. Specify year range on line 23 (default is 1990:2013)
10. Run script by clicking “Source” button at the top right of the script window
11. Look at *Assess_(YEAR).csv* in your working directory for output

Module 2: Matching ungaged sites to gaged sites

Calculates the proximity of the ungaged site to the calibration gages (models).

Input file: Modeling Workshop\Site Assignment*test.csv*

Output file: Modeling Workshop\Site Assignment*top.model.csv*

How to assign an ungauged site to a flow model:

1. Delineate watersheds, and 5-km watershed clips
2. Calculate predictors:

Variable name (CASE SENSITIVE!)	Description	Source file to use
StationCode	Unique site identifier	User
New□Lat	Latitude in decimal-degrees North. Not required for predictions, but useful for plotting.	User
New□Long	Longitude in decimal-degrees West (should be negative). Not required for predictions, but useful for plotting.	User
Imperv□percent	Mean □ imperviousness in the catchment (0-100).	[StreamStats]
URBAN□2000□WS	NLCD urban land use in the catchment (0-100). For NLCD 2000, these codes count towards urban:	NLCD2000 or NLCD2006
KFCT□AVE	Mean soil erodibility in the catchment.	[RAFI]
Ag□2000□WS	NLCD agricultural land use in the catchment (0-100). For NLCD 2000, these codes count towards urban:	NLCD2000 or NLCD2006
CODE□21□2000□WS	NLCDE Code 21 (highly managed vegetation) in the catchment (0-100). For NLCD 2000, only code 21 counts.	NLCD2000 or NLCD2006
Ag□2000□5k	NLCD agricultural land use in the 5-km clip of the catchment (0-100). For NLCD 2000, these codes count towards urban:	NLCD2000 or NLCD2006
RoadDens□5K	Road density (km□km2) in the 5-km clip of the catchment. Dirt roads do not count.	[Rafi]

1. From within R Studio, open Modeling Workshop\Site Assignment*assigning_testsites_020116.R*
2. Currently *test.csv* has dummy site information; use this as a template for your site info
3. Please see handout for GIS information required for this module
4. *top.model.csv* is the output file with top matched gage info

Note: Within a year or two automated tools from the State (SWAMP) will calculate the variables, but for now, use GIS to estimate them.

Module 3: Running hydrological model (HEC-HMS) to predict hourly flow

We run the model for current and reference or historical conditions

Output files: Modeling Workshop\Hourly To Daily Flow Conversion\Hourly Flow*SDR_AssessmentSites_Hourly_Current.csv* and *SDR_AssessmentSites_Hourly_Reference.csv*

First we will estimate current flows

1. Navigate to Modeling Workshop\HEC HMS Models\Current Conditions
2. Copy the model folder that is the top matched to your site
3. Save a copy in a new folder
4. Click on HEC-HMS icon on your desktop
5. Click on open folder tab, navigate to your new folder
6. Open file with the .hms extension
7. We need to change 5 parameters- area, imperviousness, time of concentration, storage coefficient and precipitation
8. From the “Compute” tab, right click on “Run 1” then click “Compute”
9. From the “Results” tab, double click “Run 1”, double click “Subbasin-1” then click on “Time-Series Table”
10. A window will appear shortly, from which you will copy all the data in the “Total Flow” column
11. Open the file Modeling Workshop\Hourly To Daily Flow Conversion\Hourly Flow*SDR_AssessmentSites_Hourly_Current.csv*, paste the “Total Flow” data in a new column on the right, starting on row 2
12. Put the site name in the first row of this column
13. Remove all the other columns, EXCEPT for your new column, the “Date_Time” column and one additional column of flow data (the metric calculation requires data from at least 2 sites)

Historical flows

1. Navigate to Modeling Workshop\HEC HMS Models\Reference Conditions

2. Copy the model folder that is the top matched to your site
3. Save a copy in a new folder
4. Click on HEC-HMS icon on your desktop
5. Click on open folder tab, navigate to your new folder
6. Open file with the .hms extension
7. We need to change 4 parameters- area, time of concentration, storage coefficient and precipitation
8. From the “Compute” tab, right click on “Run 1” then click “Compute”
9. From the “Results” tab, double click “Run 1”, double click “Subbasin-1” then click on “Time-Series Table”
10. A window will appear shortly, from which you will copy all the data in the “Total Flow” column
11. Open the file Modeling Workshop\Hourly To Daily Flow Conversion\Hourly Flow*SDR_AssessmentSites_Hourly_Reference.csv*, paste the “Total Flow” data in a new column on the right, starting on row 2
12. Put the site name in the first row of this new column
13. Remove all the other columns, EXCEPT for your new column, the “Date_Time” column and one additional column of flow data (the metric calculation requires data from at least 2 sites)

Module 4. Flow metrics are estimated on daily flow

Convert hourly flow output from HEC-HMS to daily flow

Input files: Modeling Workshop\Hourly To Daily Flow Conversion\Hourly Flow*SDR_AssessmentSites_Hourly_Current.csv* and *SDR_AssessmentSites_Hourly_Reference.csv*

Output files: Modeling Workshop\Hourly To Daily Flow Conversion\Daily Flow*SDR_Assessment_Daily_Current.csv* and *SDR_Assessment_Daily_Reference.csv*

1. From within R Studio, open Metric Workshop\Hourly To Daily Flow Conversion*HourlytoDailyFlow_Current.R*
2. Run install.packages(…) line, then add # to the beginning of the line
3. Run script by clicking “Source” button on the top right of the script window
4. Converted daily flow data will be in Modeling Workshop\Hourly To Daily Flow Conversion\Daily Flow*SDR_Assessment_Daily_Current.csv*
5. Repeat using Metric Workshop\Hourly To Daily Flow Conversion*HourlytoDailyFlow_Reference.R* to produce daily flow data for reference condition hourly flow data

Calculate Metrics for Daily Flow Data

Input files: Modeling Workshop\Hourly To Daily Flow Conversion\Daily Flow*SDR_AssessmentSites_Daily_Current.csv* and *SDR_AssessmentSites_Daily_Reference.csv*

Output files: Modeling Workshop\Metric Calculation \Results\ *Sdr_Current_Metrics.csv* and *Sdr_Reference_Metrics.csv*

1. From within R Studio, open Modeling Workshop\Metric Calculation*KonradMetrics_Current.R*
2. Click "Source" button in upper right corner of script window
3. Metric results will be in Modeling Workshop\Metric Calculation\Results*Sdr_Current_Metrics.csv*
4. Repeat using Modeling Workshop\Metric Calculation*KonradMetrics_Reference.R* to get metric results for reference condition flow data

Description of Metrics in QSUM (typically Median Annual Values)

Qmean [M3/S] - mean streamflow for the period of analysis

QmeanMEDIAN [M3/S] - median annual mean streamflow

QmeanIDR - (90th percentile of annual mean streamflow - 10th percentile of annual mean streamflow)/50th percentile of median annual mean streamflow

Qmed [M3/S] - median daily streamflow

Qmax [M3/S] - median annual maximum daily streamflow

QmaxIDR - (90th percentile of annual maximum streamflow - 10th percentile of annual maximum streamflow)/50th percentile of annual maximum streamflow

HighNum [events/year] - median annual number of events that flow was greater than high flow threshold, an event is a continuous period when daily flow exceeds the threshold

HighDur [days/event] - median annual longest number of consecutive days that flow was greater than the high flow threshold

Qmin [M3/S] - median annual minimum daily streamflow

QminIDR - (90th percentile of annual maximum streamflow - 10th percentile of annual maximum streamflow)/50th percentile of annual maximum streamflow

LowNum [events/year] - median annual number of events that flow was less than or equal to the low flow threshold, an event is a continuous period when daily flow was less than or equal to the threshold

LowDur [days/event]- median annual longest number of consecutive days that flow was less than or equal to the low flow threshold

NoDisturb [days] - median annual longest number of consecutive days that flow between the low and high flow threshold

Hydroperiod [0.01 = 1% of period of analysis] - fraction of period of analysis with flows

FracYearsNoFlow [0.01 = 1% of years] - - fraction of years with at least one no-flow day

MedianNoFlowDays [days/year]- median annual number of no-flow days

PDC50 [0.01=1% change in streamflow] - the median percent daily change in streamflow, no flow days are not included (0.01 = 1%)

SFR [-0.01=-1% change in streamflow]- the 90th percentile of percent daily change in streamflow on days when streamflow is receding (a measure of storm-flow recession)

BFR [-0.01=-1% change in streamflow] - the 50th percentile of percent daily change in streamflow on days when streamflow is receding (a measure of base-flow recession)

MaxMonth [1- Jan, 12-Dec] - month of maximum mean monthly streamflow

MaxMonthQ [M3/S] - maximum mean monthly streamflow

MinMonth [1- Jan, 12-Dec] - month of minimum mean monthly streamflow

MinMonthQ [M3/S] - minimum mean monthly streamflow

Q01, Q05, Q10, ...,Q99 [M3/S] - streamflow exceeded 1%, 5%, 10%, ..., 99% of the time

APPENDIX B STAKEHOLDER WORKGROUP AND SCHEDULE OF WORKGROUP MEETINGS

The demonstration project workgroup met six times between November 2015 and June 2016 (Table B1). All meetings were held in the San Diego River Watershed

Table B1. Workgroup participants

NAME	ORGANIZATION
Daron Pedroja	State Water Board
Gary Strawn	San Diego Water Board
Shannon Quiquley	San Diego River Park Foundation
Dustin Harrison	San Diego River Conservancy
Tracy Cline	San Diego County
Joanna Wisniewska	San Diego County
Eric Stein	SCCWRP
Raphael Mazor	SCCWRP
Ashmita Sengupta	SCCWRP
Alicia Kinoshita	San Diego State University
Trent Biggs	San Diego State University
Natalie Mladenov	San Diego State University
Charles Morloch	San Diego County
Rob Northcote	Padre Dam Municipal Water District
Arne Sandvik	Padre Dam Municipal Water District
Brian Olney	Helix Water District
Emily Blunt	U.S. Forest Service
Goldy Herbon	City of San Diego
Jeff Pasek	City of San Diego
Vicki Kalkirtz	City of San Diego
Andre Sonsken	City of San Diego
Jim Harry	City of San Diego
Anita Eng	City of San Diego
Doug Thomson	City of San Diego
James Dodd	City of San Diego
Maris Guerro	Army Corps of Engineers
John Rudolph	AMEC Environmental

The dates and goals of each meeting are listed below:

Meeting #1: November 18th, 2015
Meeting Goals:

- Provide an overview of the watershed demonstration project
- Discuss and agree upon portion of the watershed to focus on
- Agree on general roles and contributions of partners
- Develop general schedule for next set of meetings

Meeting #2: January 20th, 2016
Meeting Goals:

- Discuss work plan for priority actions/products from first meeting
- Agree on schedule for obtaining necessary data for analysis
- Compile list of primary contacts for participation in analysis

Meeting #3: February 17th, 2016
Meeting Goals:

- Technology transfer- using models to predict flows, and flow metrics at ungaged locations
- Discuss the process, and usability
- Discussion on final products

Meeting # 4: March 16th, 2016
Meeting Goals:

- Address outstanding issues on the hydrologic modeling tools
- Agree on management scenarios being evaluated

Meeting #5: April 20th, 2016
Meeting Goals:

- Review products and outline for final demo project report

Meeting #6: June 15th, 2016
Meeting Goals:

- Review draft demo project report

Why Develop Ecological Indicators?

- Global paradigm shift toward ecological indicators
- Provide direct evidence about resources we are trying to protect
- More relevant measures of impacts and BMP effectiveness
- Links resource protection across multiple agencies by focus on ultimate policy goals

CA's Ecological Indicators

Multiple Indicators – BMIs, algae, (fish), riparian vegetation

Multiple waterbody types – large rivers, non-perennial streams, lakes, wetlands

Start with invertebrates and perennial streams

B447

Surface Water Ambient Monitoring Program

Scoring Tools Depend on Reference Sites

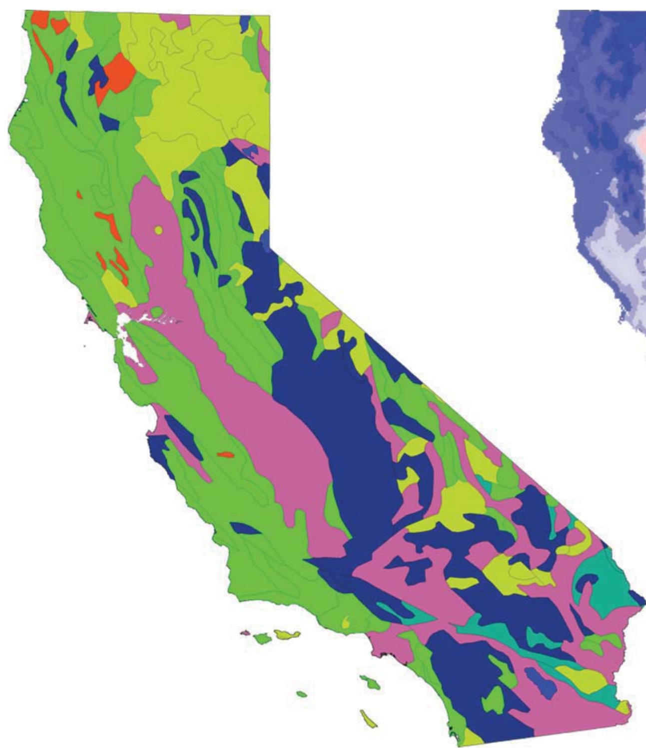
(sites with low levels of disturbance)

"What should the biology look like at a test site?"

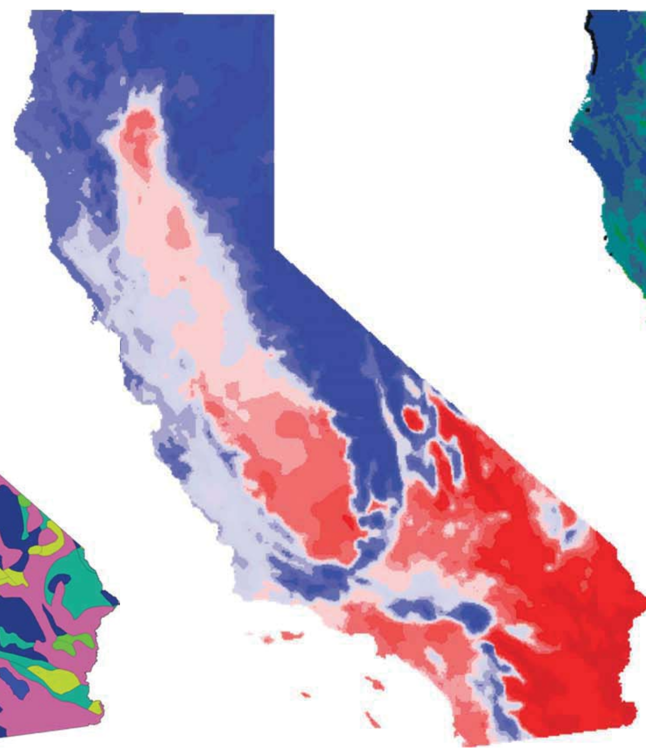
Technical Challenges:

Strong natural gradients result in natural variation in biological expectations

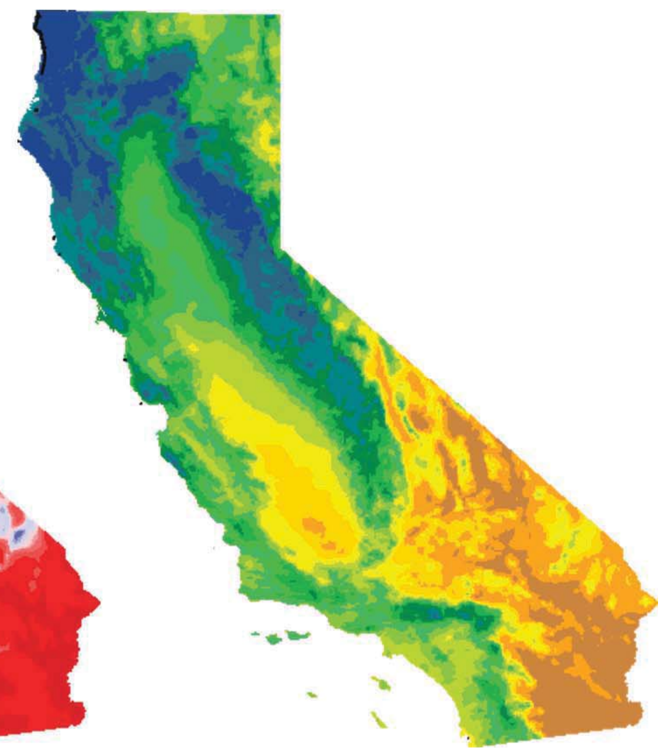
Geology



Temperature

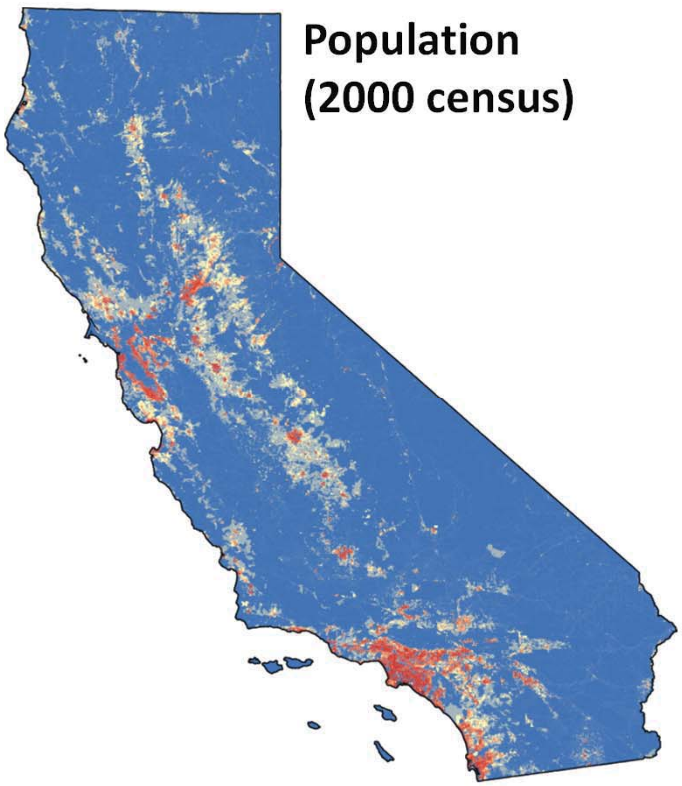


Precipitation



Technical Challenges:

Intense development can create regional gaps



Population
(2000 census)

Agricultural Areas
(2001 NLCD)

Reference Sites for Biocriteria

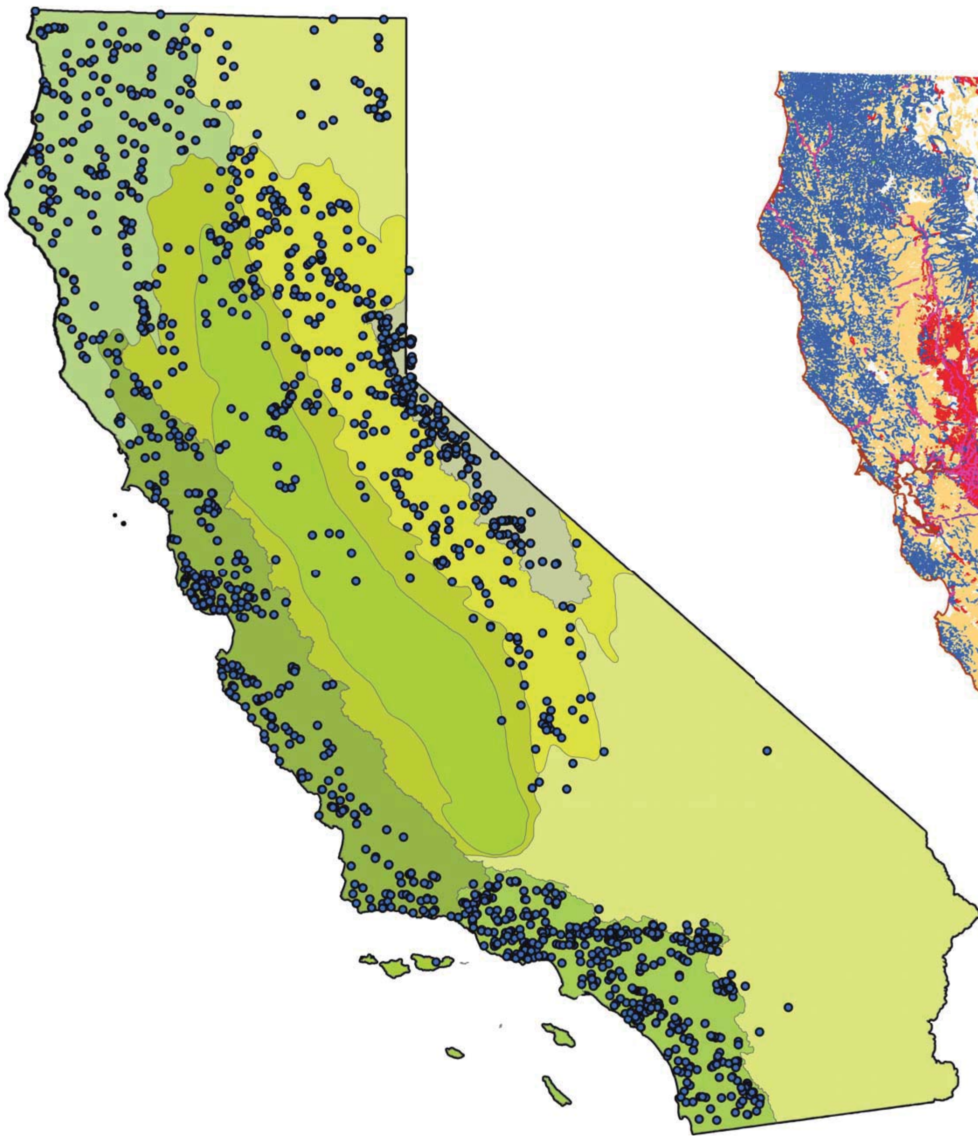
Selecting for site quality and representativeness

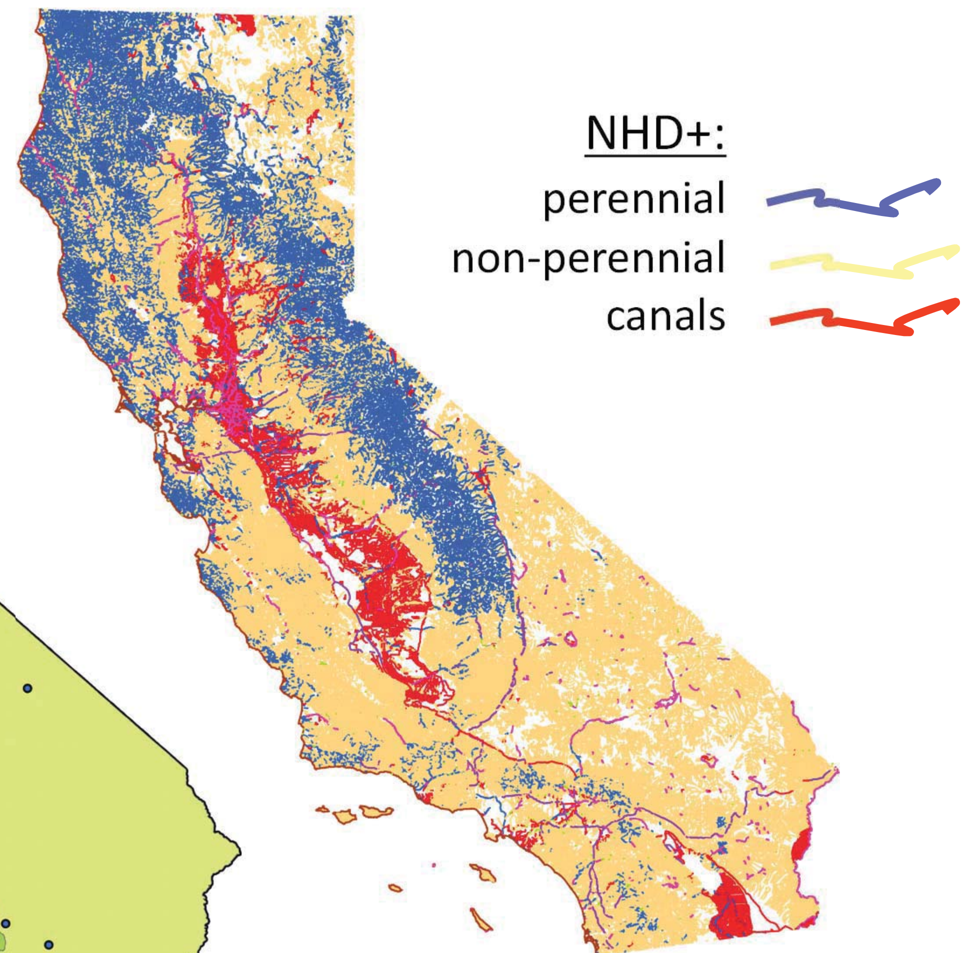
Challenge: Very few (if any) pristine streams exist; site selection process has to maximize representativeness while minimizing amount of disturbance at reference sites

Performance Objectives:

1. Reference pool represents the majority of CA streams
2. Biological "quality" is maintained at reference sites

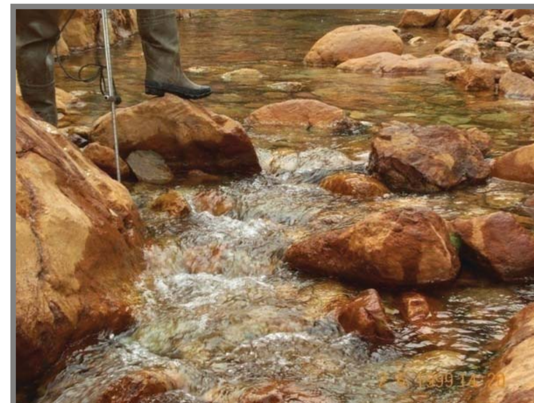
Assemble Data from > 2400 sites

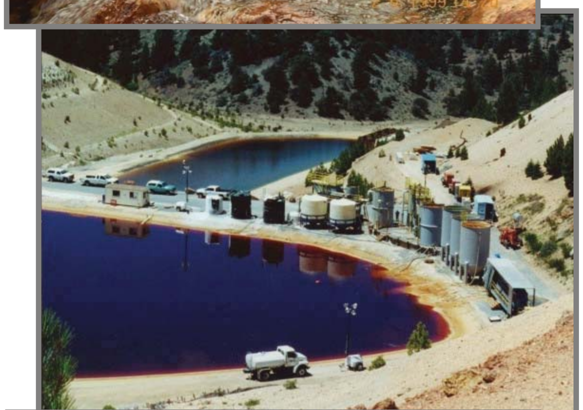


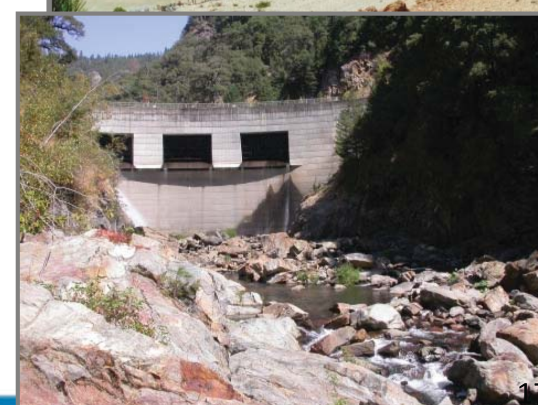


Reference sites have few sources of human stress

- **Infrastructure**: roads, railroads
- **Population**
- **Hydromodification**
  - manmade channels, canals, pipelines
- **Landuse**
  - Ag/Urban development
  - Timber Harvest, Grazing
- Fire history, dams, mines
- 303d list, known discharges
- Invasive invertebrates, plants
- Instream and riparian habitat
- Water chemistry







Thresholds are comparable or stricter than other CA indices and include many more criteria

Metric	Bio-Objectives	South Coast IBI	North Coast IBI
Local Disturbance (W1_Hall)	1.5	-	-
% Agricultural	3,3,10	5	5
% Urban	3,3,10	3	3
% Ag + Urban	5,5,10		
% Code 21	7,7,10	in urban	in urban
Road Dens (km/km^2)	1.5	2.0	1.5/ 2.0
Paved Road X-ings (#/ws)	5/10/50		
Nearest Dams	>10 km	-	-
Active Producing Mines	0 (5k)	-	-
% Canals & Pipelines	10	-	-
Gravel Mine Density	0.1 (r5k)		
Conductivity	<2000 uS, + <99%, >1%		
BPJ Screen	X	X	X

Very good geographic coverage

REGION	n
North Coast	75

Part III – Supporting Implementation
(technical support for policy decisions)

- Setting Impairment Thresholds
- Ensuring statewide consistency
- Applicability: Objective approaches for setting limits to the tools
- Summary and What's Next

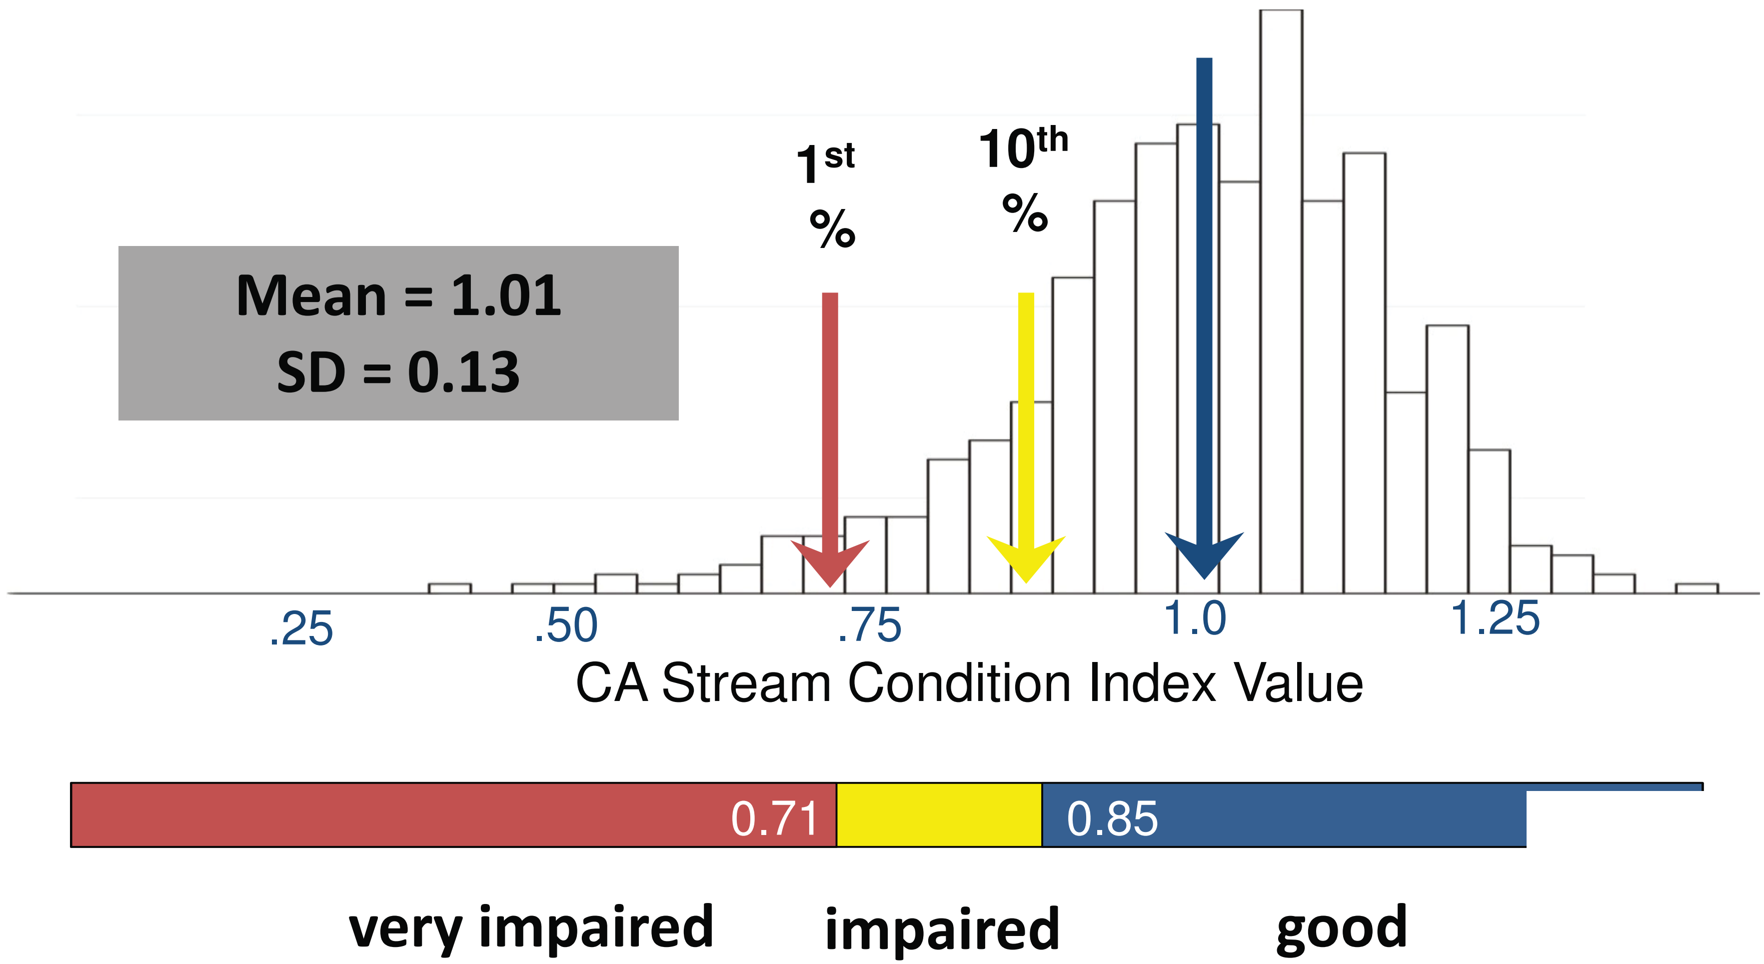
SWAMP
Surface Water Ambient Monitoring Program

Desirable Qualities of Regulatory Thresholds

- **Objective**
- **Balance false positives and false negatives** – should be protective of resource, but not over-sensitive
- **Incorporate uncertainty of site score**

SWAMP
Surface Water
Ambient Monitoring
Program

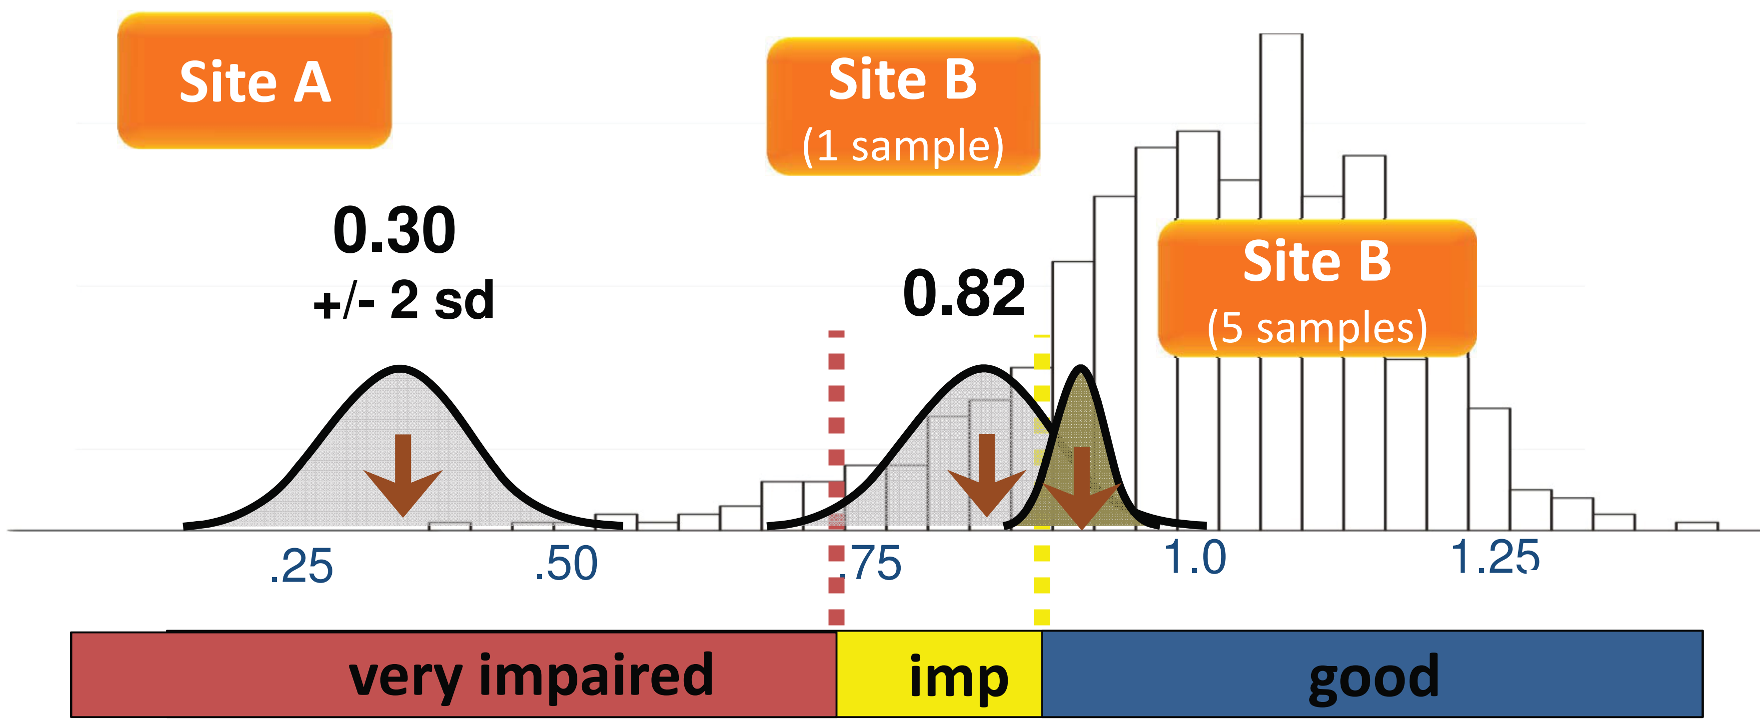
Distribution based thresholds:



B466

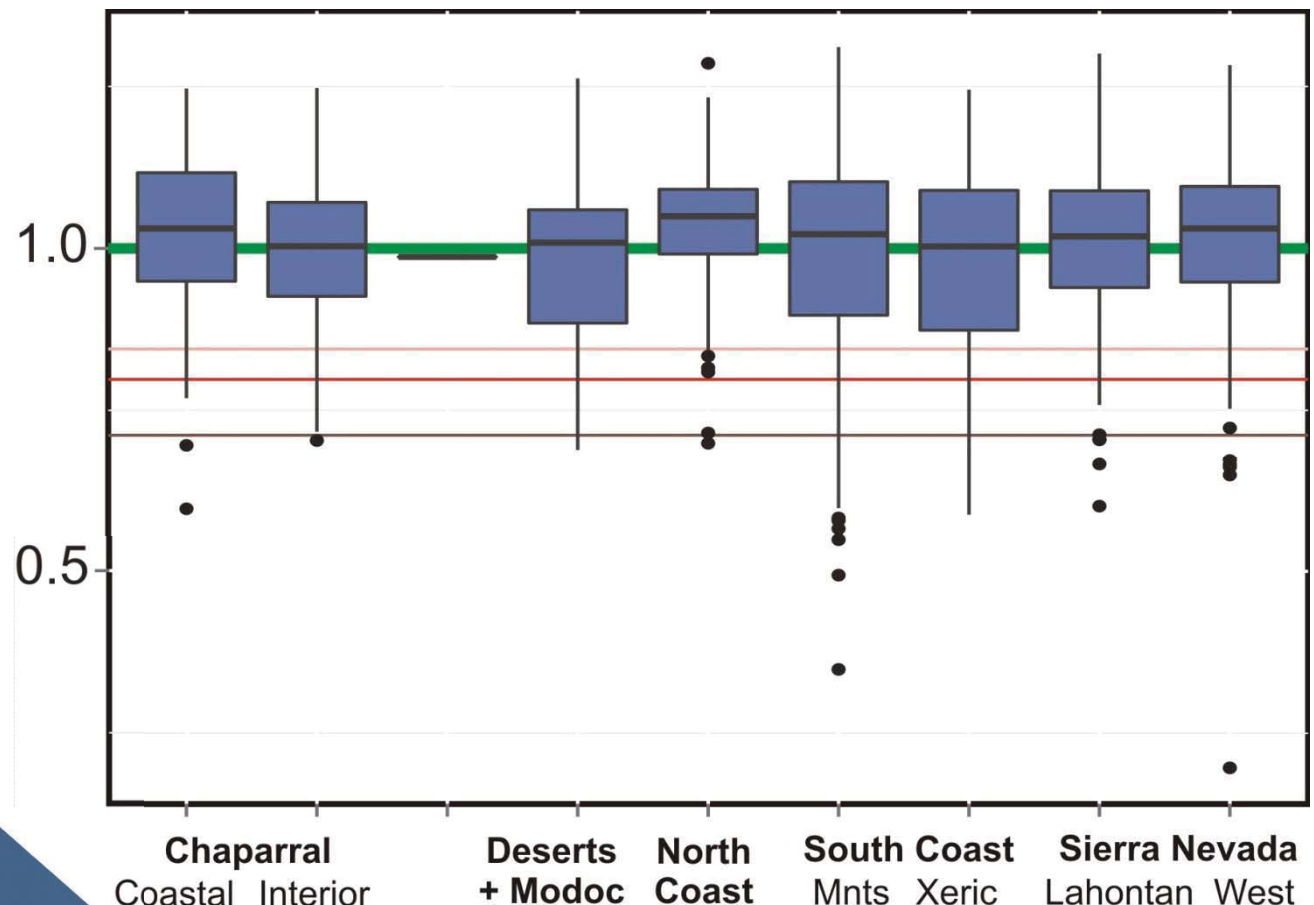
Incorporating Test Site Uncertainty

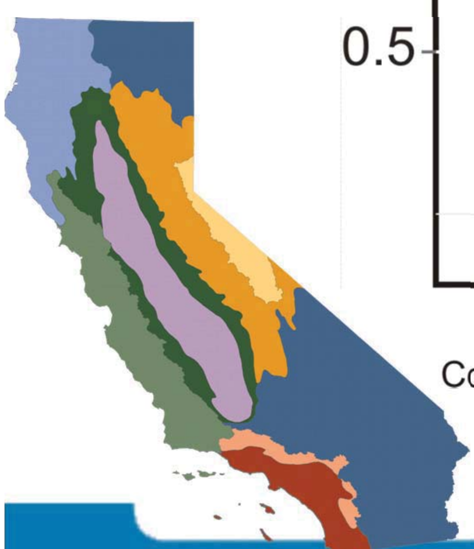
Use within-site error rate to account for uncertainty around test site score



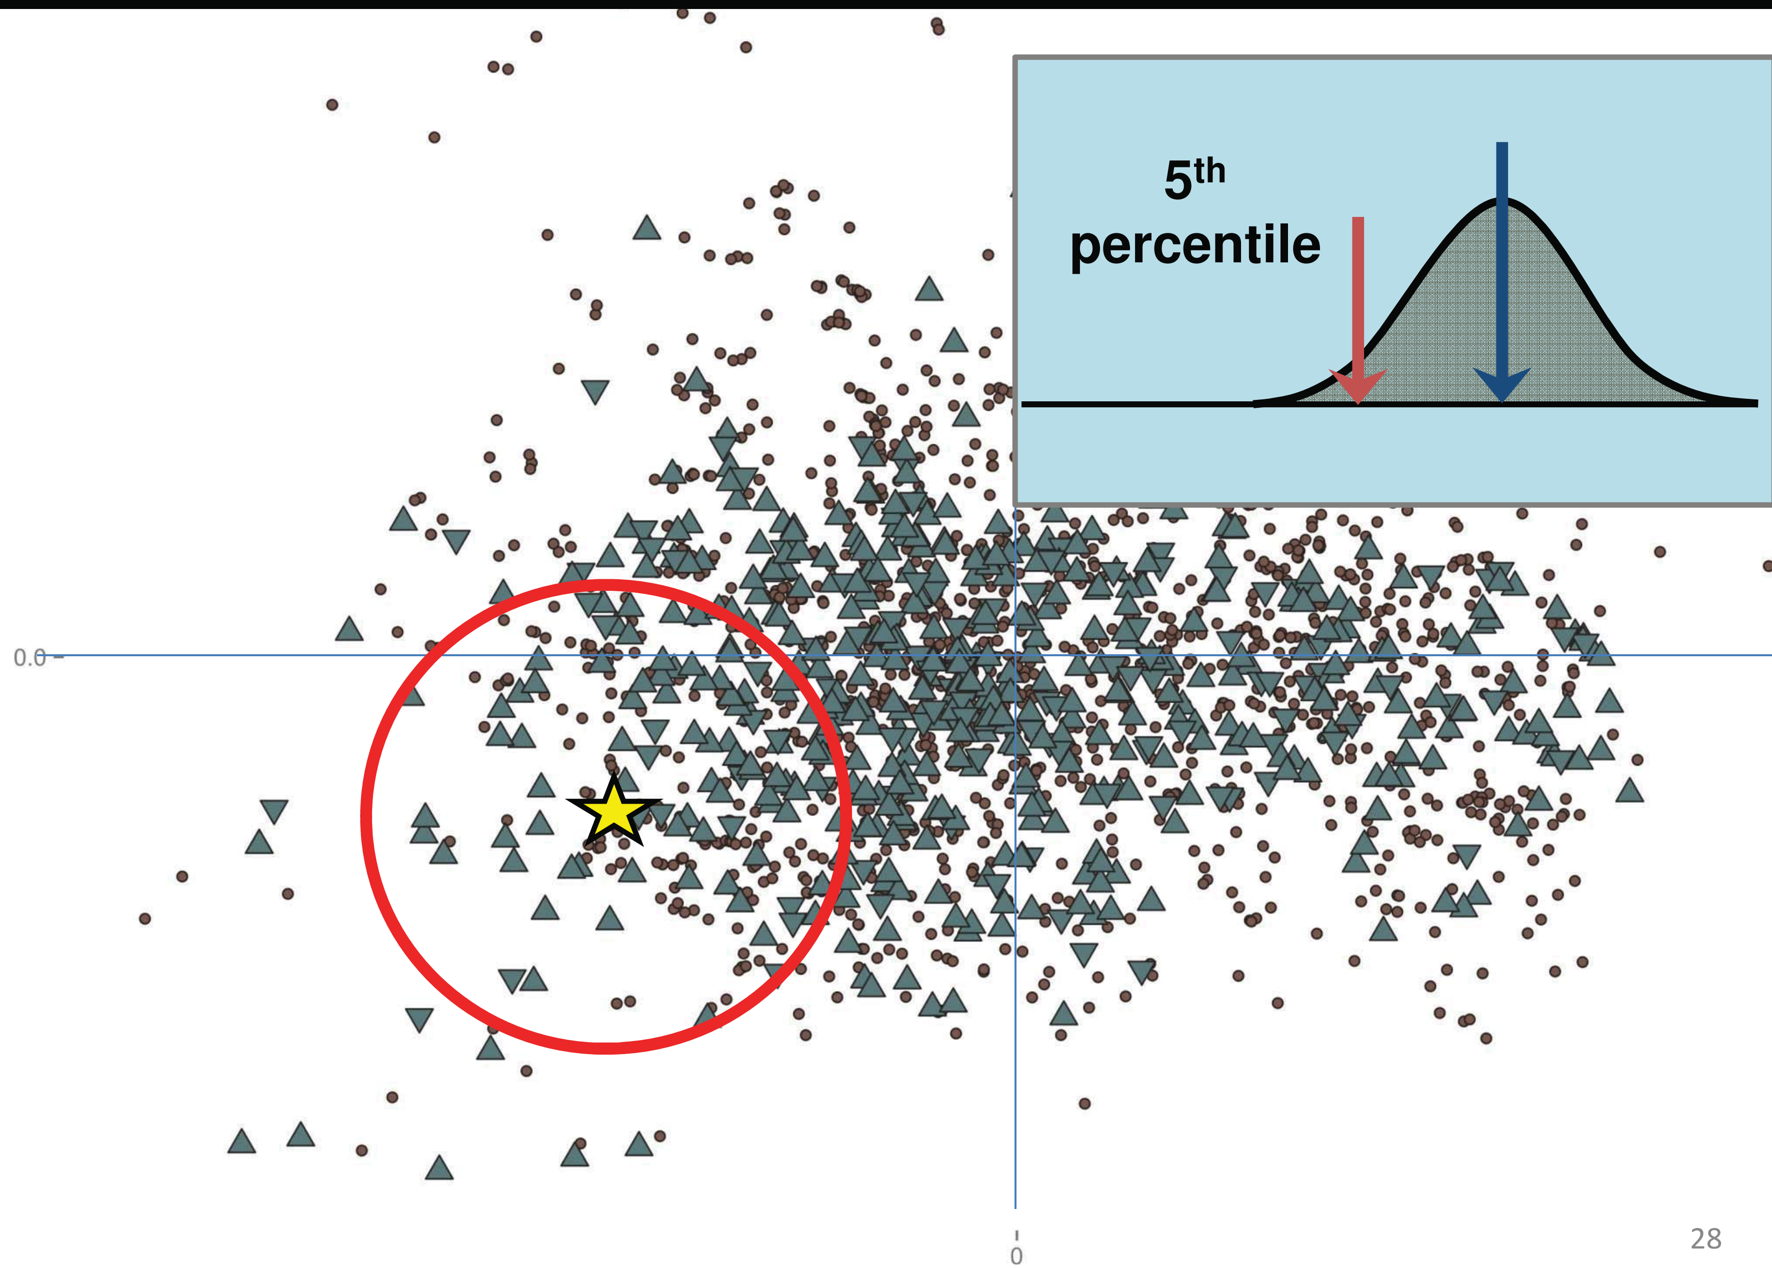
more certainty with multiple samples

Ensuring Regionally Consistent Thresholds





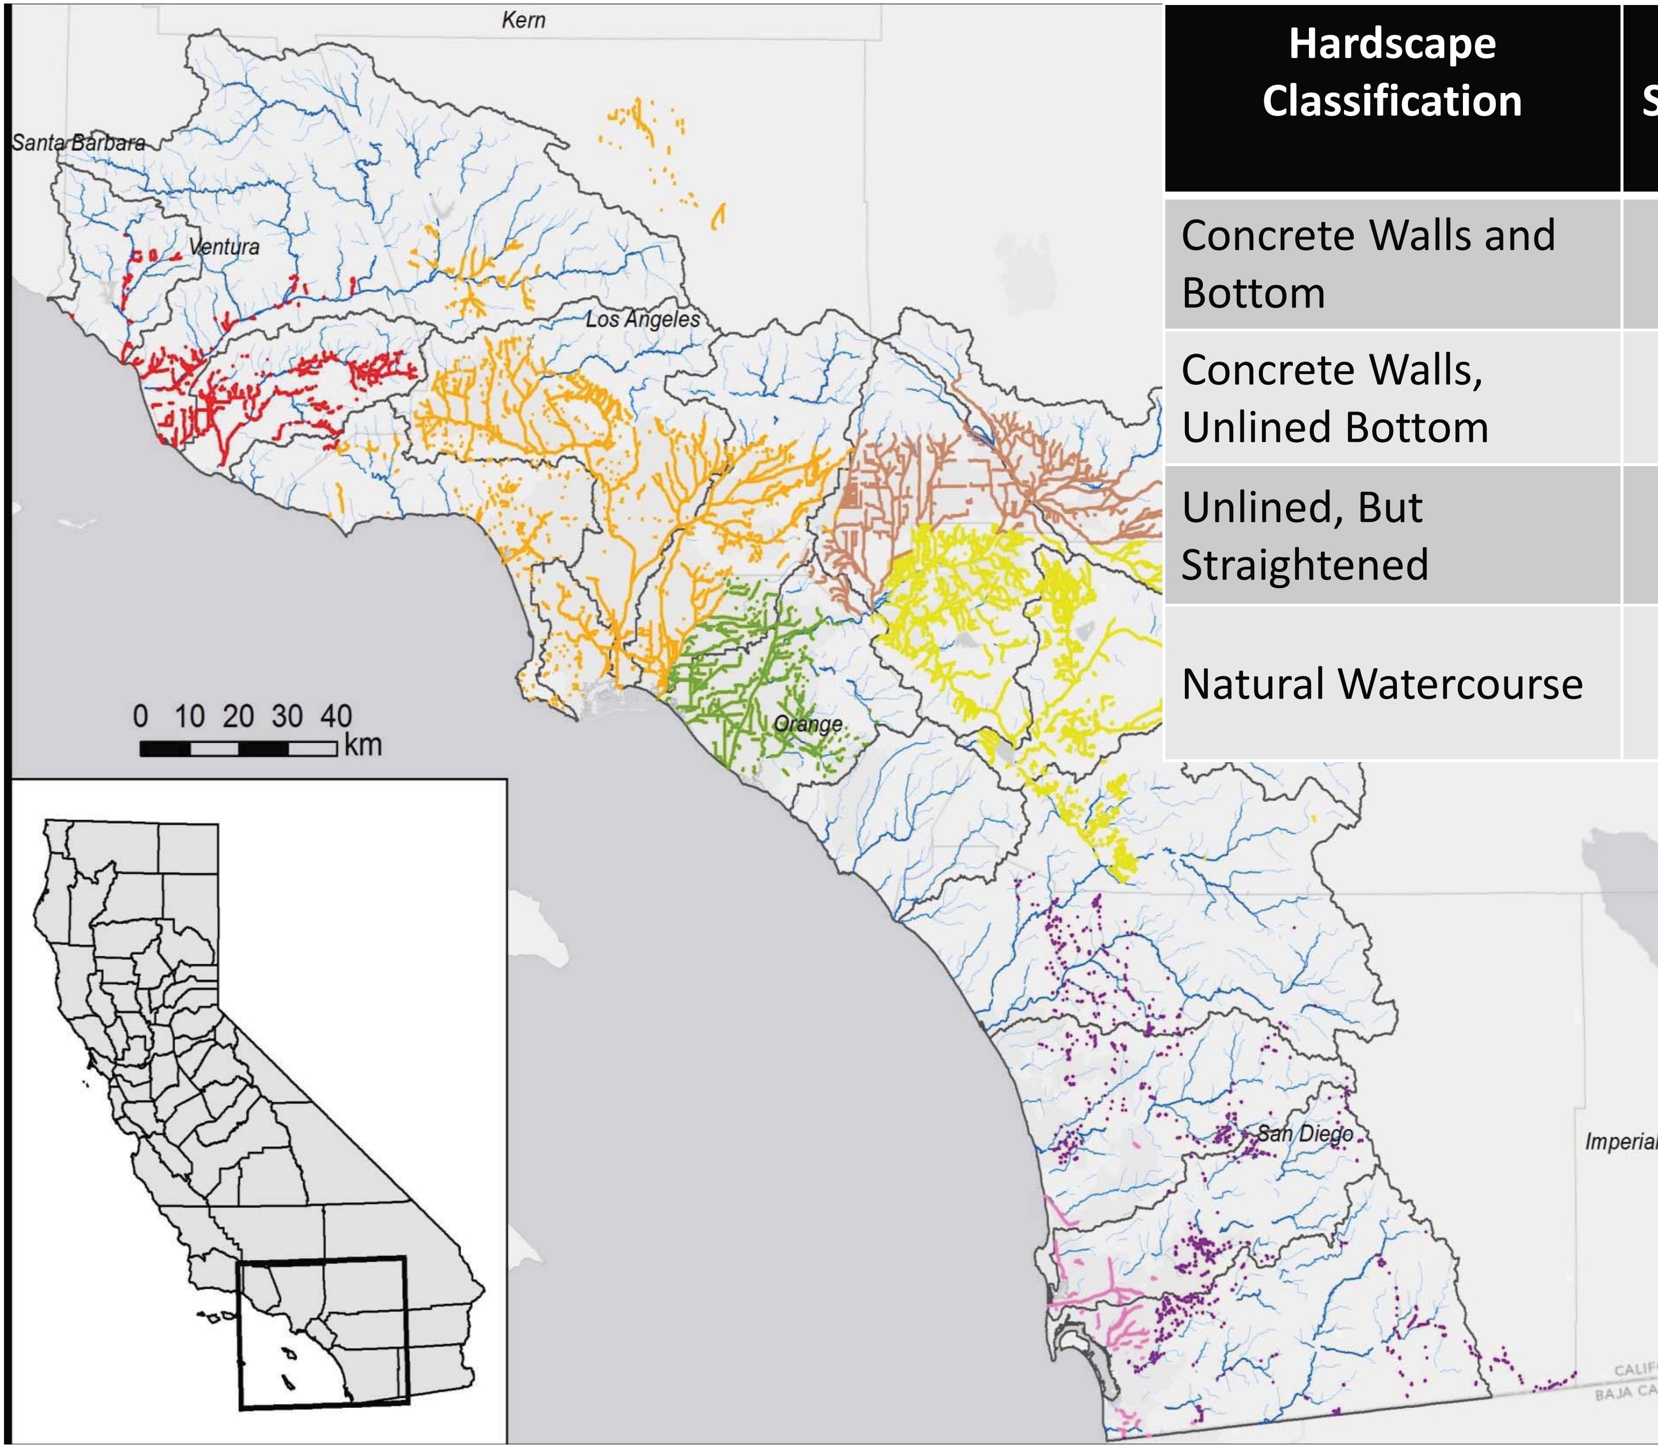
Enhancing threshold consistency



Where can we apply the CSCI?

- **Categorical** = exception classes in policy
  - Excepted regions (e.g., Central Valley)
  - Excepted waterbody types (e.g., modified channels)
- **Quantitative Approaches**

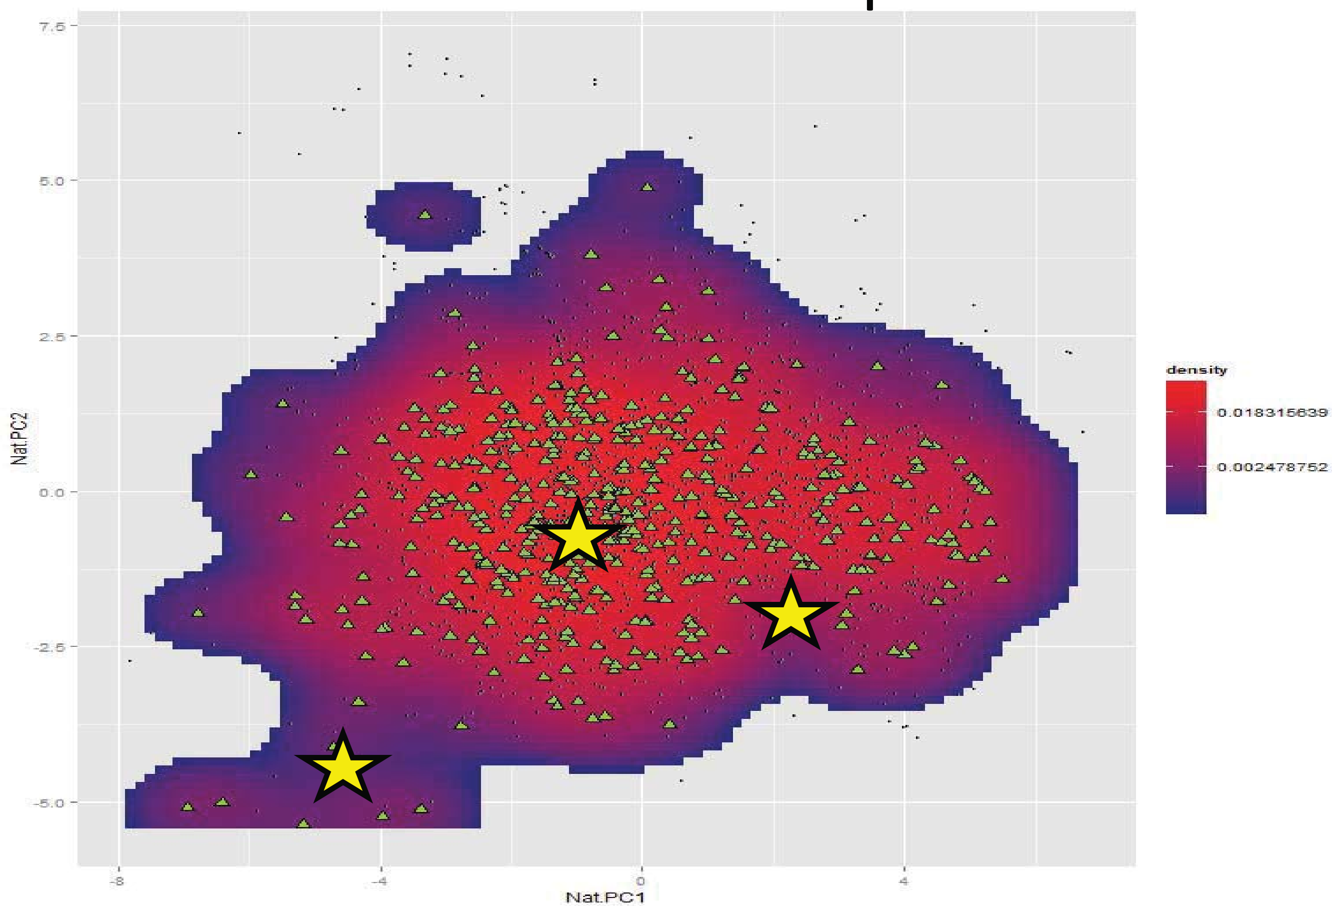
SWAMP
Surface Water
Ambient Monitoring
Program



Hardscape Classification	% of So Cal Stream Miles
Concrete Walls and Bottom	3.2%
Concrete Walls, Unlined Bottom	3.6%
Unlined, But Straightened	16.6%
Natural Watercourse	76.3%

Quantitative Approaches:

"is a test site within the experience of the model in environmental space?"



Could be used to establish exceptions for truly unique environmental settings

Applicability of the CSCI in exception class settings

- We can still use the CSCI as a ruler, but we won't regulate based a reference-based threshold
- Could use "best attainable" approach instead of "reference" to set expectation, or use to compare among sites

Questions?

Appendix 14

Science Advisory Panel Response

18 October 2012

Prioritization of Issues

- Scoring Tool
- Determining Scoring Tool Coverage
- Thresholds
- Causal Assessment
- Regulatory Guidance

Scoring Tool

- The Panel supports the use of the hybrid scoring tool
  - Includes both species-specific and biological community responses
  - Science Team will need to work on developing a simple explanation of this tool
- Some additional model evaluation would build confidence
  - Independent validation data sets
  - Simulation of impairment data to test responsiveness
  - What are the actual taxa or metrics that are driving scoring tool disagreement
- The Team will need to automate the calculation of this more complex scoring tool

Determining Scoring Tool Coverage

- A multi-variate approach is preferred
  - Include core dimensions of natural variability that biology responds to
- Guidance should be developed for stakeholders who assert their stream is not covered by this tool
- Even for sites outside the experience of the models, assessment options are still available
  - i.e., upstream-downstream

Thresholds

- Select thresholds based on distributions of reference condition
  - Need to assure some ecological meaningfulness
  - This approach can be used for developing categories of impact
- Test site uncertainty should be included
- Incorporating multiple samples at the test site is preferable: two options
  - Binomial approach (frequency of exceedence)
  - Mean site condition
- Ensure condition is assessed consistently at all sites

Causal Assessment

- Causal Assessment is important for progress in bio-objectives development
  - Panel recognizes that CADDIS is an imperfect tool and needs refinement
- CA needs to take advantage of its large data set to streamline causal assessment
  - This unique opportunity should reduce future costs
- CA needs to improve comparator site selection
  - Incorporate comparators outside the watershed
- CA needs to improve diagnostic tools
  - Regional response models (i.e., Relative risk)
  - Species specific response models
  - Laboratory based species sensitivity distributions

Regulatory Guidance

- CA’s working definition of “perennial” and “wadeable” seem appropriate
  - This definition is the foundation of the scoring tools

- Inference of segment-scale biological condition from a single site should be done cautiously
  - Additional samples at multiple locations may be needed

Appendix 15

WORK PLAN

Predicting Biological Integrity of Streams Across a Gradient of Development in California Landscapes

Raphael Mazor, Martha Sutula, Eric Stein (SCCWRP)
Andy Rehn and Pete Ode (CDFW)

Introduction

The California State Water Resources Control Board (State Water Board) is developing a combined Biostimulatory (nutrient) and Biointegrity policy for wadeable streams, hereto referred to as the Biostimulatory-Biointegrity Project. The scientific approach supporting this project is grounded in biological assessments of the health of benthic macroinvertebrate and algal communities. The State is supporting the use of standardized bioassessment indices to quantify the biological integrity and support of aquatic life uses in wadeable streams. The benthic macroinvertebrate index (i.e., the California Stream Condition Index, or CSCI) has previously been developed (Mazor et al. 2016). An algal stream condition index (ASCI) is currently under development, with a provisional ASCI expected fall 2017 (see ASCI work plan).

As natural landscapes are converted to support urban or agricultural uses, the underlying hydrologic, physical, and biogeochemical factors within the stream and its catchment that support healthy stream communities are altered, potentially harming aquatic life. Developed landscapes are associated with an increase of many stressors in streams, such as elevated contaminant and nutrient concentrations, altered flow regimes, sedimentation, and habitat degradation (e.g., Waite et al. 2012). In some streams, direct channel modifications (e.g., bank armoring) may also limit opportunities to sustain high-quality ecological conditions for aquatic life. In these highly developed settings, the large number of linked stressors may prevent a stream from supporting its beneficial uses or attaining high scores on indices of biological condition. Often, these stressors are difficult to mitigate or remove under the traditional mechanisms available to the Water Boards. In these circumstances, the range of CSCI and/or ASCI scores may be constrained, but targeted restoration could improve conditions. Key technical questions underpinning the range of options and prioritization of management actions for wadeable streams along the continuum from undeveloped to highly developed landscapes found within California are: For which streams is biological integrity constrained by development in the catchment? How can they be identified and mapped? What are the ranges of biological conditions these developed landscapes can support?

The State Water Board is seeking to protect biointegrity in streams, including streams where integrity is constrained by development. Identifying landscapes where development has a high likelihood of limiting biointegrity is an important first step to identifying effective management options. This creates a technical need for 1) a simple, reproducible, and easy-to-understand methodology for identifying landscapes where development has a high likelihood of limiting biointegrity and 2) predicting expectations for CSCI and (when available) ASCI indices screening tool or starting point for discussions on appropriate management strategies. These analyses create a technical foundation for the State Water Board and the Regional Boards to protect biological integrity in streams by informing appropriate biological condition expectations or by prioritizing sites long and short term restoration activities in these landscapes.

Geographic information systems (GIS) are commonly used to quantify landscape development within stream catchments. Estimating landscape alteration in catchments has traditionally been time-consuming for large-scale programs that monitor hundreds of sites annually, but recent tools (i.e., STREAMCAT, Hill et al. 2015) have made it possible to rapidly estimate landscape alteration in all streams in California represented by the National Hydrography Dataset Plus (NHD Plus) stream network. STREAMCAT therefore presents an opportunity to model the influence of landscape alterations on stream bioassessment scores on a large scale, and to apply predictions of these models to any stream represented in NHD Plus. These models have the potential to predict a range of likely scores in a stream given a degree of landscape alteration, setting the stage for policy discussions about the level of support that these streams in developed landscapes provide to beneficial uses.

Study Objective, Conceptual Approach to Model Landscape Influences on Stream Bioassessment Index Scores

The purpose of this study is to explore constraints on bioassessment index scores in streams across a continuum of landscape development, using a predictive, GIS approach. Key graphics from this analysis will be used to support discussions between the Water Board and its Regulatory and Stakeholder Advisory Groups on policy options to prioritize and improve the management of streams in developed landscapes.

The GIS approach involves developing models that predict a range of bioassessment index scores based on measures of landscape development. The product of these models is a map of likely CSCI (and when available, ASCI) scores for each segment. The intent of such a map is to identify watersheds where discussions of policy options for undeveloped versus developed landscapes could be productive. This map is intended to be used as a screening tool or starting point for discussions; it is not intended to be a one-off, definitive assessment that is used to set expectations for developed landscapes without further field level investigations of stressors and causal factors.

This approach relies on the following definition of “developed landscapes”:

Landscapes where development is likely to limit bioassessment index scores.

Development of a GIS model and application to predict likely bioassessment index scores in developed landscapes require three types of decisions:

1. *Developed Land Uses*. Developed landscapes can be characterized by variables in the STREAMCAT dataset related to human alterations, such as urban and agricultural land-use types in the National Land Cover Dataset, land cover imperviousness, etc. (Table 1). Other variables could be included or excluded, but must be limited to variables included in or easily added to STREAMCAT.
2. *Likelihood*. The likelihood of achieving the desired biological condition can be calculated by statistical models, but determining if a likelihood is low enough to be considered "unlikely" is a value-based (i.e., non-technical) decision.
3. *Desired biological condition:* The management objective, as defined by bioassessment index scores, here to referred to as "assessment endpoints" (Biostimulatory-Biointegrity Project Science Plan).

Decisions on which developed landscape variables to include must occur during model development, while discussion of values appropriate to set the likelihood and desired CSCI and ASCI assessment endpoints are model application questions, all of which will ultimately be made by the Water Board. In order to foster discussion and provide the regulatory (RG) and stakeholder advisory groups (SAG) an opportunity to provide feedback on these three decisions, the Technical Team will iteratively engage the RG and the SAG in the model development and model application phases to provide ample opportunity for this feedback to occur.

Scope of Work:

The study has three tasks:

1) Develop models to predict a range of CSCI and ASCI scores based on measures of landscape development from the STREAMCAT dataset;
2) Apply the models to the entire NHD Plus stream network represented in the STREAMCAT dataset, classify stream segments based on likelihood of achieving target scores, and create maps illustrating these classifications, in order to engage Water Board staff and advisory groups on decisions on likelihood and CSCI and ASCI assessment endpoints; and
3) Produce a technical memo with key graphics and model output.

Task 1. Develop models to predict a range of CSCI and ASCI scores based on measures of landscape development derived from the STREAMCAT dataset

A dataset representing CSCI scores across a range of site conditions in California will be aggregated. Index scores from each site will be snapped to the corresponding stream segment in NHD Plus. STREAMCAT data characterizing landscape alteration variables (e.g., percent urban land cover, percent cropland, catchment imperviousness; Table 1) will be associated with each bioassessment site. Appropriate statistical models (e.g., quantile random forest) will be calibrated to associate measures of landscape development with bioassessment scores. A models will also be developed for ASCI, though decisions on which land use variables and likelihood values to use will focus on CSCI only, since a provisional ASCI index is anticipated late stage (Fall 2017).

Water Board staff will make provisional decisions on land use variables to include. The initial proposal will be based on consultation with the RG. The proposed land use variables and rationale will be presented to the SAG for feedback.

Deliverable:
1.1 Draft models and related graphics to predict bioassessment scores, in iterative stages of feedback.
1.2 Descriptive summaries of models, including evaluations of model performance, and list of landscape development variables in STREAMCAT selected for use in the models.

Table 1. List of STREAMCAT variables that can be evaluated in landscape modeling exercise. Most of these variables are calculated at multiple spatial scales.

Potential variables	Description
CanalDens	Density of NHDPlus line features classified as canal, ditch, or pipeline (km/ square km)
DamDens	Density of georeferenced dams (dams/ square km)
DamNrmStor	Volume all reservoirs (NORM_STORA in NID) per unit area (cubic meters/square km)
HUDen2010	Mean housing unit density (housing units/square km)
MineDens	Density of mines sites and within 100-m buffer of NHD stream lines (mines/square km)
PctAg2006Slp10	% area classified as ag land cover (NLCD 2006 classes 81-82) occurring on slopes ≥ 10%
PctAg2006Slp20	% area classified as ag land cover (NLCD 2006 classes 81-82) occurring on slopes ≥ 20%
PctCrop2006	% area classified as crop land use (NLCD 2006 class 82)
PctHay2006	% area classified as hay land use (NLCD 2006 class 81)
PctImp2006	Mean imperviousness of anthropogenic surfaces
PctUrbHi2006	% area classified as developed, high-intensity land use (NLCD 2006 class 24)
PctUrbLo2006	% area classified as developed, low-intensity land use (NLCD 2006 class 22)
PctUrbMd2006	% area classified as developed, medium-intensity land use (NLCD 2006 class 23)
PctUrbOp2006	% area classified as developed, open space land use (NLCD 2006 class 21)
PopDen2010	Mean populating density (people/square km)
RdCrs	Density of roads-stream intersections (2010 Census Tiger Lines-NHD stream lines) (crossings/square km)
RdDens	Density of roads (2010 Census Tiger Lines) (km/square km)

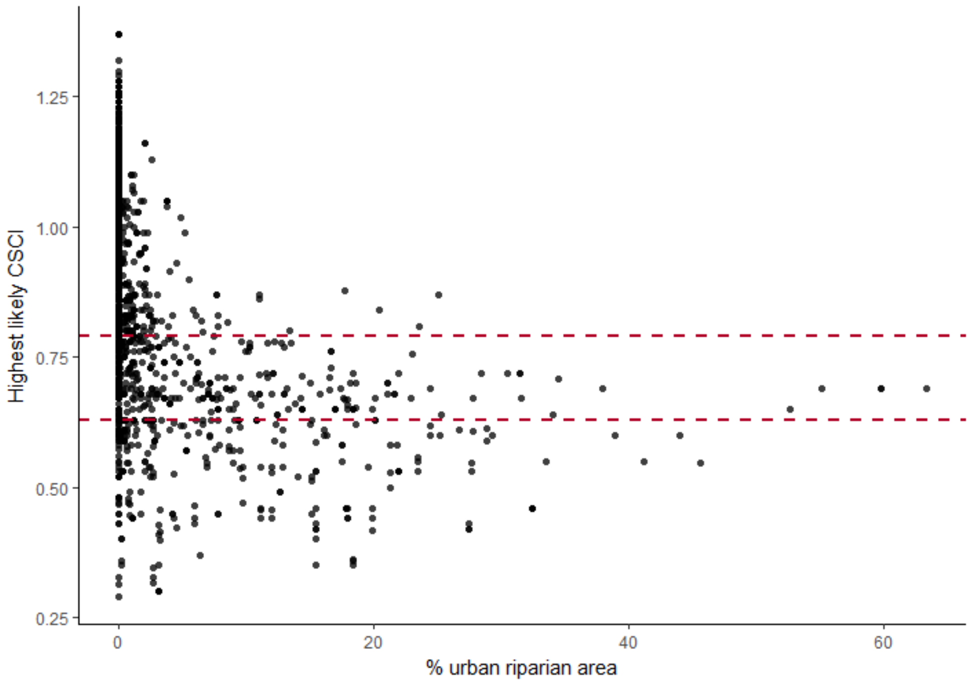

Figure 1. An example of the highest likely CSCI scores predicted by a quantile random forest model relating developed land use variables to biological integrity. The x-axis is percent of high density urban land cover within a 100-m buffer around the NHD stream lines (one of the variables included in example model). Dots above the top red line represent sites that are unconstrained by development (in this example, >10% chance of CSCI scores > 0.79). Dots between the two red lines are moderately constrained by development (<10% chance of CSCI scores > 0.79). Dots below the bottom red line are highly constrained by development (<10% chance of CSCI scores > 0.63). In this example, the 90th percentile of predicted scores represents the highest likely CSCI score.

Task 2. Apply the models to engage Water Board staff and advisory groups on discussions of sensitivity of model output to choice of likelihood and assessment endpoint

The purpose of this task is to help State Water Board staff and advisory groups understand how choice probabilities used to define modeling likelihood and desired assessment endpoint affects mapped categories of streams. The GIS mapping methodology will be applied to entire NHD Plus network of streams in California included in the STREAMCAT database. For selected regions or watersheds, the influence of key decision-points (e.g., minimum thresholds for acceptable bioassessment index scores, or minimum acceptable likelihood for attainment of these thresholds) will be illustrated by showing how the decisions described above influence the percentage and spatial extent of the stream network within the developed category. For example, the Water Board may define constrained channels as those with less than a 10% chance to achieve a CSCI score above 0.63 (e.g., dots below the bottom dashed line in Figure 1); maps will then be generated across the state to highlight which streams are designated as constrained under this definition, thereby helping stakeholders see the implications of this classification for their watersheds (e.g., segments shown as red lines in Figure 2).

Deliverable: 2.1 Interactive maps and oral presentations with maps, graphics, summary tables of the stream drainage network showing model outputs, e.g., maximum score likely to be attained in each stream segment (Figures 2 and 3) as a function of choice of likelihood and assessment endpoint value.

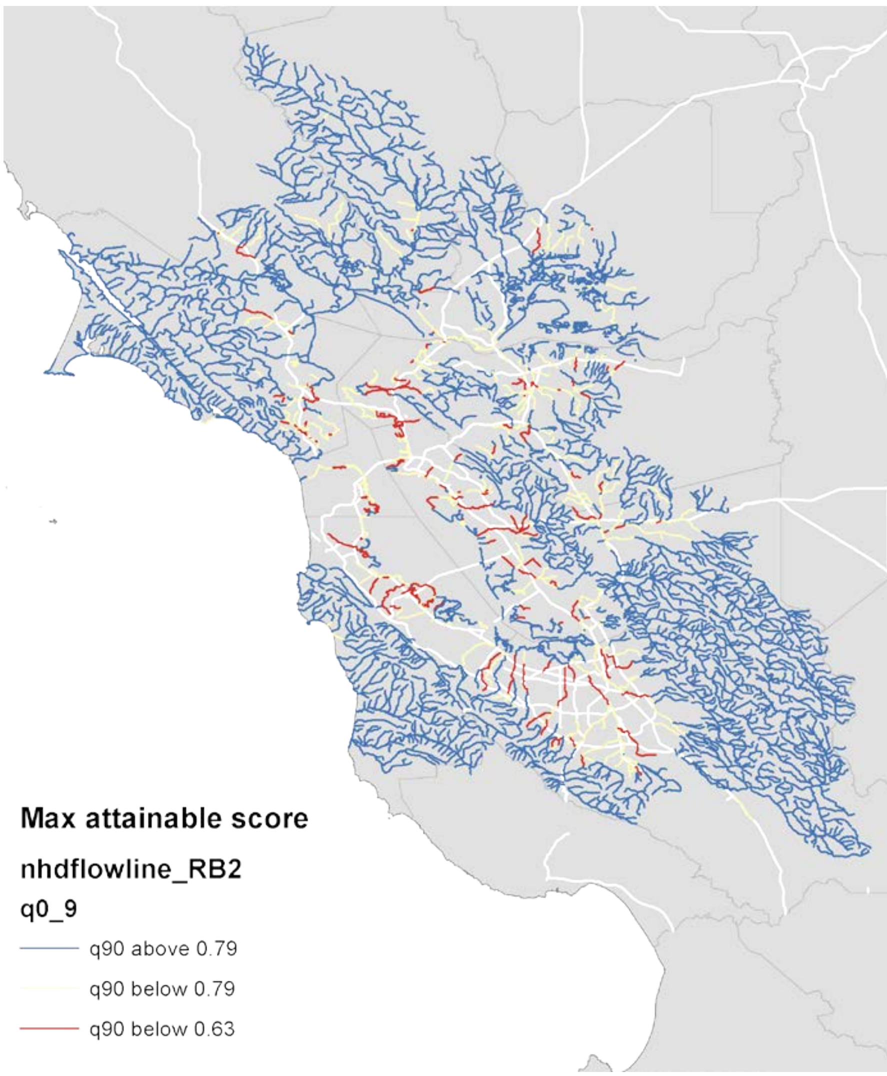

Figure 2. Map showing the classification of stream segments in the San Francisco Bay Area based on landscape development. In this map, attainability is defined as the 90th percentile of model predictions for each segment. Blue segments: Unconstrained by development, as described in Figure 1. Yellow segments: Moderately constrained by development. Red segments: Highly constrained by development.

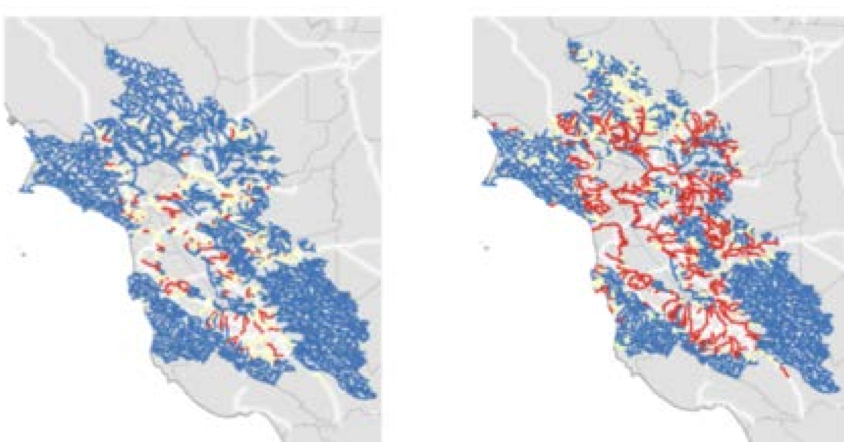

Figure 3: Example of maps generated with two different probabilities to define

likelihood. The map on the left was generated with a 10% probability to define likely scores, whereas the map on the right was generated with a 50% probability.

Task 3. Produce a Technical Memo with Key Graphics and Model Output

Based on feedback from group discussions and Water Board direction from Task 2, a reduced set of interactive maps and graphics can be generated to support this discussion. The purpose of this task is produce a technical memo with this reduced set of key graphics and model output in a format that can be easily shared and used to support discussions among Water Board staff and its advisory groups on policy options for channels in developed versus undeveloped landscapes. The maps and graphics will include ASCI scores and a linkage to Biological Condition Gradient calibration (see BCG workplan), and versions of maps and graphics to demonstrate policy options under consideration, as requested by Water Board staff.

Deliverables: 3.1) technical memo summarizing methodology and results of task 1 and 2, 3.2) model output that can be viewed in an interactive mode (e.g. Google Earth kmz file), 3.3) presentation to RG and SAG of illustrating policy options under consideration, upon request of Water Board staff.

Schedule of Interim Milestones and Deliverables

Task	Description	Estimated Date
1.1	Draft models and related graphics to predict bioassessment scores, in iterative stages of feedback	May 2017 (CSCI) September 2017 (ASCI)
1.2	Descriptive summaries of models, including evaluations of model performance, and list of landscape development variables in STREAMCAT selected for use in the models.	May 2017 and iteratively thereafter
2.1	Interactive maps and oral presentations with maps, graphics, summary tables as a function of choice of likelihood and assessment endpoint value.	May 2017 and iteratively thereafter
3.1	Draft and final technical memo summarizing methodology and results	September 2017 December 2017
3.2	Interactive model output (e.g. google earth .kmz file)	September 2017 December 2017
3.3	Presentation to RG and SAG of illustrating policy options under consideration	Upon request by Water Board staff

COMPARISON OF STREAM INVERTEBRATE RESPONSE MODELS FOR BIOASSESSMENT METRICS[1]

Ian R. Waite, Jonathan G. Kennen, Jason T. May, Larry R. Brown, Thomas F. Cuffney, Kimberly A. Jones, and James L. Orlando[2]

ABSTRACT: We aggregated invertebrate data from various sources to assemble data for modeling in two ecoregions in Oregon and one in California. Our goal was to compare the performance of models developed using multiple linear regression (MLR) techniques with models developed using three relatively new techniques: classification and regression trees (CART), random forest (RF), and boosted regression trees (BRT). We used tolerance of taxa based on richness (RICHTOL) and ratio of observed to expected taxa (O/E) as response variables and land use/land cover as explanatory variables. Responses were generally linear; therefore, there was little improvement to the MLR models when compared to models using CART and RF. In general, the four modeling techniques (MLR, CART, RF, and BRT) consistently selected the same primary explanatory variables for each region. However, results from the BRT models showed significant improvement over the MLR models for each region; increases in R^2 from 0.09 to 0.20. The O/E metric that was derived from models specifically calibrated for Oregon consistently had lower R^2 values than RICHTOL for the two regions tested. Modeled O/E R^2 values were between 0.06 and 0.10 lower for each of the four modeling methods applied in the Willamette Valley and were between 0.19 and 0.36 points lower for the Blue Mountains. As a result, BRT models may indeed represent a good alternative to MLR for modeling species distribution relative to environmental variables.

(KEY TERMS: modeling; macroinvertebrates; watershed disturbance; land use; prediction; statistical assessment.)

INTRODUCTION

Modeling has increased markedly in the past decade in all areas of ecology, and major advances have been made in conceptual models and statistical techniques (Leathwick *et al.*, 2005; Austin, 2007; Cabecinha *et al.*, 2007; Turak *et al.*, 2011), which, in turn, help practitioners derive response models that better support the needs of bioassessment programs. fundamental goal of bioassessment in stream ecology is a better understanding of the effects of human land use on stream biota and the processes at various scales that cause these effects. However, streams are complex spatial and temporal habitat mosaics that are directly and indirectly influenced by a combination of natural geology, climate, and human disturbance (Stanford *et al.*, 2005). Stream ecologists are trying to understand the spatial scales and processes associated with human and natural disturbances that are affecting the biota. Models provide a useful framework for testing hypotheses, determining potential direct and indirect linkages, and directing where further research is needed. The expansion and application of multivariate models in stream ecology are helping to address these issues and hopefully will lead to a broader understanding of ecological and anthropogenic pathways and responses (Oberdorff *et al.*, 2001; Cabecinha *et al.*, 2007; Turak *et al.*, 2011; Waite *et al.*, 2010).

Much of the research documenting the effects of land-use change on stream biota indicates that as the total watershed area in agricultural and/or urban land use increases, individual biological metrics and multimetric indices (MMIs) (such as an Index of Biotic Integrity, IBI) that reflect compositional changes in sensitive species generally decrease (Paul and Meyer, 2001; Allan, 2004; Van Sickle *et al.*, 2004; Cuffney *et al.*, 2005; Ode *et al.*, 2008; Waite *et al.*, 2010). Though some researchers have found a threshold response (i.e., a nonlinear or step function) of individual or multimetric biological indices to land-use indicators (e.g., Davis and Simon, 1995; Wang *et al.*, 2001; Walsh *et al.*, 2005; Hilderbrand *et al.*, 2010; King and Baker, 2010) much of the literature indicates that the response more often is a simple monotonic response with no initial resistance (Booth, 2005; Cuffney *et al.*, 2005, 2010; Kennen *et al.*, 2005; Morgan and Cushman, 2005; Roy *et al.*, 2005; Stanford *et al.*, 2005; Waite *et al.*, 2008, 2010). The debate about possible threshold responses continues not only because of the interest in determining, from a management perspective, where a threshold might occur along a land-use gradient, but also because of the effect thresholds and the resultant nonlinear responses have on the application of various modeling techniques. If biological responses to landscape measures are indeed complex and nonlinear, then newer modeling techniques such as classification regression trees (CART), random forest (RF) and boosted regression trees (BRT), multilevel hierarchical modeling, structural equation models, or artificial neural networks may be necessary to model these responses (Grace, 2006). However, if various biological responses to human disturbance are commonly simple and linear, then they should be more easily modeled via standard regression techniques, which are typically easier to develop and interpret.

There are three commonly used bioassessment variable types including individual biological metrics (e.g., Ephemeroptera, Plecoptera, and Trichoptera richness or EPT), combining individual metrics into a multimetric index (e.g., IBI) and development of the observed/expected ratio metric (O/E). Each method has its advantages and disadvantages, yet sometimes they can give different results in differ environmental settings (Herbst and Silldorff, 2006; Chessman *et al.*, 2010; Hawkins *et al.*, 2010). It is possible that individual metrics may be more stressor gradient specific and multimetric indices better at more general disturbance gradients, however, detailed comparison of these three methods is beyond the scope of this paper. We focus on two common individual biological metrics, the general tolerance of invertebrates to a multitude of stressors including sediment, temperature, dissolved oxygen, hydrological and habitat changes, nutrients, and contaminants following Barbour *et al.* (1999) and the ratio of the observed/expected taxa based on the RIVSPAC method (River Invertebrate Prediction and Classification System) (Clarke, 2000; Moss, 2000). The number of tolerant taxa is expected to increase while the O/E value is expected to decrease as the amount of disturbance to the stream increases.

Using the same dataset used in this paper, Waite *et al.* (2010) developed macroinvertebrate response models for three regions in the western United States (U.S.) and the best multiple linear regression (MLR) models based on Akaike Information Criterion (AIC) and R^2 from each individual region required only two or three explanatory variables to model macroinvertebrate metrics to explain 41-74% of the variation. In each region, their best model contained some measure of urban and/or agricultural land use, yet often the model was improved by including a natural explanatory variable such as mean annual precipitation or mean watershed slope (for the MLR equations, see Waite *et al.*, 2010). Two macroinvertebrate metrics, the richness of tolerant macroinvertebrates (RICHTOL) and some form of EPT richness, were common response variables in models developed among the three regions (Waite *et al.*, 2010). Models were developed for the same two invertebrate metrics even though the geographic regions they modeled reflect distinct differences in precipitation, geology, elevation, slope, population density, and land use. L. R. Brown, J. T. May, A. C. Rehn, P. R. Ode, I. R. Waite, and J. K. Kennen (personal communication) were also able to develop strong models using linear modeling techniques (MLR), they modeled an invertebrate index of biotic integrity (BIBI) across a gradient of urbanized streams in southern California and were able to explain approximately 48% of the variation based on MLR models including classification accuracy of 69 and 87% for impaired and unimpaired sites, respectively.

One important question that researchers are working to answer is whether the use of newer, more complex modeling techniques such as CART and regression trees improves our ability to predict biological metrics and potentially provide new insights into response patterns and mechanistic pathways. Generalized linear models (GLMs) and generalized additive models (GAMs) were introduced in the 1980s and 1990s as improved methods over MLR for data with non-normally distributed errors (e.g., presence–absence and count data) or nonlinear relations and usually outperform single regression trees (Elith *et al.*, 2008). Regression trees are one type of technique within the commonly used CART or decision tree family (e.g., Breiman *et al.*, 1984; De'ath and Fabricius, 2000; Prasad *et al.*, 2006). Trees attempt to explain variation in one categorical (classification) or continuous (regression) response variable by one or more explanatory variables, the resultant output being a dendogram or tree with varying numbers of branches or nodes. These techniques have a few properties that are highly desirable for ecological data analysis: (1) they can handle numeric, categorical, and censored response variables, (2) they are not affected by explanatory variables that follow non-normal distributions (i.e., skewed, Poisson, or bimodal), and (3) they can model complex interactions simply (De'ath, 2007). Maloney *et al.* (2009) found that CART models of watershed disturbance on BIBI values provided results that were intuitive and easy to interpret but they did not classify sites any better than logistic regression models; however, RF models showed minor improvements in performance over the other models. De'ath (2007) and Elith *et al.* (2008) show that BRTs outperform GLMs and GAMs in variable selection, predictive ability (higher R^2 and lower error), and can handle sharp discontinuities in data that are difficult for the other methods. Aertsena *et al.* (2010) also showed that BRT outperformed most modeling techniques (i.e., MLR, GLM, GAM, and CART), with the exception of artificial neural networks.

Over the past decade the estimate of O/E has become a common measure of biological condition for use in bioassessments (e.g., Hawkins, 2006; Carlisle *et al.*, 2008). The expected taxa for a site are commonly estimated by models (e.g., RIVPACS) (Clarke, 2000; Moss, 2000) of reference sites; this value is then compared to the actual taxa collected at a site. Models based on this approach have been developed in many international regions (e.g., Europe, New Zealand, and Australia) (Davies, 2000; Clarke and Murphy, 2006) and for separate regions within the U.S., including many states (Hubler, 2008). Recently, Hawkins *et al.* (2010) compared the response of three types of O/E models with five versions of MMIs for macroinvertebrates and found that in general, the O/E models were better able to distinguish managed or disturbed sites from reference sites than the MMIs. Due to these results and to its overall national and international popularity, we wanted to evaluate how models developed using O/E as the response variable would compare to models developed using single metrics, such as RICHTOL.

Our goal in this paper is to compare the overall performance (i.e., model fit, or R^2) of models developed using standard MLR techniques with more complex models developed using newer alternative techniques such as CART, RF, and boosted regression for the common macroinvertebrate metrics RICHTOL and O/E as the response variables. Also, we believe that the development of watershed disturbance predictive models such as those presented herein will build upon previous research to help the potential derivation of more complex models to better understand disturbance pathways in the landscape and ultimately the biocomplexity of aquatic systems.

METHODS

Data Aggregation and Landscape Analysis

For this comparative analysis we used the datasets (U.S. Geological Survey, U.S. Environmental Protection Agency, Oregon Department of Environmental Quality, and California Department of Fish and Game) previously aggregated for three regions in the western U.S. by Waite *et al.* (2010). A brief summary of the methods follows. Sites were evaluated based on the following criteria: invertebrate data sampled with comparable methods; upstream watershed area of between 13 and 259 km^2; and watersheds could not be nested (i.e., no spatial autocorrelation). Sites meeting these conservative criteria resulted in three study regions: Coastal Southern California ($n = 55$), the Blue Mountains ecoregion of eastern Oregon ($n = 148$), and the Willamette Valley ecoregion in north-central Oregon ($n = 96$) (Figure 1).

For consistency, watersheds were re-delineated for the selected sampling sites within the three study regions using USGS 7.5 min quadrangle digital raster graphics as base layers. The digital raster graphics were displayed on-screen along with National Hydrography Dataset (NHD) high resolution stream lines for each region (U.S. Geological Survey, 2007).

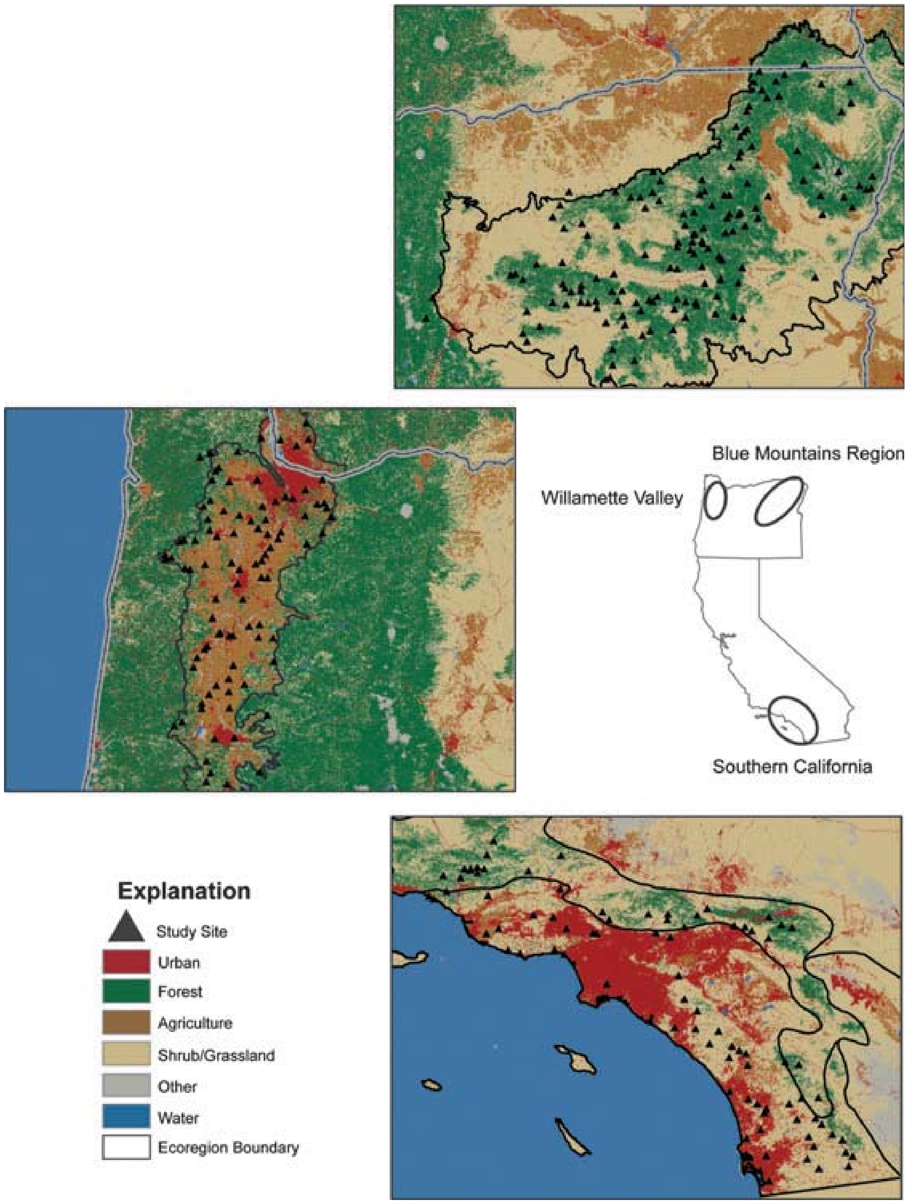

FIGURE 1. Map Showing Land Use and Land Cover for the Three Modeling Regions: Blue Mountains and Willamette Valley, Oregon, and Southern California.

Watershed boundaries were digitized on-screen at a scale of 1:10,000 or larger. Adjacent watershed polygons were edge matched to eliminate all overlaps and gaps. All work was conducted using ArcGIS, ArcMap 9.2 (Environmental Systems Research Institute, Redlands, CA; Table A1) GIS software.

Riparian buffer zone polygons were created within each watershed, extending 2 km upstream from the outlet of each watershed along the main stem and all tributaries and 90 m on either side of the stream centerlines. The buffers were created by selecting the appropriate NHD stream lines within each watershed and creating routes along each main stem and tributary flow path. The routes were then clipped to a distance of 2 km from the basin outlet and buffered. All abbreviations for riparian based explanatory variables begin with the letters "Rip"; otherwise, variables are watershed based (Table 1).

Spatial datasets representing landscape metrics of watershed disturbance were created for each watershed and riparian zone buffer from available national and regional datasets (Table A1) and included elevation, slope, land cover (1992 and 2001), population density, road networks, soil infiltration capacity, hydrography, pollution point sources, dams, and precipitation. Land-use summaries were based on either 1992 or 2001 spatial data (as described in Vogelmann *et al.*, 2001; Homer *et al.*,

TABLE 1. Description, Variable Code and Definition of Explanatory (landscape) and Predictor (invertebrate metrics) Variables Used for Response Model Development.

Explanatory Variables: Landscape		
Description	**Variable Code**	**Definition**
Watershed Scale Variables		
Percent urban land use	Urban	Percent watershed area in urban land use (NLCD 2000 categories 21, 22, 23, and 24)
Percent agricultural land use	Ag	Percent watershed area in agricultural land use (NLCD 2000 category 82)
Sum of percent Ag + Urban	Ag + Urb	Sum of percent watershed area in urban (NLCD 2000 categories 21, 22, 23, and 24) and agricultural (NLCD 82) land use
Percent forest	Forest	Percent watershed area in forest land use (NLCD 2000 categories 41, 42, 43)
Percent pasture	Pasture	Percent watershed area in pasture land use (NLCD 2000 category 81)
Percent shrub/scrub	Shrub	Percent watershed area in shrubland, shrub/scrub (NLCD 2000 category 52)
Road density	RdDens	Road density in watershed = Road length (km)/watershed area (km^2)
Mean population density	PopDen	Watershed mean population density based on 2000 census (persons/km^2)
Minimum elevation	Min-Elev	Elevation (m) at stream site, pour point of watershed
Mean slope percent	Slope	Mean percent watershed slope
Manmade stream density	MmStreams	Manmade stream density in watershed = manmade stream length (km)/ watershed area (km^2)
Mean annual precipitation	MnAnnPrecip	Mean annual precipitation (cm)
Soil infiltration rate	Soil_Mod-Infil	Hydrologic soil group B, moderate infiltration rate (min. infiltration rate 4-8 mm/h)
Riparian Scale Variables		
Percent urban land use	Rip_Urban	Percent buffer area in urban land use (NLCD 2000 categories 21, 22, 23, and 24)
Percent agricultural land use	Rip_Ag	Percent buffer area in agricultural land use (NLCD 2000 category 82)
Sum of percent Ag + Urban	Rip_Ag + Urb	Sum of percent buffer area in urban (NLCD 2000 categories 21, 22, 23, and 24) and agricultural (NLCD 82) land use
Percent forest	Rip_Forest	Percent buffer area in forest land use (NLCD 2000 categories 41, 42, 43)
Percent pasture	Rip_Pasture	Percent buffer area in pasture land use (NLCD 2000 category 81)
Percent shrub/scrub	Rip_Shrub	Percent buffer area in shrubland, shrub/scrub (NLCD 2000 category 52)
Road density	Rip_RdDens	Road density in buffer = Road length (km)/watershed area (km^2)
Mean population density	Rip_PopDens	Buffer area mean population density based on 2000 census (persons/km^2)
Mean slope percent	Rip_Slope	Mean percent buffer slope
Maximum elevation	Rip_Max-Elev	Maximum buffer elevation (m)
Response Variables: Invertebrate Metrics		
Observed/expected	O/E	Ratio of number of observed taxa at a site over the expected taxa based on modeled reference sites
Tolerant richness	RICHTOL	Average USEPA tolerance values for sample based on richness

2004), depending on which data source was closer to the macroinvertebrate sample date for that watershed. Watersheds and riparian zone buffers were used to define zones for analysis and calculate summary statistics. The 1992 and 2001 land cover datasets used slightly different classification schemes. Uniform codes based on the 2001 classification scheme were assigned to all land cover classes in the final summary statistics table (Fry *et al.*, 2009). We did not assess the distribution pattern of land use/land cover within the watershed though this can be important in some situations.

Description of Modeling Regions

The Coastal Southern California (SoCal; Southern and Central California Chaparral and Oak Woodlands Ecoregion) region has a Mediterranean climate of hot, dry summers and cool, moist winters (Ode *et al.*, 2005). Average precipitation at each site ranges from 25 to 50 cm/year. The geology of the ecoregion is dominated by recently uplifted and poorly consolidated marine sediments. Vegetative cover in this region consists mainly of chaparral and oak woodlands, though grasslands occur in some lower elevations and patches of pine are found at higher elevations (open low mountains or foothills). The landscape is currently dominated by urban development; the human population is approximately 19 million and is projected to exceed 28 million by 2025 (Ode *et al.*, 2005). Outside the urban centers, much of this region was historically grazed by domestic livestock or cultivated for fruits and vegetables, but most of this land has since been converted to urban uses.

The Blue Mountains (Blue_Mt) are the westernmost range of the Middle Rocky Mountains and, like the Cascade Range, are largely volcanic, with fertile plateaus and deeply fissured river valleys. Carved by two rivers (the John Day and Grande Ronde Rivers) the landscape has steep hillsides, bluffs and rimrock faces. Temperature and precipitation are highly correlated with elevation. Precipitation ranges from 22 to 45 cm/year along the river valleys and is >150 cm/year in the nearby mountains. This region is dominated by coniferous forests in mid to higher elevations and shrub and grassland in lower elevations, though much of the latter has been displaced by agriculture and grazing. The region has no large cities and urbanization is limited to scattered smaller cities and small towns.

The Willamette Valley (Will_V) ecoregion contains a mixture of rolling prairies, mixed forests, and extensive lowland valley wetlands. With temperate, dry summers and cool, wet winters, the Willamette River basin and surrounding area is characteristic of the Pacific Northwest climate. About 90% of the annual precipitation (100-130 cm/year) occurs during October through May (Uhrich and Wentz, 1999), falling as rain in the valley and snow in the mountains. The land use/land cover in the valley plains and foothills is primarily cultivated crops, pasture, and grasslands. Urbanization ranges from minimal to extensive (Waite *et al*., 2008). Centered on the confluence of the Columbia and Willamette Rivers, Portland is the most populous city in Oregon, with 539,000 people in city limits and nearly 3 million people in the Portland metropolitan area (U.S. Census Bureau, 2000). The population in the metropolitan area increased almost 30% from 1990 to 2000, with some suburban populations increasing more than 80% during the same period (U.S. Census Bureau, 2000). The drainage network in the Willamette Valley combines natural tributaries, complex networks of canals in agricultural areas, and stormwater canals and groundwater infiltration wells in cities.

The three geographic regions modeled in this study have differing natural settings and the extent and type of human disturbance in each respective region. SoCal has the driest climate, intermediate mean stream site elevation (Min-Elev) and percent agriculture, and the highest population density. Blue_Mt has the highest mean site elevation and mean watershed slope, intermediate mean precipitation, and the lowest population density, percent urban, and percent agriculture. Will_V has the greatest precipitation, lowest minimum site elevation, and the highest percent agriculture.

Macroinvertebrate Data

Macroinvertebrate data from 1994 to 2005 assembled for this study were considered to be comparable in terms of sampling protocols (sampled habitat, number of composite samples, and total sampled area) and laboratory procedures, including sorting, subsample count level, and taxonomic resolution (personal communication state agency personnel, 2005; Waite *et al.*, 2010). In general, all macroinvertebrate samples were collected in similar habitats using kick-net techniques from five to eight separate areas and combined for a composite sample (Moulton *et al.*, 2002; Peck *et al.*, 2006; Hubler, 2008). Extensive review of the data was completed to make sure aggregated data from disparate sources included the same taxonomic groups, followed the same nomenclature, and had appropriate taxonomic resolution before data analysis was attempted. The Invertebrate Data Analysis System software (Cuffney, 2003) was used to resolve by region all taxonomic issues (taxonomic identification level and nomenclature), to remove ambiguous taxa (Cuffney *et al.*, 2007), and to randomly subsample raw counts to an equal 300 (Will_V) or 500 specimen count (the highest possible based on the data in each region) across all study regions. In general, data for dominant aquatic insect orders were resolved at genus level. Less common orders were often aggregated to family level. Rare organisms or those with difficult taxonomy were sometimes aggregated to order or higher. The dipteran family Chironomidae is considered an important bioindicator group, yet historically a difficult group to identify to genus or species. As a result, data for this group were assigned to six taxa levels (five subfamilies plus Chironomidae) from the various family to genus level identifications within the original data. Tolerance and functional group metrics were calculated using values from Barbour *et al.* (1999), supplemented with values from Wisseman's tolerances for the Pacific Northwest (Wisseman, 1996, unpublished data). Macroinvertebrate O/E values were estimated using two existing regional models (East and West of the Cascade Mountains) that were developed by Oregon Department of Environmental Quality (Hubler, 2008). O/E models were not ready for the SoCal region at the time of analysis so we were not able to test O/E values for this area.

MODEL DEVELOPMENT

Details of MLR model development procedures are outlined in Waite *et al.* (2010). In brief, model performance was assessed using a variety of statistics, including adjusted mean sum of squares (R^2), root mean squared error, AIC, predicted sum of squares, and regression coefficients in Waite *et al.* (2010). We adopted a model fitting approach for each response variable. We used a step-wise selection based on AIC for all models ranging from 1 to 5 environmental variables, as appropriate by region. If necessary, variables were transformed to improve their distributions to better adhere to assumptions of linearity. Models were developed for each geographic region separately due to the large spatial separation between each region and as described above, because the climatic and disturbance regimes were distinct. Model residuals, potential outliers, and interaction terms were evaluated. A description of variables used in model development is provided in Table 1. A MLR model was developed for the response variable RICHTOL for all three regions; it included two predictor variables (population density and riparian road density) for SoCal, three predictor variables for Blue_Mt (percent shrubs, percent agriculture, and mean annual precipitation in the watershed) and three predictor variables for the Will_V region (percent agriculture plus urban land use in the watershed, mean annual precipitation, and percent agriculture plus urban land use in the riparian zone) (Waite *et al.*, 2010). As a comparison to the MLR models developed by Waite *et al.* (2010) for RICHTOL, new models were developed for O/E for the Blue_Mt and Will_V regions.

To gain additional insight into these data and as a comparison against the MLR models, single regression trees, RF, and BRT models were developed for each region individually. Regression trees are one type of technique within the commonly used CART or decision tree family, and their use and technical details have been described extensively in the literature (e.g., Breiman *et al.*, 1984; De'ath and Fabricius, 2000; Prasad *et al.*, 2006); therefore, we will only provide a brief overview. Trees attempt to explain variation in one categorical (classification) or continuous (regression) response variable by one or more explanatory variables, the resultant output being a dendogram, or tree, with varying numbers of branches or nodes. Trees are developed following a hierarchical binary splitting procedure that attempts to find the best single explanatory variable that minimizes the within group and maximizes the among group dissimilarity in the response variable at each split. It does this for each explanatory variable entered into model development and can thus provide a list of the explanatory or predictive power of the variables. We used R statistics scripts and software (R Development Core Team, 2007, version 2.10.0) following the procedures outlined by Therneau and Atkinson (1997) to determine the proper single regression tree and the appropriate pruning of branches (De'ath and Fabricius, 2000; Prasad *et al.*, 2006). Trees have a few properties that are highly desirable for ecological data analysis: (1) they can handle numeric and categorical variables (2) they are not affected by explanatory variables that follow non-normal distributions (i.e., skewed, Poisson, or bi-modal), and (3) they can model complex interactions simply (De'ath, 2007).

Random forests and BRT are among a family of techniques used to advance single classification or regression trees by averaging the results for each binary split from numerous trees or forests thus reducing the predictive error and improving overall performance (De'ath, 2007; Elith *et al.*, 2008). In BRT, after the initial tree has been generated, successive trees are grown on reweighted versions of the data giving more weight to those cases that are incorrectly classified than those that are correctly classified within each growth sequence. Thus, as more and more trees are grown in BRT, the large number of trees increases the chance that cases that are difficult to classify initially are correctly classified, thus representing an improvement to the basic averaging algorithm used in RF (De'ath, 2007). Boosted trees and RF models retain the positive aspects of single trees seen in CART models, yet have improved predictive performance, nonlinearities and interactions are catered to or easily assessed, and they can provide an ordered list of the importance of the explanatory variables (Cutler *et al.*, 2007; De'ath, 2007). Though RF and BRT offers improved modeling performance over CART, the simple single tree obtained from CART is lost, making it more difficult to visualize the results. Partial dependency plots (PDP) are a way to visualize the effect of a specific explanatory variable on the response variable after accounting for the average effects of all other explanatory variables (De'ath, 2007; Elith *et al.*, 2008); these are presented in this paper for select models as examples (e.g., Figures 2 and 3). Random forest models were developed using the rpart library in R following methods outlined in Cutler *et al*. (2007) and BRT models were run using the gbm library in R and specific code from Elith *et al.* (2008). We used R^2 values for assessing the amount of variation explained among the four modeling techniques since it is a common and well understood measure that allowed us to put each model on the same measurement currency; other model performance measures such as confidence intervals and p-values are not included for simplicity.

RESULTS

In general, the four modeling techniques selected the same primary explanatory variables within each

region with minor variation among model types (Table 2): (1) SoCal: population density, minimum elevation, and riparian slope, (2) Blue_Mt: percent shrub, mean annual precipitation (MnAnnPrecip), and watershed slope, and (3) Will_V: percent agriculture plus urban, MnAnnPrecip, riparian maximum elevation, and percent riparian forest (see Table 1 for definitions). Generally, the RICHTOL R^2 values for MLR were slightly higher than those for the CART and RF models for all three regions (Table 3); however, this was not the case for the O/E models for Blue_Mt. Nevertheless, these differences are probably not meaningful because the R^2 values for CART and RF models are determined by a cross-validation method that ensures no over-fitting and thus usually gives a lower, more conservative value than the MLR values. Interaction affects were tested for and found to not be significant in the models developed. Conversely, the BRT models showed considerable improvement in the R^2 values over all the other models for both response variables (i.e., RICHTOL and O/E). For example, the SoCal RICHTOL R^2 values for the MLR compared to the BRT model increased from 0.67 to 0.79, Blue_Mt showed an increase from 0.44 to 0.59 for RICHTOL and from 0.08 to 0.28 for O/E, and the Will_V R^2 values increased from 0.74 to 0.83 for RICHTOL and from 0.64 to 0.75 for O/E (Table 3).

O/E	0.08 (3)	0.15 (2)	0.07 (3)	**0.28** (3)

Notes: Number of variables in model in parentheses. MLR, multiple linear regression; CART, classification and regression trees; RF, random forest; BRT, boosted regression trees; RICHTOL, average tolerance value for sample based on richness at a site; O/E, ratio of observed/expected taxa. Highest R^2 value across all models is shown in bold.

The O/E metric derived from RIVPACS type models specifically calibrated for Oregon consistently had lower R^2 values than RICHTOL for the two regions tested (Table 3). Modeled O/E R^2 values were between 0.06 and 0.10 lower than RICHTOL values for each of the four modeling methods applied in the Will_V region and were between 0.19 and 0.36 points lower for the Blue_Mt region.

As mentioned above, all modeling procedures (i.e., MLR, CART, RF, and BRT) generally retained the same subset of explanatory variables. These variables, with some minor exceptions in the Blue_Mt study region, generally accounted for approximately a similar proportion of the variance in the

RICHTOL and O/E response models. R^2 values, however, do not provide a complete picture of the model response pattern, and the overall influence of a specific explanatory variable on the environmental system or process being modeled is typically lost when the model is fit to a linear or nonlinear form. Partial dependency plots, which are provided as a diagnostic tool in the BRT and RF model output, provide a way to more fully examine the relative influence of individual explanatory variables on the response variable given the modeled structure. As explained in De'ath (2007) and Elith *et al.* (2008), PDP provide a way to visualize the effect of a specific explanatory variable on the response variable after accounting for the average effects of all other explanatory variables. For example, PDPs for the four variables retained in the BRT model for Will_V are shown in Figure 2. In general, the plots show a near linear increase in RICHTOL as the amount of agriculture plus urban land use in the watershed increases (Figure 2A) and a decrease in RICHTOL as riparian maximum elevation increases (Figure 2D). However, the response in RICHTOL values flattens out at approximately 60% agriculture plus urban land use, then again increases rapidly from approximately 90 to 100%. Likewise, the PDP graph shows that there is rapid change in RICHTOL values from near 0 to 200 m in riparian maximum elevation followed by no response beyond 400 m. The pattern shown for mean annual precipitation (Figure 2B) follows the opposite pattern of the amount of agriculture plus urban land use in the watershed, RICHTOL values decrease rapidly from the lowest precipitation values until approximately 80 cm/year beyond which values show no response. As the amount of riparian forest cover declines (Figure 2C), RICHTOL values increase little until riparian forest values drop to about 30%, where there is a step-wise increase until the point when there is only about 5% riparian forest remaining, whereupon there is a rapid increase in tolerance values. The PDPs for O/E in the Will_V show remarkable similarity to that described above for RICHTOL except that, as one would expect due to the differences in the invertebrate metrics, the curves respond in opposite directions (Figure 3). There is a general linear decrease in O/E values as agriculture plus urban land use increases (Figure 3A), a sharp increase in O/E values as riparian maximum elevation increases to 200 m (Figure 3B) or when mean annual precipitation increases to about 70 cm/year (Figure 3C). As seen for RICHTOL, O/E showed an abrupt threshold-type response at low levels of riparian forest (Figure 3D) followed by a step

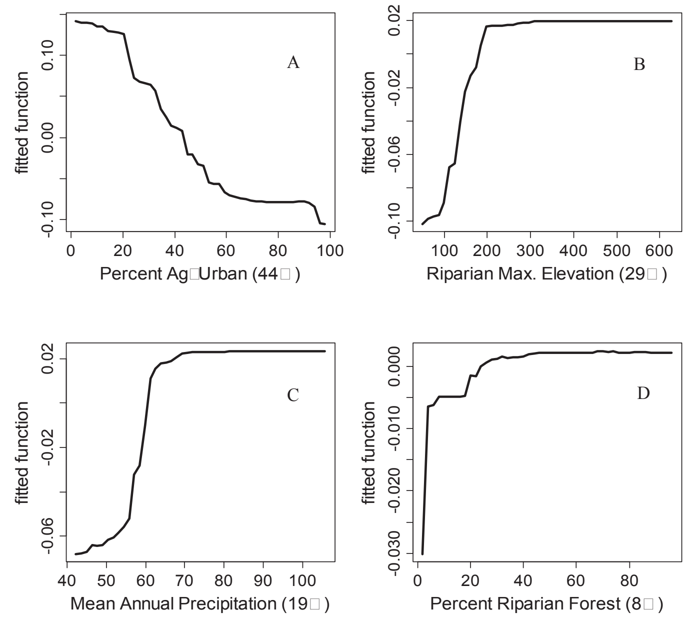

FIGURE 3. Partial Dependency Plots for Ag + Urb (A), Rip_Max-Elev (B), MnAnnPrecip (C), and Rip_Forest (D) in the Boosted Regression Model Developed for Observed/Expected (O/E) in Willamette Valley (Will_V). The y-axis represents the effect of the selected variable on the response variable O/E metric, the relative contribution of each explanatory variable is reported in parentheses. Refer to Table 1 for variable definitions.

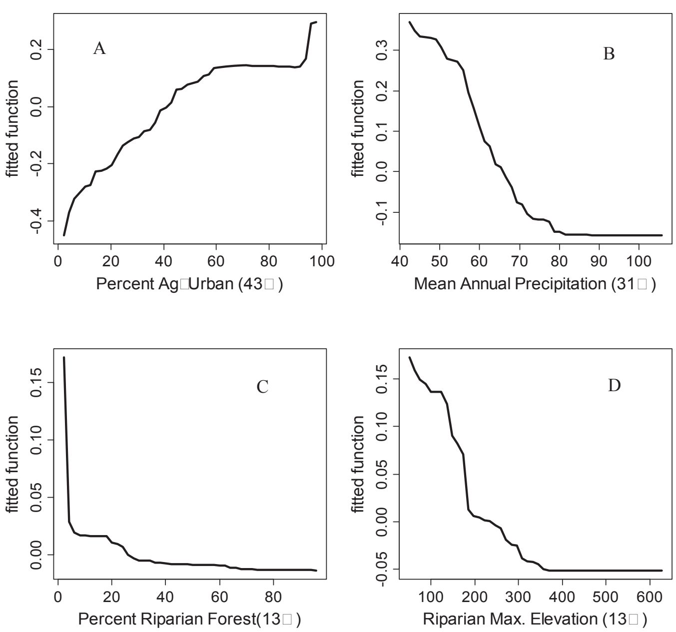

FIGURE 2. Partial Dependency Plots for Ag + Urb (A), MnAnnPrecip (B), Rip_Forest (C), and Rip_Max-Elev (D) in the Boosted Regression Model Developed for RICHTOL in Willamette Valley (Will_V). The y-axis fitted function represents the effect of the selected variable on the response variable RICHTOL; the relative contribution of each explanatory variable is reported in parentheses. increase and a plateau above approximately 30% riparian forest cover.

DISCUSSION

It is encouraging that the MLR and the CART and RF (regression tree family) modeling techniques gave similar results selecting in general the same main explanatory variables (Table 2) and explaining similar amounts of variation (Table 3), which may indicate that the MLR methods used in this study are appropriate for these types of ecological data. The BRT models, however, did show notable improvement in model fit with increases in R^2 values ranging from 0.09 through 0.15 for RICHTOL to 0.11 through 0.20 for O/E compared to MLR models (Table 3). L. R. Brown, J. T. May, A. C. Rehn, P. R. Ode, I. R. Waite, and J. K. Kennen (personal communication), using a MMI for macroinvertebrates (i.e., BIBI) sampled across a strong urbanization gradient, also showed a notable improvement in model performance for BRT compared to MLR. De'ath and Fabricius (2000) suggest that for complex or messy data, even single regression trees will often outperform MLR and are preferred for determining variable selection and interaction effects due to the issue that MLR models with complex data are frequently difficult to interpret because they will often include too many variables with high order interactions. It was found that CART and RF models did not outperform the RICHTOL MLR models in this analysis which supports our overarching hypothesis that MLR will generally perform as well as many of the tree modeling techniques when data follows a general linear response or when, in the case of the three regions evaluated, there are few explanatory variables with no high order interactions. Maloney *et al.* (2009) found that CART models of land-use disturbance on macroinvertebrate IBI metrics provided results that were intuitive, but they did not classify sites any better than logistic regression models; however, unlike in this study, their RF models showed minor improvements in performance over CART and logistic regression models.

In general, regression trees allow the inclusion of more variables in the model building phase than MLR, allow for easier testing for interaction affects and produce a list of variables explaining the importance of variation in the response variable. In addition, the PDPs from BRT or RF can offer valuable insights into the pattern or form of the response variable based on select explanatory variables improving model interpretation. For example, the PDPs for Will_V (Figures 2 and 3) revealed that the response rate changed or flattened out and provided additional insight into potential thresholds along the range of the individual explanatory variables that are not easily depicted with MLR models.

The identification of thresholds (i.e., transition points in ecological condition) is of growing interest to the scientific and regulatory community, especially for forecasting the loss of biodiversity (Hilderbrand *et al.*, 2010) or for understanding system recovery (Clements *et al.*, 2010; Qian and Cuffney, 2012). More research is clearly needed to help better detect nonlinear and possible threshold responses (Dodds *et al.*, 2010) and new analytical tools are emerging (i.e., BRT results shown in this study) that can assist with identifying changes in taxa occurrence across an environmental gradient (Qian and Cuffney, 2012).

Even though we were able to successfully develop strong MLR models indicating that the primary responses were linear in nature (Waite *et al.*, 2010), the BRT PDPs reveal potential thresholds in the response variable in at least some of the regions (e.g., the Will_V PDPs shown for RICHTOL and O/E in Figures 2 and 3) that were not seen in the MLR models. It is possible that since MLR models assume linearity that they may sometimes miss nonlinear/thresholds in some explanatory variables. The response of RICHTOL and O/E for watershed agriculture plus urban (Ag + Urb) was primarily linear with a small step function at the end (Figures 2A and 3A). The two riparian variables, riparian maximum elevation (Rip_Max-Elev; Figures 2D and 3B) and riparian forest (Rip_Forest; Figures 2C and 3D) on the other hand showed potential thresholds. The response of the two invertebrate metrics to changes in Rip_Max-Elev showed no response from 600 to 400 m for RICHTOL and to 200 m for O/E, after which there was a steep increase or decrease to the lowest elevation (Figures 2D and 3B). It is likely that riparian elevation is acting as a surrogate for the natural climatic and geologic trend that occurs in the Willamette Valley, trending from the valley floor with low stream gradient and lower elevation and precipitation to higher values for these and other variables as one moves toward the foothills of the Coast or Cascade Ranges on either side of the valley. The response of RICHTOL and O/E to changes in Rip_Forest showed a slow but continuous linear increase or decrease as the amount of Rip_Forest decreased from 100% to approximately 5%, after which there appears to be a rapid change in either of the metric values, which may indicate a strong threshold at or near the 5% level. This suggests that as percent forest in the riparian zone along streams drops below approximately 5-10%

land cover, stream integrity degrades rapidly possible due to the reduction in natural buffering capacity seen in healthy riparian systems. L. R. Brown, J. T. May, A. C. Rehn, P. R. Ode, I. R. Waite, and J. K. Kennen (personal communication) found a similar response in the MMI they modeled (BIBI) against four explanatory variables across a strong urbanization gradient in some California streams. They showed that the amount of agriculture plus urban land use in the riparian zone and mean annual precipitation in the watershed showed approximate linear responses, though in opposite directions. They also found a threshold-type response in the BIBI to low values of population density (approximately 300 persons/km^2) in the watershed. Similar to the findings in this study, L. R. Brown, J. T. May, A. C. Rehn, P. R. Ode, I. R. Waite, and J. K. Kennen (personal communication) found that the BRT method appeared to be more sensitive for detecting nonlinear response patterns such as thresholds, for determining potential surrogate variables, and for model corroboration.

The overall poorer performance of the O/E metric compared to the single metric RICHTOL across all models was notable, yet the especially poor performance in the Blue_Mt region was particularly surprising (Table 3). When comparing the ability of O/E and a multimetric invertebrate IBI to differentiate between reference and degraded sites, Herbst and Silldorff (2006) found that the two methods were in close agreement for sites in eastern Sierra Nevada of California. Hawkins *et al.* (2010) compared the performance of a multimetric index and O/E for 225 sites from five ecoregions in the interior Columbia Basin, including many of the sites used in this study from the Blue_Mt ecoregions. They found that the O/E metric was better at distinguishing among the three disturbance classes, particularly between the intermediate and high disturbance classes than the multimetric index. The discrepancy between the poor performance of O/E in the Blue_Mt region in our study and the strong performance in their study may be due to a larger underlying disturbance gradient within their dataset, which resulted from the inclusion of data from multiple ecoregions. Models derived for the Will_V region, where there was a larger disturbance gradient than that found in the Blue_Mt region, showed relatively little difference in performance between the O/E and RICHTOL metrics. It is also possible that the lower R^2 for the O/E models may be because we are not able to model nor account for the error associated with estimation of the raw O/E metric values. Chessman *et al.* (2010) found that O/E values did not distinguish among site disturbance groups based on hydrologic alteration in Australia even though taxonomic richness and assemblage composition could. However, it is yet unclear why O/E performance would be inhibited in areas with a shorter disturbance gradient than that shown in Hawkins *et al.* (2010). One possibility is that because these O/E models are based on a subset of taxa that occur at 50% of the reference sites and therefore operate with a reduced taxa list, specifically with the relatively rare and arguably with the more sensitive portion of the taxa list removed, the resulting O/E values may be less able to distinguish the small more subtle differences among sites, such as that seen in the Blue_Mt study region. In contrast, the RICHTOL metric uses all the taxa that occur at a site and may be a more sensitive measure of changes in assemblage integrity in areas of low anthropogenic disturbance.

CONCLUSIONS

Waite *et al.* (2010) were able to successfully develop MLR models for the three distinct and separate regional datasets presented in this study for individual macroinvertebrate metrics (e.g., RICHTOL, EPT). This study developed alternate models, CART, RF, BRT, for the same datasets and compared them to the MLR models previously developed. The O/E metric performed nearly as well as RICHTOL in the Will_V region where there was a strong disturbance gradient but performed poorly in Blue_Mt, a region with a relatively weak gradient. Though the data modeled in this study were not particularly noisy or complex, the BRT models, in all cases, outperformed the MLR methods and provided specific information on the form of the response function for each variable giving important insight into potential thresholds in the data. As a result of this ecological modeling comparison, BRT models may indeed represent a good alternative to MLR for modeling species distribution relative to environmental variables. Modeling results indicate that even when the response pattern is simple and strongly linear, BRT models not only markedly improve model fit, but can also help to corroborate results from other methods, provide additional information on potential interactions among variables, and support greater insight into understanding the response profile of a given metric, whether it be a linear, step, or a threshold function, across environmental gradients that may not be easily seen with MLR. Models like these can be used to better understand potential causal linkages between environmental drivers and stream biological attributes or condition and predict expected values of macroinvertebrate metrics at unsampled sites.

ACKNOWLEDGMENTS

We thank each of the individuals that provided the macroinvertebrate data and associated advice: Shannon Hubler, Oregon Department of Environmental Quality; Alan Herlihy, Oregon State University and Environmental Protection Agency; Pete Ode and Andy Rehn, California Department of Fish and Game. We thank the many dedicated USGS colleagues who acquired the biological samples used in this analysis. We also gratefully acknowledge Alan Herlihy, John Van Sickle, and Anthony Olsen (Environmental Protection Agency, Corvallis) for their insight and advice on issues related to modeling macroinvertebrates, and Dr. Yangdong Pan (Portland State University) for advice on R programming and statistics. Finally, we thank one USGS reviewer and one outside reviewer for their review of the manuscript prior to submission to the journal.

Jun Zhu
Environmental Scientist
Los Angeles Regional Water Quality Control Board
320 W 4th St., Suite 200
Los Angeles, CA 90013

RE: Draft 2016 Section 303(d) and 305(b) Integrated Report

Dear Mr. Zhu,

Please accept the following comments on the Los Angeles Regional Water Quality Control Board's (Regional Board's) 2016 Integrated Report, which are hereby submitted by Santa Barbara Channelkeeper.

Santa Barbara Channelkeeper is a non-profit environmental organization dedicated to protecting and restoring the Santa Barbara Channel and its watersheds through science-based advocacy, education, field work and enforcement. We have been conducting water quality monitoring in watersheds from Gaviota to the Ventura River since 2001. We have engaged more than 1,200 volunteers in our monitoring efforts and represent over 750 members. Our comments address the following concerns:

- Procedural issues related to data solicitation gaps
- Category 4C and Hydrologically Impaired Waterways
- Inappropriate de-listing of the Ventura River Reach 3 Pumping Impairment

Generally, Channelkeeper supports the Regional Board's ongoing efforts to document water quality impairments on the 303(d) List. Specific concerns regarding the Draft 2016 Integrated Report are summarized below.

<u>Procedural Concerns Related to Data Solicitation Gaps</u>

Channelkeeper is troubled that the Regional Board has fallen so far behind on data solicitations and review of 303(d) listings. 40 C.F.R. § 130.7(d)(1) mandates that:

> Each State shall submit ***biennially*** to the Regional Administrator beginning in 1992 the list of waters, pollutants causing impairment, and the priority ranking including waters targeted for TMDL development within the next two years as required under paragraph (b) of this section.

The 2016 Integrated Report is based on data submitted in 2010 and will not be finalized until the middle of 2017. Based on EPA Guidance, the 2016 Integrated

Report was due in April 2016.[1] Clearly, the Regional Board has failed to achieve pertinent milestones and mandates related to the biennial review process.

The lack of any recent data solicitation is particularly troubling as a fully accurate and current depiction of water quality is not available for the 2016 Integrated Report. The Regional Board has a mandate to "assemble and evaluate all existing and readily available water quality-related data and information to develop the list."[2] Accordingly, the Regional Board should base 2016 Integrated Report decisions based on "all existing and readily available" data, which includes data collected since the 2010 data solicitation. Six years of additional data is available to the Board and should be appropriately utilized for the Region's listing, de-listing and planning purposes. Channelkeeper questions how such determinations can reasonably or legally be made without consideration of the last six years of existing and readily available data.

It is additionally concerning that due to the State's new staged approach to 303(d) List review, further data solicitation will be delayed until the Los Angeles Regional Board's 2022 report, which will include data submitted through 2021. This means that the Regional Board will not have reviewed existing water quality data for our region for more than a decade. This is clearly unacceptable from a legal standpoint.

Category 4C and Hydrologically Impaired Waterways

Channelkeeper echoes and supports comments submitted to the Regional Board on March 30, 2017 by *Earth Law Center*[3] regarding the necessity for evaluation and listing for hydrologically impaired waterways to fully comply with Clean Water Act Sections 305(b) and 303(d). Such evaluation and listing is clearly called for under the Clean Water Act, is supported by EPA Guidance, and paves the way for sound public policy and planning. Many other states around the country follow such Guidance to properly identify flow impaired waterways in their Integrated Reports. Recently, the San Diego Regional Water Quality Control Board notably identified 30 waterway segments for listing in Category 4C. Channelkeeper notes with concern that the Los Angeles Region has apparently forgone assessment of Category 4C impairments altogether in the Draft 2016 Integrated Report. We question the legality of such an oversight.

Inappropriate de-listing of the Ventura River Reach 3 Pumping Impairment

The Los Angeles Regional Board currently proposes to delist Reach 3 of the Ventura River for "Pumping" impairment. Channelkeeper strongly opposes this delisting decision. On February 5, 2015 Channelkeeper submitted detailed comments (Attachment 1) and data to the State Water Resources Control Board regarding its stated intent to delist Reaches 3 and 4 of the Ventura River for pumping and diversion impairments. These comments were submitted in response to the State Water Board's Draft Staff Report for the 2012 Integrated Report dated December 31, 2014, which stated that the four listings on the existing 303(d) list due to flow related alterations in the Ballona Creek and Ventura River watersheds "will likely be proposed for delisting as part of the next Listing Cycle."

---

[1] Environmental Protection Agency. "Information Concerning 2016 Clean Water Act Sections 303(d), 305(b), and 314 Integrated Reporting and Listing Decisions." August 13, 2015.
[2] 40 C.F.R. § 130.7(b)(5)
[3] Earth Law Center. "Comment Letter – Revisions to the Los Angeles Region 303(d) List". March 30, 2017

Channelkeeper's submittal outlined in detail why Reaches 3 and 4 of the Ventura River may not be delisted from the 303(d) list as impaired for flow by pumping and diversion. The existing listings for Reaches 3 and 4 of the Ventura River accurately reflect the current diminished flows and resulting impairments to designated beneficial uses in those Reaches. The listings are legally valid, and consistent with the State Water Board's Listing Policy. In contrast, delisting Reaches 3 and 4 from the 303(d) list as impaired for flows due to excessive pumping and diversion is inconsistent with the Listing Policy, the Clean Water Act, and facts on the ground. We refer the Los Angeles Regional Board to our February 5, 2015 letter as its legal and technical merits remain unchanged.

Channelkeeper additionally submitted multiple years of continuous monitoring data (submitted electronically via file "*MasterData_2013-2014.xls*") along with our 2015 comment letter. These data were summarized in tables as well as within an example "Listing Line of Evidence" provided with our 2015 letter. Lacking any formal data solicitation by the Los Angeles Regional Board since 2010, these submittals represent existing and readily available water quality-related data and information, which should have been used to develop the Draft 2016 Integrated Report.

Since the submittal of our 2015 comment letter, Channelkeeper has collected additional water quality data that supports the existing listings for pumping and diversions in Reaches 3 and 4. We are submitting an updated data file ("*MasterData_2013-2016*") electronically along with this comment letter.

Conclusion

When Reaches 3 and 4 of the Ventura River were identified as flow-impaired by pumping and diversions on California's 1998 303(d) list, the State Water Board took an important first step towards restoring the chemical, physical, and biological integrity of these waters. However, there is ongoing documentation that flow alterations from pumping and diversions continue to degrade Reaches 3 and 4 such that these waters cannot support their designated beneficial uses and water quality standards are not attained.

Reaches 3 and 4 of the Ventura River are impaired for pumping and diversions based on the "Numeric Water Quality Objectives for Conventional or Other Pollutants in Water" listing factor, the "Situation-Specific Weight of Evidence" listing factor, as well as the "Degradation of Biological Populations and Communities" listing factor. Removing the pumping impairment listing for Reach 3 is not only illegal but will also impede existing and future efforts to remedy the ongoing flow impairments in the Ventura River. Channelkeeper strongly urges the Los Angeles Regional Board to comply with the Clean Water Act by continuing to identify Reach 3 on the 303(d) list as flow-impaired by pumping.

Thank you for your consideration of our comments.

Sincerely,

Ben Pitterle
Watershed and Marine Program Director

Re: Comment Letter—303(d) List portion of the 2012 California Integrated Report

Dear State Water Board Members and State Water Board Staff:

Thank you for the opportunity to comment on the proposed federal Clean Water Act ("Clean Water Act" or "CWA") section 303(d) list of water quality limited segments ("303(d) list") portion of the 2012 California Integrated Report as well as the associated supporting draft Staff Report and fact sheets ("2012 Integrated Report").

Santa Barbara Channelkeeper ("Channelkeeper") is a non-profit public benefit corporation whose mission is to protect and restore the Santa Barbara Channel and its tributaries for the benefit of its ecosystems and the surrounding human communities, including the Ventura River. Channelkeeper has served as a lead advocate, community organizer, educator, scientist, and monitor in the Ventura River watershed for 15 years. Based on Channelkeeper's extensive knowledge and experience surrounding the quality and flow in the Ventura River, Channelkeeper submits the following comments on the 2012 Integrated Report for the Board Member's consideration. Channelkeeper also joins and incorporates herein by reference the comments submitted by California Coastkeeper Alliance and Earth Law Center.

In its Draft Staff Report for the 2012 Integrated Report dated December 31, 2014, the State Water Board states that the four listings on the existing 303(d) list due to flow related alterations in the Ballona Creek and Ventura River watersheds "will likely be proposed for delisting as part of the next Listing Cycle." As described in detail below, Reaches 3 and 4 of the Ventura River may not be delisted from the 303(d) list as impaired for flow by pumping and diversion. The existing listings for Reaches 3 and 4 of the Ventura River accurately reflect the current diminished flows and resulting impairments to designated beneficial uses in those Reaches. The listings are legally valid, and consistent with the State Water Board's Listing Policy. In contrast, delisting Reaches 3 and 4 from the 303(d) list as impaired for flows due to excessive pumping and diversion is inconsistent with the Listing Policy, the Clean Water Act, and facts on the ground. Channelkeeper references substantial and significant evidence supporting the existing impairment listings, and submits herewith a draft Line of Evidence. The State Water Board must take all of this information into consideration prior to making any decision – information that renders delisting unsupported and illegal.

I. Consistent with the Existing 303(d) Listing, Reaches 3 and 4 of the Ventura River Are Flow Impaired by Pumping and Diversion.

Since 1998, Reaches 3 and 4 of the Ventura River have been accurately identified on California's 303(d) list as impaired by excessive pumping and diversions. Such pumping and diversions are clearly linked to reduced surface flows. Reduced surface flows and the resulting water quality degradation prevents Reaches 3 and 4 from supporting their designated and potential beneficial uses, which include endangered species habitat. In fact, pumping and diversions in Reaches 3 and 4 continue to result in flows below recommended thresholds needed to protect endangered steelhead trout.

A. The Ventura River Watershed and the Reaches 3 and 4 303(d) Impairment Listings.

The Water Quality Control Plan for the Los Angeles Region ("Basin Plan") describes the Ventura River as consisting of five reaches, which, upstream from the Pacific Ocean, are: Reach 1 (Ventura River Estuary to Main Street), Reach 2 (Main Street to Weldon Canyon), Reach 3 (Weldon Canyon to Casitas Vista Road), Reach 4 (Casitas Vista Road to Camino Cielo Road) and Reach 5 (above Camino Cielo Road). Basin Plan, pp. 2-6. There are two major dams which affect surface flows in reaches 3 and 4, Matilija and Casitas. Two major river diversions are located within these reaches, Robles Diversion Facility and the Foster Park Subsurface Diversion. The City of Ventura operates the Foster Park Subsurface Diversion ("Foster Park"). Three major municipal well fields are located in Reaches 3 and 4. These are operated by Meiners Oaks Water District, the Ventura River Water District, and the City of Ventura. Groundwater from these reaches is also pumped for agricultural and domestic purposes. *See* U.S. EPA Draft Ventura River Reaches 3 and 4 Total Maximum Daily Loads For Pumping & Water Diversion-Related Water Quality Impairments ("EPA Draft TMDL").

The designated potential and existing beneficial uses of Reaches 3 and 4 are municipal and domestic supply, industrial service supply, agricultural supply, ground water recharge, freshwater replenishment, warm freshwater habitat, cold freshwater habitat, wildlife habitat, rare, threatened, or endangered species, migration of aquatic organisms, spawning, reproduction, and/or early development, and wetland habitat. *See* Basin Plan, Table 2-1.

In 1998, the U.S. EPA approved California's list of impaired water bodies identified pursuant to Clean Water Act section 303(d) (33 U.S.C. § 1313(d)), which first listed Reaches 3 and 4 as impaired for pumping and diversion. According to Los Angeles Regional Water Quality Control Board ("Regional Board") staff, the original listing referenced a 1996 Steelhead Restoration and Management Plan for California ("Steelhead Restoration Plan") as one basis for the listing decision. The plan states, "The major obstacle to steelhead restoration in this system is blocked access to headwaters and excessive water diversion." Steelhead Restoration Plan, p. 201. The plan describes several large-scale water diversions in the river including Foster Park and the City of Ventura's wells in the lower River, which, "ha[ve] resulted in dewatering portions of the lower river during summer and fall." Steelhead Restoration Plan, p. 203.

Most recently, on August 4, 2010, the State Water Resources Control Board ("State Water Board") approved California's 2010 303(d) list. Channelkeeper notes that the supporting fact sheets for these listings state that both the Regional Board and State Water Board staff reviewed the existing Ventura River watershed listings for pumping, water diversions, and fish barriers and decided to make no modifications to the list. On October 11, 2011, the U.S. EPA approved the State Water Board's triennial review and update to the 303(d) list, which maintained the pumping and diversion impairments for Reaches 3 and 4 of the Ventura River.

B. There is an Established Relationship Between Surface Flows, Groundwater, and Pumping and Diversions in the Ventura River.

The hydraulic communication between surface and groundwater in the Ventura River has been acknowledged by experts and government agencies for several decades. The significant contribution of groundwater pumping to dewatering of the River has been similarly acknowledged, though its full extent remains undetermined.

A 1978 a Draft Environmental Impact Report on the Conjunctive Use Agreement between Casitas Municipal Water District and the City of Ventura ("Draft EIR") included the following statement:

> *There is a relationship between the groundwater in storage and the presence of year-round springs and surface flows in the live stretch between San Antonio Creek and Foster Park, and also below Foster Park. It is evident from the figure (V-3) that if the groundwater in either of the cells (above San Antonio Creek, or between San Antonio Creek and Foster Park) were to fall to very low levels, then seepage in the form of springs at the surface would stop, and surface flow would also stop.*

Draft EIR, p. V-22. Figure 1 below provides a diagram of the River's surface flows, alluvium, and alluvium with ground water cells. *See also* Draft EIR, p. V-23 (providing an example of when and where the relationship between the groundwater and surface water occurs).

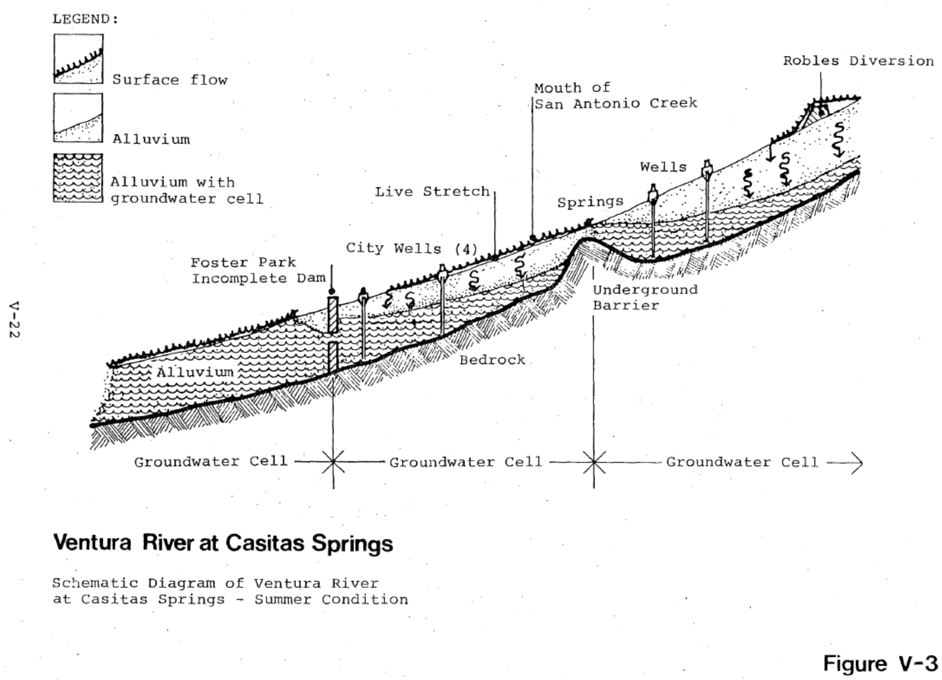

Figure 1: Excerpt figure from Draft Environmental Impact Report Ventura River Conjunctive Use Agreement. June 1978.

More recently, studies and reports continue to acknowledge the strong connection between groundwater pumping and diversions and the resulting loss of flows in the River.

For example, a National Marine Fisheries Service ("NMFS") 2007 Draft Biological Opinion ("Draft Biological Opinion") for the Army Corps of Engineers' permitting of the City of Ventura's proposed Foster Park Well Facility ("FPWF") repairs contains NMFS's summary of information available at the time and its determination that groundwater pumping and diversion at the FPWF detrimentally impacts downstream critical habitat for steelhead trout in Reach 3. On page 16 of the Draft Biological Opinion, NMFS states:

> *Water withdrawals from surface diversions and subsurface pumping have affected the timing and magnitude of the Ventura River flows in the action area* [6 miles downstream of the FPWF including Reaches 1, 2, and 3], *which has resulted in reduced surface flows. This has altered the natural hydrologic processes responsible for recharging the aquifer underlying the lower Ventura River Basin and the lower part of the action area, and has decreased the quantity and quality of critical habitat for steelhead, predominantly in the dry season.*

On page 25 of the Draft Biological Opinion, NMFS states:

> *Consequently, <u>resumed well field operations are expected to substantially reduce, and at times eliminate surface flows in the action area, and could completely</u>*

> *dewater the upper portion of the action area in the vicinity of the FPWF during most years.* (Emphasis added).

A Ventura River Natural Conditions Study further acknowledged loss of flow in the river (Reaches 3 and 4) due to ground water pumping in its model calibrations. TetraTech, 2009, p. A-3. In specific reference to Foster Park, lead authors of the Tetratech study responded to public comments by stating, "It is our understanding that water is withdrawn from pipes buried in the alluvium. Water entering these pipes comes from both flow in the river and from underlying groundwater. We agree that groundwater and surface water appear to be fully connected in this area… ." Jonathan Butcher, July 22, 2009 Memorandum to Scott Holder (VCWPD) Re: Ventura River Model Comment Response.

In December, 2012 the U.S. EPA, Region 9, released the EPA Draft TMDL. The EPA Draft TMDL clearly acknowledges the connection between surface flows, groundwater, and pumping and diversions. The EPA Draft TMDL states:

> *Flow in any particular reach of the* [Ventura] *River is additionally affected by the status of the underlying groundwater basin (whether full, filling, or emptying), the occurrence of natural recharge areas where surface flows will disappear at times, flow between groundwater basins, and the amount of surface or groundwater withdrawals for municipal, domestic, or agricultural uses. …The flow in the river is disrupted at Foster Park (which overlies the Upper Ventura River Groundwater Basin) due to subsurface diversions and groundwater extraction (p. 9).*

In June 2013, the City of Ventura conducted a preliminary hydrogeological and surface water/groundwater interaction study (Hopkins, 2013) for the City's diversions at Foster Park. In its concluding remarks, the study states, "We conclude that groundwater production at Foster Park during the low-flow season is substantially supported by underflow." In other words, the Ventura River itself accounts for a substantial proportion of the water produced by the City's wells during the low-flow season.

In the summer of 2012, using time-lapse video and a deployable pressure transducer sensor Channelkeeper and local citizens documented dramatic and irregular fluctuations in river and pool surface levels in Reach 4 near private wells and wells operated by Meiners Oaks and the Ventura River Water Districts. These observations are compiled in a YouTube video (SBCK, Watchdog Diaries – Episode 6) available at https://www.youtube.com/watch?v=JrGMRITAqH4, and provide strong evidence of surface and groundwater interactions being affected by pumping and/or diversions in Reach 4. The fluctuations captured by camera and sensor data are abrupt, dramatic, and do not resemble any known naturally occurring patterns indicating that pumping and diversions in Reach 4 are directly impacting surface flows.

C. Reduced Surface Flows Impair the Beneficial Uses of Reaches 3 and 4, Including Endangered Species Habitat.

As surface flows, groundwater, and pumping and diversions are connected, excessive pumping and diversions resulting in significantly reduced surface flows degrade critical habitat for endangered steelhead trout and impair additional designated and potential beneficial uses of the River. These impairments are documented by NMFS, U.S. EPA, and the City of Ventura.

NFMS's 2012 Southern California Steelhead Recovery Plan ("Steelhead Recovery Plan") recently affirmed the 1996 Department of Fish and Wildlife Steelhead Restoration Plan findings by describing dams, surface water diversions, and groundwater extraction as a "very high threat" to steelhead recovery in the Ventura River. NMFS found the critical recovery actions to include providing fish passage around dams and diversions, and developing and implementing water management plans for diversion operations such as Foster Park. NMFS also found that diversions from the Ventura River at Foster Park contribute to the present or threatened destruction, modification or curtailment of steelhead habitat or range, and disease and predation of steelhead. *See* Steelhead Recovery Plan, p. 9-42.

In the Draft Biological Opinion, NMFS concluded that summer and fall withdrawals from the Foster Park degrade downstream (Reaches 1, 2, and 3) habitat and water quality and decrease the functional value of these areas as an over-summering area for juvenile steelhead. NMFS states:

> *The reduction in discharge volume resulting from well-field withdrawals is expected to affect water quality within the action area… Reducing discharge and thus depth, is expected to increase water temperatures in the action area because of increased surface area to depth ratio and increased insolation of the river. Decreased flow velocities can reduce water quality by causing stagnant conditions, especially in pools, which will result in low oxygen levels (p. 27).*
>
> *After reviewing the best available scientific and commercial information, the status of the Southern California steelhead DPS, the environmental baseline, expected effects of the proposed action, cumulative effects, and the combined effects of past and present activities, the proposed action, and actions that are reasonably certain to occur, NMFS concludes the proposed action* [resumption of City pumping] *is likely to jeopardize the continued existence of the Southern California DPS, and is <u>likely to destroy or adversely modify critical habitat for this species</u> (p. 33).* (Emphasis added).

After NMFS issued its Draft Biological Opinion, Ventura dropped its permit application submitted to the Corps. However, repairs to water production facilities were completed outside of Corps jurisdiction. Therefore the diversions examined by NMFS – determined to be detrimental to critical habitat and the survival of Southern California steelhead in the River – continue unabated or unmitigated to present time.

NMFS findings were later affirmed by the City of Ventura's hydrological study (Hopkins, 2013), which included a steelhead habitat assessment examining the relationship between low flow conditions caused by pumping and steelhead habitat suitability. Surveys and data collected as part of the assessment generally support NMFS determination that the pumping at the Foster

Park well field results in degradation of downstream critical habitat and water quality. The City's study concludes:

> *The findings of this study indicate a flow threshold exists whereby when flows decrease below the threshold, the steelhead habitat suitability declines significantly…We conclude that the steelhead habitat is generally degraded throughout the low-flow season because the declining river flow results in shallower thalweg depths in pools, runs, and riffles which allows the hotter atmospheric temperatures to increase the surface water temperatures (p. 26).*

The EPA Draft TMDL further supports these findings:

> *Excess nutrients and eutrophic conditions are present in the Ventura River system. Low and intermittent flows exacerbate the nutrient-related problems (too much algae) and lead to low dissolved oxygen concentrations in the River. The cumulative impacts of these conditions result in the failure to attain several beneficial uses, as described throughout the remainder of this section (p. 11).*

Though the U.S. EPA ultimately decided to approve the State Water Board's Ventura River Algae TMDL as an alternative to its own Pumping and Diversions TMDL, a June 28, 2013 approval letter to the State Water Resources Control Board from the Executive Director of the U.S. EPA, states, "EPA found that the effects of pumping and water diversions in these reaches were correlated with the impairment of aquatic life and cold water habitat beneficial uses due to nutrient loading and algae growth."

As described above, both the U.S. EPA and NMFS have established linkages between pumping and diversions in the Ventura River and impairment of water quality standards, as pumping and diversions reduce surface flows such that Reaches 3 and 4 cannot support their beneficial uses. The City of Ventura's hydrological study of the River also confirms that surface flows and pumping and diversions are linked, and that beneficial uses are being degraded by low flows caused by pumping and diversions (Hopkins, 2013).

Channelkeeper has also conducted additional monitoring in 2013 and 2014 that demonstrates that reduced flows caused by pumping and diversion from Reaches 3 and 4 contribute to non-attainment of water quality objectives for water quality parameters indicative of low flows. As detailed in Section II.C., below, Channelkeeper's monitoring data for dissolved oxygen and temperature show that Reaches 3 and 4 are not attaining water quality objectives and/or criteria for these parameters. Specifically, Reach 3 exceeded the 7 mg/L water quality objective for dissolved oxygen on 558 occasions out of 574 samples from 2013-2014. For the 5 mg/L dissolved oxygen water quality objective Reach 3 exceeded on 459 occasions out of 574 samples from 2013-2014. Reach 4 exceeded the 7 mg/L dissolved oxygen water quality objective on 63 occasions out of 174 samples from 2013-2014. For temperature, Reach 3 exceeded the numeric criteria used for temperature by the State Water Board in prior 303(d) listings on 501 occasions out of 649 samples from 2013-2014, and Reach 4 exceeded the temperature criteria on 227 occasions out of 250 samples from 2013-2014. These exceedances of water quality objectives and/or criteria for dissolved oxygen and temperature are well above the minimum number of exceedances warranting 303(d) listing, indicate that reduced flows due to excessive pumping and diversions have and continue to degrade water quality in Reaches 3 and 4, and show that the water quality standards for these segments of the Ventura River are impaired by pumping and diversions.

D. Surface Flows in Reaches 3 and 4 Consistently Fall Below Recommended Flow Thresholds Needed to Protect Beneficial Uses.

To avoid jeopardizing steelhead existence and destruction or adverse modification of critical steelhead habitat, NMFS found that flows in the Ventura River at the Foster Park USGS gauge no. 111185000 should not fall below 11 to 12 cfs. *See* Draft Biological Opinion, p. 33. NMFS states: "This flow rate is based on past studies, which indicate that flows of 12 cfs and above will allow for natural rates of growth and high rates of survival of steelhead within the action area (Moore 1980), and essential features of critical habitat and PCEs within the action area will be preserved." *Id.*, p. 33.

The City of Ventura's hydrology study (Hopkins, 2013) also identified a protective threshold of 2 cfs at the Foster Park USGS gauge based on habitat suitability data. The study further recommended that the City consider reducing its diversion rates during the dry-season when river flows fell below this threshold.

> *We also recommend that during low flow conditions, the City observe streamflows documented by the USGS gage and consider reducing its diversion rates during the dry season as the River flow rate declines to 2 cfs. While the City has no control on how much water will seasonally flow into the Foster Park reach of the River, the reduction and eventual cessation of pumping will serve to maintain the steelhead habitat as long as it will last while the main stem of the River dries out (p. 28).*

Attachment A to Channelkeeper's draft Line of Evidence provides a summary of Foster Park well field production totals in comparison with flow thresholds recommended by NMFS and the City hydrology studies (12 and 2 cfs, respectively). As Attachment A clearly depicts, major withdrawals take place monthly despite the River being well below recommended thresholds at the USGS Foster Park Gage and even dry in many sections.

Figure 2. Dry Ventura River at the Foster Park subsurface dam and diversion on November 22, 2013. Dry conditions at Foster Park were prevalent throughout the 2013 - 2014 dry seasons.

For example, as seen in Figure 2 and as documented at the USGS gage, the River was completely dry at Foster Park throughout much of the 2013-2014 dry seasons.

Data from monitoring stations maintained by Channelkeeper further demonstrate that recommended flow thresholds needed to protect beneficial uses have not been achieved in recent years. Figure 3 identifies SBCK monitoring site locations in relation to water diversion facilities and designated Reaches of the Ventura River, and Table 1 provides the flow data at Channelkeeper's monitoring sites.

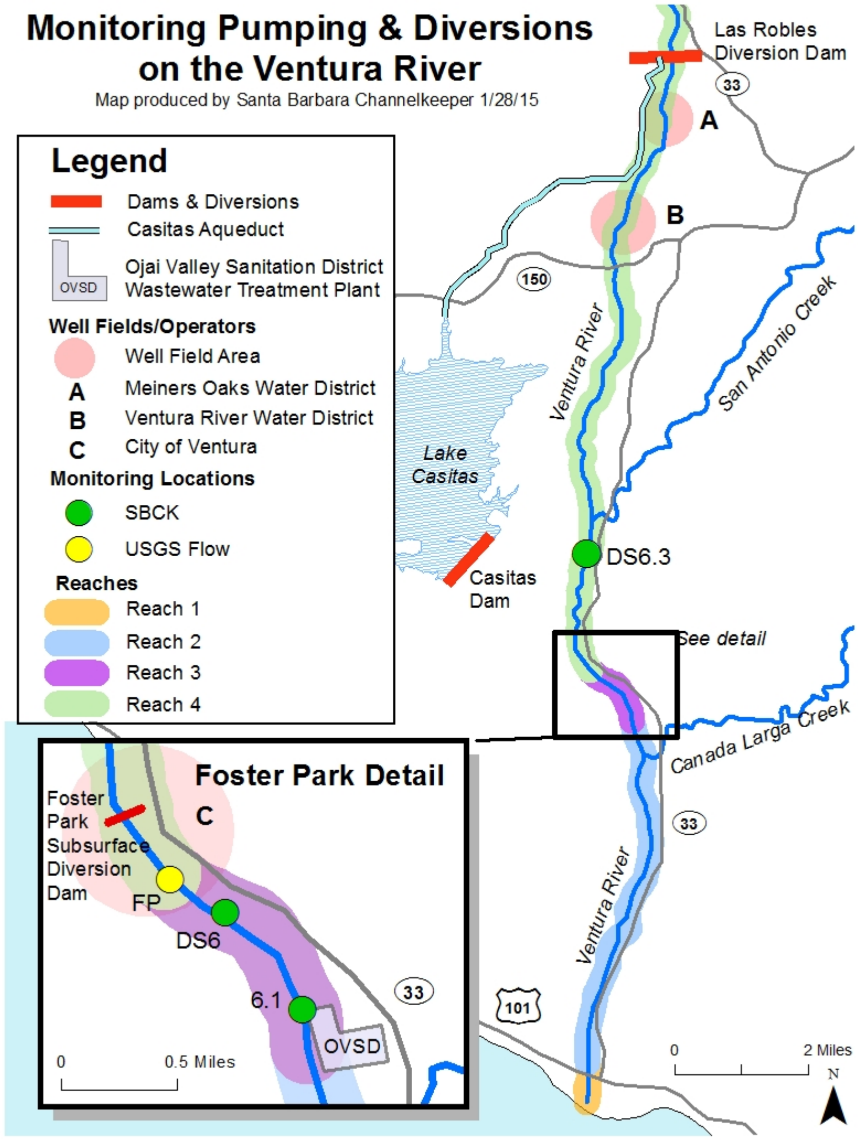

Figure 3. Monitoring sites, pumping and diversion facilities, and designated Reaches of the Ventura River

Most of Reach 4 ran dry through 2013 and 2014 including at Foster Park. Some sections of Reach 4 are known to consistently run dry during the dry season. However, additional sections such as Foster Park characterized as perennial (Beller et al., 2011) also experienced total loss of surface flows in these years. Reach 3 (downstream of Foster Park) is the primary reach for which the recommended thresholds were developed. But as shown in Figure 3 and Table 1, measurements indicate that flow levels of 11 or 2 cfs were not observed at sites in Reach 3 (6.1 and DS6. Attachment B provides a summary of flow rates at the USGS Foster Park gage from 2007 through 2014. As demonstrated in Attachment B to Channelkeeper's Line of Evidence and Table 1, Channelkeeper notes that flows have consistently fallen and remained below the recommended protective thresholds for many years.

Table 1: Flow on the Ventura River (cfs) – SBCK Monitoring

II. The Existing 303(d) Listings for Reaches 3 and 4 Are Valid Though the Listings Were Approved Before the Listing Policy Was Adopted.

In reference to the existing 303(d) listings for Reaches 3 and 4 of the Ventura River, the 2012 Integrated Report states:

> California has not considered the direct assessment of flow data since the adoption of the Listing Policy. There are four listings on the existing 303(d) List due to flow related alterations in the Ballona Creek and Ventura River watersheds. These decisions were made prior to adoption of the Listing Policy and before guidance was developed on the method to inventory waters impaired by pollution, and not pollutants. **Those four listings waters [sic] will likely be proposed for delisting as part of the next Listing Cycle**.

2012 Integrated Report, pp. 9-10 (emphasis added). The State Water Board's "likely" proposal to delist Reaches 3 and 4 of the Ventura River as flow impaired by pumping and diversion is improper for at least four reasons. First, the Clean Water Act as well as long-standing U.S. EPA Guidance provide for 303(d) listings for flow-impaired waters such as Reaches 3 and 4. Second, that Reaches 3 and 4 were listed as flow-impaired prior to adoption of a formal listing policy has no bearing on the validity of the listings. Third, the existing 303(d) listings for Reaches 3 and 4 meet the several listing factors in the State Water Board's Water

Quality Control Policy for Developing California's Clean Water act Section 303(d) List in September 2004 ("Listing Policy"). Fourth, Reaches 3 and 4 of the Ventura River must remain 303(d) listed as impaired for flow caused by pumping and diversions because no Listing Policy delisting factors can be met.

A. The Clean Water Act and U.S. EPA Guidance Provide for Flow-Impairment Listings.

Under the Clean Water Act, when effluent limitations are insufficient to ensure compliance with water quality objectives and a water body can no longer be put to its designated beneficial uses (collectively "water quality standards"), that water body's water quality standards have not been attained and its beneficial uses are impaired. The State must identify that water body on the list of impaired waters. 33 U.S.C. § 1313(d)(1). An impairment listing is required whether the impairment is caused by "pollutants" or "pollution." *See* 33 U.S.C. § 1313(d)(1)(A); *see also Pronsolino v. Nastri*, 291 F.3d 1123, 1137-38 (9th Cir. 2002), cert. denied, 123 S. Ct. 2573 (2003) ("Water quality standards reflect a state's designated *uses* for a water body and do not depend in any way upon the source of pollution").

Compliance with the Clean Water Act section 303(d), the Act's "safety net," requirements is a crucial element in achieving the Clean Water Act's goal of restoring the chemical, physical, and biological integrity of the nation's waters so that they are safe for swimming, fishing, drinking, and other "beneficial uses" that citizens enjoy, or used to be able to enjoy. It is the bedrock component of the Clean Water Act; the backstop to ensure that the goals of the Act can be achieved when initial efforts fail. Moreover, section 303(d) requires states to address comprehensively all human activities that affect the chemical, physical, and biological integrity of the nation's waters.

Consistent with the language and the purpose of Clean Water Act section 303(d), the U.S. EPA has found that "pollution" must result in a 303(d) listing if it results in impairment. *See* U.S. EPA, "Guidance for 2006 Assessment, Listing and Reporting Requirements Pursuant to Sections 303(d), 305(b) and 314 of the Clean Water Act," p. 56 ("2006 Guidance").[1] In describing categories of impairment listings, EPA specifically uses "lack of adequate flow" as an example of a cause an impairment to a water segment. *Id*.

Accordingly, a water body that cannot support its designated beneficial uses due to altered flow must be included on the State Water Board's 303(d) list as impaired. Altered flows in Reaches 3 and 4 of the Ventura River caused by pumping and diversions impair those Reaches' beneficial uses, as described in detail in Section I above. Thus, as provided by the Clean Water Act, in 1998 the State Water Board included Reaches 3 and 4 on the 303(d) list as impaired by pumping and diversion. Not only are these listings valid under the Clean Water Act, they are in line with relevant U.S. EPA Guidance.

[1] Available at: http://www.epa.gov/owow/tmdl/2006IRG/report/2006irg-report.pdf, last visited February 5, 2015.

B. A Formal Listing Policy or Guidance Are Not Prerequisites to an Impairment Listing.

As its reason for the likely proposal to delist Reaches 3 and 4 as flow-impaired, the State Water Board cites the timing of those listing decisions, which came before the adoption of the State Water Board's Listing Policy and "before guidance was developed on the method to inventory waters impaired by pollution, and not pollutants." The State Water Board's stated reason does not support delisting, however. A formal listing policy or guidance are not prerequisites to an impairment listing.

As discussed in Section II.A. above, the Clean Water Act requires that the State Water Board include all impaired water segments on the 303(d) list. The requirement to identify impaired waters on the 303(d) list is not conditioned on the existence of a *formal* listing policy. In fact, the State Water Board has issued multiple California 303(d) lists prior to the adoption of the Listing Policy. For example, in 1998 and 2003 the State Water Board issued 303(d) lists that identified numerous impaired water segments, including the pumping and diversion impairments of Reaches 3 and 4 of the Ventura River, without a formal listing policy. Because a formal listing policy had not been adopted, the State Water Board made listing determinations based on an assessment of all readily available data and facts relating to individual water bodies. *See, e.g.*, Staff Report, Vol. I, Revision of The Clean Water Act Section 303(d) List of Water Quality Limited Segments. U.S. EPA approved each of these 303(d) lists. As such, the State Water Board need not have had a formal listing policy in place to make these valid listing decisions. Channelkeeper further notes that the 2012 Integrated Report does not indicate that water segments other than the segments of the Ventura River and Ballona Creek identified as flow-impaired in 1998 and/or 2003 lists will likely be delisted on the ground that those listings were made prior to adoption of the Listing Policy.

The State Water Board also bases its likely proposal to delist Reaches 3 and 4 on its statement that those listings were made "before guidance was developed on the method to inventory waters impaired by pollution, and not pollutants." Channelkeeper understands the State Water Board to be referring to the U.S. EPA 2006 Guidance. *See* 2012 Integrated Report, pp. 9-10. As with the Listing Policy, formal guidance from U.S. EPA is not a prerequisite to impairment listings and listings issued and approved predating the 2006 Guidance are entirely valid. The State Water Board refers to no authority otherwise. In any event, as explained in Section I.A., U.S. EPA's 2006 Guidance, including the portion cited in the 2012 Integrated Report, supports the listing of Reaches 3 and 4 as flow-impaired due to pumping and diversion. *See* 2012 Integrated Report, p. 10 (explaining that water segments impaired solely by pollution should be included in category 4c of the 303(d) list, and in no way suggesting such waters not be identified as impaired on the 303(d) list).

C. Reaches 3 and 4 of the Ventura River Meet Multiple Listing Policy Factors.

Whether or not a listing policy is some how required for compliance with section 303(d) of the Clean Water Act, the pumping and diversions listings of Reaches 3 and 4 of the Ventura River meet the listing policy factors. The Listing Policy provides several different factors to use to determine whether a water segment should be identified as impaired on the 303(d) list. A water segment that meets any one of the listing factors should be included on the 303(d) list. As discussed below, Reaches 3 and 4 meet Listing Policy factors 3.2 (Numeric Water Quality Objectives for Conventional or Other Pollutants in Water), 3.9 (Degradation of Biological Populations and Communities), and 3.11 (Situation-Specific Weight of Evidence Listing Factor).

1. Reaches 3 and 4 are Impaired for Pumping and Diversions Based on the "Numeric Water Quality Objectives for Conventional or Other Pollutants in Water" Listing Factor.

Section 3.2 of the Listing Policy states that "using a binomial distribution, waters shall be placed on the 303(d) list if the number of measured exceedances supports rejection of the null hypothesis," as provided in Table 3.2 of the Listing Policy. Listing Policy, p. 4. "When continuous monitoring data are available, the seven-day average of daily minimum measurements shall be assessed." *Id*. As explained below, monitoring data for dissolved oxygen and temperature demonstrate that Reaches 3 and 4 meet the listing factor for exceedances of numeric water quality objectives or criteria. Because dissolved oxygen and temperature are parameters indicative of reduced flows, and given the connection between pumping and diversions and reduced surface flows, this listing factor supports the pumping and diversions impairment listings for Reaches 3 and 4.

<u>Dissolved Oxygen</u>

Channelkeeper deployed Onset dissolved oxygen sensors (model U26) and pressure transducers (model U20) at the Channelkeeper monitoring stations listed above from May-November in 2013 and May-October in 2014. Sensors were calibrated to collect measurements every ten minutes, 24 –hours a day, during the 2013 dry season and every 30 minutes, 24-hours a day during the 2014 dry season.

The Basin Plan states:

The dissolved oxygen content of all surface waters designated as WARM shall not be depressed below 5 mg/L as a result of waste discharges.

The dissolved oxygen content of all surface waters designated as COLD shall not be depressed below 6 mg/L as a result of waste discharges.

The dissolved oxygen content of all surface waters designated as both COLD and SPWN shall not be depressed below 7 mg/L as a result of waste discharges.

Tables 2 and Table 3 below evaluate the 2013-2014 dissolved oxygen data using this method based on the 7 mg/L and 5 mg/L dissolved oxygen water quality objectives ("WQO") set forth in the Basin Plan designated to protect Cold Water and Spawning Habitats and Warm Water Habitat beneficial uses, respectively. Based on the Listing Policy, Reach 3 and Reach 4 meet the 303(d) listing criteria for the 7 mg/L dissolved oxygen WQO to protect Cold Water and

Spawning Habitats. Reach 3 meets the listing criteria for the 5 mg/L WQO to protect Warm Water Habitat.

Table 2: Measurements Below the 7 mg/L Dissolved Oxygen Water Quality Objective

7 Day Average of Minimum DO Measurements					
Site	**Year**	**Total n**	**n <7 mg/L**	**Min n for listing**	**Meets Listing Criteria?**

	2014	68	2		
	Grand Total	174	2	29	**No**

<u>Temperature</u>

The 2010 Integrated Report (CWA Section 303(d) list) includes listings of temperature water quality impairments for water bodies in Region 3, citing an evaluation guideline of 21°C maximum temperature to protect rainbow trout. This evaluation guideline was applied to Channelkeeper sensor data from 2013 and 2014. Daily maximums were used to evaluate measurements based on a binomial distribution as applied in Section 3.2 and Table 3.2 of the Listing Policy where minimum number of samples needed for listing was calculated based on the total number of seven day averages of the daily minimum dissolved oxygen concentration. Application of this evaluation method indicates that Reach 3 and Reach 4 for meet these 303(d) listing evaluation criteria.

Table 4: Measurements Above the 21° Temperature 303(d) Listing Evaluation Criteria

Daily Maximum Temperature Measurements					
Site	**Year**	**Total n**	**n > 21° *C***	**Min n for listing**	**Meets Listing Criteria?**

	2014	126	113		
	Grand Total	250	227	42	**Yes**

2. **Reaches 3 and 4 are Impaired for Pumping and Diversions Based on the "Degradation of Biological Populations and Communities" Listing Factor.**

Section 3.9 of the Listing Policy states that "[a] water segment shall be placed on the section 303(d) list if the water segment exhibits significant degradation in biological populations and/or communities as compared to reference site(s) and is associated with water or sediment concentrations of pollutants including but not limited to chemical concentrations, temperature, dissolved oxygen, and trash." Listing Policy, p. 7. Given the biological populations and communities of steelhead in Reaches 3 and 4 of the Ventura River, this listing factor is met.

Specifically, the Ventura River watershed is home to at least 11 endangered or threatened species, including steelhead trout. *See* U.S. Fish & Wildlife Service, Listing and Occurrence for California.[2] Reaches 3 and 4 of the Ventura River are occupied by steelhead and are rated as

---

http://ecos.fws.gov/tess_public/pub/stateListingAndOccurrenceIndividual.jsp?state=CA&s8fid=112761032792&s8fid=112762573902, and http://www.dfg.ca.gov/biogeodata/cnddb/pdfs/TEAnimals.pdf, last visited February 5, 2015.

having high conservation value. *See* Draft Biological Opinion, pp. 355-56; *see also* Section I., above. These reaches of the River provide spawning and rearing habitat and serve as a migratory corridor for steelhead to upstream reaches. Draft Biological Opinion, pp. 356-57. The Ventura River (including Reaches 3 and 4), Ventura River Estuary, San Antonio Creek, Cañada Larga, Matilija Creek and North Fork Matilija Creek, among other tributaries, have been designated as critical habitat for the remaining population of the southern California Steelhead, which is estimated at less than 500 spawning adults. *See* EPA Draft TMDL, p. 104; Draft Biological Opinion, p. 354.

Before dams were constructed in the Ventura River Watershed, during normal to wet years the steelhead run was estimated at 4,000-5,000 individuals. EPA Draft TMDL, p. 100. Following the construction of Matilija Dam (located upstream of Reach 3), which cut off access to about half of the prime spawning habitat, and coincident with a drought in the late 1940s, steelhead runs dropped to about 2,000-2,500 individuals. EPA Draft TMDL, p. 101. By the 1990s there had been a 96% decline in the steelhead population in the Ventura River, prompting its listing as an endangered species in 1997. Draft Biological Opinion, p. 352; *see also* Steelhead Recovery Plan, p. 437 (describing declines in steelhead run sizes of 90% or more).

During dry years, juvenile fish unable to transit back downstream to the ocean due to low flows must survive in pools in the mainstem, i.e., Reaches 3 and 4. EPA Draft TMDL, p. 101. The fish are subjected to elevated temperatures, endure competition with other fish for a decreasing food supply, and are exposed to predators. EPA Draft TMDL, p. 101. Additional evidence of elevated temperatures is shown in Section II.C.1., above.

Since southern California steelhead were listed as endangered in 1997, the impacts leading to the listing remain prevalent and widespread. Steelhead Recovery Plan, p. 447. These impacts include present or threatened destruction, modification or curtailment of habitat or range, over-utilization of the steelhead population for commercial, recreational, scientific, or educational purposes, disease and predation, inadequacy of existing regulatory mechanisms, and other natural or human-made factors affecting continued existence. *Id*. at 448-453. As to the steelhead population in the Ventura River, NMFS found that diversions from the Ventura River at Foster Park contribute to the present or threatened destruction, modification or curtailment of steelhead habitat or range and disease and predation of steelhead. *See id.*, p. 514. The inadequacy of existing regulatory mechanisms for diversions at Foster Park contributed to the listing and continuing impacts to endangered steelhead. *See id.*, p. 514.

3. Reaches 3 and 4 are Impaired for Pumping and Diversions Based on the "Situation-Specific Weight of Evidence" Listing Factor.

The situation-specific weight of evidence listing factor provides that when information indicates non-attainment of applicable water quality standards that water segment is to be evaluated to determine whether the situation-specific weight of the evidence demonstrates that the water quality standard is not attained. *See* Listing Policy, Section 3.11, p. 8. A situation-specific weight of evidence impairment determination is to be justified by: (1) data or information including current conditions supporting the decision, (2) description of how that data or information affords a substantial basis in fact from which the impairment decision can be reasonably inferred, (3) demonstration that the weight of the evidence of the data and information indicate that the water quality standard is not attained, and (4) demonstration that the approach used is scientifically defensible and reproducible. *See id*.

Reaches 3 and 4 each meet the situation-specific weight of evidence listing factor. Current conditions show that Reaches 3 and 4 are impaired for flow, and that the impairment is caused by pumping and diversions. *See* Section I., above; *see also* Attachments A and B. The available information and data supporting impairment listing is scientifically defensible and reproducible. Further, in approving the State Water Board's TMDL for the Ventura River, U.S. EPA recognized need for further action to address flow impairment.

D. Reaches 3 and 4 of the Ventura River Must Remain 303(d) Listed as Impaired for Flow Caused by Pumping and Diversions.

If the Listing Policy applies, then it applies equally for listing and *delisting*. *See* Listing Policy, Section 4, pp. 11-13. In addition to satisfying the delisting factors, which it cannot, to remove Reaches 3 and 4 from the 303(d) list the responsible Regional Water Quality Control Board (here Region 4) must document the list change in a fact sheet and hold a public hearing to approve the change, respond in writing to all public comments, approve a resolution in support of the decision, and submit supporting fact sheets, responses to comments, documentation of the hearing process, and a copy of all data and information considered to the State Water Board. The State Water Board must also assemble supporting fact sheets and provide advance notice and opportunity for public comment on the listing decision. *See* Listing Policy, Section 6.3, p. 26. The 2012 Integrated Report makes no reference to the delisting factor, and Channelkeeper is unaware of any efforts by Region 4 or the State Water Board to comply with these delisting requirements.

Accordingly, unless the delisting factors and additional requirements are met, Reaches 3 and 4 must remain listed as flow-impaired due to pumping and diversions.

Because the existing pumping and diversion impairment listings for Reaches 3 and 4 are entirely consistent with the Clean Water Act, U.S. EPA Guidance, and the State Water Board's Listing Policy, that the impairments were identified on California's 303(d) list before the State Water Board adopted the Listing Policy or U.S. EPA adopted the 2006 Guidance in no way invalidates those listings.

III. The State Board Must Consider All Readily Available Information About Impairments to Reaches 3 and 4 Resulting from Pumping and Diversions Prior to Making a Listing Decision.

The body of regulations and guidance that bear on 303(d) listings are unambiguous about the information that should be considered in making listing decisions: *all of it*. Federal regulations state clearly that "[e]ach State shall assemble and evaluate all existing and readily available water quality-related data and information to develop the [303(d)] list." 40 C.F.R. § 130.7(b)(5). The regulations further mandate that local, state and federal agencies, members of the public, and academic institutions "should be *actively* solicited for research they may be conducting or reporting." 40 C.F.R. § 130.7(b)(5)(iii) (emphasis added). Furthermore, U.S. EPA's 2006 Guidance explicitly states that U.S. EPA's review of California's list will include an "assess[ment of] whether the state conducted an adequate review of all existing and readily available water quality-related information." 2006 Guidance, p. 29. To that end, the 2006 Guidance also requires states to provide "[r]ationales for any decision to not use any existing and readily available data and information." *Id.*, p. 18. Accordingly, any and all existing and readily available data and information must be considered to determine the health of the state's increasingly-degraded water bodies.

To provide the State Water Board with available data and information about the impairments to Reaches 3 and 4 of the Ventura River resulting from pumping and diversions described in Section I., Channelkeeper attaches hereto a draft Line of Evidence as Exhibit A. The Line of Evidence summarizes the existing flow-impairment to Reaches 3 and 4, relies on scientifically defensible and reproducible data and information,[3] and includes analysis of that data and information supporting the decision to identify Reaches 3 and 4 as flow-impaired on California's 303(d) list.

IV. Conclusion.

When Reaches 3 and 4 of the Ventura River were identified as flow-impaired by pumping and diversions on California's 1998 303(d) list, the State Water Board took an important first step towards restoring the chemical, physical, and biological integrity of these waters. However, there is ongoing documentation that flow alterations from pumping and diversions continue to degrade Reaches 3 and 4 such that these waters cannot support their designated beneficial uses and water quality standards are not attained.

Removing the impairment listings for Reaches 3 and 4 as the State Water Board says it will likely propose may impede existing and future efforts to remedy the ongoing flow-impairments of Reaches 3 and 4. Thus Channelkeeper strongly urges the State Water Board to comply with its Clean Water Act duty to continue to identify Reaches 3 and 4 on the 303(d) list as flow-impaired by pumping and diversions.

Respectfully,

[3] Data collected by Channelkeeper followed quality assurance protocols for continuous monitoring and flow measurements. *See* Attachment C. Additional data and findings referenced were produced by and for government agencies including the California Department of Fish and Game, the National Marine Fisheries Service, the City of Ventura, Ventura County, the United States Geologic Survey, the Los Angeles Regional Water Quality Control Board, the State Water Resources Control Board, and the United States Environmental Protection Agency.

Ventura River Reaches 3 and 4 Listing Line of Evidence

Pollution: Pumping and Diversions

Beneficial Uses Being Impaired: Cold Freshwater Habitat; Warm Freshwater Habitat; Rare, Threatened, or Endangered Species; Migration of Aquatic Organisms; Spawning, Reproduction, and/or Early Development; Contact and Non-Contact Water Recreation

Conclusion: Available data demonstrates that pumping and diversions are impairing the beneficial uses of Reaches 3 and 4 of the Ventura River, and that conditions in Reaches 3 and 4 meet Water Quality Control Policy for Developing California's Clean Water Act Section 303(d) List (September 2004) listing factors 3.1, 3.9, and 3.11.

Summary of Evidence: In 1998, the United States Environmental Protection Agency (EPA) approved California's list of impaired water bodies identified pursuant to section 303(d) (303(d) list) of the Federal Water Pollution Control Act (Clean Water Act), 33 U.S.C. § 1313(d), which first listed Reaches 3 and 4 of the Ventura River as impaired for pumping and diversion. The original listing referenced findings in a 1996 Steelhead Restoration and Management Plan for California as one basis for the listing decision. Over the last several decades, additional Lines of Evidence (LOE) have been produced, which verify and support the listing decision.

The hydraulic communication between surface and groundwater in the Ventura River and the contribution of groundwater pumping to dewatering of the river has been acknowledged by experts and government agencies for several decades. These relationships were clearly evaluated and established in numerous studies and reports including: (1) a Draft Environmental Impact Report on the Conjunctive Use Agreement between Casitas Municipal Water District and the City of Ventura (EDAW, Inc. et al. 1978); (2) a National Marine Fisheries Service (NMFS) 2007 Draft Biological Opinion (Draft Biological Opinion) for the Army Corps of Engineers' permitting of the City of Ventura's proposed Foster Park Well Facility repairs; (3) a Ventura River Natural Conditions Study (TetraTech, 2009); (4) the United States Environmental Protection Agency, Region 9, Draft Ventura River Reaches 3 and 4 Total Maximum Daily Loads For Pumping & Water Diversion-Related Water Quality Impairments (EPA Draft TMDL); and (5) the City of Ventura's Preliminary Hydrogeological and Surface Water/Groundwater Interaction Study (Hopkins, 2013).

Linkages have also been established between reduced surface flows caused by pumping and diverting and impairment of designated and potential beneficial uses of the River. The Draft Biological Opinion concluded that summer and fall withdrawals from Foster Park are, "likely to destroy or adversely modify critical habitat" through dewatering, reduction of water depth, and subsequent degradation of water quality (pp. 27, 33). Hopkins, 2013 concludes that pumping at Foster Park results in degradation of downstream critical habitat and water quality (p. 26). The EPA Draft TMDL found that low and intermittent flows result in, "failure to attain several beneficial uses" (p.11). During dry years, juvenile fish unable to transit back downstream to the ocean due to low flows must survive in pools in the mainstem, i.e., Reaches 3 and 4 (EPA Draft TMDL, p.

101). These oversummering fish are subjected to elevated temperatures, endure competition with other fish for a decreasing food supply, and are exposed to predators (EPA Draft TMDL, p.101).

Continuous dissolved oxygen and temperature monitoring conducted by Santa Barbara Channelkeeper through the 2013 and 2014 dry seasons confirms Reaches 3 and 4 consistently fail to meet Water Quality Objectives established in the Basin Plan to protect beneficial uses and/or criteria used in prior 303(d) listings (see Tables 1, 2, and 3 below).

To avoid jeopardizing steelhead existence and destruction or adverse modification of critical steelhead habitat, flow thresholds measured at the USGS Foster Park Gage were established by Hopkins (p. 28) and the National Marine Fisheries Service in the Draft Biological Opinion (p. 33). A comparison of Foster Park Well Field production totals with flow measurements at the USGS Foster Park Gage (Attachments A and B) clearly illustrates that pumping and diversion activities continued despite surface flows in Reaches 3 and 4 consistently falling below recommended flow thresholds. Flow monitoring in Reaches 3 and 4 conducted by Santa Barbara Channelkeeper in 2013 and 2014 further demonstrates that flows consistently fell below recommended protective thresholds through the dry seasons (see Table 4 below).

Finally, degradation of biological populations and communities has occurred and has been documented for southern California steelhead trout. By the 1990s there had been a 96% decline in the steelhead population in the Ventura River observed, prompting its listing as an endangered species in 1997 (Draft Biological Opinion, p. 352; *see also* National Marine Fisheries Service 2012 Southern California Steelhead Recovery Plan, p. 437) (Steelhead Recovery Plan) (describing declines in steelhead run sizes of 90% or more). The Steelhead Recovery Plan describes dams, surface water diversions, and groundwater extraction (including at Foster Park) as contributing to the present or threatened destruction, modification or curtailment of steelhead habitat or range and disease and predation of steelhead and as a "very high threat" to steelhead recovery in the Ventura River (p. 514).

Attachment C

LOGGERS
Continuous monitoring data are collected using Onset dissolved oxygen loggers (model U26). Specifications are found in Figure 1. All calibrations and uses are in accordance with Onset manual directives.[1]

Figure: 1 Dissolved Oxygen U26 Logger Specifications

Specifications

Dissolved Oxygen	
Sensor Type	Optical (dynamic luminescence quenching)
Measurement Range	0 to 30 mg/L
Calibrated Range	0 to 20 mg/L; 0 to 35°C (32 to 95°F)
Accuracy	0.2 mg/L up to 8 mg/L; 0.5 mg/L from 8 to 20 mg/L
Resolution	0.02 mg/L
Response Time	To 90% in less than 2 minutes
DO Sensor Cap Life	6 months (cap expires 7 months after initialization)

Temperature	
Temperature Measurement/ Operating Range	-5 to 40°C (23 to 104°F), non-freezing
Temperature Accuracy	0.2°C (0.36°F)
Temperature Resolution	0.02°C (0.04°F)
Response Time	To 90% in less than 30 minutes

Pre-deployment calibrations are performed for DO loggers using the "Lab Calibration Tool" and 100% saturation method as outlined on page 3 and 4 of the Onset U26 logger manual. Loggers will be deployed during the dry season, approximately May through October to minimize loss of instrument due to high flows.

Copper tape is applied to dissolved oxygen loggers to limit fouling. Additionally, zip ties are used to secure all loggers inside PVC piping with holes drilled at approximate 1" intervals to maintain water flow and limit fouling. The loggers and housing are mounted to the side of a 10-15 pound river rock using steel all-thread and epoxy. Rocks are carefully placed in the thalweg of the river (in flowing water) to collect representative measurements.

Data will be collected from the loggers approximately every 2-3 weeks. SBCK staff will collect dissolved oxygen calibration measurements upon arriving at each site using a Hach HQ3d portable meter, and ensuring that the meter probe is as close as possible to the dissolved oxygen logger sensor. Calibration measurements will be recorded at each site at a precise continuous sensor sampling interval (for comparison), in accordance with Ventura River Stream Team QAQC protocols with the time of calibration noted. After the field calibration is complete, the loggers will be removed from the rock. Data data will be uploaded to an Onset Hobo waterproof shuttle the dissolved oxygen coupler following procedures outlined in the shuttle manual.[2] Specifications for the shuttle are shown in Figure 2.

[1] Onset Dissolved Oxygen Logger Manual. http://www.onsetcomp.com/files/manual_pdfs/15603-E-MAN-U26x.pdf.

Figure 2: Waterproof Shuttle Specifications

Specifications

Compatibility	All HOBO U-Series loggers with optic USB. Not compatible with the HOBO U-Shuttle (U-DT-1).
Data Capacity	63 logger readouts of up to 64K each
Operating Temperature	0° to 50°C (32° to 122°F)
Storage Temperature	-20° to 50°C (-4° to 122°F)
Wetted Materials	Polycarbonate case, EPDM o-rings and retaining loop
Waterproof	To 20 m (66 feet)
Time Accuracy	±1 minute per month at 25°C (77°F); see Plot A
Logger-to-Shuttle Transfer Speed	Reads out one full 64K logger in about 30 seconds
Shuttle-to-Host Transfer Speed	Full shuttle offload (4 MB) to host computer in 10 to 20 minutes, depending on computer
Batteries	2 AA alkaline batteries required for remote operation
Battery Life	One year or at least 50 complete memory fills, typical use
Weight	150 g (4 oz)
Dimensions	15.2 x 4.8 cm (6.0 x 1.9 inches)

After data is transferred to the shuttle any fouling that has accumulated will be removed from the logger and logger housing using hands, water, and/or a toothbrush. Loggers will then be reattached to the PVC housing using zip ties and re-mounted on the rock in the flowing water. Upstream and downstream photos, as well as flow measurements (discussed below) will also be taken at each site.

After data from each site has been transferred to the shuttle, data will be transferred to an SBCK computer using Onset's Hoboware software. Recorded field calibration measurements for dissolved oxygen will be applied to the Hoboware Dissolved Oxygen Assistant for post-processing and calibration purposes. Data will be exported from Hoboware to Microsoft Excel for analysis.

[2] Onset Waterproof Shuttle Manual. http://www.onsetcomp.com/files/manual_pdfs/10264-I-MAN-U-DTW-1.pdf.

FLOW

Flow measurements will be taken by SBCK staff during each logger maintenance trip (approximately every 2-3 weeks) using a Glow Water flow meter. Specifications are shown in Figure 3.

Figure 3: Global Water Flow Meter Specifications

Flow Probe Specifications

Range: 0.3-19.9 FPS (0.1-6.1 MPS)
Accuracy: 0.1 FPS
Averaging: True digital running average. Updated once per second.
Display: LCD, Glare and UV Protected
Control: 4 button
Datalogger: 30 sets, MIN, MAX, and AVG
Features: Timer, Low battery warning
Sensor Type: Protected Turbo-Prop propeller with magnetic pickup.
Weight:
  Instrument: 2 lbs. (0.9 kg) (FP111), 3 lbs. (1.4 kg) (FP211), 2.8 lbs. (1.3 kg) (FP311)
  Shipping: 13 lbs. (5.9 kg) (FP111), 23 lbs. (10.4 kg) ((FP211), 19 lbs. (8.6 kg) ((FP311)
Expandable Length: 3.7 to 6 ft (1.1 to 1.8 m) (FP111); 5.5 to 15 ft (1.7 to 4.6 m) (FP211); 2.5 to 5.5 ft (0.76 to 1.7 m) (FP311)
Materials:
  Probe: PVC and anodized aluminum with stainless steel water bearing
  Computer: ABS/Polycarbonate housing with polyester overlay
Power: Internal Lithium Battery, Approx 5 year life with typical use, Non-Replaceable
Auto Shutoff: After 5 minutes of inactivity
Operating Temperature: -4° to 158° F (-20° to 70° C)
Storage Temperature: -22° to 176° F (-30° to 80° C)
Carrying Case: The Flow Probe is shipped in a padded carrying case.
Approvals: CE

Total width from bank to bank of the flowing water is recorded. Depth and velocity is then recorded at several (minimum of 3) equally-spaced intervals along the width. All measurements will be taken in accordance with procedures outlined in the Global Water flow meter manual.[3] Total stream flow will be calculated by adding the volume of water from each equal segment.

RE: **Comment Letter – Revisions to the Los Angeles Region 303(d) List**

We thank you for this opportunity to comment on the proposed changes to the 303(d) list prior to the upcoming public hearing on May 4, 2017. Representatives from the Lake Sherwood Joint Lake Advisory Committee plan to attend this meeting to discuss these important issues.

We appreciate the proposed removal of the two pollutants, Ammonia and Organic Enrichment/Low Dissolved Oxygen. This is gratifying and recognizes the positive results produced by the time, effort and expense the Association has put forth over many years to mitigate these concerns. Respectfully, however, we are troubled to see that Algae and Eutrophic remain on the list.

To help understand why these are still considered pollutants in Lake Sherwood, we reviewed the Los Angeles Water Board's website of the Draft 2016 303(d) List, and specifically Appendix G – Fact Sheets of the Draft. Here we see that the listing of Algae and Eutrophic are noted as "placeholders" to support decisions made prior to the 2006 Clean Water Act, and further that no evidentiary data samples were collected which could be used to assess these pollutants relative to the 2006 standards. Clearly there are zero measured exceedances of these standards at this point yet they remain on the list. It seems to us somewhat arbitrary to continue to consider these as "pollutants" in Lake Sherwood especially where there is a consistently good dissolved oxygen level, a continuous effort to remove excess plant growth via a special harvester with a full time crew, monthly monitoring of water chemistry, and special attention to and approved treatment of any algae that occurs as needed throughout the year. If sufficient justification does exist to continue to include these on the 303(d) list, we would appreciate having the reasons and rational detailed to us in writing so we may take any necessary actions to remove them in the future.

We are looking forward to the upcoming meeting. Thank you again for the opportunity to respond to the proposed changes.

Sincerely,

Annette Louder, CMCA, AMS, PCAM

CALLEGUAS CREEK

Watershed Management Plan

A COOPERATIVE STRATEGY FOR
RESOURCE MANAGEMENT & PROTECTION

March 30, 2017

Electronic Submission: losangeles@waterboards.ca.gov

California Regional Water Quality Control Board
Los Angeles Region
ATTN: Jun Zhu
320 W 4th Street, Suite 200
Los Angeles, CA 90013

Subject: Comment Letter – Revisions to the Los Angeles Region 303(d) List

Dear Dr. Zhu,

The Stakeholders Implementing Total Maximum Daily Loads (TMDLs) in the Calleguas Creek Watershed (Stakeholders) appreciate the opportunity to provide comments on the proposed revisions to the Clean Water Act Section 303(d) List of impaired waterbodies in the Los Angeles Region [hereinafter referred to as 303(d) List] which was distributed for public review on February 8, 2017.

The development and implementation of TMDLs is a significant investment of resources and it is critical that the 303(d) List be based on sound science and methodologies. The Stakeholders understand that the Los Angeles Regional Water Board (Water Board) is proposing over 200 new waterbody-pollutant segment combination 303(d) listings, of which 95 changes fall within the Calleguas Creek Watershed (CCW). The Stakeholders have developed and implemented six effective TMDLs in the CCW and thus have extensive experience in the area. The Stakeholders have serious concerns with the Region's Proposed 303(d) List and feel that it requires significant review and modification before adoption. The Stakeholders request that the issues identified in this letter be addressed and the proposed 303(d) List be released for another 60-day comment period prior to adoption. Several of the issues identified herein have resulted in the inability of the proposed 303(d) List to be fully vetted and reviewed by the Stakeholders.

The requested modifications fall into four general categories:

1. New Category 5 listings that should not be listed due to incorrect thresholds being applied for the beneficial use and incorrect interpretation of the data (e.g., mismatched units, incorrectly assigned sample locations)
2. Potential delistings that may exist if all watershed data were evaluated (e.g., TMDL monitoring program and all wastewater treatment plant NPDES monitoring).
3. New Category 5A listings that should be categorized as Category 5B because TMDLs already exist to address the pollutants.
4. Errors in the listing information that make it difficult to fully evaluate the listings. Examples include inconsistencies between the Category 5 list (Appendix B) and the Proposed updates to the 303(d) List (Appendix A), incorrect HUC/Calwater designations, incorrect beneficial uses listed for the applicable water quality objectives, and inconsistent use of thresholds for interpreting narrative objectives.

The remaining sections of this letter provide the detailed list of requested changes to the 303(d) List and the rationale for the requests. In summary, the Stakeholders request that all waterbody-pollutant combinations in **Table 1** not be listed on the 303(d) List, the waterbody-pollutant combinations in **Table 3** be considered for delisting through analysis of all available watershed data, waterbody-pollutant combinations in **Table 4** and **Table 5** be designated as being addressed by a TMDL if they remain on the 303(d) List after the reassessment, and the errors and inconsistencies identified in Comment IV be addressed for all waterbodies.

I. REQUESTED MODIFICATIONS TO THE LISTING STATUS

Based on a review of the proposed Category 5 waterbody-pollutant combinations, the Stakeholders have identified a number of waterbodies that we feel should either be delisted based on available data or proposed listings that should not be listed based on errors in the evaluation. The requested modifications are shown in **Table 1**, below, with a summary of the justifications for the requested change. A detailed discussion of each of the justifications follows the table.

Table 1. Waterbody-pollutant combinations that should not be listed

Waterbody segment	Pollutant	Justification
Calleguas Creek Reach 2 (estuary to Potrero Rd)	DDD	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.

Table 1. Waterbody-pollutant combinations that should not be listed

Waterbody segment	Pollutant	Justification
Calleguas Creek Reach 2 (estuary to Potrero Rd)	DDE	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.
Calleguas Creek Reach 2 (estuary to Potrero Rd)	Dimethoate	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.
Calleguas Creek Reach 2 (estuary to Potrero Rd)	Nitrogen, Nitrate	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.
Calleguas Creek Reach 2 (estuary to Potrero Rd)	Specific Conductivity	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.
Calleguas Creek Reach 2 (estuary to Potrero Rd)	Total Dissolved Solids	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.
Calleguas Creek Reach 3 (Potrero Road upstream to Conejo Creek confluence)	Mercury	• Data and objectives have different units (ng/L vs. µg/L); data do not exceed objectives.
Calleguas Creek Reach 4 (was Revolon Slough Main Branch)	Ammonia	• Data from agricultural drain rather than waterbody used as basis for listing decision. • TMDL data demonstrates delisting possible.
Calleguas Creek Reach 4 (was Revolon Slough Main Branch)	Bifenthrin	• Data from agricultural drain rather than waterbody used as basis for listing decision.
Calleguas Creek Reach 4 (was Revolon Slough Main Branch)	Chloride	• Data from agricultural drain rather than waterbody used as basis for listing decision.
Calleguas Creek Reach 4 (was Revolon Slough Main Branch)	Cyfluthrin	• Data from agricultural drain rather than waterbody used as basis for listing decision.
Calleguas Creek Reach 4 (was Revolon Slough Main Branch)	Cypermethrin	• Data from agricultural drain rather than waterbody used as basis for listing decision.
Calleguas Creek Reach 4 (was Revolon Slough Main Branch)	Malathion	• Data from agricultural drain rather than waterbody used as basis for listing decision.
Calleguas Creek Reach 4 (was Revolon Slough Main Branch)	Mercury	• Data and objectives have different units (ng/L vs. µg/L); data do not exceed objectives.

Table 1. Waterbody-pollutant combinations that should not be listed		
Waterbody segment	**Pollutant**	**Justification**
Calleguas Creek Reach 4 (was Revolon Slough Main Branch)	Nitrogen, Nitrate	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.
Calleguas Creek Reach 4 (was Revolon Slough Main Branch)	Permethrin	• Data from agricultural drain rather than waterbody used as basis for listing decision. • This pollutant is already covered by the Calleguas Toxicity TMDL.
Calleguas Creek Reach 4 (was Revolon Slough Main Branch)	Specific Conductivity	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.
Calleguas Creek Reach 4 (was Revolon Slough Main Branch)	Sulfates	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.
Calleguas Creek Reach 4 (was Revolon Slough Main Branch)	Total Dissolved Solids	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.
Calleguas Creek Reach 12 (was Conejo Creek/Arroyo Conejo North Fork)	Chlorpyrifos	• Data does not appear to be from a station in Reach 12.
Calleguas Creek Reach 12 (was Conejo Creek/Arroyo Conejo North Fork)	Diazinon	• Data does not appear to be from a station in Reach 12.
Calleguas Creek Reach 12 (was Conejo Creek/Arroyo Conejo North Fork)	Malathion	• Data does not appear to be from a station in Reach 12.
Calleguas Creek Reach 12 (was Conejo Creek/Arroyo Conejo North Fork)	Temperature, water	• Inappropriately applied beneficial use criteria (see temperature comment below).
Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2	Sulfate	• Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody. *
Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2	Specific Conductivity	• Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.*

Table 1. Waterbody-pollutant combinations that should not be listed

Waterbody segment	Pollutant	Justification
Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2	Total Dissolved Solids	• Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.*
Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No. 2	Toxaphene	• J-flagged data incorrectly used in assessment.
Rio De Santa Clara/Oxnard Drain No. 3	Nitrogen, Nitrate	• Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.*
Rio De Santa Clara/Oxnard Drain No. 3	Sulfate	• Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.*
Rio De Santa Clara/Oxnard Drain No. 3	Specific Conductivity	• Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.*
Rio De Santa Clara/Oxnard Drain No. 3	Total Dissolved Solids	• Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.*
Rio De Santa Clara/Oxnard Drain No. 3	Toxicity	• Insufficient exceedances to warrant listing.
La Vista Drain (Ventura County)	Chlordane	• Data from agricultural drain rather than waterbody used as basis for listing decision. • J-flagged data incorrectly used in assessment.
La Vista Drain (Ventura County)	Chlorpyrifos	• Data from agricultural drain rather than waterbody used as basis for listing decision.
La Vista Drain (Ventura County)	Copper	• Data from agricultural drain rather than waterbody used as basis for listing decision.
La Vista Drain (Ventura County)	DDD	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.

Table 1. Waterbody-pollutant combinations that should not be listed

Waterbody segment	Pollutant	Justification
La Vista Drain (Ventura County)	DDE	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.
La Vista Drain (Ventura County)	DDT	• Data from agricultural drain rather than waterbody used as basis for listing decision.
La Vista Drain (Ventura County)	Indicator Bacteria	• Data from agricultural drain rather than waterbody used as basis for listing decision.
La Vista Drain (Ventura County)	Mercury	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Data and objectives have different units (ng/L vs. µg/L); data do not exceed objectives.
Santa Clara Drain	Chlordane	• Data from agricultural drain rather than waterbody used as basis for listing decision.
Santa Clara Drain	Chlorpyrifos	• Data from agricultural drain rather than waterbody used as basis for listing decision.
Santa Clara Drain	Cypermethrin	• Data from agricultural drain rather than waterbody used as basis for listing decision.
Santa Clara Drain	DDD	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using COMM criteria; public access is prohibited by chain link fencing and locked gates.
Santa Clara Drain	DDE	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using COMM criteria; public access is prohibited by chain link fencing and locked gates.
Santa Clara Drain	DDT	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using COMM criteria; public access is prohibited with chain link fencing and locked gates.
Santa Clara Drain	Nitrogen, Nitrate	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.
Santa Clara Drain	Specific Conductivity	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.

Table 1. Waterbody-pollutant combinations that should not be listed		
Waterbody segment	**Pollutant**	**Justification**
Santa Clara Drain	Sulfates	• Data from agricultural drain rather than waterbody used as basis for listing decision.
Santa Clara Drain	Total Dissolved Solids	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.
Santa Clara Drain	Toxaphene	• Data from agricultural drain rather than waterbody used as basis for listing decision.
*Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2 and Rio De Santa Clara/Oxnard Drain No. 3 are not listed in the Basin Plan and therefore do not have assigned beneficial uses but they are tributaries to Mugu Lagoon which does not have a MUN beneficial use and are brackish waterbodies that would not support the MUN beneficial use.		

1. Agricultural Drain monitoring data incorrectly used as basis for listing decisions. There are multiple instances where listing decisions are based on data from the Ventura County Agricultural Irrigated Lands Group (VCAILG) which include monitoring data from agricultural drains. In several cases, data from agricultural drains that discharge to waterbody reaches were used to list the waterbody reach. The drains are not listed tributaries or waterbodies in the Basin Plan and are not located within the waterbody that is being listed. As a result, the data should not be used for the listing decisions for these waterbodies. Calleguas Creek Reach 2 and Reach 4 were listed using data from the VCAILG monitoring sites 02D_BROOM (Reach 2) and 04D_ETTG (Reach 4), which are the locations of agricultural drains which drain to Reach 2 and 4. These agricultural monitoring sites were selected to be representative of agricultural discharges to Calleguas Creek Reaches 2 and 4 and are not representative of receiving water conditions. Therefore, any data collected from these sites cannot be used to list the downstream Calleguas Creek Reaches. All listings should be evaluated to ensure that the monitoring locations were in receiving waters rather than agricultural drains.

In addition, La Vista Drain and Santa Clara Drain were listed as new waterbodies never before included in the previous 303(d) List even though data have been collected on both agricultural drains by the MS4 program since the early 1990s. These waterbodies are not designated in the Basin Plan or listed as a tributary in the Basin Plan appendices. The La Vista Drain is an agricultural drain designed to convey excess irrigation water from agricultural lands, and as such, it is predominantly an open ditch that flows alongside W. Los Angeles Avenue and then along Santa Clara Avenue where it becomes the Santa Clara Drain. Additionally, inclusion of the COMM beneficial use for the Santa Clara Drain is inappropriate, as public access is prohibited because of fencing and locked gates maintained by the Ventura County Watershed Protection District. Inclusion of the MAR and EST beneficial uses are also inappropriately applied to the Santa Clara Drain because the drain is located upstream of Highway 101 and is not tidally influenced. The monitoring location on each drain was selected to represent agricultural discharges for the Agricultural Waiver and was not designed to characterize receiving waters. Because these are agricultural drains and not tributaries, they should be removed from the Draft Category 5 list.

Requested Action:

- **Remove all listings shown in Table 1 that were based on Ag monitoring data from agricultural drains not representative of the listed waterbody and evaluate remaining listings to ensure no other listings are based on agricultural drain monitoring rather than receiving water monitoring.**
- **Remove the La Vista Drain and the Santa Clara Drain from the List as they are agricultural drains and not waterbodies that fall under the jurisdiction of the 303(d) List.**

2. Remove any pollutant listing based on municipal drinking water objectives where the MUN beneficial use does not apply.

Numerous listings were made using water quality objectives for the protection of the municipal drinking for waterbodies that do not have applicable municipal drinking water beneficial uses. Many of the waterbodies listed are brackish waterbodies for which no beneficial uses are designated or waterbodies designated for the municipal beneficial use with an asterisk (i.e., P*) in the Basin Plan. The asterisked MUN beneficial use should not be used to propose new 303(d) listings. Fact Sheets for previous 303(d) listing cycles have clearly noted that the asterisked MUN beneficial uses should not be used for 303(d) listing purposes.

State Board Resolution No. 88-63 (Sources of Drinking Water) and Regional Board Resolution 89-03 (Incorporation of Sources of Drinking Water Policy into the Water Quality Control Plans (Basin Plans)), state that "All surface and ground waters of the State are considered to be suitable, or potentially suitable, for municipal or domestic waters supply and should be so designated by Regional Boards… [with certain exceptions which must be adopted by the Regional Board]." The Regional Board adopted a Water Quality Control Plan for the Los Angeles Region (Basin Plan) on June 4, 1994, that included provisions to implement State Water Board Resolution 88-63. On May 26, 2000, the USEPA approved the revised Basin Plan except for the implementation plan for potential MUN-designated water bodies. On August 22, 2000, the City of Los Angeles, City of Burbank, City of Simi Valley, and the County Sanitation Districts of Los Angeles County challenged USEPA's water quality standards action in the U.S. District Court. On December 18, 2001, the court issued an order remanding the matter to USEPA to take further action on the 1994 Basin Plan consistent with the court's decision. On February 15, 2002, USEPA revised its decision and approved the 1994 Basin Plan in whole. In its February 15, 2002 letter, USEPA stated:

> *"EPA bases its approval on the court's finding that the Regional Board's identification of waters with an asterisk ("*") in conjunction with the implementation language at page 2-4 of the 1994 Basin Plan, was intended "to only conditionally designate and not finally designate as MUN those water bodies identified by an ("*') for the MUN use in Table 2-1 of the Basin Plan, without further action." Court Order*

at p. 4. Thus, the waters identified with an ("") in Table 2-1 do not have MUN as a designated use until such time as the State undertakes additional study and modifies its Basin Plan. Because this conditional use designation has no legal effect, it does not constitute a new water quality standard subject to EPA review under section 303(c)(3) of the Clean Water Act ("CWA"). 33 U.S.C. § 1313(c)(3)."*[1]

In addition to the above decision, the Basin Plan states that until the additional study is undertaken and the Basin Plan is modified "no new effluent limitations will be placed in Waste Discharge Requirements as a result of these designations". The Regional Board has also determined that water quality objectives applicable to the MUN beneficial use will not be used to assess impairments under the 303(d) listing programs. For constituents that only have objectives that are applicable to the MUN beneficial use, the decision Fact Sheets for the 303(d) listing process state that there are no applicable water quality objectives in waterbodies designated with an asterisk ("*"). In the 2010 listing cycle, a number of 303(d) listings were actually removed based on this determination. Below is an example of the language from a listing decision for Los Angeles River Reach 1:

"The listing for aluminum in this water body was originally based on data assessed using the MCL for aluminum. Since MUN is a "potential" beneficial use, it is not appropriate to use the MCL to evaluate aluminum data from this reach. Thus, there is no aluminum objective for this reach and the original listing is faulty."

Based on this evidence, it is clear that for waterbodies with a MUN designation that includes an asterisk ("*"), water quality objectives specific to the MUN beneficial use are not applicable. As such, water quality data collected in these receiving waters should not be compared to water quality objectives applicable to the MUN beneficial use.

The listings of total dissolved solids, sulfates, and conductivity are all based on secondary maximum contaminant levels applied to protect the MUN beneficial use. In addition, Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2 and Rio De Santa Clara/Oxnard Drain No. 3 are maintained as fresh/brackish water via tide gates on both drains and do not have designated MUN beneficial uses. Therefore, the listing of TDS, sulfate, and specific conductivity is inappropriate as naturally occurring levels of these three constituents in groundwater entering both drains within the footprint of Naval Base Ventura County far exceed the secondary MCLs upon which these listings are based. USEPA validated this reasoning in its "TMDLs for Pesticides, PCBs and Sediment Toxicity for Oxnard Drain 3",[2] where the MUN beneficial use was not considered to be "relevant to the impairments" addressed by the TMDL and so was not included in the TMDL. Additionally, Calleguas Creek Reach 2 and Reach 4 are considered brackish waterbodies according to the California Toxics Rule thresholds and

---

[1] Language adapted from the 2014 National Pollutant Discharge Elimination System permit findings for wastewater treatment plants in the Calleguas Creek Watershed.

[2] Total Maximum Daily Loads for Pesticides, PCBs, and Sediment Toxicity in Oxnard Drain 3. Approved by USEPA on October 6, 2011.

are designated with an asterisked MUN beneficial use. Due to the brackish nature of these waterbodies, other Basin Plan objectives for TDS and sulfate are not considered to be applicable to Reach 2 or Reach 4 below Laguna Road. For all of these reasons, these proposed listings summarized in **Table 1** should not be listed.

The proposed Calleguas Creek Reach 2 dimethoate listing was based on three lines of evidence which the Fact Sheet states all show no exceedances (this appears to be a typo). However, it appears that the only line of evidence that shows an exceedance is based on the potential (P*) MUN, which as described above, cannot be used to justify a listing. Furthermore, the Fact Sheet cites a guideline from the California Department of Health Services Notification Levels (1 µg/L) which has not yet gone through the formal MCL regulatory process and it is not clear that this threshold would meet the Listing Policy requirements.

Requested Action:

- **Revise all of the new listings in the Fact Sheets to ensure that none are based on municipal drinking water objectives when the MUN beneficial use does not apply.**
- **Remove the segment-pollutant combinations for total dissolved solids, specific conductivity, sulfates, nitrogen, nitrate, dimethoate, and other MUN-based pollutants listed in Table 1 above from the 303(d) List.**

3. Reassess mercury listings using correct objective and correct units

The data used to assess mercury for Calleguas Creek Reach 3, Reach 4, and La Vista Drain are in ng/L and the objective is µg/L. The data have to be converted to the same units as the objective before an exceedance can be determined. The Stakeholders expect that after this calculation has been performed the waterbodies will no longer meet the listing guidelines for mercury. Additionally, although a California Toxics Rule objective exists for mercury, an EPA nationally recommended criterion was used for the assessment. An explanation for the use of a recommended criterion when an established water quality objective exists should be provided.

Requested Action:

- **Repeat the mercury analysis after correcting the units error.**

4. Incorrect location and data were used for listings in Reach 12

The name of the monitoring site presented in the Fact Sheet for the chlorpyrifos, diazinon and malathion listings in Calleguas Creek Reach 12 is unclear. The University site is in Reach 3, not 12 and TO1 is an MS4 discharge characterization site, not a receiving water monitoring location. Therefore, TO1 should not be used for a 303(d) listing decision and University data is not from Reach 12. A review of the datasets provided in the link on the Fact Sheet only show data from University (ME-CC) and the number of samples appears to match up with the sample numbers shown in the Fact Sheet. As a result, it appears that the chlorpyrifos, diazinon and malathion listings do not apply to Reach 12.

In addition, the Stakeholders request that only data collected *after* the implementation of applicable pesticide use restrictions were in place for these pesticides be considered in the listing decisions. Data from the Calleguas Creek TMDL watershed monitoring program that were not used in the assessment (see Comment II) demonstrates a marked reduction in these pesticides in receiving water since the use restrictions were implemented (approximately 2009 to present), particularly for receiving waters downstream of urban areas (e.g., Reach 12). Given the changed condition resulting from the pesticide use restrictions, monitoring data collected prior to 2009 is not representative of waterbody conditions for these constituents. Therefore, these constituents should not be listed unless data collected after the use restrictions were implemented demonstrates a continued impairment.

Requested Action:

- **Remove listings for Reach 12 that are not based on receiving water data from that reach.**
- **Remove listings for chlorpyrifos, diazinon, and malathion based on historic data that are not representative of conditions after implementation of pesticide use restrictions.**

5. Correct the proposed temperature listing for Calleguas Creek Reach 12 (was Conejo Creek/Arroyo Conejo North Fork on 1998 303d list) which is based on incorrect criteria.

The temperature listing for Reach 12 uses an evaluation guideline of 13-21°C as the optimum growth range for rainbow trout. However, the beneficial use listed for Reach 12 is WARM. The rainbow trout growth range threshold used for the listing is only applicable to the COLD beneficial use. This guideline should be removed and the number of exceedances recalculated based on the Basin Plan criteria for WARM. [3]

The basin plan criteria for WARM beneficial uses states the following: "*For waters designated as WARM, water temperature shall not be altered more than 5 degrees F above the natural temperature. At no time shall these WARM designated waters be raised above 80 degrees F as a result of waste discharges.*" The Fact Sheet states that of 567 samples there were 3 instances of the downstream sample exceeding 80°F and in some cases a 30°F difference between upstream and downstream reaches. The Fact Sheet statement is unclear because Reach 12 is the upstream location and is not downstream of a waste discharge. Reach 12 drains a portion of the City of Thousand

[3] Notwithstanding that the evaluation guideline of 13-21°C is inappropriate for Calleguas Creek Reach 12 given the water body's beneficial uses, the manner in which the evaluation guideline is applied is also inappropriate. Line of Evidence (LOE) 85933 references Moyle 1976 as the source of the evaluation guideline. Moyle 1976 was revised and expanded by Moyle 2002[1]. Moyle 2002 states: "Rainbows are found where daytime temperatures range from nearly 0°C in winter to 26-27°C in summer, although extremely low (<4°C) or extremely high (>23°C) temperatures can be lethal if the fish have not previously been gradually acclimated. Even when acclimation temperatures are high, temperatures of 24-27°C are invariably lethal to trout, except for very short exposures (25, 26)." As such, while temperatures above 21°C may not be optimal according to Moyle 1976, Moyle 2002 clearly states that lethal temperatures are those greater than 23°C which indicates that the evaluation guideline of 21°C is more appropriately applied as a chronic guideline (necessitating the establishment of an averaging period) and 23°C is the more appropriate "not-to-exceed" guideline if used for listing.

Oaks and open space areas and is located upstream of the Thousand Oaks Wastewater Treatment Plant. Therefore, it is unclear if the exceedances discussed in the Fact Sheet actually occur in Reach 12 and if exceedances do occur, whether they are a result of waste discharge or are a natural condition. The data provided for review was not compiled in a way that made it possible to easily review the assessment to determine if the exceedances were observed in Reach 12 (upstream) or Reach 10 (downstream).

Regardless of the location of the samples, if there were 3 instances of temperature above 80°F and if they can be confirmed to be a result of waste discharge and not natural temperature conditions, according to the SWRCB 2015 303(d) Listing Policy[4] three samples out of 567 would not meet the minimum number of measured exceedances needed to place a water segment on the 303(d) List (see Listing Policy table 3.2). According to the binomial test, with a sample size of 500+ there would need to be well over 20 exceedances in order to be added to the 303(d) List, however, the Fact Sheet mentions only three exceedances of the Basin Plan criteria. According to the SWRCB's own guidance, this proposed listing should be removed.

Requested Action:

- **Do not use the 13-21°C rainbow trout evaluation guideline which only applies to COLD beneficial use segments.**
- **Remove the temperature listing for Reach 12 as it does not meet the minimum listing requirements based on the binomial test described above and ensure that the analysis is applied to the correct reach.**

6. Ensure no J-flagged data were used in the assessment.

The Listing Policy specifically prohibits the use of J-flagged ("estimated") data that fall below the quantitation limit but above the water quality standard. Section 6.1.5.5 of the Listing Policy specifically states:

> "*When the sample value is less than the quantitation limit and the quantitation limit is greater than the water quality standard, objective, criterion, or evaluation guideline, the result shall not be used in the analysis. The quantitation limit includes the minimum level, practical quantitation level, or reporting limit.*"

All listings based on the use of J-flagged data should, therefore, be removed from the draft 303(d) List. Specific instances are included in **Table 1** and further explained in **Table 2** below, but this list is by no means inclusive; this significant error will have to be addressed by a thorough review of all listing data to confirm that no J-flagged data were used to justify listings.

---

[4] State of California State Water Resources Control Board (SWRCB) Water Quality Control Policy for Developing California's Clean Water Act Section 303(d) List. Amended February 3, 2015.

Table 2. Incorrect use of J-flagged data

Segment	Pollutant	Comment
Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No. 2	Toxaphene	The Lines of Evidence (LOE) for Toxaphene lists the number of exceedances incorrectly at two. However, only one of six samples exceeded the indicated criterion. The other sample was reported by the laboratory as "estimated" (J-flagged). Because only one of six samples showed an exceedance this listing should be removed as it does not meet the binomial test limits set forth in the Listing Policy.
Rio de Santa Clara/Oxnard Drain No. 3	Chlordane	The LOE for Chlordane erroneously states that four out of five samples exceed the objectives. A review of the data shows that only 3 out of 5 samples exceed indicated criteria. The remaining 2 results were (1) not detected and (2) "estimated" (J-flagged) by the laboratory because results were below the reporting limit.
La Vista Drain	Chlordane	The LOE for chlordane shows that one of the samples used to justify the listing is based solely on estimated (J-flagged) data because results were below the reporting limit. Because Chlordane has only one detected value for two sampling events, more monitoring data are needed to justify the listing and the proposed listing should be removed.

Requested Action:

- **Review all Fact Sheets and LOEs for the use of J-flagged data and remove any instances where J-flagged data were used.**
- **Delist toxaphene for Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No. 2, chlordane for La Vista Drain, and any other pollutants listed in Tables 1 and 2 that lack the minimum number of exceedances required to justify a listing.**

7. Remove listings where a waterbody assessment does not meet listing thresholds based on data provided.

Finally, the toxicity listing for Rio De Santa Clara/Oxnard Drain No. 3 does not meet the minimum requirements to be listed according to the Listing Policy (pg. 9). According to the Listing Policy, a waterbody can be listed only when the number of exceedances meets the binomial test; in the case of this waterbody, four samples were collected and only one sample showed an exceedance. However, two exceedances would be required for the waterbody to be added to the 303(d) List. Therefore, toxicity was incorrectly listed for this waterbody and should be removed entirely from the 303(d) List.

Requested Action:

- **Remove the toxicity listing for Rio De Santa Clara/Oxnard Drain No. 3 based on meeting listing threshold requirements in the Listing Policy.**

II. REQUESTED REASSESSMENTS USING COMPLETE DATA SET

The assessments for the Calleguas Creek watershed do not appear to include any of the submitted Calleguas Creek Watershed TMDL monitoring data, monitoring data from the Camarillo Sanitary District, or monitoring data from the Simi Valley Wastewater Treatment Plant. All of this monitoring data has been provided to the Regional Board in annual monitoring reports and all data were collected using approved QAPPs. As a result, there is no reason why this data should not be included in the 303(d) listing process.

In 2013, the Stakeholders did an assessment of the watershed using all watershed data through 2012 and found that multiple waterbody-pollutant combinations could potentially be delisted as shown in **Table 3**. A summary of the assessment is included as an attachment to this letter and the datasets used in the analysis as well as all of the TMDL annual monitoring reports are available upon request.

Table 3. Waterbody-Pollutant Combinations to Consider for Delisting

Waterbody segment	Pollutant
Calleguas Creek Reach 1	Copper Dieldrin Endosulfan Mercury Nickel Zinc
Calleguas Creek Reach 2	Ammonia Copper
Calleguas Creek Reach 3	Ammonia Chlordane PCBs
Calleguas Creek Reach 4	Diazinon Dieldrin Endosulfan PCBs
Calleguas Creek Reach 6	Ammonia Chlordane Diazinon Dieldrin
Calleguas Creek Reach 7	Ammonia Diazinon
Calleguas Creek Reach 9A	Chlordane DDT Dieldrin Endosulfan Gamma HCH Nitrate as Nitrate Nitrogen, Nitrate PCBs Toxaphene
Calleguas Creek Reach 9B	Ammonia Chlordane Chlorpyrifos

Waterbody segment	Pollutant
	Diazinon Dieldrin Endosulfan PCBs Sulfates
Calleguas Creek Reach 10	Ammonia Chlordane Chlorpyrifos DDT Diazinon Dieldrin Endosulfan Fecal Coliform/Indicator Bacteria Nitrogen, Nitrite PCBs Sulfates Total Dissolved Solids Toxaphene
Calleguas Creek Reach 12	Ammonia DDT Dieldrin PCBs Toxaphene
Calleguas Creek Reach 13	Ammonia Chlordane DDT Dieldrin Endosulfan PCBs Toxaphene

While we recognize that this assessment uses two additional years of data than the current 303(d) listing analysis, a number of these waterbodies had many more samples than were necessary for delisting. As a result, we feel if all the watershed data were used in the assessment, a number of these waterbodies (particularly for metals) would be delisted. We also feel this assessment would demonstrate that several of the proposed listings, particularly for diazinon and chlorpyrifos and a number of organochlorine pesticides, are not warranted. A large number of new proposed listings are being added that are already covered by a TMDL. While the list acknowledges that a TMDL does not need to be developed by categorizing these new listings in Category 5B, in several cases, the watershed now has sufficient data to delist, whereas the listing is an artifact of old data being used to make the listing decision. These listings should not be added to the current list only to be removed during the next listing cycle as an artifact of the timing of the listing assessments.

Requested Action:
- **Reassess all Calleguas Creek waterbodies using all available data.**

III. REQUESTED CATEGORY ASSIGNMENT CHANGES

8. Correct pollutants listed as Category 5A which should be 5B based on coverage by an existing TMDL.

There are a number of proposed new listings for pollutants that are already covered by an existing TMDL and are incorrectly categorized as 5A. While the Stakeholders maintain that all of these listings should be removed entirely because of the issues detailed in Comment I, if they are not removed they should, at a minimum, be changed from 5A to 5B, as applicable.

A nutrient TMDL addressing nitrogen has been in effect since 2003, including for Reach 9A where a new 5A listing for nitrite is proposed. In 2006, the Toxicity and OC Pesticide and PCBs TMDLs for the Calleguas Creek watershed were established to address chlordane, chlorpyrifos, DDT, DDE, DDD, dieldrin, PCBs, sediment toxicity, and toxaphene. The La Vista Drain and Santa Clara Drain ultimately flow into Calleguas Creek Reach 4 (was Revolon Slough Main Branch), which is already addressed by an OC Pesticides and PCBs TMDL, the Toxicity TMDL, the Salts TMDL, and the Metals TMDL and therefore all of these proposed listings should be Category 5B. Furthermore, two other segments were listed for Chlorpyrifos – Honda Barranca and Duck Pond Agricultural Drains – but were correctly listed as Category 5B, citing the 2006 Toxicity TMDL. The Stakeholders request that any listings in **Table 4** and **Table 5** that are maintained after addressing the issues in Comment I should also be corrected to be designated as Category 5B.

Table 4. 303(d) Category 5A listings which should be changed to 5B listings

Segment	Pollutant	Proposed 303(d) Category	Requested 303(d) Category	Existing CCW TMDL[5,6,7,8,9,10]
Calleguas Creek Reach 2 (estuary to Potrero Rd)	Specific Conductivity	5A	5B	Salts TMDL
	Total Dissolved Solids	5A	5B	Salts TMDL
Calleguas Creek Reach 3 (Potrero Road upstream to Conejo Creek)	Mercury	5A	5B	Metals TMDL
Calleguas Creek Reach 4	Mercury	5A	5B	Metals TMDL
	Specific Conductivity	5A	5B	Salts TMDL
	Total Dissolved solids	5A	5B	Salts TMDL
	Sulfates	5A	5B	Salts TMDL
Calleguas Creek Reach 9A	Nitrogen, Nitrite	5A	5B	Nitrogen TMDL
Calleguas Creek Reach 12	Chlorpyrifos	5A	5B	Toxicity TMDL
	Diazinon	5A	5B	Toxicity TMDL
Honda Barranca	DDT	5A	5B	OC Pesticides and PCBs TMDL
Rio De Santa Clara/Oxnard Drain No. 3	Toxicity	5A	5B	Oxnard Drain #3 Pesticides, PCBs, Sediment Toxicity TMDL
La Vista Drain (Ventura County)	Chlorpyrifos	5A	5B	Toxicity TMDL
	Chlordane	5A	5B	OC Pesticides and PCBs TMDL
	DDT	5A	5B	OC Pesticides and PCBs TMDL
	DDE	5A	5B	OC Pesticides and PCBs TMDL
	DDD	5A	5B	OC Pesticides and PCBs TMDL
	Copper	5A	5B	Metals TMDL
	Mercury	5A	5B	Metals TMDL
Santa Clara Drain	Chlordane	5A	5B	OC Pesticides and PCBs TMDL
	Chlorpyrifos	5A	5B	Toxicity TMDL
	DDD	5A	5B	OC Pesticides and PCBs TMDL
	DDE	5A	5B	OC Pesticides and PCBs TMDL
	DDT	5A	5B	OC Pesticides and PCBs TMDL
	Nitrogen, Nitrate	5A	5B	Nutrients TMDL
	Specific Conductivity	5A	5B	Salts TMDL

[5] The Calleguas Creek Watershed Metals TMDL. RS 2006-012. Approved by USEPA on March 26, 2007.

In addition, we feel that the Toxicity TMDL should cover all new listings in the watershed for pyrethroids and organophosphate pesticides (e.g., malathion) if they are not removed as requested in the first comment. The Toxicity TMDL includes a trigger for additional investigation if ongoing toxicity is identified in the watershed. The toxicity trigger has resulted in the identification of pyrethroids as a potential cause of toxicity and the Stakeholders have already begun actions to address these pesticides in addition to the organophosphate pesticides included in the TMDL. The structure of the TMDL is designed to proactively prevent toxicity and therefore it is not necessary to develop another TMDL for these constituents. There are already sufficient controls in place through the agricultural waiver and MS4 permit. As a result, if the waterbodies are placed on the 303(d) List as new listings, we request that the waterbodies in **Table 5** be changed from 5A to 5B.

Table 5. Pyrethroid and Organophosphate listings which covered by the existing Toxicity TMDL[11]

Segment	Pollutant	Proposed 303(d) Listing Category	Requested 303(d) Listing Category
Calleguas Creek Reach 4 (was Revolon Slough Main Branch)	Bifenthrin	5A	5B
	Cyfluthrin	5A	5B
	Cypermethrin	5A	5B
	Malathion	5A	5B
	Permethrin	5A	5B
Calleguas Creek Reach 12 (was Conejo Creek/Arroyo Conejo North Fork)	Malathion	5A	5B
Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2	Bifenthrin	5A	5B
Honda Barranca	Bifenthrin	5A	5B
Santa Clara Drain	Cypermethrin	5A	5B

Requested Action:

- **Change all pollutant-waterbody segment combinations in Table 4 and Table 5 from 5A to 5B or 4A based on coverage by an existing USEPA approved TMDL.**

---

9 The Calleguas Creek Watershed Salts TMDL. RS 2007-016. Approved by USEPA on December 2, 2008.
10 Total Maximum Daily Loads for Pesticides, PCBs, and Sediment Toxicity in Oxnard Drain 3. Approved by USEPA on October 6, 2011.
11 The Calleguas Creek, Its Tributaries, and Mugu Lagoon Toxicity, Chlorpyrifos and Diazinon TMDL. RS 2005-009. Approved by USEPA on March 24, 2006.

IV. ADDRESS ALL OTHER INCONSISTENCIES AND ERRORS IN LIST

In reviewing the list the Stakeholders identified a large number of inconsistencies and issues in the list that should all be addressed prior to adoption. The summary below provides examples of issues identified and is not a comprehensive list as in many cases the information provided made it challenging to provide comprehensive comments.

9. Correct Appendix G Fact Sheets. The Appendix G Fact Sheets often include incorrect information and discussion. While most of the identified issues do not appear to impact the listing decisions, they make the review of information difficult. Examples of errors found include:

- Incorrect beneficial uses assigned to a waterbody. For example, MUN beneficial uses assigned to a tidally-influenced waterbody (e.g., Duck Ponds Agricultural Drain).
- Incorrect beneficial uses assigned to objectives. For example, MUN beneficial uses listed when aquatic life objectives are presented in the Fact Sheet.
- Incorrect TMDLs assigned to a pollutant. For example, for chlordane in Calleguas Creek Reach 2, the applicable TMDL is listed as the Calleguas Creek Metals TMDL. It should be the Organochlorine Pesticides, PCBs, and Siltation TMDL.
- Incorrect QAPPs identified. For example, the VCAILG QAPP is often referenced for the Ventura County MS4 monitoring data set.
- Incorrect number of samples evaluated and incorrect number of criteria exceedances. For example, the number of samples evaluated for toxaphene on the Rio de Santa Clara/Oxnard Drain No. 3 is identified as 2 samples, whereas data files obtained from the Regional Board website contain 5 samples for the date range indicated in Fact Sheets, including 3 samples with results of "ND". Stating that a pollutant actually exceeds criteria in only 40% of samples, versus 100% exceedances as presented in Fact Sheets, provides a more accurate picture of the degree of impairment for that pollutant in a waterbody. The inclusion of J-flagged data when enumerating exceedances (e.g., for chlordane in the same waterbodies) further exacerbates these numbering inaccuracies.

  Requested Action:
  Correct the Appendix G Fact Sheets for errors such as incorrectly assigned beneficial uses, existing TMDLs, QAPPs, and number of samples/number of exceedances.

10. Correct the Appendices and Fact Sheet Categories. Appendix A, Appendix B, Appendix C, and Appendix G are inconsistent which makes the analysis of new additions very difficult since it is unclear which segment-pollutant combinations actually are new listings. Following are examples of a number of identified issues that need to be corrected to allow the Stakeholders to fully vet and understand the proposed listings.

A number of proposed "name changes" in Appendix A are not shown in Appendix B and there are not associated Fact Sheets describing the name change (e.g., Reach 4 listings for chlorpyrifos and total DDT). This makes it very challenging to assess the validity or basis for the name change. In other instances, listed name changes are found in Appendix B or C but not supported by an explanation for the name change in Appendix G. The Fact Sheets for the following name changes should provide justification or explanation for the name change as many appear to be switching tissue or sediment listings to water listings. If this is, in fact, the change being made, the justification for the water listing needs to be provided in the Fact Sheet. It is not appropriate to modify the medium that is the basis for the listing as a name change.

Table 6. Listed as Name Changes in Appendix A

CCW Segment	Pollutants
Reach 1	Toxicity
Reach 2	Chlordane, Endosulfan, Toxaphene
Reach 4	Chlorpyrifos (tissue), Fecal Coliform, Total DDT
Reach 12	DDT (tissue), Ammonia
Rio De Santa Clara/Oxnard Drain No. 3	Toxicity
Duck Pond	ChemA

There are a number of inconsistencies where Appendix A does not include all of the new 2014 listings found in Appendix B. Below are a few examples of such inconsistencies.

Table 7. Incorrectly listed waterbody segment-pollutant combinations

Segment	Pollutant	Issue
La Vista Drain	DDT	Not included as a new change in Appendix A but listed as a new 2014 5A listing in Appendix B.
Honda Barranca	Bifenthrin	Not included as a new change in Appendix A but listed as a new 2014 5A listing in Appendix B.
Rio De Santa Clara/Oxnard Drain No. 3	Total Dissolved Solids	Not included as a new change in Appendix A but listed as a new 2014 5A listing in Appendix B.
	Toxicity	Listed only as a "name change" in Appendix A but listed as a new 2014 5A listing in Appendix B.
Calleguas Creek Reach 2 (estuary to Potrero Rd)	Indicator Bacteria	Not included as a change in Appendix A but listed as a new 5A listing in Appendix B. Clarify if this is a new listing or a "coliform bacteria" name change as described for Calleguas Reaches 6, 9A, 10, and 11.
	PCBs	Not included as a new change in Appendix A but listed as a new 2014 5B listing in Appendix B.
	Toxicity	Not included as a new change in Appendix A but listed as a new 2014 5B listing in Appendix B.
	ChemA	Not included as a new change in Appendix A but listed as a new 2014 5B listing in Appendix B despite cited as a historical use of pesticides and lubricants.
Calleguas Creek Reach 4	Cyfluthrin	Not included as a new change in Appendix A but listed as a new 2014 5A listing in Appendix B.

There are also a number of instances where existing waterbody-pollutant listings from the 2010 303(d) List were not stated as delisted in Appendix A and do not appear in Appendix B, C, or G under the waterbodies to delist. The Stakeholders would like clarification if these listings are in fact being delisted as some align with the assessment shown in **Table 3**.

Table 8. Not described as delisted in Appendix A but not found Appendix B or C

CCW Segment	Pollutants
Reach 2	Ammonia
Reach 3	Ammonia
Reach 4	Chlordane (tissue & sediment), DDT (tissue & sediment), PCBs (tissue), Toxaphene (tissue & sediment)
Reach 5	Chlordane (tissue & sediment), Chlorpyrifos (tissue), DDT (tissue & sediment), Dieldrin (tissue), Endosulfan (tissue & sediment), Nitrogen, PCBs (tissue), Toxaphene (tissue & sediment)
Reach 6	DDT (sediment)
Reach 9A	Chlorpyrifos, DDT (tissue), Dieldrin (tissue), Endosulfan (tissue), PCBs (tissue), Toxaphene (tissue & sediment)
Reach 9B	Endosulfan (tissue), Toxaphene (tissue & sediment)
Reach 10	DDT (tissue)
Reach 11	DDT (tissue), Endosulfan (tissue), Toxaphene (tissue & sediment)

Requested Action:
Correct the numerous inconsistencies described above in Table 6, Table 7, and Table 8 and ensure that all of the proposed 303(d) List appendices are internally consistent.

11. Correct the waterbody assigned Hydrologic Unit (HUCs) and Calwater numbers to reflect those listed in the Basin Plan. There are multiple instances of what appear to be incorrectly Hydrologic Unit numbers (HUCs) and Calwater numbers assigned to the various waterways. For instance, a comparison of the 8 digit HUCs listed in Appendix B of the 303(d) List to the 12 digit HUCs listed in Appendix I of the Basin Plan indicate a number of inconsistencies such that waterbodies present in the Santa Clara River Watershed (e.g., Santa Clara River Reach 1, 2, and 3) are listed with a Calleguas watershed HUC (18070103) while the same reaches are listed as 18070102 in the Basin Plan. This makes identifying the location of unknown waterbodies not previously listed or described in the Basin Plan to assess if they are receiving waters that should be assessed especially difficult. A full review of the 303(d) List HUCs should be completed to correct all errors.

Requested Action:
Perform a full review of HUCs and Calwater numbers listed in Appendix B through F and correct any inconsistencies with the Basin Plan.

12. Correct or clarify inconsistencies in the staff report. There is inconsistent discussion in the staff report about some proposed listings that should be clarified to avoid confusion about the listings. For instance, on page 10 of the Staff Report there is a discussion about existing TMDLs covering newly proposed pollutants "*For example, the proposed new listings for DDE and DDD in Calleguas Creek Reach 3 … are being addressed by the Calleguas Creek Organochlorine Pesticides, PCBs and Siltation TMDL … and would then be in Category 4A.*" However, we could find no listings of DDE and DDD for Reach 3 in any Appendix of the report including Appendix C – Category 4A Waterbody Segments. Furthermore, the Fact Sheets in Appendix G state that DDE and DDD should *not* be listed for Reach 3. We ask the RWQCB to either clarify or remove the above referenced statement and clarify any other inconsistencies between the staff report and the list.

Requested Action:
Correct or remove language cited on page 10 of the staff report regarding DDE and DDD listing of Calleguas Creek Reach 3 and clarify any other identified inconsistencies within the staff report.

13. Ensure that all thresholds being used for assessment are consistent and valid under the Listing Policy. In many cases, the same pollutant is assessed using different thresholds without any explanation for the basis of the threshold. Additionally, in several cases, an LC50 or threshold for individual species were used for the assessment, which is inconsistent with the Listing Policy which states that it must be demonstrated that an evaluation guideline is *"applicable to the beneficial use, protective of the beneficial use, scientifically-based and peer reviewed, and well described"*. Because it has not been demonstrated that the individual species response to these pollutants is applicable and protective of the beneficial use these guidelines should not be used to make a listing. The Stakeholders ask that the Board review all assessments for consistency, especially for the pesticides (bifenthrin, cyfluthrin, cypermethrin, malathion, permethrin) as well as applicability to the beneficial use as described in the Listing Policy.

Table 9. 303(d) Pollutants Using Thresholds for Interpreting Narrative Objectives

Pollutant	Segment	Objective Used
Bifenthrin	CCW Reach 4	0.0006μg/L (4-day average) from UC Davis[1]
	Honda Barranca	0.0006μg/L (4-day average) from UC Davis[1]
	Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2	0.00397μg/L mean acute value for mysid from Cal Dep of Fish and Game[2]
Cyfluthrin	CCW Reach 4	LC50: 29000μg/L from the USEPA OPP Pesticide Ecotox database
Cypermethrin	CCW Reach 4	0.002μg/L from the Cal Dep of Fish and Game[2]

Malathion	CCW Reach 4	0.28µg/L (4-day average) from UC Davis[1]
	CCW Reach 12	0.1µg/L USEPA[3]
Permethrin	CCW Reach 4	0.0002µg/L from UC Davis[1]
[1]Aquatic life water quality criteria derived via the UC Davis method: II. Pyrethroid insecticides. Reviews of Environmental Contamination and Toxicology 216:51-103.		
[2] Hazard Assessment of the Synthetic Pyrethroid Insecticides Bifenthrin, Cypermethrin, Esfenvalerate, and Permethrin to Aquatic Organisms in the Sacramento-San Joaquin River System; 2000. Cal Dept. of Fish and Game. Report 00-6.		
[3] USEPA National Recommended Water Quality Criteria (Red Book). 1976. United States Environmental Protection Agency. Office of Water. Office of Science and Technology.		

The 303(d) List includes new listings for bifenthrin, cyfluthrin, cypermethrin, malathion, and permethrin in CCW. Currently, no water quality objectives have been promulgated by USEPA or the State of California for these pollutants and so the criteria listed are from a variety of studies. Some issues with these criteria include the following (this list is by no means inclusive; a thorough review of all listings for these pollutants should be undertaken):

- The criterion used for listing bifenthrin on Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2 is 0.00397 µg/L based on the CDFG criteria. The selective use of a saltwater genus mean acute value is inappropriate when the CDFG study clearly states in the "Conclusions and Recommendations" section that "insufficient freshwater and saltwater acute toxicity data were available to calculate CMC values for bifenthrin." The same use of a criterion unsupported by the study author(s) applies to cypermethrin on the Santa Clara Drain.
- Use of LC50 for listing of cyfluthrin for CCW Reach 4 is inappropriate. LC50s do not meet the standard set forth in the Listing Policy as stated on page 20 " *the evaluation guideline… identifies a range above which impacts occur and below which no or few impacts are predicted*." By definition, an LC50 is simply the concentration at which half of the population of the tested species has died. The LC50 should not be used as the evaluation guideline.
- The criterion used for listing permethrin for Calleguas Creek Reach 4 is 0.0002µg/L based on the UC Davis[12] criteria. However, upon reviewing the UC Davis source the listed chronic standard for permethrin is 2 ng/L (page 92) which is 0.002µg/L, not 0.0002µg/L as listed in the 303(d) List.
- In many instances the incorrect evaluation guideline and guideline reference are used. For example, the evaluation guideline (i.e., criterion) provided for cyfluthrin (a pyrethroid) in LOEs 84065, 83200, and 88712 is for the chlorinated herbicide 2,4,5-TP. The stated criterion (29 mg/L) was not found in the cited guideline reference. Many additional instances were noted in LOEs for phorate, dimethoate, disulfoton, endosulfan sulfate, and many other LOEs. Because the numeric guidelines (and reference documents from which these are obtained)

[12] Aquatic life water quality criteria derived via the UC Davis method: ll. Pyrethroid insecticides. Reviews of Environmental Contamination and Toxicology 216:51-103.

form the basis for any listing, it is critical that these be carefully reviewed and verified prior to issuing the final Fact Sheets and 303(d) List.

Requested Action:

- **Review the guidelines used for interpreting narrative objectives and ensure that they are consistently applied and use correct unit conversions.**
- **Remove all guidelines that do not comply with the stated Listing Policy as described above.**

The Stakeholders appreciate the opportunity to comment on the 303(d) List and look forward to continuing to work with the Water Board to address these concerns. Thank you for your time and consideration of these comments. If you have questions, please contact Ashli Desai at (310) 394-1036 / AshliD@lwa.com or me at (805) 388-5334.

Sincerely,

Lucia M. McGovern

Lucia McGovern
Chair of Stakeholders Implementing TMDLs in Calleguas Creek Watershed

Attachment A: Data Tables from CCW Water Quality Priorities Memorandum

Calleguas Creek Watershed Assessment

1. Data Sources

In order to fully evaluate the progress of TMDL implementation, as well as the general state of the watershed, data was collected from a variety of CCW stakeholders. Data sources include NPDES monitoring data from three Publicly Owned Treatment Works (POTWs) in the watershed along with long-term MS4 monitoring data from the County of Ventura. Ventura County Agricultural Irrigated Lands Group (VCAILG) monitoring data and available Navy data was also provided. Water, sediment, fish tissue, and toxicity data from ongoing TMDL and data was also retrieved from the State Water Quality Control Board's California Environmental Data Exchange Network (CEDEN).

Overall, a data set of over 375,000 data points gathered between 2003 and 2014 was compiled. The data set was then refined by focusing the analysis on receiving water samples and removing POTW effluent, MS4 outfalls, and agricultural discharge data.

The aggregation of data spanning the ten year study period revealed varying levels of completeness in the monitoring data; therefore several conservative assumptions were necessary to carry out the analysis. Where appropriate, constituents sampled under unknown wet/dry conditions were assumed to be sampled during dry weather conditions and were thus subject to dry weather criteria. POTW metals data reported without indication whether they were in the dissolved or total fraction were assumed to be reported in their dissolved fraction for constituents with dissolved targets (copper, nickel, and zinc). Mercury and selenium targets are for the total fraction; undesignated data for these constituents was assumed to be total. These assumptions were intended to provide the most conservative analysis of the data in light of the uncertainty related to the incomplete data.

Table 1. Summary of Receiving Water Data Used in Analysis

Monitoring Program/Data Source	Date Range		Number of Samples by Reach														Total

1.1 METALS AND SELENIUM TMDL

The Los Angeles Regional Water Quality Control Board (RWQCB) adopted Resolution No. R4-2006-012 to address water quality issues related to metals and selenium in Calleguas Creek, its tributaries and Mugu Lagoon.

Table 2 summarizes the analysis of available receiving water data for constituents included in the Metals TMDL, as well as the number of exceedances of the final numeric targets. The table illustrates that in most cases a sufficient number of samples is available and the data supports a delisting of the metals. It is important to note that compliance with metals and selenium targets in reach 2 was assessed using data from CCW TMDL monitoring site 01_RR_BR, which is located at the break between reach 1 and 2. Much of the POTW data did not distinguish between the dissolved and total fraction for metals constituents. For metals with dissolved targets (copper, nickel, and zinc) a conservative approach was used by comparing undistinguished metals samples to the dissolved targets. Mercury and selenium have established targets for total metals, in these instances all total and undistinguished samples were compared to these targets. For conservative analysis, available fish tissue mercury data was compared to the lowest fish tissue target for all samples.

Table 2. Analysis of Metals TMDL Constituents in Receiving Water by Reach

Table 3. Analysis of Metals TMDL Constituents in Sediment by Reach

Reach	Constituent	Date Range Available		TMDL target (ppb)[1]	Previous 10 Years			Previous 5 Years			Potential for Delisting
					N	N Detect	N Exceed	N	N Detect	N Exceed	
1	Copper	5/3/2003	8/18/2011	34,000	18	18	1	5	5	0	PD[2]
	Nickel	5/3/2003	8/18/2011	20,900	18	18	6	5	5	0	PD[2]
	Zinc	5/3/2003	8/18/2011	150,000	18	18	3	5	5	0	PD[2]
2	Copper	2/3/2004	8/22/2013	34,000	11	11	4	3	3	0	PD[2]

1. TMDL target only applies if sediment toxicity occurs.
2. No exceedances in most recent five years with a significant number of samples. Considering the exceedances that occurred more than five years ago would inappropriately categorize this as a higher priority.

PD (Potential Delisting) - Insufficient data to information listing decision, however a significant number of the most recent 5 years of monitoring are non-detect. The potential for delisting the reach may exist.

1. Mercury was compared against Methyl-Mercury final numeric targets.

NE (No Exceedances) – Insufficient data to inform listing decision, however no exceedances were reported in the available monitoring data

1.2 NUTRIENT TMDL

The Calleguas Creek Nitrogen Compounds and Related Effects (Nitrogen TMDL) was incorporated into the Water Quality Control Plan for the Los Angeles Region (Basin Plan) through the RWQCB adoption of Resolution No. R4-2002-017. An update to the Nitrogen TMDL has since been adopted (Resolution No. 2008-009) and went into effect on October 15, 2009. **Table 5** summarizes the comparison of available receiving water data to numeric objectives identified in the Nitrogen TMDL. The data supports the delisting of Ammonia-N and Nitrite-N in many of the river reaches where sufficient data is available.

ID (Insufficient Data) – Insufficient data to inform listing decision, however a single exceedance was detect and the potential for listing may exist.

1.3 OC PESTICIDES AND PCBS TMDL

The RWQCB adopted Resolution No. R4-2005-010 to incorporate the OC Pesticides and PCBs TMDL in Calleguas Creek, its Tributaries, and Mugu Lagoon into the Basin Plan. The TMDL became effective on March 24, 2006. Final numeric targets are specified for water, fish tissue, and/or sediment depending on the constituent. The TMDL also specifies load reductions for sediment and habitat preservation in Mugu Lagoon. **Table 6** summarizes the evaluation of receiving water concentrations in the watershed to TMDL targets. However, when TMDL numeric targets were found to be greater than the Human Health Consumption Criteria for Organisms Only, as outlined in Table (b)(1) §131.38 of 40 CFR Part 131, the Human Health Criteria were used in the analysis. Overall, constituents covered by the OC Pesticides and PCBs TMDL have not been detected in the previous ten years in water samples. DDT compounds, chlordane, and toxaphene are the exception, with exceedances within the past 5 years.

Table 6. Analysis of OC Pesticides and PCBs TMDL Constituents in Receiving Water by Reach.

1.4 TOXICITY TMDL

The RWQCB adopted Resolution No. R4-2005-009 to incorporate the Toxicity, Chlorpyrifos and Diazinon (Toxicity) TMDL in Calleguas Creek, its Tributaries, and Mugu Lagoon into the Basin Plan. The TMDL was effective as of March 25, 2006. Chlorpyrifos and diazinon have been phased out from non-agricultural uses and it was recently announced that additional restrictions on the use of chlorpyrifos on farms may be enacted.

Table 9. Analysis of Toxicity TMDL Constituents in Receiving Water by Reach.

ID (Insufficient Data) – Insufficient data to inform listing decision, however a single exceedance was detect and the potential for listing may exist.

1.5 SALTS TMDL

The Boron, Chloride, Sulfate, TDS (Salts) TMDL was incorporated into the Basin Plan through the RWQCB's adoption of Resolution No. R4-2007-016. **Table 10** summarizes the comparison of available receiving water grab sample data to the final numeric targets established in the Salts TMDL. This evaluation does not include consideration of continuous monitoring for salts at the receiving water compliance points, however, grab samples collected at these locations to calibrate and verify the sensors are a part of the dataset. Additionally, reaches 1 and 2 are tidally influenced and salts targets do not apply, therefore, those reaches are not considered.

Table 10. Analysis of Salts TMDL Constituents in Receiving Water by Reach

1.6 INDICATOR BACTERIA FECAL COLIFORM

Reaches in the CCW are listed for Indicator Bacteria and Fecal Coliform. The recent revision to bacteria objectives in the Basin Plan replaced limits on Fecal and Total Coliforms in REC1 designated waters with geometric means and instantaneous limits on *E. coli*. This analysis compared available *E. coli* monitoring data to the updated instantaneous objectives of 235 MPN/100mL. Table 11 summarizes the findings of the analysis.

Subject: Comment Letter – Revisions to the Los Angeles Region 2016 (303(d) List

Dear Mr. Zhu:

TECS Environmental is pleased to comment on the Regional Board's proposed 2016 303(d) list revisions.

Because there are almost 900 listing revisions for water quality segments in the Los Angeles County Basin, it would be impossible to address each one. Therefore, I will restrict my comments to general issues.

To begin with, I am sure that a number of MS4 Permittees and industrial dischargers will be pleased to know that many of the pollutants proposed on the 303(d), which are current TMDLs or are scheduled to become ones, have been placed on the "de-list" or placed on the "do not list" category. Most conspicuous are metals for Reach 2 of the Rio Hondo[1] and Reach 3 of the San Gabriel River[2]. Although the 2010 303(d) list did not list any of these reaches for metals-related impairment, they were nevertheless required to comply with metals TMDLs (Los Angeles River Metals TMDL for Reach 2 of the Rio Hondo and the San Gabriel River Metals TMDL for Reach 3 of the San Gabriel River). The 2016 303(d) list proposes to rectify this mistake by placing both of these reaches under the "do not list" category for copper, lead, selenium and zinc, which form the basis for both of the TMDLs.

[1]Alhambra (partially), Arcadia, Bradbury, Duarte, El Monte, Irwindale (partially), Monrovia, Montebello (partially), Monterey Park, Pasadena (partially), Rosemead, San Gabriel, San Marino, Sierra Madre, South El Monte, South Pasadena (partially) and Temple City.
[2]Azusa, Baldwin Park, Claremont, Covina, Duarte (partially), El Monte, Glendora, Irwindale, La Verne, Pomona, South El Monte, and West Covina.

However, the proposed 2016 303(d) list did not place any of the Arroyo Seco reaches on the "do not list." Like Reach 2 of the Rio Hondo and Reach 3 of the San Gabriel River, Arroyo Seco Reaches 1 and 2 were not on 2010 303(d) list, nor were they on the 2012 303(d) list, which did not make it to Los Angeles Basin Plan as an amendment. Nevertheless, the Los Angeles MS4 Permit subjects MS4 Permittees by extending the Los Angeles River Metals TMDL to Arroyo Seco reaches. The 2016 303(d) list should place these reaches on the "do not list" category for metals.
Recommendation: place Arroyo Seco Reaches 1 and 2 on the "do not list" for any metal.

I. CTR and 303(d) Listing Policy

Nevertheless, additional pollutants should be considered for exclusion because they were not established in accordance with the California Toxics Rule (CTR) adopted in 2000; and/or did comply with the *Water Quality Control Policy for California's Clean Water Act Section 303(d) List* (Listing Policy), which was adopted in 2004.

- *California Toxic Rule*

CTR was adopted to provide a mathematical method for establishing ambient (dry weather) water quality standards for toxics necessary to protect beneficial uses of receiving waters. The LAR-MTMDL, however, along with other TMDLs, does not comply with CTR in two significant respects.

First, the TMDL calculates numeric water quality standards/TMDLs for both wet weather and ambient receiving water conditions instead of only on ambient. The LAR-TMDL misinterprets CTR by claiming EPA did not differentiate between wet and dry weather conditions when establishing metals and toxics limitations. There is nothing in CTR that supports that view. CTR makes it clear that its purpose is to establish ambient water quality standards: *This final rule establishes ambient water quality for priority toxic pollutants.* USEPA defines ambient as:

> *Natural concentration of water quality constituents prior to mixing of either point or nonpoint source load of contaminants. Reference ambient concentration is used to indicate the concentration of a chemical that will not cause adverse impact to human health.*

In other words, ambient is the normal reference condition of a receiving water. This is also the clear understanding of the Regional Board's Surface Water Ambient Monitoring Program (SWAMP). MS4 and other point source stormwater (wet weather) outfall discharges, using sampling and analysis results, are measured against the ambient target for a pollutant established by CTR. For example, suppose a copper limitation is set at 37 micrograms per liter for a given water body. This limit is required to protect fish. Persistent exceedances of the limit based on outfall monitoring would necessitate a revision to the MS4 Permittee's stormwater management program.

Second, CTR requires a hardness parameter (calcium carbonate) to make chemical water quality analysis of metals and toxics more accurate. Generally, the higher the hardness value the higher the toxic/metal pollutant expressed as a numeric limit. And, the higher the limit there less difficult it is to meet. The metals and toxics TMDLs rely on differing hardness values. For the Dominguez Channel/Harbor Toxics TMDL an average hardness value of 50 mg/l is used. For Ballona Creek hardiness values for setting the wet weather TMDLs metals are varied, based on an average or median hardness that ranged from 77 mg/l to 108 mg/l. For dry weather, a median hardness value of 300 mg/l was applied. As mentioned, CTR is expressed exclusively as ambient and not wet weather standards. Thus the77 mg/l to 108 mg/l hardness values relative to wet weather are meaningless. For dry weather, a median value of 300 mg/l was used. For the Los Angeles River Metals TMDL variable hardness values were also used for wet and dry weather. The same is true to the San Gabriel River Metals TMDL. In any case, CTR requires actual hardness value to be determined at the time samples of metals/toxic pollutants are taken.

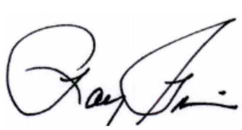
Thus, in the final analysis, each of the metals/toxics pollutants that was placed on the “list” or “do not de-list” category should be placed on the “de-list” or “do not list” category because they were not established in ambient terms only and failed to use an actual hardness value.

- *303(d) Listing Policy*

The Listing Policy was adopted to provide a statistical method to determine how many water quality samples that exceed a water quality standard are required to place a pollutant on the 303(d) list. That method is a binomial distribution based on the rejection of a null hypothesis measured against sample sizes (see attachment □1). A review of the 2016 303(d) list fact sheets reveals that many of the metals and toxics placed on previous 303(d) lists did not conform to the Listing Policy. Those that do not should be placed on the “de-list” or “do not list” category.

This concludes my comments. Should you have any questions or require additional information please let me know.

Sincerely,



Ray Tahir

Los Angeles, CA 90013

Subject: **Comment Letter – Revisions to the Los Angeles Region 303(d) List**

Dear Dr. Zhu:

On behalf of the Ventura Countywide Stormwater Quality Management Program (Program), which includes the Watershed Protection District, the County of Ventura and the incorporated cities of Camarillo, Fillmore, Moorpark, Ojai, Oxnard, Port Hueneme, Ventura, Santa Paula, Simi Valley, and Thousand Oaks, we thank you for the opportunity to provide input on the proposed revisions to the Clean Water Act Section 303(d) list of impaired waterbodies in the Los Angeles Region [hereinafter referred to as 303(d) list] which was distributed for public review on February 8, 2017.

The Program has many concerns with the draft 2016 Los Angeles Water Board's proposed revisions to the 303(d) list of impaired waters. Several errors and inconsistencies hampered our ability to fully vet and review the proposed 303(d) list. It is our opinion that significant review and modifications must be made before adoption and additional public review after modifications will be necessary.

Requested Action:
After full consideration of all comments, revise draft 303(D) list, and allow for another 60-day comment period prior to adoption.

It is critical that the Los Angeles Water Board's proposed revisions to the 303(d) list follow the State Water Resources Control Board (SWRCB) Listing Policy and be based on sound science and methodologies. The development and implementation of Total Maximum Daily Loads (TMDLs) is already a significant investment of resources, and the 303(d) list will drive pollutant waterbody prioritization under the potential Watershed Management Plan option in our next NPDES MS4 Permit.

800 South Victoria Avenue • Ventura CA 93009-1610
805/654-2002 • FAX 805/654-3350

Without closely following the Listing Policy, pollutants may be listed where an impairment does not exist leading to misplaced priorities and squandered resources. Focused attention should be paid to identifying beneficial uses, impairments due to natural conditions, and applicability of data.

Data from a single point in time, or which is not representative of the receiving water, should be excluded from this effort as should data with results reported below reporting limits (J-flagged). It appears the Program's outfall data was erroneously included for the Santa Clara River. This sampling location represents the runoff discharging from an MS4, not the receiving water quality, and is mostly from infrequent and short-term rain events. Of special concern is where the beneficial use MUN is driving 303(d) listings even though it should not be applied because it is identified as P* and is a conditionally applicable beneficial use.

> **Requested Action:**
> **Strictly comply with the State Water Resources Control Board (SWRCB) Listing Policy on identifying beneficial uses, impairments due to natural sources, and the appropriate data to support a listing.**

The Program supports the comments from the County of Ventura where a more detailed description of the issues identified here is discussed. The Program also supports the comments from the Calleguas Creek Watershed Stakeholders, as well as the Ventura County Irrigated Lands Group (VCAILG) who will be submitting separate comment letters regarding the proposed listing changes in the Calleguas Creek Watershed and VCAILG-affected waterbody segments.

Significant resources are expended when a pollutant is included on the 303(d) list. Errors in this process, and the challenges of delisting a pollutant, divert our limited funding and staff time away from improving water quality. We greatly appreciate your attention to these requests and look forward to a 303(d) list that appropriately identifies the water quality issues within Ventura County.

If you have questions, please contact me at Arne.Anselm@ventura.org or (805) 654-3942.

Sincerely,

Arne Anselm, Chair
On Behalf of the Ventura Countywide Stormwater Management Committee

Los Angeles, CA 90013

RE: Comment Letter – Proposed Revisions to the Clean Water Act Section 303(d) List for the Los Angeles Region and the 2016 Integrated Report

Attn: Jun Zhu,

Ventura Water, a department of the City of San Buenaventura (City), appreciates the opportunity to comment on the proposed revisions to the Clean Water Act Section 303(d) list for the Los Angeles Region and the 2016 Integrated Report (hereinafter "303(d) list"). The City's Public Works Department is submitting a concurrent letter that discusses the overall proposed listings that impact the City generally. The specific focus of this comment letter by Ventura Water is on the Santa Clara River Estuary (SCRE) proposed listings. New constituents on the list for the SCRE include ammonia and pH. Constituents that are proposed to remain on the list of particular note include nitrate and toxicity.

Ventura Water specifically requests the Los Angeles Regional Water Quality Control Board (Regional Board):

- Reconsider proposed ammonia listing by recalculating the exceedances and using more recent data sets currently available to the Regional Board.
- Reconsider the proposed pH listing based on consideration of reference conditions data, which indicate that substantial fluctuations in estuarine pH values are typical, and consistent pH values that comply with water quality objectives are not biologically attainable within estuaries.
- Delist nitrate based on a recalculation using appropriate data and correct use of averaging periods for the data.
- Reevaluate toxicity listing once the data is appropriately aggregated and averaged.
- Reevaluate ChemA, Taxophene, and Indicator Bacteria listings once more recent data is taken into consideration.
- Address the issues identified in this letter and release a revised, proposed 303(d) list for another 60-day comment period prior to adoption.

Relevant Background Information. It is important to our overall comments on the 303(d) list to understand the context of the Santa Clara River and SCRE. Like many southern California rivers, the Santa Clara River has very minimal flows in the dry months leading to stagnant conditions in the SCRE that encourage algae growth and variations in both dissolved oxygen (DO) and pH due to the algae respiration cycles, as is the case to some extent even in more natural estuaries where conditions have not been modified. The river ends in the SCRE, which experiences both open and closed mouth periods due to beach berm formation and periodic, typically wet weather breaches. The SCRE is wind-mixed and mostly uniform in water quality, especially during closed mouth conditions. The Ventura Water Reclamation Facility (VWRF) discharges approximately 8 million gallons per day (mgd) of disinfected, tertiary effluent first to wildlife/water quality ponds, and then to the SCRE. During dry weather, the tertiary treated flows can be the dominate supply of water to the SCRE to support wildlife species that utilize it. Species that utilize the SCRE include the following state and federally listed species: steelhead trout, tidewater goby, snowy plover, and California least tern.

Ventura Water has spent many years studying the SCRE both independently, and pursuant to requirements of its NPDES permits. Ventura Water has invested more than $21,000,000 dollars in treatment process upgrades of the Ventura Water Reclamation Facility (VWRF) to improve the quality of the tertiary treated flows discharged to the SCRE. Ventura Water also currently recycles approximately 1 mgd for urban irrigation. Ventura Water is also currently working on implementing a potable reuse program that would divert up to 100% of its discharges to water reclamation uses, and identifying how much effluent can be diverted from the SCRE while still protecting its ecology and ecology-related beneficial uses and without "taking" (as that term is defined under the state and federal Endangered Species Acts, as applicable) any of the listed species that use or occupy the SCRE.

General Comments. Of particular concern to Ventura Water with regard to the proposed 303(d) list is that much of the data used to determine water quality impairment for the SCRE is older data that is not representative of current conditions. The Staff report states, "Data used as part of the 2016 Integrated Report were received through August 30, 2010." The report then goes on to later say, "All readily available data and information in the administrative record was considered in the development of the 2016 Integrated Report." These statements are at odds with each other as by choosing to only rely on data collected through 2010; quite clearly the 303(d) list was not developed with all readily available data as required by the Listing Policy. Significant plant improvements have be implemented since 2010. VWRF monitoring data since the plant upgrades are readily available and should be included within the 303(d) list determination analyses.

The SCRE has also been heavily regulated by the VWRF's NPDES permits. Many of those permit requirements have become more stringent since 2010, with the application of technology based limitations. By Ventura Water's estimation, many of constituents on the proposed 303(d) list are not appropriate given recent water quality data.

Lastly, based on current data and the State Water Resources Control Board's "Water Quality Control Policy For Developing California's Clean Water Act Section 303(d) List" ("Listing Policy")[1] requirements to aggregate the data by appropriate reach or area and to use appropriate averaging periods, Ventura Water disagrees with some of the constituent listings and requests recalculation of exceedances. This letter addresses the proposed 303(d) listings and presents current data for each proposed SCRE impairment listing.

Ammonia Comments

The new ammonia listing cites that it is based on 4 exceedances out of 42 samples based on un-ionized ammonia concentrations using data collected from 1997 to 2010. While this meets the technical, formulaic requirements for number of exceedances set forth in the Listing Policy Table 3.1 for placing a waterbody on the 303(d) list, the methods and data used to calculate the exceedances are not clear. To calculate the concentration of un-ionized ammonia, total ammonia must be converted to un-ionized ammonia using site specific pH and temperature conditions within the SCRE at the time of the ammonia sampling. No conversion calculations for total ammonia were provided in the data set provided in the fact sheet; therefore, it is difficult to determine which pH and temperature data were used to correlate to corresponding total ammonia data. An accurate analysis should ideally connect pH, temperature, and ammonia data with a reasonable averaging criteria or statistical determination if multiple data points were used. Ventura Water requests recalculation of the exceedances based on current total ammonia data as well as proper calculations of un-ionized ammonia that take into account temperature and pH conditions that occurred, or should have been expected during the total ammonia sampling events.

More specifically, closer inspection of the 1997 through 2010 data set used to determine the 4 exceedances indicates that the pH data used to calculate un-ionized ammonia was potentially data retrieved from a continuous monitoring, multiparameter Sondes (2009-2010) deployed for the City's Phase 1 Estuary Study (Stillwater Sciences 2011), among other data. The only total ammonia data collected as part of the Phase 1 study were collected on 6 days in 2009 and 2010. Corresponding pH and temperature were collected along with these samples. However, Ventura Water is concerned that these data do not represent the SCRE as a whole, specifically after the improvements to the VWRF (after November 2011). Moreover, only total ammonia is shown in that data set, and the data set does not include the calculation of un-ionized ammonia. Monthly grab sample temperature and pH data for the receiving water exists for some of the monitoring years cited (1997 - 2010), but grab data is not reliable for purposes of determining the one-hour maximum values for temperature and pH.

In light of the aforementioned issues with the methods that appear to have been used to calculate un-ionized ammonia using a 1997 to 2010 data set, Ventura Water requests the Regional Board provide the

[1] California State Water Resources Control Board, "Water Quality Control Policy For Developing California's Clean Water Act Section 303(d) List," Adopted September 30, 2004, Amended February 3, 2015.

calculation for the un-ionized ammonia, and update the calculation as appropriate to include more recent and more valid total ammonia, pH, and temperature assumptions from other data sets readily available to the Regional Board. Based on Ventura Water's more recent monitoring results, all of which constitute data readily available to the Regional Board, it does not appear that the SCRE un-ionized ammonia water quality objective is likely to have been exceeded a sufficient number of times to warrant a listing. Ventura Water requests the Regional Board utilize the data submitted to it by Ventura Water more recently than 2010 to assure that the evaluation of receiving water conditions in the SCRE is reasonably representative of current conditions.

The Regional Board imposed stringent ammonia limits and a time schedule to attain those limits on VWRF discharges of tertiary treated flows in both its 2008 and 2013 NPDES permits. To comply with these limits and to better control nitrates, Ventura Water invested more than $21 million in a VWRF plant improvement project to implement nutrient removal in its biological processes. This treatment upgrade project undertaken to meet the stringent NPDES permit ammonia effluent limits came online in November 2011. Since then, VWRF NPDES permit effluent limits for ammonia, including its water quality based effluent limits, have only been exceeded once, indicating that ammonia conditions in the SCRE have changed since November 2011, and the data relied upon in developing the proposed 303(d) list is not representative of conditions within the SCRE.

The receiving water standards for the SCRE (used to establish the NPDES effluent limitation) are set based on un-ionized ammonia for saltwater criteria. The limits used to determine the 303(d) listing are the same criteria that are used to calculate limits in the NPDES permit (1999 Update of Ambient Water Quality Criteria for Ammonia):

- One Hour Concentration = 0.233 mg/l unionized ammonia, based on fish spawning, and
- 4 day average of 0.035 mg/L of unionized ammonia

The total ammonia NPDES effluent limit calculated to meet this water quality objective is total ammonia of 1.07 mg/l average monthly and 1.17 mg/l max daily in the summer. Limits in the winter months are slightly higher. The limits were determined in accordance with EPA standards by considering the 50th and 90th percentile pH and temperature for considering chronic and acute toxicity.

As shown in Figure 1 below, the total effluent ammonia from 2012 to 2016 only exceeded 1 mg/l once out of 59 samples, thus not exceeding the Listing Policy's binomial distribution null hypothesis Table 3.1 criteria for listing a constituent on the 303(d) list (i.e., would need at least 5 exceedances). Similarly, the receiving water samples from 2012 to 2016 only exceeded 1 mg/l total ammonia twice out of 60 samples, so also not meeting the Table 3.1 criteria for listing a constituent on the 303(d) list.

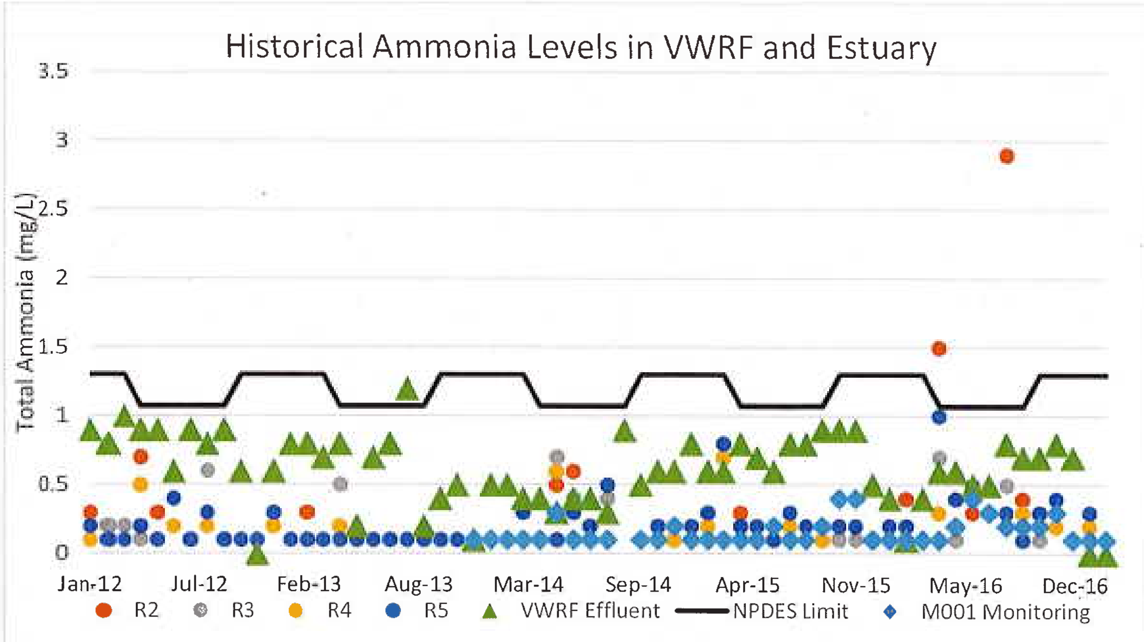

Figure 1 Historical Effluent and Receiving Water Ammonia Monitoring

The effluent compliance point for all constituents except for flow in the 2013 NPDES permit for the VWRF is station M001, which is located at the Effluent Transfer Station (ETS) right before discharge into the wildlife ponds. Station M001A is located downstream of the wildlife ponds. It is only used for compliance with flow, but ammonia levels have been monitored there, starting in December 2013. Total ammonia actually drops from the compliance point to M001A as water passes through the wildlife ponds, likely due to a combination of volatilization and vegetative uptake. Therefore, the ammonia concentrations in the discharges into the SCRE are well below the permit standards that were set up to meet the ammonia receiving water quality objectives for saltwater, which are more stringent than freshwater standards. The comparison of ETS versus M001A data is shown in Figure 2.

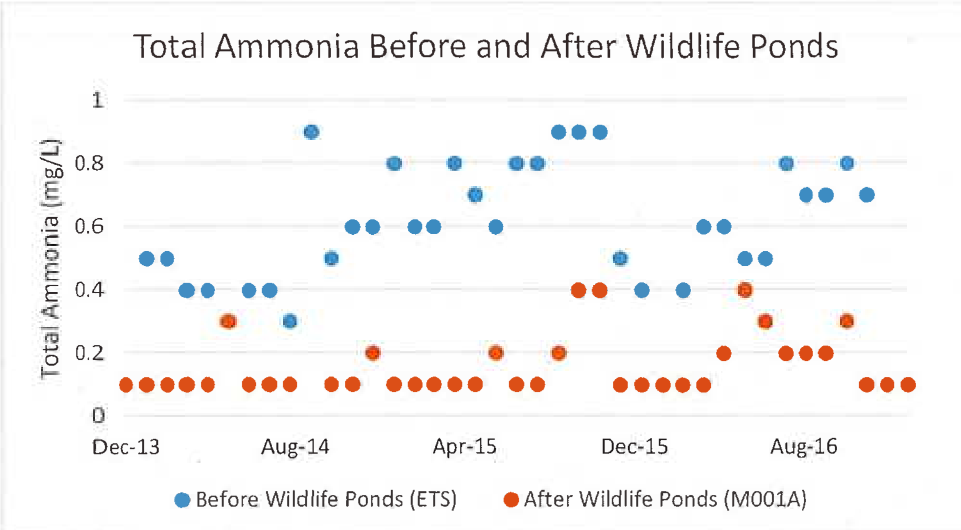

Figure 2 Historical Effluent Ammonia Before and After Wildlife Ponds

In light of the treatment plant upgrades implemented to reduce ammonia, and the fact that more recent data indicates only 1 exceedance in 59 samples, Ventura Water requests recalculation of the exceedances for ammonia and reconsideration of the listing decision based on the more recent data set currently available to the Regional Board.

pH Comments

It is important to understand that many estuaries exhibit wide daily variations in pH mediated by algae as the result of daily photosynthesis and nighttime respiration (Park et al 1958).[2] Beyond potential connections between algal productivity with the multiple nutrient sources to the SCRE (e.g., VWRF, agricultural runoff, groundwater, riverine, VWRF, ocean exchanges), algal growth and pH variations in the SCRE are exacerbated by physical factors as well (e.g., shallow waters, lack of consistent riverine flows, intermittent breaching and limited tidal exchange with the ocean). Consideration of the estuarine conditions likely to induce large pH swings is supported by recent monitoring data fully available to the Regional Board that shows that the VWRF plant tertiary treated flows are always in compliance with pH effluent limits (shown as a black dot on Figure 3). However, despite the very steady and compliant pH values for the tertiary treated flows, the receiving water does experience wide swings in pH as shown in Figure 3 below even when data collected from 2012 through 2016 is analyzed. However, it is important to note that the receiving water pH data is collected by grab samples (via boat) in the SCRE, likely at

[2] Park, K., D.W. Hood, and H.T. Odum. 1958. Diurnal pH variation in Texas bays, and its application to primary production estimation. Publication of the Institute for Marine Sciences, Texas 5: 47–64.

similar times of day and therefore does not necessarily reflect actual conditions in the estuary over the course of the day or the month.

The receiving water data collected could theoretically meet the Listing Policy formulaic criteria. However, the determination whether to list should not be considered in a vacuum, but rather must also take into account the "type of waterbody (Bay and Harbors, Coastal Shoreline, *Estuary*, Lake/reservoir...)" being considered for impairment.[3] One way to take into account the type of waterbody considered for a 303(d) listing is to consider "reference conditions" as defined in Section 7 of the Listing Policy to understand the characteristics of estuarine water bodies that are least impaired by human activities to determine attainable biological conditions for such waterbodies in southern California. As discussed earlier, studies of pH variation in estuaries reveals that wide swings in pH due to the presence of algae constitute reference conditions for typical estuaries.

The proposed listing does not appropriately demonstrate that the high pH was a result of waste discharge as required in the Los Angeles Region Basin Plan (Basin Plan).[4] As stated in the Fact Sheets and according to the Basin Plan, "The pH of inland surface waters shall not be depressed below 6.5 or raised above 8.5 as a result of waste discharges."[5] However, it was not demonstrated for the SCRE that the elevated pH levels were a result of waste discharge as opposed to natural causes. Therefore, the Regional Board should either provide evidence that the elevated pH was a result of waste discharge and detail that in the Fact Sheets or, if not such evidence exists, the Regional Board should remove this proposed listing.

Ventura Water requests reconsideration of the proposed pH listing for the SCRE based on consideration of reference conditions data, which indicate that substantial fluctuations in estuarine pH values are typical, and consistent pH values that comply with water quality objectives are not biologically attainable within estuaries.

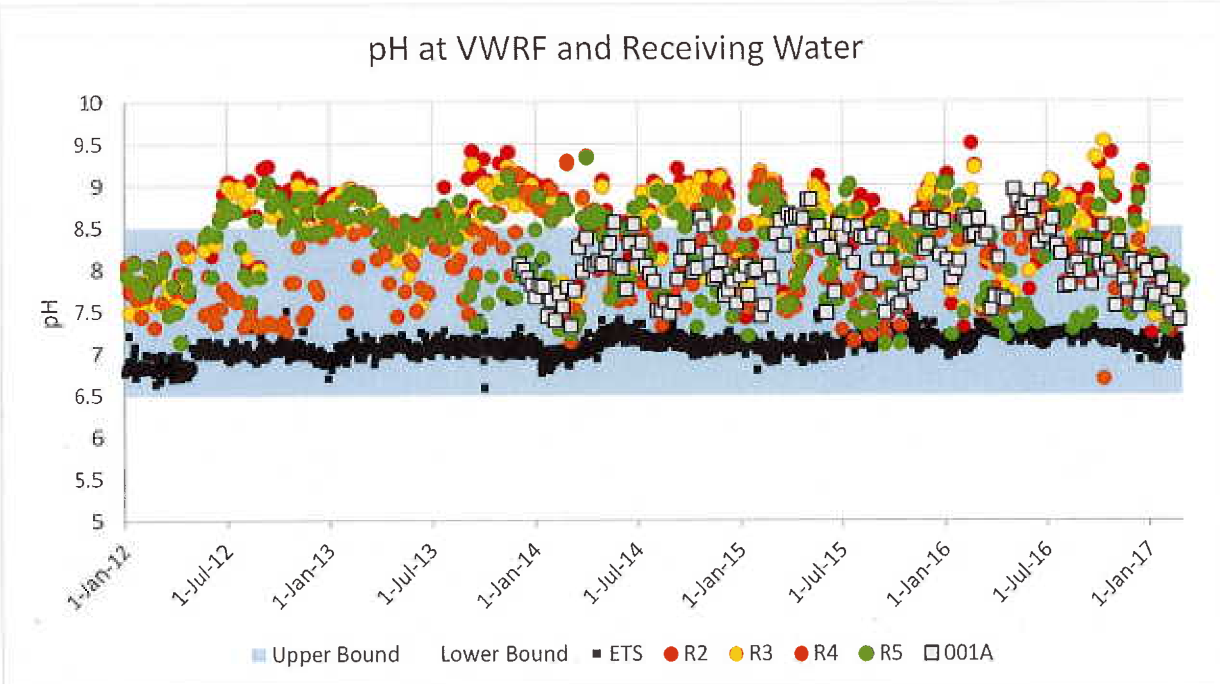

Figure 3 pH at VWRF and Receiving Water Locations

Nitrogen and Nitrate Comments

Nitrogen/nitrate (collectively "nitrate") was originally listed on the 303(d) list adopted in 2012. The nitrate listing is based on receiving water samples collected between 2002 and 2007. Given that Ventura Water implemented a nitrification and denitrification project in November 2011, nitrate data collected before 2011 is no longer representative of SCRE conditions, and is therefore not reliable for determining current SCRE exceedance estimates. In reviewing receiving water data collected monthly from 2012 through 2016 (60 sample dates), which is submitted to the Regional Board as part of NPDES reporting and is therefore readily available data under the Listing Policy, there were only 5 days during which SCRE water quality exceeded the nitrate receiving water quality objective of 10 mg/l . Because the SCRE is wind-mixed and fairly uniform (Phase 1 Estuary Subwatershed Study, Stillwater 2011), we would argue that on any given day, sampling at a given location is strongly influenced by conditions at other nearby locations. The Listing Policy states:

> "Based on these evaluations of the water body setting, the Regional Water Boards should aggregate the data by appropriate reach or area. ... To be considered temporally independent, samples collected during the averaging period shall be combined and considered one sampling

event. ... If the averaging period is not stated for the standard, objective, criterion, or evaluation guideline, then the samples collected less than 7 days apart shall be averaged."[6]

As shown in Figure 4 below, exceedances in multiple locations occurring in the SCRE on the same sampling date should be considered a single event because the multiple sampling results are designed to provide a spatial representation of the estuary during any particular event of exceedance. According to the binomial distribution null hypothesis (Listing Policy Table 3.1), the listing requirement for 60 to 71 data points is 6 exceedances, which is more than the current 5 exceedances demonstrated by the more recent data set developed after Ventura Water's implementation of treatment plant and treatment process upgrades.

Section 4 of the Listing Policy states that a water segment shall be removed from a 303(d) listing if the water meets the water quality standards. Using Policy Table 4.1, the null hypothesis indicates that for 60 to 71 data points, if there are 5 exceedances or less, then the water segment can be delisted. **Based on current data, the number of exceedances (5) meets the delisting criteria, and given that VWRF already has an NPDES permit limit for nitrate, Ventura Water requests recalculation of the exceedances based on current data and correct use of averaging periods for the data (data collected on the same day to be averaged). Ventura Water requests that based on this recalculation, nitrate be removed from the 303(d) list for the SCRE.**

[6] Listing Policy, pp. 23, 24.

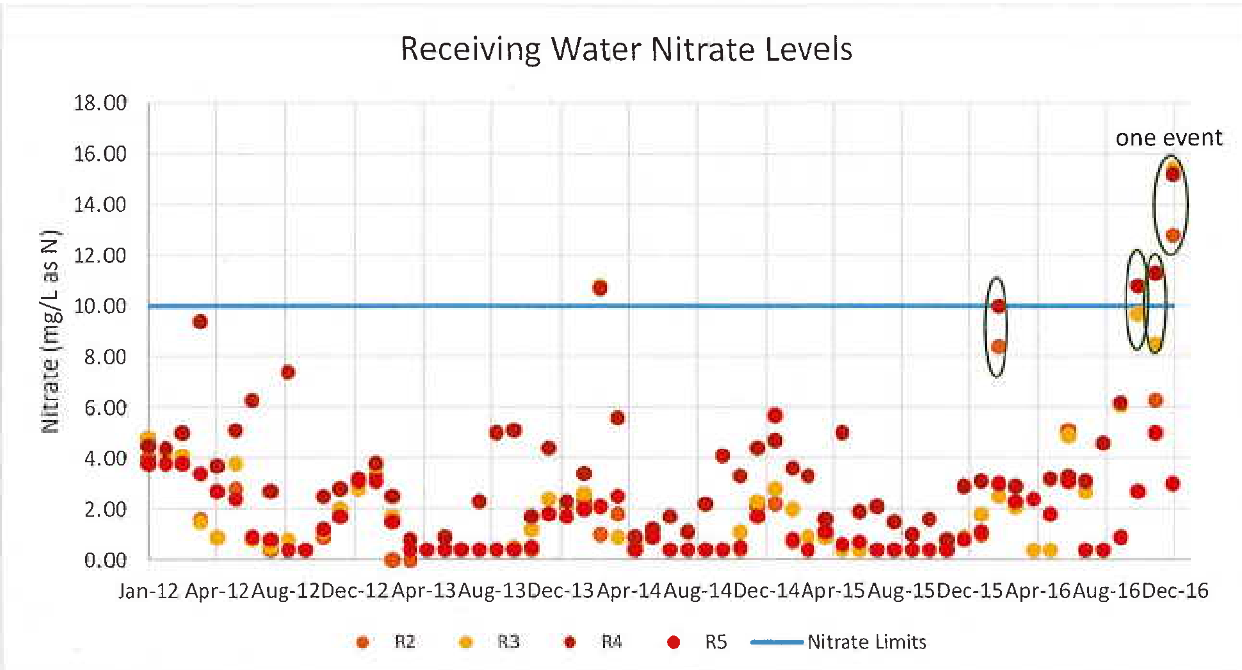

Figure 4 Receiving Water Nitrate Levels

Toxicity Comments

The City monitors chronic toxicity using Selanstrum for both effluent and receiving water. Using readily available data collected by Ventura Water from 2012 – 2016 and submitted to the Regional Board, the VWRF tertiary treated flows consistently met toxicity criteria of 1 TUc for the 60 samples, as shown in Figure 5. However, receiving water monitoring data does not similarly show consistent and full attainment of toxicity criteria. The receiving water monitoring locations have a data set of 25 sample dates. **Using the argument presented above that the data should be aggregated and appropriate averaging should be used, Ventura Water requests that each sampling event (day) be considered separately and the data points be averaged.**

To meet the Listing Policy Table 4.1 requirements for delisting, with 26 data points there would need to be 2 or fewer exceedances of toxicity objectives for the SCRE. Even considered as single events, there have been more than 2 exceedances of a 1 TUc, although those exceedances are unrelated to toxicity of tertiary treated flows, which did not show exceedances. Therefore, it does not appear that delisting the SCRE for toxicity would be appropriate at this time, even though toxicity exceedances are unrelated to VWRF tertiary treated flows. **However, Ventura Water requests this listing be reevaluated once the data is appropriately aggregated and averaged.**

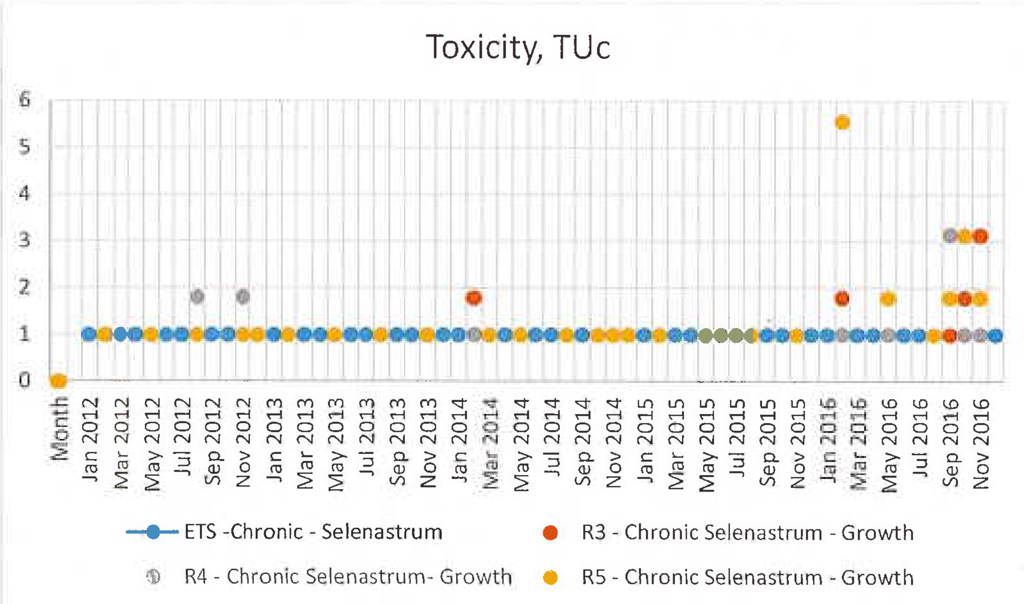

Figure 5 Effluent and Receiving Water Toxicity

ChemA

ChemA is being included on the 303(d) list without any supporting data. The reasons for its listing are that the U.S. EPA approved a TMDL for the estuary in 2011. However, no data, historic or otherwise, were used to support the continued placement on this list. **Ventura Water requests that recent data be taken into consideration when assessing the placement of ChemA on the 303(d) list.**

Toxaphene

Similar to ChemA, toxaphene was included on the 303(d) list due to its TMDL status with the U.S. EPA, circa 2011. No new information or data was brought forward to support the status on the list. Based on data collected semiannually by the VWRF, toxaphene has not even been detected in either the effluent or the receiving water in recent memory. **Ventura Water requests that recent readily available data be taken into consideration when assessing the placement of toxaphene on the 303(d) list.**

Indicator Bacteria

Similar to ChemA and toxaphene, indicator bacteria was included in the 303(d) list due to its TMDL status with the U.S. EPA, circa 2011. No new information or data was brought forward to support the status on the list. **Ventura Water requests that recent data be taken into consideration when assessing the placement of indicator bacteria on the 303(d) list.**

Summary/Conclusion

Ventura Water appreciates the opportunity to comment on the proposed 303(d) list. Based on the analysis presented above using more recently collected, readily available data that properly represents existing conditions in the SCRE (2012 - 2016), our findings include:

- Appropriate ammonia data were not considered in the proposed listing and current data do not meet the Listing Policy criteria for 303(d) listing.
- A listing for pH is not warranted in light of reference conditions for pH within estuaries, which indicates that steady state pH values in compliance with water quality objectives are not biologically attainable even in high functioning estuaries.
- Nitrate should be delisted based on relevant Listing Policy criteria.
- Toxicity is unrelated to VWRF discharges of tertiary treated water to the SCRE, and the listing should be reevaluated once the data is appropriately aggregated and averaged.
- Chem A, Toxaphene, and Indicator Bacteria listings did not include recent data and should be reevaluated based on current data.

It is important to note the City has been conducting studies on the SCRE since 2009 per the special studies requirements in the NPDES permits for the VWRF. These studies analyze the existing discharge impacts/benefits to aquatic habitat, and evaluate alternatives that include a reduction in discharge, improvement in discharge water quality, or a combination of both, for the purpose of improving aquatic habitat. These studies are site specific, taking into account the listed species using or occupying the SCRE, and the associated physical/chemical parameters that contribute to site specific aquatic habitat conditions. The results of the studies will be presented in the Phase 3 Estuary Studies Report (expected January 2018), and will provide a detailed understanding of the SCRE and information relevant to the 303(d) listing process.

Respectfully,

Gina Dorrington

Regular Meeting of the California Regional Water Quality Control Board

Los Angeles Region

Consideration of the Proposed Revisions to the Clean Water Act Section 303(d) List of Impaired Waterbodies in the Los Angeles Region

(Note: Appendix B through Appendix H are available and will be updated next week at http://www.waterboards.ca.gov/losangeles/water_issues/programs/303d/2016/2016_303d.shtml)

Consideration of the Proposed Revisions to the Clean Water Act Section 303(d) List of Impaired Waterbodies in the Los Angeles Region

EXECUTIVE SUMMARY

California Regional Water Quality Control Board
Los Angeles Region
May 4, 2017

Item Number	9
Proposed Board Action	Approval of Revisions to the Clean Water Act Section 303(d) List of Impaired Waterbodies in the Los Angeles Region
Need for Action	**Background.** The federal Clean Water Act requires each state to assess the status of water quality in the state (per section 305(b)), and provide a list of impaired waterbodies (per section 303(d)) to the U.S. Environmental Protection Agency (USEPA) every two years. An "Integrated Report" documents the outcome of these two efforts.

These efforts entail reviewing available monitoring data for surface waters, including river reaches, tributaries, lakes, and coastal waters. Waterbodies are evaluated for their support of beneficial uses including, among others, aquatic life support, fish consumption, recreation, and municipal and domestic supply based on a comparison of water quality data to applicable water quality objectives. Waterbodies are placed into one of five non-overlapping categories based on the overall beneficial use support of the water segment and the need for a TMDL.

Waterbody Categories

Category	Description
1	All assessed beneficial uses supported and no beneficial uses known to be impaired.
2	There is insufficient information to determine beneficial use support.
3	There is insufficient data to make a beneficial use support determination but data indicate beneficial uses may be threatened.
4	At least one beneficial use is not supported, but a TMDL is not needed.
4a	*One or more TMDLs have been developed and approved by USEPA for all pollutants causing impairment.*
4b	*Another regulatory program is reasonably expected to result in attainment of the water quality standard.*
4c	*The impairment is the result of pollution, not a pollutant.*
5	At least one beneficial use is not supported and a TMDL is still needed.

EXECUTIVE SUMMARY

Waterbodies listed in categories 4a, 4b and 5 make up the 303(d) list. For water quality limited segments (a.k.a. impaired waterbodies) included on the 303(d) list, the state is required to develop a Total Maximum Daily Load (TMDL) or take other action to address the impairment.

Scheduling. The State Water Board has established a procedure for developing California's statewide "Integrated Report," including its 303(d) list, in which groups of three Regional Water Boards submit their regional "Integrated Reports" and 303(d) lists in a rotating fashion every six years. The State Water Board established this procedure in consideration of the large size of the State, the extensive amount of data to evaluate, and the increasing complexity of data analysis. In addition, beginning with the 2018 303(d) list, all data to be evaluated by the Water Boards for the Integrated Report and 303(d) list must be submitted to the California Environmental Data Exchange Database (CEDEN).

The State Water Board adopted these changes as amendments to the *Water Quality Control Policy for Developing California's Clean Water Act Section 303(d) List* (Listing Policy) in February 2015. The purpose of these and other changes is to improve the State of California's ability to produce a statewide 303(d) list every two years.

The last update to the State's 303(d) list that included the Los Angeles Region was the 2010 303(d) list. The 2010 303(d) list included data submitted through February 28, 2007. For the 2016 303(d) list, the State Water Board accelerated the schedule for Regions 2, 4 and 8 and set a deadline of May 2017 for these Regional Water Boards to provide their region's changes to the 303(d) list. The State Water Board determined that the 2016 303(d) list for these three regions would only address data submitted prior to August 30, 2010, which is the same data period as for the other six regions' most recent 303(d) lists. The State Water Board intends to consider the 303(d) lists for Regions 2, 3, 4, 5, 8, and 9 in fall 2017. The State Water Board previously approved the 303(d) lists for Regions 1, 6, and 7.

Workflow. During this process, the State and Regional Water Boards have divided the work in the following manner. State Water Board staff solicited data, reviewed the data received, entered all acceptable data into the California Water Quality Assessment (CalWQA) database, and created lines of evidence (LOEs) to be considered at the decision-making stage. Each LOE addresses a specific waterbody pollutant combination. The key fields in the LOEs include, but are not limited to, waterbody name, pollutant, beneficial use assessed, sample type (water, sediment, or tissue), evaluation guideline (i.e., applicable water quality objective), number of samples and number of exceedances.

Each LOE also identifies the spatial and temporal representation of the samples as well as quality assurance information. Regional Water Board staff assessed the LOEs in CalWQA and made the listing recommendations of "list," "do not list," "delist" or "do not delist." For this list update, Regional Water Board staff reviewed approximately 11,000 LOEs and made approximately 5,800 decisions.

All of the waterbodies assessed, whether in previous listing cycles or this listing cycle, are grouped into the categories presented in the table above. The waterbodies in each category are listed in appendices to the Staff Report. As previously indicated, the lists of waterbodies in categories 4a, 4b and 5 are those that comprise the 303(d) list. Lists of the waterbodies in the other categories are provided, but do not require Board approval per the State's Listing Policy.

The Staff Report and Appendix A to the Staff Report, "Proposed Updates to the 303(d) List," are included in the Board Package. Appendices B - H are provided as web links due to the length of the documents, and to preserve access to hyperlinks embedded in these appendices. For each proposed change to the 303(d) list, a "factsheet" with detailed information on the decision is available (Appendix G).

Stakeholder Participation

The State Water Board issued a public solicitation for water quality data on January 14, 2010 (and an amended solicitation on May 24, 2010). The data solicitation closed on August 30, 2010.

The Los Angeles Water Board publicly noticed the Tentative Resolution and Staff Report with appendices including factsheets for this listing cycle on February 8, 2017 for a 30-day public comment period. In response to stakeholder requests, the Los Angeles Water Board extended the public comment deadline to March 30, 2017. During the public comment period, Board staff met with several commenters.

Summary of Comments

The Los Angeles Water Board received 32 comment letters from municipalities, POTW agencies, other dischargers, and environmental non-profit organizations.

The majority of comments concerned the appropriateness of a specific pollutant or waterbody condition being included or not included on the 303(d) list of impaired waters. The Board's responses are included in the Response to Comments. We present some of the key comments and responses below.

Several commenters identified instances where data submitted to the State Water Board by the August 2010 deadline were not included in the CalWQA database. Several commenters also noted that LOEs were developed to evaluate a municipal and domestic water supply (MUN) beneficial use in waters where the MUN use was conditionally designated (i.e., identified as MUN P in the Basin Plan). These LOEs were developed in error. To address these comments, Regional Water Board staff will work with the State Water Board staff to resolve them prior to consideration by the State Water Board.

In addition, several commenters identified instances where data were not assigned to the correct waterbody because the mapping underlying the CalWQA database did not match the waterbody delineations in the Los Angeles Region Basin Plan. Board staff will work with State Water Board staff to correct the CalWQA mapping and propose revised decisions, where appropriate. This will be addressed as soon as possible and no later than the next listing cycle for the Los Angeles Region.

Two commenters, Wishtoyo and Earth Law Center, provided comments on flow and flow-related listings that have long been on the Los Angeles Water Board's 303(d) list, such as listings for "fish barriers," "pumping" and "water diversion." The State's Listing Policy clarifies that the 303(d) list only covers waterbody impairments by "pollutants" (rather than flow-related listings such as pumping or water diversion). In addition, a TMDL already addresses four of these flow-related listings in the Ventura River. In cases where a TMDL is addressing the listing, Board staff proposes to retain the listing as "being addressed by a TMDL" in the 4a category (or 5B if another pollutant requires a TMDL in that waterbody). In the other cases, Board staff proposes to remove the listing from the 303(d) list, since it is not a "pollutant". The Water Boards do not have a defined methodology or established thresholds for determining impairment due to non-pollutant related pollution and, more specifically, the Water Boards do not have an established approach to analyzing the extent to which flow-related alterations may cause water quality impairments relative to applicable water quality standards.

The Farm Bureau of Ventura County provided comments on listing decisions that were based primarily on data collected under the Irrigated Lands Conditional Waiver program. The Farm Bureau maintains that several of the waterbodies assessed are "agricultural ditches" and, therefore, not candidates for identification on the 303(d) list. Board staff finds that all these surface waters are subject to the provisions of section 303(d). However, we intend to review the data with the commenter to determine if waterbody-pollutant combinations could be included in Category 4b (where another regulatory program such as the Irrigated Lands Program is reasonably expected to result in attainment of the water quality standard within a reasonable, specified timeframe).

Many commenters noted that the proposed 303(d) list revisions only consider data up to 2010 and that more recent data would support different listing decisions. As discussed in the summary above, the State Water Board determined that the Water Boards would only consider data through August 2010 for the 2016 303(d) list.

Finally, in response to comments, we have made a number of corrections to the 303(d) list by identifying more waterbody-pollutant combinations that are within the category of "being addressed by a TMDL."

Status of Response to Comments

The comment letters received are included in the Board Package. The Response to Comments will be included in a supplement to the Board Package.

Alternatives

Alternatives for Board consideration include:

1. Approve the proposed 303(d) list.

   The approved Los Angeles Region 303(d) list will be forwarded to the State Water Board for inclusion in the Statewide 303(d) list. The Statewide list will be made available for public comment and will require approval by the State Water Board before being forwarded to USEPA for final approval.

   The 303(d) list is always a work-in-progress; new data are being collected continually, waterbody delineations are periodically updated, water quality objectives are added and/or modified, analytical methodologies advance, etc. While the 303(d) list is approved at set intervals, the Water Boards are continually working on it in some fashion. In light of this reality, and as indicated earlier, Regional Water Board staff will work with State Water Board staff to address several of the issues described above either prior to State Water Board consideration, or for mapping inconsistencies, as soon as possible and no later than the next listing cycle.

2. Do not approve the proposed 303(d) list.

   The State Water Board will proceed with its action to consider a consolidated 2014/2016 303(d) list based on the approved or proposed 303(d) lists for each of the six Regional Water Boards, including the Los Angeles Water Board.

Recommendation

Staff recommends approval of the proposed 303(d) list.

State Of California
California Regional Water Quality Control Board, Los Angeles Region

RESOLUTION NO. R17-XXX

April 6, 2017

Approval of Recommendations for the Federal Clean Water Act (CWA) Section 303(d) List

T E N T A T I V E

WHEREAS, the California Regional Water Quality Control Board, Los Angeles Region finds that:

3. Section 303(d) of the CWA and Title 40, Code of Federal Regulations Section 130.7 require states to develop and submit to the U.S. Environmental Protection Agency (U.S. EPA) for approval a list of water bodies for which water quality standards (beneficial uses and water quality objectives) are not attained, or are not expected to be attained, with the implementation of certain technology-based controls. This list is commonly referred to as the "303(d) List" or the "List of Impaired Waters."

2. Section 305(b) of the CWA requires states to monitor, assess and submit biennially to the U.S. EPA a report assessing statewide surface water quality.

3. The California Integrated Report includes the requirements of CWA Section 305(b) and Section 303(d).

4. The 303(d) List must include a description of the pollutants causing impairment and a completion date for prioritizing the development of a Total Maximum Daily Load (TMDL) for each pollutant.

5. Only the 303(d) List portion of the California Integrated Report requires approval by the State Water Resources Control Board (State Water Board) and the U.S. EPA. Neither agency approves the 305(b) Report portion of the California Integrated Report.

6. The process for developing and approving the 303(d) List, including requests for review of specific listing recommendations by a Regional Water Quality Control Board is outlined in the *Water Quality Control Policy for Developing California's Clean Water Act Section 303(d) List* (Listing Policy).

7. Upon approval, the Los Angeles Water Board's recommended 303(d) List will be submitted to the State Water Board and compiled into a statewide 303(d) List. The

statewide 303(d) List is subject to the approval of the State Water Board and the U.S. EPA.

8. In accordance with sections 6.2 and 6.3 of the Listing Policy, before the Executive Director of the State Water Board or the State Water Board approves the California section 303(d) List, the State Water Board shall provide advance notice and opportunity for public comment. Public comment will be limited to listing recommendations that are timely requested for review pursuant to section 6.2 of the Listing Policy unless the Executive Director or the State Water Board elects to consider recommendations on other waters. To request that the State Water Board or Executive Director review specific listing recommendations approved by a Regional Water Board, the request must be submitted to the State Water Board within 30 days after the Regional Water Board approval.

9. In January of 2010, the State Water Board solicited water quality data from the public with a formal "Notice of Public Solicitation of Water Quality Data and Information for the California Integrated Report," which was sent to interested persons subscribed to the State Water Board's Integrated Report e-mail distribution list. In addition, the Los Angeles Water Board sent the notice to persons subscribed to the Los Angeles Water Board's Basin Plan Amendments and TMDL e-mail distribution lists.

10. In developing the 2016 Integrated Report for CWA Section 305(b) and the Section 303(d) List, the Los Angeles Water Board considered all readily available data and information submitted to the State Water Board during the State Water Board data solicitation period of January 14, 2010 to August 30, 2010.

11. After reviewing all relevant evidence submitted, Los Angeles Water Board staff has:

    - For 305(b), made overall beneficial use support ratings for the water bodies that have been assessed for this 2016 assessment cycle. Categories 1, 2, 3, 4, and 5 of the Los Angeles Water Board's Integrated Report reflect the outcome of the overall use support ratings.

    - For 303(d), made recommendations to add, remove or change the 2016 CWA Section 303(d) List of Impaired Waters for the Los Angeles Water Board's 2016 Integrated Report. The 303(d) List is reflected in Categories 4a, 4b, and 5 of the Integrated Report.

12. On February 8, 2017, the Los Angeles Water Board provided public notice of the 2016 Integrated Report for the Los Angeles Region and a 30-day comment period; issued a Notice of Hearing to interested persons; and published notice of the 2016 Integrated Report and the hearing in the Los Angeles Times and Ventura County Star.

13. Los Angeles Water Board staff responded in writing to the written comments received during the public comment period and revised staff's recommendations for additions, deletions, and changes to the 303(d) List, the supporting 2016 Integrated Report, and water body fact sheets as appropriate.

14. No action is required by the Los Angeles Water Board for staff's assessment of non-impaired water bodies under Section 305(b).

15. On April 6, 2017, the Los Angeles Water Board held a Public Hearing to consider and approve the recommendations for the 303(d) List. The Los Angeles Water Board considered all evidence provided by Los Angeles Water Board staff and the public.

THEREFORE BE IT RESOLVED THAT:

1. The Los Angeles Water Board hereby approves the recommendations for the 2016 303(d) List for the Los Angeles Region.

2. The Executive Officer is to transmit the Los Angeles Water Board's proposed recommendations for the 2016 Integrated Report with its supporting information and evidence including approved revisions, to the State Water Board for its consideration and incorporation into the final 2016 California Integrated Report.

I, Samuel Unger, Executive Officer, do hereby certify the foregoing is a full, true, and correct copy of a resolution adopted by the California Regional Water Quality Control Board, Los Angeles Region, on April 6, 2017.

1. Introduction

The federal Clean Water Act (CWA) gives states the primary responsibility for protecting and restoring water quality. Under CWA Section 305(b), states are required to report biennially to the United States Environmental Protection Agency (USEPA) on the water quality conditions of their surface waters. The USEPA then compiles these assessments into their biennial "National Water Quality Inventory Report" to Congress. Under CWA Section 303(d), states are required to review, makes changes as necessary, and submit to the USEPA a list identifying waterbodies not meeting water quality standards and identifying the water quality parameter (i.e., pollutant) not being met (303(d) list). Placement on this list generally triggers development of a pollution control plan called a total maximum daily load (TMDL) for each waterbody/pollutant pair on the list.

In 2002, the USEPA issued guidance to states requiring that the 305(b) water quality assessment and the 303(d) list of impaired waters be integrated into a single report. This report is called the Integrated Report, and it satisfies both the CWA Section 305(b) and Section 303(d) requirements. The Los Angeles Regional Water Quality Control Board (Los Angeles Water Board) is responsible for developing and adopting the 2016 Integrated Report for waters within the Los Angeles Region of California. Following adoption by the Los Angeles Water Board, the 2016 Integrated Report will be transmitted to the State Water Resources Control Board (State Water Board), where it will be considered by the State Water Board in combination with other Regional Water Board Integrated Reports.

The purpose of this staff report is to describe the assessment process (the procedures used by the State Water Board and Los Angeles Water Board staff to analyze data and information), provide a report of surface water quality in the Los Angeles Region as required by CWA Section 305(b), and provide Los Angeles Water Board staff recommendations for additions, deletions, and changes to the California CWA Section 303(d) List.

The results of the staff analysis are presented as staff recommendations in the form of fact sheets that contain a decision and supporting lines of evidence for each water body/pollutant pair assessed. A summary of staff recommendations can be found in Section 4. The fact sheets are available in Appendix G of this Staff Report.

2. Legal Requirements and Policy

This section provides a summary of the federal and state legal requirements and applicable policies for the 2016 Integrated Report.

2.1 Federal Requirements

2.1.1 CWA Section 303(d) – Impaired Waters

Section 303(d) of the Clean Water Act requires states to identify waters that do not meet applicable water quality standards after the application of certain technology-based controls.[1] The Section 303(d) List must include a description of the pollutants causing the violation of water quality standards (40 CFR §130.7(b)(iii)(4)) and a priority ranking of the water quality limited segments, taking into account the severity of the pollution and the uses to be made of the waters.

Water quality standards include the designated beneficial uses of a waterbody, the adopted water quality objectives to protect those uses (numeric and narrative), and the State's Antidegradation Policy (State Water Board Resolution No. 68-16) (SWRCB 1968).

Federal regulation defines a "water quality limited segment" as "any segment [of a surface waterbody] where it is known that water quality does not meet applicable water quality standards, and/or is not expected to meet applicable water quality standards, even after application of technology-based effluent limitations required by CWA Sections 301(b) or 306" (40 CFR 130.2(j)).

States are required to review the Section 303(d) List in even-numbered years, make changes as necessary, and submit the list to the USEPA for approval. A TMDL is generally developed for a water quality limited segment. A TMDL is the sum of the individual waste load allocations for point sources, load allocations for nonpoint sources, and natural background (40 CFR 130.2(i)).

2.1.2 CWA Section 305(b) – Water Quality Assessment

Under CWA Section 305(b), states are required to report biennially to the USEPA on the water quality conditions of their surface waters. The USEPA then compiles these assessments into their biennial "National Water Quality Inventory Report" to Congress.

2.1.3 The Integrated Report and Waterbody Categories

In 2002, the USEPA issued guidance to states requiring that the 305(b) water quality assessment and the 303(d) list of impaired waters be integrated into a single report. This report is called the Integrated Report, and it satisfies both the CWA Section 305(b) and Section 303(d) requirements.

To meet CWA Section 305(b) requirements of reporting on water quality conditions, the Integrated Report places each assessed waterbody segment into one of five non-overlapping

1 Technology-based controls are defined in CWA Section 301. They include effluent limits (primary and secondary treatment requirements) for industrial discharges and discharges from publically owned treatment works.

categories based on the overall beneficial use support of the water segment and the need for a TMDL. Water segments are evaluated for at least one of six "core" beneficial uses including: municipal and domestic supply, aquatic life support, fish consumption, shellfish harvesting, contact recreation, and non-contact recreation.

Table 1. Integrated Report Categories

Category	Description
1	All assessed beneficial uses supported and no beneficial uses known to be impaired.
2	There is insufficient information to determine beneficial use support.
3	There is insufficient data and/or information to make a beneficial use support determination but information and/or data indicates beneficial uses may be potentially threatened.
4	At least one beneficial use is not supported but TMDL is not needed.
4a	A TMDL has been developed and approved by U.S.EPA for any waterbody-pollutant combination and the approved implementation plan is expected to result in full attainment of the water quality standard within a specified time frame..
4b	Another regulatory program is reasonably expected to result in attainment of the water quality standard within a reasonable, specified time frame.
4c	The non-attainment of any applicable water quality standard for the waterbody segment is the result of pollution and is not caused by a pollutant.
5	At least one beneficial use is not supported and a TMDL is needed.

A waterbody will often have multiple pollutants impairing multiple beneficial uses. In these cases, when the waterbody has TMDLs for all the impaired uses, the waterbody is placed in category 4a; when the waterbody is lacking a TMDL for at least one impairment, the waterbody is placed in category 5.

2.2 California Requirements

On September 30, 2004, the State Water Board adopted the "Water Quality Control Policy for Developing California's Clean Water Act Section 303(d) List," also known as the Listing Policy (SWRCB 2004a) in accordance with California Water Code Section 13191.3(a). The Listing Policy identifies the process by which the State Water Board and the Regional Water Quality Control Boards will comply with the listing requirements of CWA Section 303(d). The Listing Policy became effective in December 2004. Justification of each portion of the Listing Policy is presented in the Final Functional Equivalent Document (SWRCB, 2004b) that was developed to support the provisions of the Listing Policy.

The objective of the Listing Policy is to establish a standardized approach for developing California's Section 303(d) List with the overall goal of achieving water quality standards and maintaining beneficial uses in all of California's surface waters. TMDLs will generally be developed as needed for the waters identified under the provisions of the Listing Policy.

The Listing Policy outlines a "weight of evidence" approach that provides the rules for making decisions based upon different kinds of data, an approach for analyzing data statistically, and requirements for data quality, data quantity, and the administration of the listing process. Decision rules for listing and delisting are provided for chemical-specific water quality standards; bacterial water quality standards; health advisories; bioaccumulation of chemicals in aquatic life tissues; nuisance such as trash, odor, and foam; nutrients; water and sediment toxicity; adverse biological response; and degradation of aquatic life populations and communities. The Listing Policy also requires that situation specific weight of evidence listing or delisting factors be used if available information indicates water quality standards are attained or not attained and the other decision rules do not support listing or delisting.

The Listing Policy also provides direction related to:

- The definition of readily available data and information.
- Administration of the listing process including data solicitation and fact sheet preparation.
- Interpretation of narrative water quality objectives using numeric evaluation guidelines.
- Data quality assessments.
- Data quantity assessments including waterbody specific information, data spatial and temporal representation, aggregation of data by reach/area, quantitation of chemical concentrations, evaluation of data consistent with the expression of water quality objectives or criteria, binomial model statistical evaluation, evaluation of bioassessment data, and evaluation of temperature data.

The Listing Policy requires that *all* surface waters that do not meet water quality standards be placed on the Section 303(d) List. The Policy also states that the California 303(d) List includes (1) waters still requiring a TMDL under Category 5, and (2) waters where the water quality limited segment is being addressed under Category 4. Waterbodies in the "Water Quality Limited Segments Being Addressed" category must meet either of the following conditions:

1. A TMDL has been approved by USEPA and is expected to result in full attainment of the standard within a reasonable, specified time frame (Category 4a).

2. It has been determined that an existing regulatory program is reasonably expected to result in the attainment of the water quality standard within a reasonable, specified time frame (Category 4b).

Waterbodies that are impaired by a non-pollutant source (Category 4c) do not require a TMDL and the State Water Board, in accordance with the Listing Policy, does not consider waters in Category 4c as a part of the 303(d) List. This means that, for California, waters that fall into the Integrated Report Categories 4a, 4b, and 5 are considered part of the California 303(d) List. The USEPA considers Category 5 waterbodies as the only category that constitutes the 303(d) List.

2.3 TMDL Scheduling

In conformance with Section 5 of the Listing Policy, a TMDL completion schedule date is required for all waterbody-pollutant combinations placed on the 303(d) List. Water Board staff relied on guidance from the USEPA (1997), which states that “schedules should be expeditious and normally extend from eight to thirteen years in length, but could be shorter or slightly longer depending on State-specific factors.” Therefore, the timeline for completing TMDLs for waterbodies listed for the first time as part of the 2016 Integrated Report is estimated to be no longer than thirteen years, which equates to an estimated completion date of 2029. Expected TMDL completion dates are proposed by Los Angeles Water Board staff in the fact sheets of this report (Appendix G).

2.4 2010 303(d) List of Impaired Waters

The 2010 303(d) list was adopted by the Los Angeles Water Board on July 16, 2009, in Resolution No. R09-004; adopted by the State Water Board on August 4, 2010, in Resolution No. 2010-0040; and approved by the USEPA on October 11, 2011. The 2010 list included data submitted through February 28, 2007. The 2010 303(d) list is the most recent list which included updates from the Los Angeles Region.

2.5 Changes to California’s Integrated Report 303(d) and 305(b) Process

In February 2013, the State Water Board announced a new strategy for the development of the State’s Integrated Report including establishing three groups of Regional Water Boards and submitting an Integrated Report for one group per listing cycle (i.e. every two years). This strategy was formally described in an *Integrated Report Update Memo* in November 2013 (SWRCB, 2013). The Listing Policy was amended to reflect this and other changes on February 3, 2015.

Therefore, the 2012 Integrated Report consisted of data submitted for the North Coast Regional Water Quality Control Board (Region 1), the Lahontan Regional Water Quality Control Board (Region 6), and the Colorado River Basin Regional Water Quality Control Board (Region 7). On July 30, 2015, the USEPA issued its final decision this update to the 303(d) list and this 2012 303(d) list replaced the 2010 303(d) list as California's current 303(d) list.

The Central Coast Regional Water Quality Control Board (Region 3), the Central Valley Regional Water Quality Control Board (Region 5), and the San Diego Regional Water Quality Control Board (Region 9) recently approved Integrated Reports including a 303(d) list for their respective regions. Region 9 approved its 303(d) list in October 2016 and Regions 3 and 5 approved their 303(d) lists in December 2016. These updates to the 303(d) list were to be approved by the State Water Board as the 2014 303(d) list.

The 2016 Integrated Report will consist of data for the San Francisco Bay Regional Water Quality Control Board (Region 2), the Los Angeles Water Board (Region 4), and the Santa Ana Regional Water Quality Control Board (Region 8). Each of these Regions is expected to approve their lists by April 2017. Until the 2014 and 2016 303(d) list updates are approved by the USEPA, the current list is the 2012 303(d) list.

Due to the volume of data received during the 2010 data solicitation period, the State Water Board determined that no additional data would be solicited or analyzed until all the 2010 data are assessed. Each of the 2012, 2014 and 2016 303(d) lists have assessed only data from the 2010 data solicitation.

In addition, changes to the procedures included in the February 2015 amendment to the Listing Policy, included a requirement that all data be submitted to the California Environmental Data Exchange Database (CEDEN); this change will significantly improve the efficiency of the listing and delisting process so that even with regional updates only once every six years, California will have a more comprehensive assessment and 303(d) list than in the past. The CEDEN website has a new page dedicated to the 303(d) list: http://www.ceden.org/303d_list.shtml.

The data solicitation for the 2018 303(d) list was released on November 3, 2016. The 2018 303(d) list will address Regions 1, 6, and 7.

The Los Angeles Water Board will develop its next Integrated Report, including an updated 303(d) list, in 2022. Los Angeles Water Board staff estimates that the 2022 303(d) list will include data submitted through 2021.

2.6 Public Review and Board Approval of the 2016 303(d) List

Pursuant to section 6.2 of the Listing Policy, waterbodies listed in Category 4a, 4b, or 5, which make up the 303(d) list, are subject to public review and approval by the Los Angeles Water Board. Waterbodies listed in Categories 1, 2, 3, or 4c are provided to the public and to the Los Angeles Water Board as additional waterbody information. All categories will be submitted to the State Water Board for inclusion into the California Integrated Report. Once compiled, the State Water Board will provide public notice of the California Integrated Report for additional public review prior to approval by the State Water Board, as outlined in section 6.3 of the Listing Policy. Waterbodies in Categories 4a, 4b, and 5 will be considered for inclusion in the California 303(d) list.

It is anticipated that the State Water Board will approve the 2014 list updates of Regional 3, 5 and 9 and the 2016 list updates of Regions 2, 4, and 8, during the same State Water Board hearing in 2017.

The California 303(d) list will require final approval by USEPA. If USEPA determines that changes are needed to the submitted report they will initiate further public review before finalizing and publishing the report.

3. Development of the 2016 Los Angeles Region 303(d) List

This section provides a review of the data analysis for the Los Angeles Region's 2016 Integrated Report.

3.1 Data Solicitation for the 2016 303(d) List

In January of 2010, the State Water Board solicited data from the public with a formal "Notice of Public Solicitation of Water Quality Data and Information for the California Integrated Report" (Notice), which was sent to interested persons subscribed to the State Water Board's Integrated Report e-mail distribution list. In addition, the Los Angeles Water Board sent the notice to persons subscribed to the Los Angeles Water Board's Basin Plan Amendments and TMDL e-mail distribution lists. Data used as part of the 2016 Integrated Report were received through August 30, 2010. Data sources include government agencies, municipalities, environmental groups, citizen groups, receiving water data from the National Pollutant Discharge Elimination System (NPDES) dischargers and data collected by the Regional and State Water Boards under the Surface Water Ambient Monitoring Program (SWAMP).

All data and information submitted are available as part of the electronic administrative record (Appendix H). Data and information pertaining to specific waterbody-pollutant assessments are provided in the fact sheets (Appendix G) and link directly to the administrative record.

3.2 Data Processing and Analysis

All readily available data and information in the administrative record was considered in the development of the 2016 Integrated Report. However, only high-quality data supported by a Quality Assurance Project Plan was used to make determinations of water quality standards attainment. In the absence of quality assurance documentation, data is used only as supporting evidence and is not the basis of a listing decision.

Fact sheets and overall beneficial use support determinations were developed in the California Water Quality Assessment (CalWQA) database. Lines of evidence (LOE) summarize: water quality data, information pertaining to where and when the water quality monitoring took place, the pollutant sampled, the beneficial use affected, the water quality objective or guideline protective of the beneficial use, the number of samples collected, and how many samples exceeded the objective or guideline. Potential sources are identified in fact sheets in some cases, otherwise, the potential source was marked "Source Unknown".

Data were aggregated by waterbody segment following the requirements of Section 6.1.5.4 of the Listing Policy, and assessments were performed on the individual segments. Waterbodies were segmented to account for hydrologic features.

Spatial and temporal representation of data was assessed using the requirements and guidance of the Listing Policy. The available data were used to represent concentrations during the averaging period associated with the particular pollutant and water quality objective, as required by Section 6.1.5.6 of the Listing Policy. For example, if only one data point was available during a 4-day period, it was used to represent the four-day average concentration for that period.

Following data assessment, Los Angeles Water Board staff determined whether or not the waterbody was attaining relevant water quality standards. Decision recommendations were completed to summarize all relevant LOEs for a waterbody-pollutant combination and, based on the statistical evaluation described in the Listing Policy, to state if the exceedances of water quality standards constituted an impairment of a beneficial use and, thus, necessitated a 303(d) listing.

3.3 Water Quality Standards Used in the Data Assessment

Beneficial uses for waters in the Los Angeles Region are identified in Table 2-1, 2.1a and 2.3 of the Los Angeles Regional Water Quality Control Plan (Basin Plan).

Water Board staff assessed data using regulatory limits when available. The most common regulatory limits used include water quality objectives in the Basin Plan or any statewide Water Quality Control Plans applicable to the waterbody, including objectives for toxic chemicals promulgated by the USEPA under the California Toxics Rule (40 CFR §131.38). When numeric regulatory limits were not available, evaluation guidelines were considered to interpret narrative water quality objectives. Evaluation guidelines are selected in conformance with section 6.1.3 of the Listing Policy.

3.4 Determination of Beneficial Use Support and Integrated Report Categories

To meet CWA Section 305(b) requirements of reporting on water quality conditions, the Integrated Report places each assessed waterbody segment into one of five non-overlapping categories based on the overall beneficial use support of the water segment and the need for a TMDL. Water segments were evaluated for at least one of six “core” beneficial uses including: municipal and domestic supply, aquatic life support, fish consumption, shellfish harvesting, contact recreation, and non-contact recreation. For each core beneficial use associated with each waterbody segment, a rating of fully supporting, not supporting, or insufficient information was assigned based on the assessment of readily available data and information.

Table 2. Los Angeles Integrated Report Waterbody Categories, 2016 303(d) List

Category	Description	Waterbody Segments
1	All assessed beneficial uses supported and no beneficial uses known to be impaired.	**38**
2	There is insufficient information to determine beneficial use support.	**55**
3	There is insufficient data and/or information to make a beneficial use support determination but information and/or data indicates beneficial uses may be potentially threatened.	**13**
4	At least one beneficial use is not supported but TMDL is not needed.	
4a	A TMDL has been developed and approved by U.S.EPA for any waterbody-pollutant combination and the approved implementation plan is expected to result in full attainment of the water quality standard within a specified time frame.	**77**
4b	Another regulatory program is reasonably expected to result in attainment of the water quality standard within a reasonable, specified time frame.	**0**
4c	The non-attainment of any applicable water quality standard for the waterbody segment is the result of pollution and is not caused by a pollutant.	**3**
5	At least one beneficial use is not supported and a TMDL is needed.	**134**
Total Waterbodies Assessed		**320**

Detailed Category Reports can be found in Appendices B-F.

Pursuant to Section 2 of the Listing Policy, waterbodies remain in Category 5 until all 303(d)-listed pollutants are addressed by USEPA-approved TMDLs or by another regulatory program that is expected to result in the reasonable attainment of the water quality standards, at which point the waterbody will be placed into Category 4a or 4b. Impaired waters are placed in Category 4c if the impairment is not caused by a pollutant but rather caused by pollution, such as flow alteration or habitat alteration. Waterbodies placed in Category 4c are not included as part of the 303(d) list and do not require the development of a TMDL.

Waterbody-pollutant combinations listed in Category 5 (Appendix B) show the TMDL requirement status. If a “TMDL is still needed” for the waterbody-pollutant combination, the TMDL requirement status is labeled 5A. If the waterbody-pollutant combination is “being addressed by a USEPA approved TMDL”, the TMDL requirement status is labeled 5B. If the waterbody-pollutant combination is “being addressed by an action other than a TMDL”, the TMDL requirement status is labeled 5C. These labels were created for internal tracking and are not Integrated Report sub-categories required by the USEPA.

4. Proposed Changes to the Section 303(d) List

While, due to the changes to the 303(d) process described in Section 2.5, data review was restricted to data collected prior to September 2010, a significant number of changes to the Los Angeles Region's 303(d) list are proposed. The 211 proposed new listings include:

- Additional PCB and pesticide listings arising from California's Surface Water Ambient Monitoring Program (SWAMP) water quality sampling conducted in 2009 focusing on lakes and reservoirs. For example, staff has proposed new listings for Castaic Lake (PCBs), Pyramid Lake (chlordane, dieldrin, DDT and PCBs) and Echo Park Lake (dieldrin).

- Additional pesticide and other pollutant listings in Ventura County waters draining agricultural lands including the Santa Clara Drain, Tapo Canyon, Wheeler Canyon and Boulder Cove, arising from the Ventura County Agricultural Irrigated Lands Group water quality monitoring.

- Additional toxicity listings in the Los Angeles River arising from water quality sampling conducted the City of Los Angeles' Bureau of Sanitation, required pursuant to the City's NPDES permits.

- Various other proposed listings arising from special studies or ongoing water quality monitoring programs.

Most of the proposed new listings are new waterbody segment-pollutant combinations where a TMDL will be needed. These waterbodies would then be in Category 5. However, several of the proposed new listings identify additional impairments in watersheds already being addressed by a TMDL for that pollutant. For example, the proposed new listings for mercury in Calleguas Creek Reach 3 and the proposed DDT listings in Hondo Barranca are being addressed by the Calleguas Creek Metals TMDL and the Organochlorine Pesticides, PCBs and Siltation TMDL. In addition, the proposed Los Angeles River Reach 3 indicator bacteria listing is already being addressed by the Los Angeles River Bacteria TMDL. These waterbodies would then be in Category 4a unless another waterbody pollutant combination requires a TMDL such that the waterbody would remain in Category 5.

The proposed 48 delistings include:

- Several proposed delistings for indicator bacteria at Santa Monica Beaches, including Abalone Cove Beach, Bluff Cove Beach, Outer Cabrillo Beach, Manhattan Beach and Hermosa Beach. It is important to note that the Santa Monica Bay Bacteria TMDL remains in effect for those beaches even if the delistings are fully approved.

- Various other proposed delistings arising from special studies or ongoing water quality monitoring programs.

In a number of cases, in both fresh and marine waters, listings for “coliform bacteria” were renamed “indicator bacteria” based on USEPA’s recommendation and for statewide consistency.

In addition, because 21 TMDLs including 252 listings, have gone into effect since the development of the 2010 303(d) list, a number of Category changes are proposed to change waterbody-pollutant combinations from “requiring a TMDL” (Category 5A) to “being addressed by a USEPA approved TMDL” (Category 5B or, if all waterbody-pollutant combinations have been addressed for that waterbody, Category 4a).

For detailed information on proposed changes, refer to the waterbody-pollutant “fact sheets” in Appendix G.

As discussed in Section 2.6, it is anticipated that the State Water Board will approve the 2014 list updates of Regions 3, 5 and 9 and the 2016 list updates of Regions 2, 4, and 8, during the same State Water Board hearing in 2017. Table 3, below, shows the 303(d) list changes approved by Regional Water Boards 3, 5 and 9 and the 303(d) list changes proposed, at this time, for approval by the staff of Regional Water Boards 2, 4, and 8.

Table 3. Summary of 2014 and 2016 Changes to the California 2012 303(d) List

2014-2016 INTEGRATED REPORT						
REGION	2012 303(d) LIST	2014 and 2016 303(d) List proposed changes				
	Total 303(d) Listings (Categories 4a, 4b and 5)	Regional Water Board 303(d) Listing Recommendations		Miscellaneous Changes*		Total proposed 303(d) Listings (Categories 4a, 4b and 5)
		New Listings	New Delisting	Resulting in Listings	Resulting in Delistings	
1	159	0	0	0	0	159
2	333	41	7	0	9	358
3	712	269	48	0	23	910
4	823	211	48	0	0	986
5	730	269	45	0	0	954
6	155	0	0	0	0	155
7	68	0	0	0	0	68
8	132	31	16	0	0	147
9	445	244	14	0	0	675
Totals	3557	1065	178	0	32	4412

*Miscellaneous changes include adjustments to the 303 (d) list when waterbody reaches are combined or split resulting in a decrease or increase in the number of listings.

** Additional listings and delistings can be an artifact created from mapping changes such as the splitting of a water body into additional segments or the merging of water bodies into one single water body. Original 303(d) listings are copied to new segments and then delisted from the old segment. This generates listings and delistings that should not be included in important counts of new listings and delistings.*

Response to Comments on the Draft 2016 303(d) List
Comment Deadline: March 30, 2017

No.	Comment	Response
1.	Wishtoyo Foundation and Ventura Coastkeeper (VCK), March 24, 2017	
1.1	In reviewing the Draft 303(d)/305(b) List and in corresponding with Los Angeles Regional Water Quality Control Board ("Los Angeles Regional Board") staff, it has come to our attention that almost all of the proposed 303(d)/305(b) listings (See Attachment A) and accompanying supporting data timely submitted on August 30, 2010 by Wishtoyo Foundation's Ventura Coastkeeper Program ("VCK") were not assessed for inclusion in the Draft 303(d)/305(b) List. Attachment A and Attachment B **<u>Nicholas Canyon Creek (San Nicolas Canyon Creek)</u>** Trash. Five out of 7 Nicholas Canyon Creek monitoring events showed the presence of trash.	Inadvertently, the data submitted by Wishtoyo was not entered into the CalWQA database for assessment. Los Angeles Water Board Staff is working with State Board staff to assess all the data from Wishtoyo that were submitted by August 30, 2010. These data will be assessed and used in decision-making either as the State Board staff prepares the 303(d) list for approval by the State Board in the fall, or prior to the next listing cycle that includes the Los Angeles Region.
1.2	**<u>San Jon Barranca / Creek (Sanjon Barranca Creek)</u>** Trash. Eight out of 8 San Jon Barranca / Creek monitoring events showed the presence of trash. E. Coli. Five out of 8 San Jon Barranca / Creek monitoring events showed exceedance of E coli.	See response to comment 1.1.
1.3	**<u>Ormond Beach Lagoon (Ormond Beach Wetlands)</u>** Trash. Nine out of 9 Ormond Beach Lagoon monitoring events showed the presence of trash. E. Coli. Six out of 32 monitoring events showed exceedance of E coli. pH. Six out of 8 monitoring events showed exceedance of pH. Nitrate. Eleven out of 14 monitoring events showed exceedance of Nitrate.	See response to comment 1.1.

No.	Comment	Response
1.4	**Bubbling Springs (Hueneme Drain)** Trash. Nine out of 9 monitoring events showed presence of trash. VCK's Data not assessed E. coli. Five out of 11 monitoring events showed exceedance of E coli. VCK's Data not assessed	See response to comment 1.1.
1.5	**J-Street Drain** Trash. Nine out of 9 monitoring events showed presence of trash.	See response to comment 1.1.
1.6	**Oxnard Industrial Drain (Oxnard Drain)** Trash. Eight out of 8 monitoring events showed presence of trash. E. Coli. Five out of 11 monitoring events showed exceedance of E coli. pH. Six out of 7 monitoring events showed exceedance of pH. Nitrate. Eight out of 8 monitoring events showed exceedance of Nitrate.	See response to comment 1.1.
1.7	**Santa Clara River Estuary** Trash. Eight out of 8 monitoring events showed presence of trash. Dissolved Oxygen. The City's sondes, violated the Basin Plan numeric water quality standard for Dissolved Oxygen of 5 mg/l for surface waters designated as WARM and 6mg/l for surface waters designated as COLD on over 40 days between 2009 and 2010. Nitrate. Eight out of 8 monitoring events showed exceedance of Nitrate. Phosphate. Ten out of 10 monitoring events showed exceedance of Phosphate.	See response to comment 1.1. The Los Angeles Water Board is not considering listing decisions for flow at this time. See response to comments 21.1-21.11 for a detailed discussion of flow.

No.	Comment	Response
	pH. E recordings taken on separate days in the Santa Clara River Estuary via the City's North and South Sondes, pH levels in the Santa Clara River Estuary water column exceeded Low Flows. Santa Clara River Reach 1, and Santa Clara River Reach 2 are deprived of sufficient flows during the wet season for Southern California Steelhead smolt and migrating adults	
1.8	**<u>Santa Clara River Reach 1</u>** Low Flows. Santa Clara River Reach 1, and Santa Clara River Reach 2 are deprived of sufficient flows during the wet season for Southern California Steelhead smolt and migrating adults. Trash. Nine out of 9 monitoring events showed presence of trash.	See response to comment 1.1. The Los Angeles Water Board is not considering listing decisions for flow at this time. See response to comments 21.1-21.11 for a detailed discussion of flow.
1.9	**<u>Santa Clara River Reach 2</u>** Low Flows. Santa Clara River Reach 1, and Santa Clara River Reach 2 are deprived of sufficient flows during the wet season for Southern California Steelhead smolt and migrating adults Fish Passage. the Vern Freeman Diversion Dam with its current fish ladder are a fish barrier to migrating Southern California Steelhead in Santa Clara River Reach 2 and 3.	The Los Angeles Water Board is not considering listing decisions for flow at this time. See response to comments 21.1-21.11 for a detailed discussion of flow.
1.10	**<u>Santa Clara River Reach 3</u>** E Coli. Five out of 27 monitoring events showed exceedance of E coli. Trash. Trash. Twenty-six out of 31 monitoring events showed presence of trash. Fish Passage. the Vern Freeman Diversion Dam with its current fish ladder are a fish barrier to migrating Southern California Steelhead in Santa Clara River Reach 2 and 3.	The Los Angeles Water Board is not considering listing decisions for flow at this time. See response to comments 21.1 21.11 for a detailed discussion of flow.
1.11	**<u>Santa Clara River Reach 4a</u>**	See response to comment 1.1.

No.	Comment	Response
	Trash. Seven out of 8 monitoring events showed presence of trash.	
1.12	**<u>Santa Clara River Reach 5 or 6</u>** Trash. Five out of 7 monitoring events showed presence of trash.	See response to comment 1.1.
1.13	We thus respectfully request the Los Angeles Regional Board assess all of VCK's proposed 303(d)/305(b) listings and accompanying data submitted in 2010, and ensure VCK's proposed listings are included in the 2016 303(d)/305(b) List. All of VCK's proposed listings meet the requirements for listing in the State Water Resources Control Board's Water Quality Control Policy for Developing California's Clean Water Act Section 303(d) List. Notably, as demonstrated by VCK August 30, 2010 proposed listing submission, VCK's watershed monitoring data supporting the proposed listings were collected and analyzed in accordance with VCK's Quality Assurance Project Plan (QAPP) approved by the Los Angeles Regional Water Quality Control Board.	See response to comment 1.1.
1.14	Furthermore, we ask the Board to include on the list, the dissolved oxygen ("DO") data submitted by VCK that supports the Santa Clara River Estuary ("Estuary") being included on the 2016 Draft 303(d)/305(b) list for DO impairment. Even one event where DO levels drops below Basin Plan thresholds can be catastrophic for native and endangered aquatic life, including the Southern California Steelhead and Tidewater Goby that use the Estuary as habitat and that need healthy and suitable water quality in the Estuary to survive and recover. It only takes one event of low DO for these species to perish, and the Los Angeles Regional Board was provided over 200 separate data entries indicating that DO fell in the Estuary below Basin Plan thresholds and non-harmful levels for aquatic life. Attached to this letter is are two studies by a Regional Board Scientist (Carter 2005 and 2008) that further details the harms of low DO on aquatic life and native and endangered species, including Southern California Steelhead.	See responses to comments 1.1 and 1.7.
1.15	VCK's mission is to protect, preserve, and restore the ecological integrity and water quality of Ventura County's inland and coastal waterways. In 2009 and 2010, VCK, in coordination with the Los Angeles Regional Water Quality Control Board and State Water Resources Control Board Clean Water Team, dedicated a	See response to comment 1.1.

No.	Comment	Response
	tremendous amount of resources to its watershed monitoring program that resulted in VCK's proposed 303(d)/305(b) listings. These resources include VCK running volunteer stream teams, utilizing staff time to collect and analyze water quality data, purchasing and maintaining field equipment, and running a laboratory. It would be a shame, and detrimental to Ventura County's inland and coastal waterways and their beneficial uses, if the water quality impairments discovered, rigorously documented by VCK, and provided to the state did not result in 2016 303(d)/305(b) listings, especially on the account that they were not assessed. It is without second thought that the Los Angeles Regional Board assessing our proposed 303(d)/305(b) listings and accompanying data from August 30, 2010, and ensuring these proposed listings are included in the 2016 303(d)/305(b) List, is critical to the protection of Ventura County's waters for all the people, wildlife, communities, and the Chumash Native American Peoples that depend upon clean and healthy waters to sustain their health, wellbeing, and life ways.	
2.	City of Rolling Hills Estates, March 28, 2017	
2.1	The City is pleased that that Palos Verdes Peninsula beaches are being proposed for delisting for indicator bacteria. This is also consistent with Regional Board Resolution No. 2006-008 reviewing the Implementation Plan submitted by Jurisdictional Group 7 for the Santa Monica Bay Beaches Bacteria Wet Weather TMDL which noted that "Palos Verdes Peninsula have had historically fewer exceedances than the reference beach". and " .... existing water quality is equivalent to compliance with the Santa Monica Bay Beaches Wet Weather TMDL."	Comment noted.
2.2	**City of Rolling Hills Estates Comments on Proposed Revisions to 303(d) List** **Water Body/Pollutant: Los Angeles-Long Beach Inner Harbor/Zinc** **Comment:** We are in agreement with Decision ID 33644 LARWCB staff recommendation to delist the water body both due to flaws in the original listing and because applicable water quality standards are not being exceeded this recommendation, however Appendix A does not reflect this proposed change. **Recommendation:** Add a "Y" in the New Delistings column in Appendix A for	The Los Angeles-Long Beach Inner Harbor recommendation for Zinc is DO NOT DELIST. This is unchanged from 2006. The Water Board recommendation in 2006 was to delist, however EPA decided to not delist based on information in the LOEs indicating sediment toxicity.

No.	Comment	Response
	Zinc in Los Angeles-Long Beach Inner Harbor.	The factsheet has been edited for clarity and to update that the listing is being addressed by the Dominguez Channel Los Angeles and Long Beach Greater Harbor Waters Toxic Pollutants TMDL.
2.3	**Wilmington Drain/Lead** **Comment:** We are in agreement with Appendix G Decision ID 35085 to delist the Wilmington Drain for lead based on the weight of evidence. Additionally, the weight of evidence is stronger than indicated because data was included in this fact sheet from Compton Creek. LOE 90133 included in Fact Sheet 35085 describes data collected in Compton Creek which is unrelated to the Wilmington Drain. **Recommendation:** Remove LOE 90133 from Fact Sheet 35085 and revise the supporting evidence statement to the Regional Board Staff Conclusion to state that "0 of 33 samples exceeded the CRITERIA."	As noted by the commenter, the current decision is to delist Wilmington Drain for lead. Los Angeles Water Board staff will work with State Board staff to correct the LOEs and the decision, if necessary, as the State Board staff prepare the Integrated Report and 303(d) list for State Board approval later this year, or not later than the next listing cycle that includes the Los Angeles Region.
2.4	**Wilmington Drain/Copper** **Comment:** The Appendix G Decision ID 44676 regarding copper in Wilmington Drain includes a data set that should not have been included: LOE ID 90473 describes data collected in Compton Creek which is unrelated to Wilmington Drain. Removal of this data set from Decision ID 44676 would still leave LOE ID 90131 which is described as 33 samples, only two (2) of which exceeded the criteria for copper. This revised data set now meets the SWRCB Delisting criteria because the number of exceedances is 2 or less in a data set size of 28-36 samples. **Recommendation:** Remove LOE ID data set 90473 from Decision ID 44676 and revise the recommendation to Delist from 303(d) List.	Los Angeles Water Board staff will work with State Board staff to correct the LOEs and the decision, as appropriate, as the State Board staff prepare the Integrated Report and 303(d) list for State Board approval later this year, or not later than the next listing cycle that includes the Los Angeles Region.
2.5	**Machado Lake/Algae, Ammonia, ChemA, Eutrophic, Odor, Trash** **Comment:** These listings for Machado Lake are included in Appendix B Category 5 (a water segment where standards are not met and a TMDL is required but not yet completed) however all of these pollutant listings are being addressed by USEPA approved TMDLs.	The Machado Lake listings for Algae, Ammonia, Eutrophic, Odor and Trash were assigned to category 4a in 2010 and that assessment has not changed. ChemA was reassigned to 4a in this listing cycle.

No.	Comment	Response
	Recommendation: These listings should be moved to Category 4a in Appendix C. An explanation that "TMDL status changed from TMDL still required to Being Addressed by Completed TMDL" should be included in Appendix A under the "Other Revisions" column for each of these pollutants in Machado Lake.	Because all the individual Machado Lake listings were categorized as 5B (category 5B is for listings "being addressed by a TMDL"), the waterbody as a whole should have been in the Category 4 Appendix, not the Category 5 Appendix. The Category Appendices have been updated to make this correction.
2.6	**Los Angeles-Long Beach Outer Harbor (inside breakwater)/DDT, PCBs and Toxicity; Los Angeles Harbor Inner Cabrillo Beach/DDT, PCBs; San Pedro Bay Near-Off Shore/Chlordane, PCBs, Total DDT, and Toxicity** **Comment:** These are included in Appendix B Category 5 (a water segment where standards are not met and a TMDL is required but not yet completed) however all of these listings are being addressed by the USEPA approved TMDL for Dominguez Channel and Greater Los Angeles and Long Beach Harbors. These changes are explained in Appendix A summary under "other revisions". **Recommendation:** These listings for DDT, PCBs and Toxicity should be moved to Category 4a in Appendix C.	Although the Los Angeles-Long Beach Outer Harbor (inside breakwater) DDT and PCBs listings were included in the Category 5 Appendix, they were listed as "being addressed by a TMDL" (5B); however, the toxicity listing was incorrectly categorized as needing a TMDL (5A). The toxicity listing has now been updated to "being addressed by a TMDL," so the waterbody as a whole will move to category 4a. Los Angeles Harbor Inner Cabrillo Beach DDT and PCBs listings have been reassigned to "being addressed by a TMDL" and the waterbody as a whole will move to category 4a. Although the San Pedro Bay Near-Off Shore Chlordane, PCBs, and Total DDT listings were included in the Category 5 Appendix, they were listed as "being addressed by a TMDL" (5B); however, the toxicity listing was incorrectly categorized as needing a TMDL (5A). The toxicity listing has now been updated to "being addressed by a TMDL," so the waterbody as a whole will move to category 4a.

No.	Comment	Response
2.7	**San Pedro Bay Near-Off Shore Zones/Zinc** **Comment:** Appendix G Decision ID 42798 to Delist San Pedro Bay Near/Off Shore Zones for Zinc because applicable water quality standards are not being exceeded. This recommendation is not reflected in Appendix A summary of recommended changes. **Recommendation:** Insert a "Y" in the New Delistings column of Appendix A for San Pedro Bay Near/Off Shore Zones for zinc.	Zinc was delisted in the 2010 303(d) list. New data was assessed during this listing cycle but the decision remains "delist." This is not a New Delisting. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
2.8	**San Pedro Bay Near-Off Shore Zones/Chromium** **Comment:** Appendix G Decision ID 42525 restates and does not revise the original recommendation to delist San Pedro Bay Near/Off Shore Zones for Chromium, however delisting does not seem to have occurred since the pollutant-waterbody combination still appears in Appendix A. **Recommendation:** Insert a "Y" in the New Delistings column of Appendix A for San Pedro Bay Near/Off Shore Zones for PAHs and remove the "Y" from the Pollutant Name Changes column since there does not appear to have been any name change made for this pollutant.	Chromium was delisted in the 2010 303(d) list. This is not a New Delisting. The name has been changed. In the 2010 list it was "chromium (sediment)" and now it is "chromium". Chromium is included in Appendix A to show the recommended name change. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
2.9	**San Pedro Bay Near-Off Shore Zones/Copper** **Comment:** Appendix G Decision ID 44434 to Delist San Pedro Bay Near/Off Shore Zones for Copper based on flaws in the original listing. This recommendation is not reflected in Appendix A summary of recommended changes.	Copper was delisted in the 2010 303(d) list. New data was assessed during this listing cycle but the decision remains "delist." This is not a New Delisting. The name has been changed. In the 2010 list it was "Copper (sediment)" and now it is "copper". Copper is included in Appendix A to

No.	Comment	Response
	Recommendation: Insert a "Y" in the New Delistings column of Appendix A for San Pedro Bay Near/Off Shore Zones for copper.	show the recommended name change. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
2.10	**San Pedro Bay Near-Off Shore Zones/ Polycyclic Aromatic Hydrocarbons (PAHs)** **Comment**: Appendix G Decision ID 43259 to Delist San Pedro Bay Near/Off Shore Zones for PAHs because applicable water quality standards are not being exceeded. This recommendation is not reflected in Appendix A summary of recommended changes. **Recommendation:** Insert a "Y" in the New Delistings column of Appendix A for San Pedro Bay Near/Off Shore Zones for PAHs.	PAHs (Polycyclic Aromatic Hydrocarbons) was delisted in the 2010 303(d) list. New data was assessed during this listing cycle but the decision remains "delist." This is not a New Delisting. The name has been changed. In the 2010 list it was "PAHs (Polycyclic Aromatic Hydrocarbons) (sediment)" and now it is "PAHs (Polycyclic Aromatic Hydrocarbons)". PAHs (Polycyclic Aromatic Hydrocarbons) is included in Appendix A to show the recommended name change.
2.11	**Santa Monica Bay Offshore- Nearshore/Chlordane** **Comment:** The revised Appendix G Fact Sheet associated with Decision ID 37492 recommending delisting Santa Monica Bay Offshore-Nearshore waters for chlordane is not reflected in the Appendix A summary of recommended changes. **Recommendation:** Revise Appendix A to place a "Y" in the New Delisting column for Santa Monica Bay Offshore/Nearshore line for Chlordane.	Chlordane was delisted in 2010. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
2.12	**Santa Monica Bay Offshore- Nearshore/ Polycyclic Aromatic Hydrocarbons (PAHs)** **Comment:** The revised Appendix G Fact Sheet associated with Decision ID 32656 recommending delisting Santa Monica Bay Offshore-Nearshore waters for	PAHs were delisted in 2010. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is

No.	Comment	Response
	PAHs is not reflected in the Appendix A summary of recommended changes. **Recommendation:** Revise Appendix A to place a "Y" in the New Delisting column for Santa Monica Bay Offshore/Nearshore line for PAHs.	marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
2.13	**Santa Monica Bay Offshore- Nearshore/ Arsenic** **Comment:** Santa Monica Bay Offshore-Nearshore areas are being proposed for listing for Arsenic based on sampling conducted for the City of Los Angeles Hyperion Wastewater Treatment Plant NPDES Permit. Samples were collected during August 2006, October and November 2007, and August through September of 2007 from nearfield and from Zones 4 & 5—these sampling areas are north of Redondo Beach Pier. **Recommendation:** This listing should be narrowed in geographic scope and should exclude Offshore-Nearshore waters of the Palos Verdes Peninsula because the data supporting the listing is not spatially representative of the Palos Verdes Peninsula waters since there is little to no influence from the Hyperion Wastewater Treatment Plant discharge on these waters. The fact sheet (Decision ID 67208) should be revised to discuss the spatial extent of this listing in relation to the data supporting the listing and to exclude areas south of Redondo Beach Pier which are outside of Zones 4 and 5.	The CalWQA database does not at this time allow for listing only portions of defined waterbodies. However, the fact sheet does state where the fish were collected. At the time a TMDL is developed, or other regulatory program is developed, for arsenic in Santa Monica Bay, then the more detailed geographic scope can be identified considering collection sites and fish movement. However, a review of this decision is in process at this time in order to review the data included in the analysis and the applicable evaluation guideline.
2.14	**Santa Monica Bay Offshore- Nearshore/Mercury** **Comment:** Santa Monica Bay Offshore-Nearshore areas are being proposed for listing for Mercury based on sampling conducted for the City of Los Angeles Hyperion Wastewater Treatment Plant NPDES Permit. Samples were collected during August 2006, October and November 2007, and August through September of 2007 from nearfield and from Zones 4 & 5. **Recommendation:** This listing should be narrowed in geographic scope and should exclude Offshore-Nearshore waters of the Palos Verdes Peninsula because the data supporting the listing is not spatially representative of the Palos Verdes Peninsula waters since there is little to no influence from the Hyperion	The CalWQA database does not at this time allow for listing only portions of defined waterbodies. The fact sheet does state where the fish were collected. At the time a TMDL is developed, or other regulatory program is developed, for mercury in Santa Monica Bay, then the more detailed geographic scope can be identified considering collection sites and fish movement.

	Wastewater Treatment Plant discharge on these waters. The fact sheet should be revised to (Decision ID 67209) discuss the spatial extent of this listing in relation to the data supporting the listing and to exclude areas south of Redondo Beach Pier which are outside of Zones 4 and 5.	However, a review of this decision is in process at this time in order to review the data included in the analysis.
3.	City of Rosemead, March 28, 2017	
3.1	**I. Summary** The 2016 303(d) revisions for the several reaches (water quality segments) of the Los Angeles River and tributaries propose to de-list, do not de-list, and do not list metals-related pollutants including copper, lead, selenium and zinc. These pollutants are the subject of the Total Maximum Daily Loads for Metals for the Los Angeles River (LARMTMDL) adopted by Regional Board in 2007. This TMDL has been incorporated into the current Los Angeles County MS4 Permit MS4 Permit (MS4 Permit). The MS4 Permit enables compliance with TMDL waste load allocations (WLAs) -- also referred to as numeric targets. The numeric targets are translated into water quality based effluent limitations (WQBELs) which are applied to MS4 outfall discharges and to receiving waters as limitations. To comply with both, the MS4 Permit coercively encourages compliance through Watershed Management Programs (E/WMPs). Although many metals have either been placed on the "de-list" or "do not list" categories for Los Angeles River water quality segments, many also have been placed on the "list" and do not de-list categories. These listings should be voided because: 1. Although the LAR-MTMDL claims to have developed water quality standards (includes TMDLs) in accordance with the federal California Toxic Rule (CTR) adopted in 2000, it actually has not; and 2. The LAR-MTMDL is based on water quality samples that were conducted before the Water Quality Control Policy for California's Clean Water Act Section 303(d) List (Listing Policy), which was adopted in 2004.	Comments on TMDLs and MS4 permits are outside the scope of this action. Pollutants, including metals, are assessed as "de-list," "do not list," "list," and “do not delist” based on available data, not on the status of TMDLs. See also, response to comment 3.2, 3.3, and 3.4.

No.	Comment	Response
3.2	**California Toxic Rule** CTR was adopted to provide a mathematical method for establishing ambient (dry weather) water quality standards for toxics necessary to protect beneficial uses of receiving waters. The LAR-MTMDL, however, along with other TMDLs, does not comply with CTR in two significant respects. First, the TMDL calculates numeric water quality standards/TMDLs for both wet weather and ambient receiving water conditions instead of only on ambient. The LAR-MTMDL misinterprets CTR by claiming EPA did not differentiate between wet and dry weather conditions when establishing metals and toxics limitations. There is nothing in CTR that supports that view. CTR makes it clear that its purpose is to establish ambient water quality standards: *This final rule establishes ambient water quality for priority toxic pollutants*. USEPA defines ambient as: *Natural concentration of water quality constituents prior to mixing of either point or nonpoint source load of contaminants. Reference ambient concentration is used to indicate the concentration of a chemical that will not cause adverse impact to human health.* In other words, ambient is the normal reference condition of a receiving water. This is also the clear understanding of the Regional Board's Surface Water Ambient Monitoring Program (SWAMP). MS4 and other point source stormwater (wet weather) outfall discharges, using sampling and analysis results, are measured against the ambient target for a pollutant established by CTR. For example, suppose a copper limitation is set at 37 micrograms per liter for a given water body. This limit is required to protect fish. Persistent exceedances of the limit based on outfall monitoring would necessitate a revision to the MS4 Permittee's stormwater management program. Second, CTR requires a hardness parameter (calcium carbonate) to make chemical water quality analysis of toxics more accurate. Generally, the higher the hardness value the higher the toxic pollutant expressed as a numeric limit. The LAR-MTMDL calculates CTR for metals/toxics using a hardness value of 100 milligrams per liter (mg/l). It contends that this is the hardness value required by	Comments on TMDLs are outside the scope of this proposed action.

No.	Comment	Response
	CTR. This is false. CTR requires actual hardness to be determined by water quality sampling and analysis at the same time a toxic pollutant is sampled. The Regional Board's SWAMP abides by this requirement. Therefore, the LAR-MTMDL establishes limitations for metals and toxics that are more stringent than necessary. This provides another reason for voiding the LAR-MTMDL and revising it with a recalculated limitation for each metal by using an actual hardness value based on future ambient water quality sampling and analysis.	
3.3	**California 303(d) Listing Policy (Listing Policy)** The Listing Policy was adopted to provide a statistical method to determine how many water quality samples that exceed a water quality standard are required to place a pollutant on the 303(d) list. That method is a binomial distribution based on the rejection of a null hypothesis measured against sample sizes (see attachment #1). A review of the 2016 303(d) list fact sheets reveals that the metals placed on previous 303(d) lists did not conform to the Listing Policy. In fact, the LAR-MTMDL is based on water quality data that was developed prior to the adoption of the Listing Policy in 2004. According to the LAR-MTMDL, the metals numeric targets were based on data that was limited to 2002. Based on this fact alone the LAR-MTMDL should be voided.	The Los Angeles Water Board disagrees. While the current and past 303(d) lists of impaired waterbodies pre-date the State's Listing Policy, this does not invalidate previous listing decisions. The Listing Policy does not support delisting a waterbody pollutant combination simply because it was listed prior to adoption of the Listing Policy and, as such, a different data assessment method may have been used. The 303(d) list includes assessments of readily available data and uses data assessment guidelines available at the time of preparation. The list is periodically updated based on newer readily available data and, if newer assessment guidelines or methods are available, these are used. Accordingly, several of the existing waterbody pollutant combinations originally listed in the TMDL are recommended for delisting, while several are not recommended for delisting. Additionally, several new waterbody pollutant combinations for metals are recommended for listing based on new readily available data since the last update of the list for the Los Angeles Region.

No.	Comment	Response
		Finally, comments on the LA River Metals TMDL are outside the scope of this proposed action.
3.4	MS4 Permittees located in Reach 2 of the Rio Hondo will be pleased to know that the 2016 303(d) list does not propose to list it for any of the metals covered by the LARMTDL. This makes sense given that this reach was not listed for metals impairment on the 2010 303(d) list. Further, LAR-MTMDL makes no mention of Reach 2 of the Rio Hondo. As result, the following cities should not be subject to this TMDL: Alhambra (partially); Arcadia; Bradbury; Duarte; El Monte; Irwindale (partially); Montebello (partially); Monterey Park; Pasadena (partially); Rosemead; San Gabriel; San Marino; South El Monte; Irwindale (partially); and South Pasadena (partially). However, it is noted that Reaches 1 and 2 of the Arroyo Seco was not placed on the "do not list" for metals. It should have been for the same reason Reach 2 of the Rio Hondo was. Neither Reach 1 nor Reach 2 of the Arroyo Seco appears on the 2010, 2006, or 2002 303(d) list for metals. The Regional Board may wish to update the 2016 303(d) list to place the Arroyo Seco on the "do not list" category.	Comments on the applicability of TMDLs are outside the scope of this action. The Integrated Report and the 303(d) list do not include any decisions for metals in the Arroyo Seco because no metals data were available or assessed for the Arroyo Seco. The decision "do not list" is only made when there are data in the CalWQA database that support a "do not list" decision.
4.	City of Compton, March 29, 2017	
4.1	**I. 	Ambient Monitoring Program (SWAMP). MS4 and other point source stormwater (wet weather) outfall discharges, using sampling and analysis results, are measured against the ambient target for a pollutant established by CTR. For example, suppose a copper limitation is set at 37 micrograms per liter for a given water body. This limit is required to protect fish. Persistent exceedances of the limit based on outfall monitoring would necessitate a revision to the MS4 Permittee's stormwater management program. Second, CTR requires a hardness parameter (calcium carbonate) to make chemical water quality analysis of toxics more accurate. Generally, the higher the hardness value the higher the toxic pollutant expressed as a numeric limit. The LAR-MTMDL calculates CTR for metals/toxics using a hardness value of 100 milligrams per liter (mg/l). It contends that this is the hardness value required by CTR. This is false. CTR requires actual hardness to be determined by water quality sampling and analysis at the same time a toxic pollutant is sampled. The Regional Board's SWAMP abides by this requirement. Therefore, the LAR-MTMDL establishes limitations for metals and toxics that are more stringent than necessary. This provides another reason for voiding the LAR-MTMDL and revising it with a recalculated limitation for each metal by using an actual hardness value based on future ambient water quality sampling and analysis.	
4.3	**California 303(d) Listing Policy (Listing Policy)** The Listing Policy was adopted to provide a statistical method to determine how many water quality samples that exceed a water quality standard are required to place a pollutant on the 303(d) list. That method is a binomial distribution based on the rejection of a null hypothesis measured against sample sizes (see attachment #1). A review of the 2016 303(d) list fact sheets reveals that the metals placed on previous 303(d) lists did not conform to the Listing Policy. In fact, the LAR-MTMDL is based on water quality data that was developed prior to the adoption of the Listing Policy in 2004. According to the LAR-MTMDL, the metals numeric targets were based on data that was limited to 2002. Based on this fact alone the LAR-MTMDL should be voided.	See comment 3.3.

No.	Comment	Response
4.4	**II. Los Angeles River Reach/Tributary Specific Comments** Presented below are specific justifications for removing metals that fall under either the “list” or “do not list” categories because they do not conform to CTR or the Listing Policy. Almost all of them fall into these categories. **1. Compton Creek** Of the 4 subject LAR-MTMDL metals, the 2016 303(d) list only places selenium on the “do not list” for the Creek. According to the fact sheet, copper is placed on the “do not de-list” based on 1 of 15 samples that exceeded dissolved copper. This result, however, does not meet the 3.1 Listing Policy’s binomial test requirement. The policy explains that the application of the binomial test requires a minimum sample size between 2 and 24, with at least 2 exceedances required for 303(d) listing placement. But, the Listing Policy also mentions that a sample size less than 16 is insufficient to meet the listing test. Lead is also placed under the “do not de-list” category. <u>This appears to be in error</u>. According to the fact sheet, 1 of 15 samples and 0 of 3 samples exceeded the criteria for this sample size to determine the applicable beneficial use. However, 1 exceedance out of 15 and 0 out of 3 samples do not meet the Listing Policy for 303(d) list placement. Not only is the exceedance frequency insufficient, but the sample size is too small. The same is true of zinc, which was placed on the “list” category because 2 of the 15 samples exceeded the allowable frequency. That cannot be. Once again, a sample size of 15 is too small. Further, it is not clear whether the samples were taken from the Creek during a storm event or during an ambient water body condition. It should also be noted that according Regional Board SWAMP data taken in June of 2005, no exceedances were reported for copper, lead, or zinc.	“DO NOT DELIST” is the appropriate recommendation for copper and lead. Section 3.1 and Table 3.1 of the Listing Policy include a *minimum* sample size to *list* a pollutant, while Section 4.1 of the Listing Policy states, “[t]he binomial distribution cannot be used to support a delisting with sample sizes less than 28.” Listed waterbodies are evaluated and delisting decisions are made based on Section 4 of Listing Policy, not Section 3. Based on Section 4, there are insufficient samples to delist based on the binomial distribution. The SWAMP line of evidence has also been considered in the decision recommendation. The LOEs that support the copper and lead listings are “placeholder” LOEs to show a finding of impairment made prior to 2006. The lead recommendation also includes a third LOE, which is a “placeholder” LOE to show a finding of impairment made prior to 2006. The “placeholder” LOEs are valid LOEs; however, the data for these are not in the CalWQA database. However, Section 4.1 of the Listing Policy still requires a minimum of 28 samples (and fewer exceedances than listed in Table 4.1) to delist. See response to comment 3.3 for additional discussion on listing prior to the adoption of the Listing Policy.

No.	Comment	Response
	Based on the foregoing, it is recommended that copper, lead, and zinc be placed on the "do not list" category. Table I Compton Creek **[See the posted letter for Table I]**	
4.5	**2. Los Angeles River Reach 1 (Estuary to Carson)** Copper, lead, and zinc were listed, while selenium was not. The justification for their listing is questionable. The listing fact sheet indicates 7 out of 18 samples exceeded CTR criteria. Because the LAR-MTMDL asserts that CTR limitations can be based on both wet weather and dry weather (ambient) sampling, the Regional Board needs to provide data that shows which samples were based on wet weather and dry weather. As mentioned above, CTR limitations are exclusively expressed as ambient standards. Wet weather samples should be excluded. If the number of excluded samples does not meet the Listing Policy requirement for minimum sample size, then the sampling data is invalid. Further, it is not clear when the samples were taken, nor whether the actual hardness value was applied. Based on this information, copper, lead, and zinc should be de-listed. Table II LAR Reach 1. **[See the posted letter for Table II]**	The decisions for copper, lead, and zinc are previous listing decisions. No new data were assessed by the Board for the current cycle. See response to comment 4.4 regarding "placeholder" LOEs. The Listing Policy neither indicates that wet weather data should be excluded from the assessment nor that data from wet and dry weather must be assessed separately. While Section 6.1.5.3 of the Listing Policy states "… *If the majority of samples were collected on a single day or during a single short-term natural event (e.g., a storm, flood, or wildfire), the data shall not be used as the primary data set supporting the listing decision*", it does not state that wet weather samples should be excluded from the assessment. Comments on the TMDL are outside the scope of this action.
4.6	**3. Los Angeles River Reach 2 (Carson to Figueroa)** Copper and lead are carried-over from the 2010 303(d) list and placed in the "do not delist" category. Selenium and zinc were not listed. Copper and lead should be	The LOEs which support the copper and lead listings are "placeholder" LOEs to show a finding of impairment made prior to 2006. The CalWQA database does not include the "placeholder" LOE

<table>

<tr><td>5.</td><td colspan="2">City of Redondo Beach, March 29, 2017</td></tr>
<tr><td>5.1</td><td>However, after reviewing the proposed changes to the 303(d) List, the City remains concerned about a number of specific issues, which are detailed below. The City's comments are generally grouped within two categories:

• Segment specific comments on the proposed 303(d) List; and
• Inconsistencies within the 303(d) List.

I. Segment Specific Comments on the Proposed 303(d) List

A. Dominguez Channel (lined portion above Vermont)
<u>Comment 1: The benthic community effects listing (Decision ID 66165) appears to be flawed and should be removed.</u>
The listing for benthic community effects should be removed because it is based on flawed data and/or analyses. The basis for this comment is as follows:
The sample size did not meet the minimum criteria pursuant to the Listing Policy. According to Section 3.9 Degradation of Biological Populations and Communities of the Listing Policy, The analysis should rely on measurements from at least two stations. The Appendix G Fact Sheets list only one sample site, however it treats the data from the one site as three separate samples, which is incorrect. As a result, there are not enough data to justify a listing.
The benthic community effects listing for the lined portion of Dominguez Channel lacks a sufficient reference site. Since this section of the Dominguez channel is lined, it does not have a traditional bed structure or substrates found in a typical stream. The classic Index of Biotic Integrity (181) stream assessment score does not take into consideration that lined channels naturally have lower IBI scores as noted in the recently released</td><td>Listings related to benthic community impairment in the Dominguez Channel and other channels that are lined entirely with concrete have been reassigned to Category 3 (i.e., insufficient information to assess beneficial use support, but some uses may be threatened) until such time as benthic community condition scores have been more specifically calibrated for concrete-lined channels.

See response to comments 11.19 and 11.24.</td></tr>
</table>

No.	Comment	Response
	SCCWRP Special Study on Engineered Channels. In order to make a robust assessment, the reference site should also be a lined channel that has not been subject to anthropogenic influences, however such a reference site was not used in the analysis. • The IBI is not the assessment tool that should be used to determine benthic community effects. As acknowledged in the Appendix G Fact Sheets: *The CSCI is applicable statewide, accounts for a much wider range of natural variability, and provides equivalent scoring thresholds in all regions of the state. The CSCI will be used in the future for water quality assessment purposes statewide over the regional indices of biologic integrity (IBIs).* We agree with this statement and also note that some IBI scores are especially skewed when utilized for hardened channels since they heavily rely on macroinvertebrates, which are inherently more common in natural bottom stream beds. Other assessment tools such as the diatom IBI may also be used to assess the benthic community of a hardened channel as demonstrated by the SCCWRP Study on Engineered Channels referenced earlier. Therefore, the IBI assessment tool should not be used as the sole basis for a listing in this lined channel. • The benthic community effects exceedance should not be linked to diazinon as a way to establish a causal effect since this pollutant has been delisted with respect to the Dominguez Channel (lined portion above Vermont) (Decision ID 33061). *Requested Action*: • *Remove the benthic community effects listing/or Dominguez Channel since the sample size does not meet the minimum criteria, this section of channel lacks a proper reference site, and is based on an inappropriate assessment tool.* • *If the listing is not removed, the diazinon linkage to benthic community effects should be removed since this pollutant has been delisted.*	
5.2	<u>Comment 2: The ammonia listing (Decision ID 35134) should be updated to consider all readily available data.</u>	See response to comment 11.6.

No.	Comment	Response
	Ammonia was not de listed based on the existence of 2 exceedances out of 21 samples collected from 7/1/2009 to 8/13/2009 at Western Ave., Manhattan Beach Blvd, and El Segundo Blvd. Additional samples were also collected at a sample site just across Vermont Ave. (33° 52' 16" N, 118° 17' 23" W), however these samples were not included in the analysis. The Basin Plan lists Vermont Ave. as the reach break between the Dominguez Channel and Dominguez Channel Estuary and, therefore, it appears a decision was made to include the Vermont Ave. samples in the downstream segment - the Dominguez Channel Estuary (unlined portion below Vermont Ave.) The City maintains that the Vermont Ave. samples should be considered in the Dominguez Channel (lined portion above Vermont) based on their direct proximity to the end of the reach, offering optimal spatial representation of the water body segment. Furthermore, the sample site is located less than 100 meters from the lined portion of Dominguez Channel and according to the Listing Policy, a sample collected 200 meters upstream, in the lined portion of the Channel, would be considered the same station location. If the additional 8 samples from the Vermont Ave. station are included in the Dominguez Channel (lined portion above Vermont) analysis, the total samples in exceedance would be 2 out of 29. These data would then meet the requirement to delist ammonia as stated in Section 4.1 of the California Delisting Factors set in the Listing Policy - i.e., these samples support rejection of the null hypothesis using the binomial distribution and the sample size is greater than 28. Specifically, Table 4.1 at page 14 of the Listing Policy demonstrates that where 2 or less exceedances are identified in a sample size of 28-36 samples, such as here, then the water segment shall be removed from the 303(d) List. Therefore, based on the updated and appropriate sample size, which includes Vermont Ave. samples, and number of exceedances, ammonia should be delisted for this reach. *Requested Action*: • *Include the Vermont Ave. sampling data in the analysis of the ammonia listing for Dominguez Channel (lined portion above Vermont).* • *Delist ammonia based on the updated analysis.*	

No.	Comment	Response
5.3	**B. Dominguez Channel Estuary (unlined portion below Vermont Ave)** Comment 3: Delist Ammonia (unionized) due to lack of exceedances. A listing for ammonia was shown in the Appendix G Fact Sheets, however none of the cited lines of evidence (LOE) shows evidence of an exceedance. One LOE is an unspecified placeholder for a listing decision made prior to 2006, however the other two LOE show 0 out of 28 and 0 out of 7 exceedances. Based on the data, this pollutant meets the Section 4 California Delisting Factors set in the Listing Policy. *Requested Action*: • *Delist ammonia (unionized) (Decision ID 34669) based on lack of evidence and exceedances*.	The decision has been updated to "DELIST."
5.4	**C. Santa Monica Bay Offshore/Nearshore** Comment 4: The arsenic and mercury fish tissue listings are not based on all readily available data, are not spatially representative of the water body, and samples were not treated as temporally independent. The samples used for the proposed 5A Arsenic and Mercury fish tissue listings (Decision ID: 67208 and 67209) are not spatially representative of the water body. Samples used for these listings were collected for the City of Los Angeles Hyperion Treatment Plant NPDES Permit (NO. CA0109991). The permit designates 5 different sampling zones along the coast of the Santa Monica Bay of which the City falls along the border of zones 4 and 3 (see map in Attachment B). All of the samples used for these listings were collected from zones 4 and 5 - no representative samples were collected from zone 3, which includes the southern end of Santa Monica Bay and a substantial portion of the City's drainage area. Therefore, using current samples to list the entire Santa Monica Bay Offshore/Nearshore would incorrectly list zone 3 of the bay despite a lack of representative samples from this area. This would contradict the Listing Policy which states that "*samples should represent statistically or in a consistent targeted manner the segment of the water body*". The spatial coverage of the samples should be considered and the listing reassessed by either segmenting the water	See response to comment 2.13 for Arsenic and 2.14 for Mercury and spatial representativeness. See response to comment 32.3 for a discussion of readily available data. See response to comment 11.21 and 11.22 for fish temporal independence.

No.	Comment	Response
	body or using samples from all representative zones of Santa Monica Bay. In addition, sampling data beyond the 19 samples collected in 2006-2007 should be available from the City of Los Angeles' Hyperion Treatment Plant NPDES permit. It is unclear why only the 2006-2007 samples were used when there are presumably more samples available from the Hyperion Treatment Plant NPDES monitoring program. The City requests that the Water Board review all available data for fish tissue before making a listing for Arsenic and/or Mercury. Finally, the fish tissue assessment for arsenic and mercury did not properly categorize the data in a way that is temporally independent. The Listing Policy states that samples should be temporally independent; however, in some cases fish collected on the same day were treated as unique data points. In addition, the samples collected were from August 2006, October 2007- November 2007, and August - September 2007. Because both arsenic and mercury bioaccumulate over the lifetime of the individual species an averaging period of at least a year should be considered. Therefore, instead of considering 19 individual samples these data should only be considered representative of 2 years thus supporting the need for additional data as previously requested. *Requested Action*: • *Either (1) segment the Santa Monica Bay listing since the data used to list arsenic and mercury are not representative of the entire water body as required by the Listing Policy, or (2) seek additional data from all zones<~(Santa Monica Bay to ensure proper spatial representation of the data prior to listing.* • *Seek and reanalyze additional sample data from the City of Los Angeles beyond the 19 samples from 2006 and 2007 that were originally used/or the analysis*. • *The mercury and arsenic fish tissue data should be aggregated based on a more reasonable temporal resolution*.	
5.5	<u>Comment 5: Sediment toxicity should be delisted; no justification was provided for the name change in the Fact Sheets</u>.	The decision recommendation has been updated to "DELIST."

No.	Comment	Response
	The Santa Monica Bay Offshore/Nearshore toxicity listing (Decision ID 34120) was marked only as a name change in Appendix A. However, a TMDL for DDTs and PCBs was developed and approved by USEPA in 201210 which evaluated sediment toxicity resulting in a recommendation for delisting: *"Our evaluation of the data showed only 3 out of 116 samples exhibited toxicity. Following the California listing policy, Santa Monica Bay is meeting the toxicity objective and there is sufficient evidence to delist sediment toxicity. We therefore make a finding that there is no significant toxicity in Santa Monica Bay and recommend that Santa Monica Bay not be identified as impaired by toxicity in the California's next 303(d) list."* Based on the statement above and data summarized on pages 19 and 20 of the TMDL there is sufficient evidence to delist sediment toxicity for Santa Monica Bay Offshore/Nearshore. The listed name change appears to be a change from "sediment toxicity" to "toxicity" based on the Appendix G Fact Sheets. We assume that this name change is the result of the Water Board's acknowledged systems and clerical errors in Appendix A. In the event that it is not a mere error that will be corrected by the Water Board, the City requests that justification be provided to support the name change. This name change should only occur if new data is used to support the observation of toxicity in the water column as outlined in section 3.6 of the Listing Policy, however no new data was presented and a reason for this name change was not discussed in the staff report. *Requested Action*: • *Delist sediment toxicity for Santa Monica Bay based on the data analysis performed in the 2012 DDTs and PCBs TMDL.* • *Correct the name change error*	The name change is not in error. The 303(d) list no longer includes separate listings for different environmental media, that is, data for sediment toxicity and data for water toxicity are both considered in an assessment of toxicity. In fact, water, sediment and tissue may be considered in one assessment for waterbodies that have data for all three environmental media.
5.6	**II. Inconsistencies within the 303(d) List** As noted by Water Board staff, the Appendices of the proposed 303(d) List have a number of inconsistencies. The inconsistencies listed below are a few examples	Diazinon is recommended for delisting for the Dominguez Channel above Vermont.

No.	Comment	Response
	and should not be considered an exhaustive list. We request that the Water Board do a thorough review of all of the Appendices to ensure that they are internally consistent with the changes listed in the Appendix G Fact Sheets. Table 1. Inconsistencies in the Proposed 303(d) List Appendices **Waterbody Segment: Dominguez Channel (lined portion above Vermont)** **Pollutant(s)**: Diazinon **Comment/Requested Action**: This pollutant is shown as "delisted" in Appendix A with a note "TMDL status changed from TMDL still required to Being Addressed by Completed TMDL ". In Appendix G the same pollutant is listed as "Delist from 303(d) list (being addressed by USEPA approved TMDL)". **The City would like clarification that this listing will be entirely removed from the 303(d) list and not categorized as 4A as indicated by the note in Appendix A.**	Los Angles Water Board staff found several inconsistencies with Appendix A as released for public comment. Appendix G is correct and Appendix A has been revised to align with the fact sheets in Appendix G.
5.7	**Waterbody Segment: Dominguez Channel (lined portion above Vermont)** **Pollutant(s):** Aldrin, Chem A, Chlordane, Chromium, DDT, Dieldrin, PAHs, and PCBs **Comment/Requested Action**: These pollutants are shown as delisted in the Appendix G factsheets, however they are not listed as changed in Appendix A. **All of these pollutants should be delisted due to flaws in the original listing (as noted within the factsheets).**	Aldrin, Chem A, Chlordane, Chromium, DDT, Dieldrin, PAHs, and PCBs were delisted in 2010. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a “Y” or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
5.8	**Waterbody Segment: Dominguez Channel (lined portion above Vermont)** **Pollutant(s)**: Chromium and Dieldrin **Comment/Requested Action**: These pollutants are shown as “name changes” in Appendix A, however we could find no evidence of a name change throughout the	In prior 303(d) lists, “Chromium” was ”Chromium (total)” and “Dieldrin” was “Dieldrin (tissue).”

No.	Comment	Response
	rest of the document. **Any name change should be supported by a reason detailing the need for the change in the Fact Sheets. Furthermore both of these listing should be delisted based on the comment above.**	
5.9	**Waterbody Segment: Dominguez Channel Estuary (unlined portion below Vermont Ave)** **Pollutant(s)**: Aldrin, Chem A, Chromium (total), and PAHs **Comment/Requested Action**: These pollutants are not listed as a change in Appendix A, but shown as "delisted" in Appendix G. **All listings should be delisted either because of flaws in the original listing or lack of an exceedance.**	Aldrin, Chem A, Chromium (total), and PAHs were delisted in 2010. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
5.10	**Waterbody Segment: Dominguez Channel Estuary (unlined portion below Vermont Ave)** **Pollutant(s)**: DDT **Comment/Requested Action**: This listing is missing from Appendix B or C and has not been listed as changed in Appendix A, however the Appendix G factsheets lists DDT as being addressed with a USEPA approved TMDL and therefore **should be categorized as 5B or 4A**.	The waterbody pollutant combination, Dominguez Channel Estuary/DDT, is categorized 5B because it is being addressed by the Dominguez Channel and Greater Los Angeles and Long Beach Harbor Waters Toxics TMDL. Appendix G is correct and Appendix A has been revised to align with it.
5.11	**Waterbody Segment: Dominguez Channel Estuary (unlined portion below Vermont Ave)** **Pollutant(s)**: Dieldrin **Comment/Requested Action**: Listed in Appendix A as "*TMDL status changed from TMDL still required to Being Addressed by Completed TMDL*", however the pollutant does not appear in Appendix B or C and is listed as "*List on 303(d) list (being addressed by USEPA approved TMDL*)" in Appendix G. **This pollutant should be listed as 4A or delisted.**	The waterbody pollutant combination, Dominguez Channel Estuary/Dieldrin is categorized 5B; it is being addressed by the Dominguez Channel and Greater Los Angeles and Long Beach Harbor Waters Toxics TMDL. Appendix G is correct and Appendix A has been revised to align with it.

No.	Comment	Response
5.12	**Waterbody Segment: Dominguez Channel Estuary (unlined portion below Vermont Ave)** **Pollutant(s)**: Chlordane (tissue) **Comment/Requested Action**: Listed in Appendix A as unchanged but not found in Appendix B or C. The Appendix G Fact Sheets list this pollutant as "*Do not delist (being addressed with USEPA approved TMDL)*". **The City would like clarification if this pollutant has been delisted or recategorized as 5B.**	The waterbody pollutant combination, Dominguez Channel Estuary/Chlordane is categorized 5B; it is being addressed by the Dominguez Channel and Greater Los Angeles and Long Beach Harbor Waters Toxics TMDL. The pollutant was recategorized as 5B.
5.13	**Waterbody Segment: The Santa Monica Bay Offshore/Nearshore** **Pollutant(s)**: Chlordane and PAHs **Comment/Requested Action**: Not listed as a change in Appendix A but shown as "delisted" in Appendix G. **These pollutants should be delisted.**	Chlordane and PAHs were recommended for delisting in the 2010 303(d) list. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
5.14	**Waterbody Segment: Redondo Beach** **Pollutant(s)**: DDT **Comment/Requested Action**: Listed in Appendix A only as a "name change", however Appendix G lists this as "*TMDL status changed from TMDL still required to Being Addressed by Completed TMDL*". The 2010 303(d) list shows Redondo Beach DDT listing was Category SA however in the newly proposed 303(d) list the pollutant is listed as 4A in Appendix C. Category 4A is the correct category for this pollutant since a USEPA-approved TMDL does exist to manage DDT which is expected to result in full attainment of the water quality standard within a specified time frame. **The City would like Appendix A edited to reflect new 4A listing**. Furthermore if this is in fact a name change, as stated in Appendix A, **an explanation including supporting data for the name change should be**	Redondo Beach DDT is both a name change and a TMDL status change. Los Angles Water Board staff has found several inconsistencies with Appendix A as released for public comment. Appendix G is correct and Appendix A has been revised to align with it. In prior 303(d) lists, "DDT" was "DDT (Dichlorodiphenyltrichloroethane)."

No.	Comment	Response
	included in the Appendix G Fact Sheets.	
6.	City of Santa Clarita, March 29, 2017	
6.1	**Change All Listings to "*Being Addressed by Action Other Than a TMDL*"** Due to the extensive studies and long term implementation efforts contained in the EWMP, the City requests all pollutants remaining on the 303(d) list without a developed TMDL should be changed to the Category 4B for the Clean Water Act as "Being Addressed by Action Other Than a TMDL." More specifically, the pollutants will be addressed through the long-term implementation of the EWMP. In addition, the City requests a focus be placed on "Delisting" pollutants by the Regional Board so that limited resources can be better applied to applying long-term strategies of the approved EWMP.	The implementation of the EWMPs is likely to make a significant improvement in water quality in the affected watersheds. However, MS4 discharges may not be the only source of pollutants causing the impairment of these waterbodies; therefore, the actions identified in the EWMPs may not be the only implementation required. A source assessment and linkage analysis, during development of a TMDL, or during development of another regulatory program, or as a special study would be necessary to determine the relative contribution of all the sources and all the actions necessary to restore affected waterbodies to a condition of full water quality standards attainment.
6.2	The City requests the following amendments for the 2017 303(d) List. The affected water quality objectives are listed below. **Affected Waterbodies, Water Quality Objectives, and Suggested Revisions** <u>*Santa Clara River Reach 5 (Blue Cut Gauging Station to West Pier Highway 99 Bridge)*</u> Ammonia should be revised to "Being Addressed by Completed TMDL." The Nitrogen and Effects TMDL for the Santa Clara River was completed in 2004. The Los Angeles County Sanitation Districts revised their operations at the Saugus Water Reclamation Plant and the Valencia Water Reclamation Plant and installed a Nitrification-Denitrification (NDN) process in 2004. The applicable water quality standards for nitrate, nitrite, and ammonia are not being exceeded. Decision ID 34352 states that no discharges exceeded limits.	Because the applicable water quality standard for ammonia is not being exceeded, Santa Clara River Reach 5 Ammonia is proposed to be delisted (CalWQA Decision 34352). The listing decision is "Delist from 303(d) list (being addressed by USEPA approved TMDL)."

No.	Comment	Response
6.3	Benthic Community Effects should be revised to "Being Addressed by Action Other Than a TMDL." Decision ID 44468 states that the water body is impaired with multiple pollutants, including zinc, iron, bacteria, and chloride. However, Line of Evidence 88732 states that 0 out of 153 samples had any exceedance for zinc. Although iron is naturally occurring in the Santa Clara River watershed, Line of Evidence 88656 found 6 of 81 samples exceeded and Line of Evidence 88648 found 0 of 2 samples exceeding water quality limits. There were no samples taken for coliform bacteria, and therefore, no exceedances recorded as per Line of Evidence 4156. Line of Evidence 88792 states that none of the two samples taken exceeded the criterion for chloride. Further, the listing was based on the Southern Coastal California Index of Biotic Integrity (SCIBI). However, the SCIBI-based analysis is inadequate for use in low-gradient and low-elevation waters, such as the Upper Santa Clara River. Through the implementation of the EWMP, the benthic community should rebound to its natural populations as the EWMP addresses toxicity, metals, pesticides, and other metrics that affect benthic communities.	See response to comment 6.1. For a discussion of low elevation and benthic macroinvertebrate impairments, see response to comment 26.13.
6.4	Chloride should be revised to "Being Addressed by Completed TMDL." The Santa Clara River chloride TMDL was approved by the United States Environmental Protection Agency (USEPA) on April 28, 2005. The site-specific water quality objective for Santa Clara River Reach 5 is 100 mg/L. The primary source of chloride was determined to be potable water derived from a blend of the State Water Project and local groundwater. Santa Clarita Valley residents have relinquished over 8,200 salt-based water softeners that had previously contributed to excessive chloride levels found in the Santa Clara River. The Los Angeles County Sanitation Districts has proposed to install reverse-osmosis technology at their Valencia Water Reclamation Plant and Saugus Water Reclamation Plant, as part of an overall chloride reduction plan.	The listing decision (Decision 32396) is, in fact, "Do Not Delist from 303(d) list (being addressed with USEPA approved TMDL)" and so does not require revision.
6.5	Indicator bacteria should be revised to "Being Addressed by Action Other Than a TMDL." Through the implementation of the EWMP, indicator bacteria should fall to levels found in ambient waters.	The listing decision (Decision 34306) is "Do Not Delist from 303(d) list (being addressed with USEPA approved TMDL)" as the waterbody pollutant combination is currently being addressed

No.	Comment	Response
		by the TMDL for Indicator Bacteria in Santa Clara River Estuary and Reaches 3, 5, 6, and 7 (approved by USEPA on Jan. 31, 2012). The listing decision does not require revision.
6.6	Iron should be revised to "Being Addressed by Action Other Than a TMDL." Iron was modeled and will be addressed by the implementation of the EWMP for the Upper Santa Clara River.	See response to comment 6.1.
6.7	Nitrate and nitrite should be revised to "Being Addressed by Completed TMDL." The Nitrogen and Effects TMDL for the Santa Clara River was approved by the USEPA in 2004. The original listing was made in 1998. Since then, the Los Angeles County Sanitation Districts underwent significant upgrades to their operations including incorporation of nitrification/de-nitrification treatment at the Valencia Water Reclamation Plant in 2003, specifically aimed at addressing nitrogen in the Upper Santa Clara River. Decision ID 32484 states that the decision to delist from 303(d) list was previously approved by the State Water Resources Control Board and the USEPA.	The listing decision for Decision 32484 is "Do Not Delist from 303(d) list (being addressed with USEPA approved TMDL)" as the waterbody pollutant combination is currently being addressed by the Santa Clara River Nitrogen Compounds TMDL. The listing decision does not require revision.
6.8	Toxicity should be revised to "Being Addressed by Action Other Than a TMDL." Toxicity was modeled and will be addressed by the implementation of the EWMP for the Upper Santa Clara River.	See response to comment 6.1.
6.9	*Santa Clara River Reach 6 (West Pier Highway 99 to Bouquet Canyon Road)* Ammonia should be revised to "Being Addressed by Completed TMDL" or "Delist from 303(d) list." The Nitrogen and Effects TMDL for the Santa Clara River was approved by the USEPA in 2004. The original listing was made in 1998. Since then, the Los Angeles County Sanitation Districts underwent significant upgrades to their operations, including incorporation of nitrification/de-nitrification treatment at the Valencia Water Reclamation Plant in 2003, specifically aimed at addressing nitrogen in the Upper Santa Clara River. Decision ID 32462 states that the decision to delist from 303(d) list was previously approved by the State Water Resources Control Board and the USEPA.	Santa Clara River Reach 6 Ammonia is proposed to be delisted. The listing decision (Decision 32462) is "Delist from 303(d) list (being addressed by USEPA approved TMDL)" and does not require revision.

No.	Comment	Response
6.10	Chloride should be revised to "Being Addressed by Completed TMDL" or "Delist from 303(d) list." The Santa Clara River chloride TMDL was approved by the USEPA on April 28, 2005. The site-specific water quality objective for Santa Clara River Reach 5 is 100 mg/L. The primary source of chloride was determined to be potable water derived from a blend of the State Water Project and local groundwater. Santa Clarita Valley residents have relinquished over 8,200 salt-based water softeners that had previously contributed to excessive chloride levels found in the Santa Clara River. The Los Angeles County Sanitation Districts has proposed to install reverse-osmosis technology at their Valencia Water Reclamation Plant and Saugus Water Reclamation Plant, as part of an overall chloride reduction plan.	Decision 32397 is a “carryover” decision. No new data was assessed or LOE created, so the listing remains what it was on the last 303(d) list. The listing decision is "List on 303(d) list (being addressed by USEPA approved TMDL)" as the waterbody pollutant combination is currently being addressed by the Upper Santa Clara River Chloride TMDL. The listing decision does not require revision.
6.11	For chlorpyrifos, Decision ID 33024 states samples were collected from August 2002 through April 2003. It should be noted that USEPA phased out all residential use of chlorpyrifos products since 2004. Since the samples were taken prior to being phased out and no further positive results are presented, this information is no longer relevant. Due to the long term implementation efforts contained in the EWMP, this pollutant should be changed to “Being Addressed by Action Other Than a TMDL.”	Decision 33024 was made based on LOE 2134, where 10 of 39 samples were found to exceed the evaluation guidelines. While USEPA phased out all residential use of chlorpyrifos products since 2004 and the data used in LOE 2134 were collected from August 2002 to April 2003, there is no new evidence/data in CalWQA to support a delisting decision. Therefore, the listing decision remains as "Do Not Delist". See, also, response to comment 6.1.
6.12	Copper was modeled for and will be addressed by the implementation of the EWMP for the Upper Santa Clara River. Copper should be revised to “Being Addressed by Action Other Than a TMDL.”	See response to comment 6.1.
6.13	Decision ID 44805 states samples for diazinon were collected from August 2002 through April 2003. It should be noted that USEP A phased out all residential use of diazinon products since 2004. Only data generated from after the ban should be considered. For a sample size of 28-36, Table 4.1 of the State's Listing Policy recommends delisting a previously listed pollutant if the numbers of exceedances	Decision 44805 was made based on LOE 2135, where 28 of 29 samples were found to exceed the evaluation guideline. While USEPA phased out all residential use of diazinon products since 2004 and the data used in LOE 2135 were collected

No.	Comment	Response
	are less than two. Since no other samples show an exceedance, diazinon should be delisted. In addition, due to the implementation of the EWMP, this pollutant could also be changed to “Being Addressed by Action Other Than a TMDL.”	from August 2002 to April 2003, there is no new evidence/data indicating that the waterbody is not impaired by diazinon. Therefore, the listing decision should remain as "Do Not Delist". See, also, response to comment 6.1.
6.14	Iron is abundant in the natural soils in the Santa Clarita Valley. In addition, iron was modeled for and will be addressed by the implementation of the EWMP for the Upper Santa Clara River. Iron should be revised to “Being Addressed by Action Other Than a TMDL.”	Regional board staff reassessed the LOEs associated with this decision. The listing decision has been changed to "Delist from 303(d) list".
6.15	According to the National Weather Service, ambient air temperature for Santa Clarita during the summer months regularly exceeds 100 degrees Fahrenheit due to a semi-arid climate. The Santa Clara River is an ephemeral stream with water flow quickly subsiding into the natural sandy, soft- bottom riverbed. It is noted that all samples registering over 80 degrees Fahrenheit occurred between the months of May and August. It is reasonable that hot and dry air temperatures correlate to warmer water temperatures in shallow, sandy soils. Receiving waters in the Santa Clara River registering above 80 degrees Fahrenheit are the result of natural, ambient conditions and should not be considered as a result of storm drain or treatment discharge.	See response to comment 17.4.
6.16	In Line of Evidence 88683, it is noted that toxicity data was not reported with a control, and therefore anything reported as < 100% (chronic) or < 100% survival (acute) was considered an exceedance. In addition, toxicity was modeled for and will be addressed by the implementation of the EWMP for the Upper Santa Clara River. Toxicity should be revised to “Being Addressed by Action Other Than a TMDL.”	Decision 33550 is supported by two LOEs. 4 of 4 samples were in exceedance in LOE 2137 and 4 of 40 samples were in exceedance in LOE 88683. Even though there was lack of control data for LOE 88683, the original listing decision was justified by LOE 2137 and there is no new evidence/data supporting a delisting decision. Therefore, the listing decision will remain as "Do Not Delist". A review of LOE 88683 is in process at this time.

No.	Comment	Response
		For a more detailed discussion of toxicity, see response to comment 26.7. See, also, response to comment 6.1.
7.	Farm Bureau of Ventura County (FBVC), March 29, 2017	
7.1	Approximately 98 of the new 303(d) listings being proposed by the Los Angeles Regional Water Quality Control Board (Regional Board) are in Ventura County, and many are apparently driven by data collected through VCAILG's Conditional Waiver monitoring program. We have reviewed these proposed listings, and found numerous factual and legal errors that must be corrected. In some cases, the errors or ambiguities in the proposed listings are such that we and our technical consultants found it impossible to properly analyze them.	See response to comment 7.4 -7.102 for specific responses.
7.2	The development and implementation of TMDLs represents a significant investment of our members' resources, and compliance imposes a significant burden on agricultural operators, so it is critical that the 303(d) list be based on sound science and methodologies. We therefore ask that the issues identified in this letter be addressed, and that the proposed 303(d) list be revised and released for another 60-day comment period before adoption.	The Los Angeles Water Board recognizes the significant implications of the 303(d) list and TMDLs. The 303(d) list is based on sound science and readily available data. However, as the Los Angeles Water Board determines its priorities for TMDL development or other regulatory programs, it will not depend exclusively on the 303(d) list or the data contained therein (currently only through 2010). See response to comment 32.1 for additional discussion of additional comment periods.
7.3	The requested modifications fall into four general categories: 1. New Category 4 and 5 listings that should not be listed due to incorrect thresholds being applied for the beneficial use and incorrect interpretation of the data (e.g. mismatched units, incorrectly assigned sample locations). This comment category also addresses the issue of agricultural drains and ditches — which are	See response to comment 7.4 -7.102 for specific responses. Los Angeles Water Board staff will make the necessary corrections in the CalWQA database and make the appropriate listing/delisting

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td></td><td>not legally recognized as waterbodies — being inappropriately included in the listings.
2. Potential delistings that may be justified if all watershed data were evaluated (e.g. TMDL monitoring program and all wastewater treatment plant NPDES monitoring).
3. New Category 5A listings that should be categorized as Category 5B because TMDLs already exist to address the pollutants.
4. Errors in the listing information that make it difficult to fully evaluate the listings. Examples include inconsistencies between the Category 5 list (Appendix B) and the Proposed updates to the 303(d) list (Appendix A), incorrect HUC/Calwater designations, incorrect beneficial uses listed for the applicable water quality objectives, and inconsistent use of thresholds for interpreting narrative objectives.</td><td>decisions as the State Board staff prepare the Integrated Report and 303(d) list for State Board approval later this year, or during the next Listing Cycle that includes the Los Angeles Region.</td></tr>
<tr><td>7.4</td><td>The remaining sections of this letter provide the detailed list of requested changes to the 303(d) list and the rationale for the requests. In summary, FBVC requests that all waterbody pollutant combinations in Table 1 not be listed on the 303(d) list, that waterbody pollutant combinations in Table 3 and Table 4 be designated as being addressed by a TMDL if they remain on the 303(d) list after the reassessment, and the errors and inconsistencies identified in Comment IV be addressed for all waterbodies. Furthermore, FBVC supports the 303(d) list comment letter submitted by the Stakeholders Implementing TMDLs in the Calleguas Creek Watershed.</td><td>See response to comment 7.4 -7.102 for specific responses.</td></tr>
<tr><td>7.5</td><td>I. REQUESTED MODIFICATIONS TO THE LISTING STATUS
Based on a review of the proposed Category 4 and 5 waterbody pollutant combinations, FBVC has identified a number of waterbodies that we feel should either be delisted based on available data, or which should not be listed based on errors in the evaluation. The requested modifications are shown in Table 1, below, with a summary of the justifications for the requested change. A detailed discussion of each of the justifications follows the table.

Table 1. Waterbody-pollutant combinations that should not be listed</td><td>The Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. LOE 83044 will be retired. Los Angeles Water Board staff's intention will be to make the necessary corrections in the CalWQA database and make the appropriate listing/delisting decisions as the State Board staff prepare the Integrated Report and 303(d) list for State Board approval later this year or prior to the next Listing Cycle that includes the Los Angeles</td></tr>
</table>

No.	Comment	Response
	Waterbody segment: **Boulder Creek (Ventura County)** Pollutant: Chlordane Justification: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody. • J-flagged data incorrectly used in assessment (WARM).	Region. J-flagged data was incorrectly used in the original assessment. LOE 83043 will be modified. Decision 60531 will be changed to "Do Not List" due to insufficient information. Los Angeles Water Board staff's intention will be to enter the data, as appropriate, into the CalWQA database and make the listing/delisting decisions as the State Board staff prepare the Integrated Report and 303(d) list for State Board approval later this year or prior to the next Listing Cycle that includes the Los Angeles Region.
7.6	**Boulder Creek (Ventura County)** Pollutant: Nitrogen, Nitrate Justification: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	The Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. LOE 83048 and Decision 60506 will be retired. Los Angeles Water Board staff's intention will be to make the necessary corrections in the CalWQA database and make the appropriate listing/delisting decisions as the State Board staff prepare the Integrated Report and 303(d) list for State Board approval or prior to the next Listing Cycle that includes the Los Angeles Region.
7.7	**Boulder Creek (Ventura County)** Pollutant: Specific Conductivity Justification: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	The Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. LOE 83138 and Decision 60539 will be retired. Los Angeles Water Board staff's intention will be to make the necessary corrections in the CalWQA database and make the appropriate listing/delisting decisions as the State Board staff prepare the

No.	Comment	Response
		Integrated Report and 303(d) list for State Board approval or prior to the next Listing Cycle that includes the Los Angeles Region.
7.8	**Boulder Creek (Ventura County)** Pollutant: Toxicity Justification: • Listed based on toxicity observed during a single sampling event (6/4/07). According to the Listing Policy, a larger number of samples is required to justify this listing.	Because the data collected are temporally independent, it is appropriate to assess the data as individual samples even though they were collected at the same site. However, a review of the decision is in process at this time in order to confirm the number of toxicity tests completed.
7.9	Waterbody segment: **McGrath Lake Agricultural Drain** Pollutant: Bifenthrin Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	The decision for this waterbody-pollutant combination has been changed to "do not list," due to insufficient information at this time to determine whether the McGrath Lake Agricultural Drain should be included in the region's water quality assessment pursuant to sections 305(b) and 303(d) of the Clean Water Act. Once such a determination is made by the Los Angeles Water Board, necessary changes, if any, will be transmitted to the State Water Board, so that the GIS mapping component of CalWQA can be updated. Additionally, the Los Angeles Water Board will re-evaluate the LOE(s), as appropriate.
7.10	**McGrath Lake Agricultural Drain** Pollutant: Chlordane Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • This pollutant is already covered by the McGrath Lake PCBs, Pesticides and Sediment Toxicity TMDL.	See response to comment 7.9. This notwithstanding, as noted by the commenter, should McGrath Lake Agricultural Drain be included in the region's water quality assessment, chlordane would be categorized as 5B, which recognizes that it is being addressed by the McGrath Lake PCBs, Pesticides and Sediment Toxicity TMDL.

No.	Comment	Response
7.11	**McGrath Lake Agricultural Drain** Pollutant: Chlorpyrifos Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.9.
7.12	**McGrath Lake Agricultural Drain** Pollutant: DDT Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • This pollutant is already covered by the McGrath Lake PCBs, Pesticides and Sediment Toxicity TMDL.	See response to comment 7.9. This notwithstanding, as noted by the commenter, should McGrath Lake Agricultural Drain be included in the region's water quality assessment, DDT would be categorized as 5B, which recognizes that it is being addressed by the McGrath Lake PCBs, Pesticides and Sediment Toxicity TMDL.
7.13	**McGrath Lake Agricultural Drain** Pollutant: Toxaphene Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • This pollutant is already covered by the McGrath Lake PCBs, Pesticides and Sediment Toxicity TMDL.	See response to comment 7.9. This notwithstanding, note that toxaphene as an individual pollutant was not addressed by the McGrath Lake PCBs, Pesticides and Sediment Toxicity TMDL.
7.14	Waterbody segment: **Calleguas Creek Reach 2 (estuary to Potrero Rd)** Pollutant: DDD Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	The decisions for Calleguas Creek Reach 2 have been revised to not use the data from the Ventura County Agriculture Irrigated Lands Group (VCAILG) monitoring site at Broome Ranch Road (02D_BROOM). This site is not located in Calleguas Creek Reach 2. If the Los Angeles Water Board determines that this monitoring site should be included in the region's water quality assessment pursuant to sections 305(b) and 303(d)

No.	Comment	Response
		of the Clean Water Act, staff will work with the State Water Board to modify the GIS mapping component of CalWQA and re-evaluate the LOE(s). Additionally, the Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. LOE 83361 will be modified. These changes are in process at this time.
7.15	**Calleguas Creek Reach 2 (estuary to Potrero Rd)** Pollutant: DDE Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.14. Additionally, the Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. LOE 83362 will be modified. These changes are in process at this time.
7.16	**Calleguas Creek Reach 2 (estuary to Potrero Rd)** Pollutant: Dimethoate Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.14. Additionally, the Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. The LOE will be modified. These changes are in process at this time.
7.17	**Calleguas Creek Reach 2 (estuary to Potrero Rd)** Pollutant: Nitrogen, Nitrate Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.14. Additionally, the Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. LOE 83204 and Decision 61025 will be retired. These changes are in process at this time.

No.	Comment	Response
7.18	**Calleguas Creek Reach 2 (estuary to Potrero Rd)** Pollutant: Specific Conductivity Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.14. Additionally, the Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. LOE 83257 and Decision 61028 will be retired. These changes are in process at this time.
7.19	**Calleguas Creek Reach 2 (estuary to Potrero Rd)** Pollutant: Total Dissolved Solids Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody. • Salts criteria do not apply below Potrero Rd.	See response to comment 7.14. Additionally, there is no water quality objective applied to this waterbody segment, since this reach is tidally influenced. LOE 83270 and Decision 61035 will be retired. These changes are in process at this time.
7.20	Waterbody segment: **Calleguas Creek Reach 3 (Potrero Road upstream to Conejo Creek confluence)** Pollutant: Mercury Justification: • Data and objectives have different units (ng/L vs. µg/L); data do not exceed objectives.	Data did not exceed the objectives. LOE 83210 will be modified. Decision 61085 will be changed to "Do Not List". These changes are in process at this time.
7.21	Waterbody segment: **Calleguas Creek Reach 4 (was Revolon Slough Main Branch)** Pollutant: Ammonia Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • TMDL data demonstrates delisting possible.	The decisions for Calleguas Creek Reach 4 have been revised to not use the data from the VCAILG monitoring sites at Etting Road (04D_ETTG) and S. Las Posas Road (04D_LAS). These sites are not located in Calleguas Creek Reach 4. If the Los Angeles Water Board determines that these monitoring sites should be included in the region's water quality assessment pursuant to sections 305(b) and 303(d) of the Clean Water Act, staff

No.	Comment	Response
		will work with the State Water Board to modify the GIS mapping component of CalWQA and re-evaluate the LOE(s). For a discussion of readily available data see response to comment 32.3
7.22	**Calleguas Creek Reach 4 (was Revolon Slough Main Branch)** Pollutant: Bifenthrin Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.21.
7.23	**Calleguas Creek Reach 4 (was Revolon Slough Main Branch)** Pollutant: Chloride Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.21. Additionally, the Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. LOE 83171 will be retired. These changes are in process at this time.
7.24	**Calleguas Creek Reach 4 (was Revolon Slough Main Branch)** Pollutant: Cyfluthrin Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.21.
7.25	**Calleguas Creek Reach 4 (was Revolon Slough Main Branch)** Pollutant: Cypermethrin Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.21.
7.26	**Calleguas Creek Reach 4 (was Revolon Slough Main Branch)**	See response to comment 7.21.

No.	Comment	Response
	Pollutant: Malathion Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	
7.27	**Calleguas Creek Reach 4 (was Revolon Slough Main Branch)** Pollutant: Mercury Justification: • Data and objectives have different units (ng/L vs. µg/L); data do not exceed objectives.	Data did not exceed the objectives. LOE 83434 will be modified. Decision 61211 will be changed to "Do Not List". These changes are in process at this time.
7.28	**Calleguas Creek Reach 4 (was Revolon Slough Main Branch)** Pollutant: Nitrogen, Nitrate Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.21. Additionally, the Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. LOE 83450 and Decision 61212 will be retired. These changes are in process at this time.
7.29	**Calleguas Creek Reach 4 (was Revolon Slough Main Branch)** Pollutant: Permethrin Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • This pollutant is already covered by the Calleguas Toxicity TMDL.	See response to comment 7.21. Permethrin is not addressed in the Calleguas Creek Toxicity TMDL.
7.30	**Calleguas Creek Reach 4 (was Revolon Slough Main Branch)** Pollutant: Specific Conductivity Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.21. The Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. LOE 83410 and Decision 61214 will be retired. These changes are in process at this time.

No.	Comment	Response
7.31	**Calleguas Creek Reach 4 (was Revolon Slough Main Branch)** Pollutant: Sulfate Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.21. The Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. LOE 83411 will be retired. Decision 42845 will be changed to "Do Not List" due to insufficient information. These changes are in process at this time.
7.32	**Calleguas Creek Reach 4 (was Revolon Slough Main Branch)** Pollutant: Total Dissolved Solids Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.21. The Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. LOE 83416 will be retired. Decision 42771 will be changed to "Do Not List" due to insufficient information. These changes are in process at this time.
7.33	Waterbody segment: **Calleguas Creek Reach 12 (was Conejo Creek/Arroyo Conejo North Fork)** Pollutant: Chlorpyrifos Justification: • Data does not appear to be from a station in Reach 12.	A review of the Calleguas Creek Reach 12 decisions are in process at this time. This requested change may require a change to the CalWQA underlying map, which is maintained by State Board. It is the intention of the Los Angeles Water Board staff to work with State Board staff to resolve mapping issues where they exist, and reassess the LOEs and decisions for these reaches, as appropriate, prior to the State Board approval of the 2016 303(d) list, or prior to the next Listing Cycle that includes the Los Angeles Region.
7.34	**Calleguas Creek Reach 12 (was Conejo Creek/Arroyo Conejo North Fork)** Pollutant: Diazinon Justification: • Data does not appear to be from a station in Reach 12.	See response to comment 7.33.
7.35	**Calleguas Creek Reach 12 (was Conejo Creek/Arroyo Conejo North Fork)**	See response to comment 7.33.

No.	Comment	Response
	Pollutant: Malathion Justification: • Data does not appear to be from a station in Reach 12.	
7.36	**Calleguas Creek Reach 12 (was Conejo Creek/Arroyo Conejo North Fork)** Pollutant: Temperature, water Justification: • Inappropriately applied beneficial use criteria (see temperature comment below)	LOE 83538 was based on the correct criteria/objective, which states "For waters designated WARM, water temperature shall not be altered by more than 5 deg. F above the natural temperature. At no time shall these WARM-designated waters be raised above 80 deg. F as a result of waste discharges." The decision (#61523) does not require revision. See, also, response to comment 17.4.
7.37	Waterbody segment: **Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2** Pollutant: Nitrogen, Nitrate Justification: • Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No. 2 are tributaries to Mugu Lagoon; therefore, they will be assessed for the same beneficial uses and objectives as the downstream Mugu Lagoon. The MUN beneficial use does not apply and a review of the decision is in process at this time.
7.38	**Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2** Pollutant: Nitrogen Justification: • Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.37.
7.39	**Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2** Pollutant: Sulfate Justification:	See response to comment 7.37.

No.	Comment	Response
	• Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	
7.40	**Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2** Pollutant: Specific Conductivity Justification: • Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.37.
7.41	**Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2** Pollutant: Total Dissolved Solids Justification: • Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.37.
7.42	**Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2** Pollutant: Toxaphene Justification: • J-flagged data incorrectly used in assessment.	J-flagged data was incorrectly used in the assessment. LOE 84178, LOE 84179 and LOE 84180, which include J-flagged data will be modified. Additionally, see response to comment 7.37. A review of the decision is in process at this time. Decision 33913, however, will remain as "Do Not Delist from 303(d) list (being addressed with USEPA approved TMDL)" as LOE 2030, which was established in 2006, supports the listing decision.
7.43	Waterbody segment: **Ellsworth Barranca** Pollutant: DDE Justification:	The Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation.

No.	Comment	Response
	• Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody. • J-flagged data incorrectly used in assessment.	The "Beneficial Use Assessed" will be changed to "Warm Freshwater Habitat" and the evaluation guideline for Freshwater Aquatic Life Protection Continuous Concentration of 0.001 ug/L will be used. LOE 84304 will be modified. These changes are in process at this time. Additionally, staff is reviewing the data to ensure that J-flagged data were not incorrectly used in the original assessment.
7.44	Waterbody segment: **Fox Barranca** Pollutant: DDE Justification: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	A review of the decision is in process at this time. The "Beneficial Use Assessed" will be changed to "Warm Freshwater Habitat" and the evaluation guideline for Freshwater Aquatic Life Protection Continuous Concentration of 0.001 ug/L will be used. LOE 84487 will be modified.
7.45	Waterbody segment: **Honda Barranca** Pollutant: DDD Justification: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	A review of the decision is in process at this time. The "Beneficial Use Assessed" will be changed to "Warm Freshwater Habitat" and the evaluation guideline for Freshwater Aquatic Life Protection Continuous Concentration of 0.001 ug/L will be used. LOE84752 will be modified.
7.46	**Honda Barranca** Pollutant: DDE Justification: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	A review of the decision is in process at this time. The "Beneficial Use Assessed" will be changed to "Warm Freshwater Habitat" and the evaluation guideline for Freshwater Aquatic Life Protection Continuous Concentration of 0.001 ug/L will be used. LOE 84758 will be modified.
7.47	Waterbody segment: **Rio De Santa Clara/Oxnard Drain No. 3** Pollutant: Nitrogen, Nitrate	A review of the decision is in process at this time. Rio De Santa Clara/Oxnard Drain No. 3 is

No.	Comment	Response
	Justification: • Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	tributary to Mugu Lagoon and the MUN beneficial use does not apply. It is the intention of the Los Angeles Water Board staff to work with State Board staff to resolve mapping issues and reassess the LOEs and decisions for these reaches, as appropriate, prior to the State Board approval of the 2016 303(d) list, or prior to the next Listing Cycle that includes the Los Angeles Region.
7.48	**Rio De Santa Clara/Oxnard Drain No. 3** Pollutant: Nitrogen Justification: • Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.47.
7.49	**Rio De Santa Clara/Oxnard Drain No. 3** Pollutant: Sulfate Justification: • Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	A review of the decision is in process at this time. Rio De Santa Clara/Oxnard Drain No. 3 is tributary to Mugu Lagoon and the MUN beneficial use does not apply.
7.50	**Rio De Santa Clara/Oxnard Drain No. 3** Pollutant: Specific Conductivity Justification: • Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	A review of the decision is in process at this time. Rio De Santa Clara/Oxnard Drain No. 3 is tributary to Mugu Lagoon and the MUN beneficial use does not apply.
7.51	**Rio De Santa Clara/Oxnard Drain No. 3** Pollutant: Total Dissolved Solids	A review of the decision is in process at this time. Rio De Santa Clara/Oxnard Drain No. 3 is

No.	Comment	Response
	Justification: • Maintained as a brackish waterbody therefore criteria do not apply. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	tributary to Mugu Lagoon and the MUN beneficial use does not apply..
7.52	**Rio De Santa Clara/Oxnard Drain No. 3** Pollutant: Toxicity Justification: • Insufficient exceedances to warrant listing.	The “DO NOT DELIST” decision was based on LOE 4382, which is a ‘placeholder’ LOE to support a 303(d) listing decision made prior to 2006. There is insufficient information to support a delisting decision.
7.53	Waterbody segment: **La Vista Drain (Ventura County)** Pollutant: Chlordane Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • J-flagged data incorrectly used in assessment.	The decision for this waterbody-pollutant combination has been changed to “do not list,” due to insufficient information at this time to determine whether the La Vista Drain should be included in the region’s water quality assessment pursuant to sections 305(b) and 303(d) of the Clean Water Act. Once such a determination is made by the Los Angeles Water Board, necessary changes, if any, will be transmitted to the State Water Board, so that the GIS mapping component of CalWQA can be updated. Additionally, the Los Angeles Water Board will re-evaluate the LOE(s), as appropriate. This notwithstanding, as noted by the commenter, should La Vista Drain (Ventura County) be included in the region’s water quality assessment, the LOE would be reassessed to remove J-flagged data.
7.54	**La Vista Drain (Ventura County)**	See response to comment 7.53.

No.	Comment	Response
	Pollutant: Chlorpyrifos Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	
7.55	**La Vista Drain (Ventura County)** Pollutant: Copper Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.53.
7.56	**La Vista Drain (Ventura County)** Pollutant: DDD Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.53. This notwithstanding, as noted by the commenter, should La Vista Drain (Ventura County) be included in the region's water quality assessment, the LOE would be reassessed to not reference the MUN beneficial use.
7.57	**La Vista Drain (Ventura County)** Pollutant: DDE Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.53. This notwithstanding, as noted by the commenter, should La Vista Drain (Ventura County) be included in the region's water quality assessment, the LOE would be reassessed to not reference the MUN beneficial use.
7.58	**La Vista Drain (Ventura County)** Pollutant: DDT Justification:	See response to comment 7.53.

No.	Comment	Response
	• Data from agricultural drain rather than waterbody used as basis for listing decision.	
7.59	**La Vista Drain (Ventura County)** Pollutant: Indicator Bacteria Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.53.
7.60	**La Vista Drain (Ventura County)** Pollutant: Mercury Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Data and objectives have different units (ng/L vs. μg/L); data do not exceed objectives.	See response to comment 7.53. This notwithstanding, should La Vista Drain (Ventura County) be included in the region's water quality assessment, the LOE 85332 would be modified.
7.61	Waterbody segment: **Santa Clara Drain** Pollutant: Chlordane Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	The decision for this waterbody-pollutant combination has been changed to "do not list," due to insufficient information at this time to determine whether the Santa Clara Drain should be included in the region's water quality assessment pursuant to sections 305(b) and 303(d) of the Clean Water Act. Once such a determination is made by the Los Angeles Water Board, necessary changes, if any, will be transmitted to the State Water Board, so that the GIS mapping component of CalWQA can be updated. Additionally, the Los Angeles Water Board will re-evaluate the LOE(s), as appropriate.
7.62	**Santa Clara Drain** Pollutant: Chlorpyrifos	See response to comment 7.61.

No.	Comment	Response
	Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	
7.63	**Santa Clara Drain** Pollutant: Cypermethrin Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.61.
7.64	**Santa Clara Drain** Pollutant: DDD Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using COMM criteria; public access is prohibited by chain link fencing and locked gates.	See response to comment 7.61. This notwithstanding, should Santa Clara Drain be included in the region's water quality assessment, the LOE would be reassessed to not reference the COMM beneficial use. Santa Clara Drain drains to Calleguas Creek Reach 4 and COMM is not a beneficial use for Calleguas Creek Reach 4. Beneficial Use Assessed would be changed to "Warm Freshwater Habitat" for LOE 88067.
7.65	**Santa Clara Drain** Pollutant: DDE Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using COMM criteria; public access is prohibited by chain link fencing and locked gates.	See response to comment 7.61 and 7.64.
7.66	**Santa Clara Drain** Pollutant: DDT Justification:	See response to comment 7.61 and 7.64.

No.	Comment	Response
	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using COMM criteria; public access is prohibited by chain link fencing and locked gates.	
7.67	**Santa Clara Drain** Pollutant: Nitrogen, Nitrate Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.61. This notwithstanding, the Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. Should Santa Clara Drain be included in the region's water quality assessment, the LOE would be reassessed to not reference the MUN beneficial use.
7.68	**Santa Clara Drain** Pollutant: Specific Conductivity Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.61. This notwithstanding, the Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. Should Santa Clara Drain be included in the region's water quality assessment, the LOE would be reassessed to not reference the MUN beneficial use.
7.69	**Santa Clara Drain** Pollutant: Sulfate Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.61.
7.70	**Santa Clara Drain** Pollutant: Total Dissolved Solids Justification:	See response to comment 7.61. This notwithstanding, the Los Angeles Water

No.	Comment	Response
	• Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. Should Santa Clara Drain be included in the region's water quality assessment, the LOE would be reassessed to not reference the MUN beneficial use.
7.71	**Santa Clara Drain** Pollutant: Toxaphene Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.61.
7.72	Waterbody segment: **Santa Clara River Reach 3** Pollutant: Chlordane Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	The decisions for Santa Clara River Reach 3 have been revised to not use the data from the Ventura County Agriculture Irrigated Lands Group (VCAILG) monitoring site S03D_BARDS or from the Ventura County Stormwater Monitoring Program site, 11th Street Drain. These sites are not located in Santa Clara River Reach 3. If the Los Angeles Water Board determines that these monitoring sites should be included in the region's water quality assessment pursuant to sections 305(b) and 303(d) of the Clean Water Act, staff will work with the State Water Board to modify the GIS mapping component of CalWQA and re-evaluate the LOE(s).
7.73	**Santa Clara River Reach 3** Pollutant: Chlorpyrifos Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.72.

No.	Comment	Response
7.74	**Santa Clara River Reach 3** Pollutant: Cyfluthrin Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Criterion listed is for 2,4,5-TP, not cyfluthrin.	See response to comment 7.72. This notwithstanding, should a waterbody including the monitoring sites be included in the region's water quality assessment, LOE 88712 will be modified to reflect the correct evaluation guideline - "UC Davis Aquatic Life Criteria: Aquatic life should not be affected unacceptably if the 4-day average concentration of cyfluthrin does not exceed 0.00005 ug/L and if the 1-h average concentration does not exceed 0.0003 ug/L. For this assessment, the 4-day average concentration was used. Mixtures of cyfluthrin and other pyrethroids should be considered in an additive manner. (Fojut et al. 2012) ". These changes are in process at this time.
7.75	**Santa Clara River Reach 3** Pollutant: Cypermethrin Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.72.
7.76	**Santa Clara River Reach 3** Pollutant: DDD Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.72. This notwithstanding, the Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. These changes are in process at this time.
7.77	**Santa Clara River Reach 3** Pollutant: DDE	See response to comment 7.72.

No.	Comment	Response
	Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	The Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. LOE 88736 will be modified. These changes are in process at this time.
7.78	**Santa Clara River Reach 3** Pollutant: DDT Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.72.
7.79	**Santa Clara River Reach 3** Pollutant: Mercury Justification: • Data and objectives have different units (ng/L vs. µg/L); data do not exceed objectives.	See response to comment 7.72. This notwithstanding, the data did not exceed the objectives. LOE 88761 will be modified. These changes are in process at this time.
7.80	Waterbody segment: **Tapo Canyon** Pollutant: Chlordane Justification: • Includes LOE for toxicity to support the chlordane listing. This LOE should be removed since there is a separate LOE specifically for toxicity.	Toxicity LOE 89343 will be removed from Decision 64350. The listing decision for Decision 64350, however, will not be affected and will remain the same. These changes are in process at this time.
7.81	**Tapo Canyon** Pollutant: DDD Justification: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody. • Includes LOE for toxicity to support the DDD listing. This LOE should be removed since there is a separate LOE specifically for toxicity.	The Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. In LOE 89233, the “Beneficial Use Assessed” will be changed to "Warm Freshwater Habitat" and the evaluation guideline for Freshwater Aquatic Life Protection Continuous Concentration of 0.001 ug/L will be used.

No.	Comment	Response
		Decision 64445 however, will not be affected and will remain the same. Additionally, the Toxicity LOE 89343 will be removed from Decision 64445, since it is already associated with Decision 64544 for Toxicity. The listing decision for Decision 64445, however, will not be affected and will remain the same. These changes are in process at this time.
7.82	**Tapo Canyon** Pollutant: DDE Justification: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody. • Includes LOE for toxicity to support the DDE listing. This LOE should be removed since there is a separate LOE specifically for toxicity.	The Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. In LOE 89247, the "Beneficial Use Assessed" will be changed to "Warm Freshwater Habitat" and the evaluation guideline for Freshwater Aquatic Life Protection Continuous Concentration of 0.001 ug/L will be used. LOE 89247 will be modified. Decision 64446 however, will not be affected and will remain the same. Additionally, the Toxicity LOE 89343 will be removed from Decision 64446, since it is already associated with Decision 64544 for Toxicity. The listing decision for Decision 64446, however, will not be affected and will remain the same. These changes are in process at this time.
7.83	**Tapo Canyon** Pollutant: Nitrogen, Nitrate Justification:	The Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. LOE 89235 and

No.	Comment	Response
	• Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	Decision 67273 will be retired. These changes are in process at this time.
7.84	**Tapo Canyon** Pollutant: Specific Conductivity Justification: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	The Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. LOE 88296 and Decision 64538 will be retired. These changes are in process at this time.
7.85	Waterbody segment: **Wheeler Canyon/Todd Barranca** Pollutant: Chlordane Justification: • J-flagged data incorrectly used in assessment. • Includes LOE for toxicity to support the chlordane listing. This LOE should be removed since there is a separate LOE specifically for toxicity.	The LOEs for this waterbody pollutant combination will be modified to remove J-flagged data. However, chlordane data is a sum of cis- and trans- chlordane, cis- and trans- nonachlor, and oxychlordane. Disregarding the j-flagged data, the remaining valid data still show chlordane having 2 of 2 exceedances for the beneficial use of Commercial or Recreational Collection of Fish, Shellfish or Organisms. This meets the requirements for listing. The listing decision for Decision 63509, therefore will remain the same. Toxicity LOE 90290 will be removed from Decision 63509. The listing decision for Decision 63509, however, will not be affected and will remain the same. These changes are in process at this time.
7.86	**Wheeler Canyon/Todd Barranca** Pollutant: Specific Conductivity Justification: • Incorrectly listed using guideline for MUN beneficial use that is not	The Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. LOE 90237 and Decision 63585 will be retired. These changes are

	applicable to waterbody.	in process at this time.
7.87	Waterbody segment: **Ventura River Reach 3** Pollutant: Mercury Justification: • Data and objectives have different units (ng/L vs. μg/L); data do not exceed objectives.	Data did not exceed the objectives. LOE 89901 will be modified. Decision 63958 will be changed to "Do Not List". Use rating will be changed to "Fully Supporting". These changes are in process at this time.
7.88	**1. *Agricultural Drain monitoring data incorrectly used as basis for listing decisions.*** There are multiple instances where VCAILG monitoring data from agricultural drains that discharge to waterbody reaches were used to list these waterbody reaches. The drains are not listed tributaries or waterbodies in the Basin Plan and are not located within the waterbody that is being listed. As a result, the data should not be used for the listing decisions for these waterbodies. Calleguas Creek Reach 2 and Reach 4 were listed using data from the VCAILG monitoring sites 02D_BROOM (Reach 2) and 04D_ETTG and 04D_LAS (Reach 4), which are the locations of agricultural drains which drain to Reach 2 and 4. Santa Clara River Reach 3 was listed using data from the VCAILG sampling location S03D_BARDS, which is located on an agricultural drain that ultimately discharges into Santa Clara River Reach 3. These agricultural monitoring sites were selected to be representative of agricultural discharges to Calleguas Creek Reaches 2 and 4 and Santa Clara River Reach 3, and are not representative of receiving water conditions. Therefore, data collected from these sites cannot be used to list the downstream Calleguas Creek or Santa Clara River Reaches. All listings should be evaluated to ensure that the monitoring locations were in receiving waters rather than agricultural drains. In addition, La Vista Drain and Santa Clara Drain were listed as new waterbodies never before included in the previous 303(d) list, even though data has been collected on both agricultural drains by the MS4 program since the early 1990s. These waterbodies are not designated in the Basin Plan or listed as tributaries in	See response to comments 7.9, 7.14, 7.21, 7.53, 7.61, and 7.72.

No.	Comment	Response
	the Basin plan appendices. The La Vista Drain is an agricultural drain designed to convey excess agricultural irrigation water from agricultural lands, and as such, it is predominantly an open ditch that flows alongside W. Los Angeles Avenue and then along Santa Clara Avenue where it becomes the Santa Clara Drain. Additionally, inclusion of the COMM beneficial use for the Santa Clara Drain is inappropriate, as public access is prohibited because of fencing and locked gates maintained by the Ventura County Watershed Protection District. It is inappropriate to apply the MAR and EST beneficial uses to the Santa Clara Drain because the drain is located upstream of Highway 101 and is not tidally influenced. The monitoring location on each drain was selected to represent agricultural discharges for the Agricultural Waiver and was not designed to characterize receiving waters. Because these are agricultural drains and not tributaries, they should be removed from the Draft Category 5 list. McGrath Lake Agricultural Drain is also an agricultural drain comprised of a small open ditch that conveys water from surrounding agricultural lands. A monitoring site was selected on this drain for VCAILG Conditional Waiver monitoring to represent agricultural discharges and was not designed to characterize receiving waters. Moreover, discharges from this drain are already being addressed under the McGrath Lake PCBs, Pesticides and Sediment Toxicity TMDL, which has identified this drain as the "Central Ditch" (the Monitoring Program for the Conditional Waiver also identifies this monitoring site as the Central Ditch). Implementation activities that reduce loadings of chlorinated pesticides and PCBs will also reduce loadings of toxaphene, bifenthrin and chlorpyrifos. For the foregoing reasons, McGrath Lake Agricultural Drain should be removed from the Draft Category 5 list. **Requested Action:** **• Remove all listings shown in Table 1 that were based on VCAILG Conditional Waiver monitoring data from agricultural drains not representative of the listed waterbody, and evaluate remaining listings to ensure no other listings are based on agricultural drain monitoring rather than receiving water monitoring.**	

No.	Comment	Response
	• Remove La Vista Drain and Santa Clara drain from the list as they are agricultural drains and not waterbodies that fall under the jurisdiction of the 303(d) list. **• Remove the McGrath Lake Agricultural Drain because it is not a waterbody that falls under the jurisdiction of the 303(d) list, and because there is an effective TMDL that addresses discharges from this agricultural drain ("Central Ditch") to McGrath Lake.**	
7.89	2. ***Remove any pollutant listing based on municipal drinking water objectives where the MUN beneficial use does not apply***. Numerous listings were based on water quality objectives for the protection of municipal drinking water for waterbodies that do not have applicable municipal drinking water beneficial uses. Many of the waterbodies listed are brackish waterbodies for which no beneficial uses are designated, or waterbodies designated for the municipal beneficial use with an asterisk (i.e., P*) in the Basin Plan. The asterisked MUN beneficial use should not be used to propose new 303(d) listings. Fact sheets for previous 303(d) listing cycles have clearly noted that the asterisked MUN beneficial uses should not be used for 303(d) listing purposes. State Board Resolution No. 88-63 (Sources of Drinking Water) and Regional Board Resolution 89-03 Incorporation of Sources of Drinking Water Policy into the Water Quality Control Plans) state, "All surface and ground waters of the State are considered to be suitable, or potentially suitable, for municipal or domestic waters supply and should be so designated by Regional Boards… (with certain exceptions which must be adopted by the Regional Board)." The Regional Board adopted a Water Quality Control Plan for the Los Angeles Region (Basin Plan) on June 4, 1994, that included provisions to implement State Water Board Resolution 88-63. On May 26, 2000, the USEPA approved the revised Basin Plan, except for the implementation plan for potential MUN-designated water bodies. On August 22, 2000, the City of Los Angeles, City of Burbank, City of Simi Valley, and the	As stated in previous responses, the Los Angeles Water Board will not assess any water body or pollutant on the basis of a P* MUN beneficial use designation. See response to comments 7.5- 7.7, 7.14 - 7.19, 7.28, 7.30-7.32, 7.37-7.41, 7.43-7.51, 7.56, 7.57, 7.67, 7.68, 7.70, 7.76, 7.77, 7.81-7.84, and 7.86.

No.	Comment	Response
	County Sanitation Districts of Los Angeles County challenged USEPA's water quality standards action in the U.S. District Court. On December 18, 2001, the court issued an order remanding the matter to USEPA to take further action on the 1994 Basin Plan consistent with the court's decision. On February 15, 2002, USEPA revised its decision and approved the 1994 Basin Plan in whole. In its February 15, 2002 letter, USEPA stated: *"EPA bases its approval on the court's finding that the Regional Board's identification of waters with an asterisk ("*") in conjunction with the implementation language at page 2-4 of the 1994 Basin Plan, was intended "to only conditionally designate and not finally designate as MUN those water bodies identified by an ('*') for the MUN use in Table 2-1 of the Basin Plan, without further action." Court Order at p. 4. Thus, the waters identified with an ("*") in Table 2-1 do not have MUN as a designated use until such time as the State undertakes additional study and modifies its Basin Plan. Because this conditional use designation has no legal effect, it does not constitute a new quality standard subject to EPA review under section 303(c)(3) of the Clean Water Act ("CWA"). 33 U.S.C. § 1313(c)(3)."* In addition to the above decision, the Basin Plan states that until the additional study is undertaken and the Basin Plan is modified, "no new effluent limitations will be placed in Waste Discharge Requirements as a result of these designations". The Regional Board has also determined that water quality objectives applicable to the MUN beneficial use will not be used to assess impairments under the 303(d) listing programs. For constituents that only have objectives that are applicable to the MUN beneficial use, the decision fact sheets for the 303(d) listing process state that there are no applicable water quality objectives in waterbodies designated with an asterisk ("*"). In the 2010 listing cycle, a number of 303(d) listings were actually removed based on this determination. Below is an example of the language from a listing decision for Los Angeles River Reach 1: *"The listing for aluminum in this water body was originally based on data assessed using the MCL for aluminum. Since MUN is a "potential"*	

No.	Comment	Response
	beneficial use, it is not appropriate to use the MCL to evaluate aluminum data from this reach. Thus, there is no aluminum objective for this reach and the original listing is faulty." Based on this evidence, it is clear that for waterbodies with a MUN designation that includes an asterisk ("*"), water quality objectives specific to the MUN beneficial use are not applicable. As such, water quality data collected in these receiving waters should not be compared to water quality objectives applicable to the MUN beneficial use. The listings of total dissolved solids, sulfates, and conductivity are all based on secondary maximum contaminant levels applied to protect the MUN beneficial use. In addition, Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2 and Rio De Santa Clara/Oxnard Drain No. 3 are maintained as fresh/brackish water via tide gates on both drains and do not have designated MUN beneficial uses. Therefore, the listing of TDS, sulfate, and specific conductivity is inappropriate, as naturally occurring levels of these three constituents in groundwater entering both drains within the footprint of Naval Base Ventura County far exceed the secondary MCLs upon which these listings are based. USEPA validated this reasoning in its "TMDLs for Pesticides, PCBs and Sediment Toxicity for Oxnard Drain 3", where the MUN beneficial use was not considered to be "relevant to the impairments" addressed by the TMDL and so was not included in the TMDL. Additionally, Calleguas Creek Reach 2 and Reach 4 are considered brackish waterbodies according to the California Toxics Rule thresholds and are designated with an asterisked MUN beneficial use. Due to the brackish nature of these waterbodies, other Basin Plan objectives for TDS and sulfate are not considered to be applicable to Reach 2 or Reach 4 below Laguna Road. For all of these reasons, these proposed listings summarized in Table 1 should be removed. The proposed Calleguas Creek Reach 2 dimethoate listing was based on three lines of evidence, which the Fact Sheet states all show no exceedances (this appears to be a typo). However, it appears that the only line of evidence that	

No.	Comment	Response
	shows an exceedance is based on the potential (P*) MUN, which, as described above, cannot be used to justify a listing. Furthermore, the fact sheet cites a guideline from the California Department of Health Services Notification Levels (1 µg/L) which has not yet gone through the formal MCL regulatory process, and it is not clear that this threshold would meet the Listing Policy requirements. **Requested Action:** **• Revise all of the new listings in the fact sheets to ensure that none are based on municipal drinking water objectives when the MUN beneficial use does not apply.** **• Remove the segment-pollutant combinations for total dissolved solids, specific conductivity, sulfates, nitrogen, nitrate, dimethoate, and other MUN-based pollutants listed in Table 1 above from the 303(d) list.**	
7.90	**3. *Reassess mercury listings using correct objective and correct units*.** The data used to assess mercury for Calleguas Creek Reach 3, Reach 4, La Vista Drain, Santa Clara Reach 3, and Ventura River Reach 3 are in ng/L and the objective is in µg/L. The data have to be converted to the same units as the objective before an exceedance can be determined. Our consultants believe that after this calculation has been performed, the waterbodies will no longer meet the listing guidelines for mercury. Additionally, although a California Toxics Rule objective exists for mercury, an EPA nationally recommended criterion was used for the assessment. Regional Board staff should explain why they used a recommended criterion instead of an established water quality objective. **Requested Action:** **• Repeat the mercury analysis after correcting the units error.**	As indicated in previous responses, the corrections are in process at this time. . See response to comments 7.20, 7.27, 7.60, 7.79, and 7.87.
7.91	**4. *Remove toxicity Lines of Evidence (LOE) from pollutant fact sheets when an LOE specifically for toxicity already exists*.** Numerous pollutants listed for Calleguas Creek Reach 3, Tapo Canyon and Wheeler Canyon/Todd Barranca include an LOE to support the pollutant listing,	As indicated in previous responses, Toxicity LOEs are being removed as LOEs from pollutant specific factsheets where a Decision for Toxicity already exists (and those LOEs are associated with that decision). See response to comments 7.80,

No.	Comment	Response
	when a toxicity LOE already exists for the waterbody. These pollutant-specific toxicity LOEs include no scientific evidence that the specific pollutant was the cause of observed toxicity and so should be removed from the fact sheet. The toxicity LOE listed for the waterbody is sufficient as it is intended to identify the cause of observed toxicity through established and accepted methodologies.	7.81, 7.82, and 7.85.
7.92	**5. Incorrect location and data were used for listings in Reach 12.** The name of the monitoring site presented in the fact sheet for chlorpyrifos, diazinon and malathion listings in Calleguas Creek Reach 12 is unclear. The University site is in Reach 3, not 12, and TO1 is an MS4 discharge characterization site, not a receiving water monitoring location. Therefore, TO1 should not be used for a 303(d) listing decision, and University data are not from Reach 12. A review of the datasets provided in the link on the fact sheet only show data from University (ME-CC) and the number of samples appears to match up with the sample numbers shown in the fact sheet. As a result, it appears that the chlorpyrifos, diazinon and malathion listings do not apply to Reach 12. In addition, FBVC requests that only data collected after applicable pesticide-use restrictions were in place for these pesticides be considered in the listing decisions. Data from the Calleguas Creek TMDL watershed monitoring program that were not used in the assessment (see Comment II) demonstrate a marked reduction in these pesticides in receiving water since the use restrictions were implemented (approximately 2009 to present), particularly for receiving waters downstream of urban areas (e.g., Reach 12). Given the changed condition resulting from the pesticide-use restrictions, monitoring data collected prior to 2009 are not representative of current waterbody conditions for these constituents. Therefore, these constituents should not be listed unless data collected after the use restrictions were implemented demonstrates continued impairment. **Requested Action:** **• Remove listings for Reach 12 that are not based on receiving water data from that reach.** **• Remove listings for chlorpyrifos, diazinon, and malathion based on historic**	See response to comments 7.33, 7.34, and 7.35. In addition, for a discussion of the readily available data assessed in this listing cycle see response to comment 32.3. The next listing cycle which includes the Los Angeles Region will assess more recent data and, should the information on pesticide use restrictions and the data support not considering data collected before a use restriction, a decision to assess only data collected after the use restriction may be appropriate.

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td></td><td>data that are not representative of conditions after implementation of pesticide-use restrictions.</td><td></td></tr>
<tr><td>7.93</td><td>6. Ensure no J-flagged data were used in the assessment.

The listing policy specifically prohibits the use of J-flagged (“estimated”) data that fall below the quantitation limit but above the water quality standard. Section 6.1.5.5 of the Listing Policy specifically states:

“When the sample value is less than the quantitation limit and the quantitation limit is greater than the water quality standard, objective, criterion, or evaluation guideline, the result shall not be used in the analysis. The quantitation limit includes the minimum level, practical quantitation level, or reporting limit.”

All listings based on the use of J-flagged data should therefore be removed from the draft 303(d) list. Specific instances are included in Table 1 and further explained in Table 2 below, but this list is by no means inclusive; this significant error will have to be addressed by a thorough review of all listing data to confirm that no J-flagged data were used to justify listings.

Table 2. Incorrect use of J-flagged data
• Waterbody segment: Boulder Creek (Ventura County)
Pollutant: Chlordane
Comment: The LOE for Chlordane erroneously states that three out of five samples exceed the objectives. A review of the data shows that only 1 out of 5 samples exceed indicated criteria. The remaining 4 results were (1) not detected and (2) “estimated” (J-flagged) by the laboratory because results were below the reporting limit. Because only 1 sample showed an exceedance, this listing should be removed as it does not meet the binomial test limits set forth in the Listing Policy.

• Waterbody segment: Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No. 2
Pollutant: Toxaphene</td><td>For J-flagged data, see response to comments 7.5, and 7.42, 7.43, 7.53, and 7.85.

For Boulder Creek, chlordane, see response to comment 7.5.

For Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No. 2, toxaphene, see response to comment 7.42.

For La Vista Drain, chlordane, see response to comment 7.53.

In regards to chlordane in the Rio de Santa Clara, chlordane data are a sum of cis- and trans- chlordane, cis- and trans- nonachlor, and oxychlordane. Disregarding the j-flagged data, the reaming valid data still shows Chlordane having 4 of 5 exceedances for the beneficial use of Commercial or Recreational Collection of Fish, Shellfish or Organisms. This meets the requirements for listing. The listing decision (Decision 33192), therefore, will remain the same. These changes are in process at this time.</td></tr>
</table>

No.	Comment	Response
	Comment: The Lines of Evidence (LOE) for Toxaphene lists the number of exceedances incorrectly at two. However, only one of six samples exceeded the indicated criterion. The other sample was reported by the laboratory as "estimated" (J-flagged). Because only one of six samples showed an exceedance, this listing should be removed as it does not meet the binomial test limits set forth in the Listing Policy. • Waterbody segment: **Rio de Santa Clara/Oxnard Drain No. 3** Pollutant: Chlordane Comment: The LOE for Chlordane erroneously states that four out of five samples exceed the objectives. A review of the data shows that only 3 out of 5 samples exceed indicated criteria. The remaining 2 results were (1) not detected and (2) "estimated" (J-flagged) by the laboratory because results were below the reporting limit. • Waterbody segment: **La Vista Drain** Pollutant: Chlordane Comment: The LOE for chlordane shows that one of the samples used to justify the listing is based solely on estimated (J-flagged) data because results were below the reporting limit. Because Chlordane has only one detected value for two sampling events, more monitoring data are needed to justify the listing and the proposed listing should be removed. Additionally, refer to comment 1 regarding the inappropriateness of this drain being a listed waterbody. **Requested Action:** **• Review all fact sheets and LOEs for the use of J-flagged data and remove any instances where J-flagged data were used.** **• Delist toxaphene for Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No. 2, chlordane for La Vista Drain (though we also disagree with the listing of this as a waterbody to begin with), and any other pollutants listed in Tables 1 and 2 that lack the minimum number of exceedances required to justify a listing.**	
7.94	**7.** ***Remove listings where a waterbody assessment does not meet listing***	See response to comment 7.52.

No.	Comment	Response
	***thresholds based on data provided*.** Finally, the toxicity listing for Rio De Santa Clara/Oxnard Drain No. 3 does not meet the minimum requirements to be listed according to the Listing Policy (pg. 9). According to the Listing Policy, a waterbody can be listed only when the number of exceedances meets the binomial test; in the case of this waterbody, four samples were collected and only one sample showed an exceedance. However, two exceedances would be required for the waterbody to be added to the 303(d) list. Therefore, toxicity was incorrectly listed for this waterbody and should be removed entirely from the 303(d) list. **Requested Action:** **• Remove the toxicity listing for Rio De Santa Clara/Oxnard Drain No. 3, based on failure to meet listing threshold requirements in the Listing Policy.**	
7.95	**II. REQUESTED REASSESSMENTS USING COMPLETE DATA SET** As manager of the VCAILG program, FBVC is a stakeholder in the Calleguas Creek Watershed TMDL monitoring program and represents the agricultural responsible parties listed in the TMDLs. As such, FBVC supports the comments made by the Stakeholders Implementing TMDLs in the Calleguas Creek Watershed regarding the use of all appropriate monitoring data for the 303(d) listing process. The assessments for the Calleguas Creek watershed do not appear to include any of the submitted Calleguas Creek Watershed TMDL monitoring data, monitoring data from the Camarillo Sanitary District, or monitoring data from the Simi Valley Wastewater Treatment Plant. All of this monitoring data has been provided to the Regional Board in annual monitoring reports and all data were collected using approved QAPPs. As a result, there is no reason why this data should not be included in the 303(d) listing process. Please refer to the letter submitted by the Calleguas Creek Watershed Stakeholders for details regarding the waterbody/pollutant combinations eligible for delisting. While this comment is specific to knowledge regarding monitoring programs in the Calleguas Creek	See response to comment 32.3.

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td></td><td>Watershed, it should be applied to the other watersheds in Ventura County.

Requested Action:
• Reassess all Ventura County waterbodies using all available data.</td><td></td></tr>
<tr><td>7.96</td><td>III. REQUESTED CATEGORY ASSIGNMENT CHANGES

8. Correct pollutants listed as Category 5A that should be 5B based on coverage by an existing TMDL.

There are number of proposed new listings for pollutants that are already covered by an existing TMDL and are incorrectly categorized as 5A. Although we contend that all of these listings should be removed entirely because of the issues detailed in Comment I, if they are not removed they should, at a minimum, be changed from 5A to 5B as applicable.

Because discharges from the McGrath Lake Agricultural Drain (i.e., “Central Ditch”) are already being addressed by the McGrath Lake PCBs, Pesticides and Sediment Toxicity TMDL (effective June 30, 2011), toxaphene should be changed from Category 5A to Category 5B. A Calleguas Creek nutrient TMDL addressing nitrogen has been in effect since 2003, including for Reach 9A where a new 5A listing for nitrite is proposed. In 2006, the Toxicity and OC Pesticide and PCBs TMDLs for the Calleguas Creek watershed were established to address chlordane, chlorpyrifos, DDT, DDE, DDD, dieldrin, PCBs, sediment toxicity, and toxaphene.

The La Vista Drain and Santa Clara Drain ultimately flow into Calleguas Creek Reach 4 (was Revolon Slough Main Branch), and although we oppose the inclusion of these listings on the grounds that they are not waterbodies, the actual receiving waters are already addressed by an OC Pesticides and PCBs TMDL, the Toxicity TMDL, the Salts TMDL, the Nitrogen TMDL, and the Metals TMDL, and therefore all of these proposed listings should be Category 5B. Furthermore, two other segments were listed for chlorpyrifos – Honda Barranca and Duck Pond Agricultural Drains – but were correctly listed as Category 5B, citing the 2006 Toxicity TMDL.</td><td>For the McGrath Lake Agricultural Drain toxaphene, see response to comment 7.13.

For the La Vista Drain and Santa Clara Drain, see responses to comments 7.53- 7.71.

The list and the factsheets have been updated to reflect the nitrogen, nitrate listings on Boulder Creek and Tapo Canyon are being addressed by the Santa Clara River Nitrogen TMDL.

The Calleguas Creek Toxicity TMDL specifically addresses the organophosphate pesticides, chlorpyrifos and diazinon, and does not apply to pyrethroids. The Toxicity TMDL would need to be revised to identify pyrethroid targets, and include the other required elements of a TMDL for pyrethroids specifically.

For Calleguas Creek Reach 2 listings see response to comments 7.18 and 7.19

The list and the factsheets have been updated to reflect the Calleguas Creek Reach 3 mercury listing is being addressed by a TMDL.

The list and the factsheets have been updated to reflect the Calleguas Creek Reach 4 mercury has been updated to being addressed by a TMDL.</td></tr>
</table>

No.	Comment	Response
	The nitrogen, nitrate listings on Boulder Creek and Tapo Canyon are being addressed under the Santa Clara River TMDL, in effect since 2004. • We request that any listings in Table 3 and Table 4 that are maintained after addressing the issues in Comment I also be corrected to be designated in Category 5B. Table 3. 303(d) Category 5A listings which should be changed to 5B listings (see comment letter) In addition, we believe the Calleguas Creek Watershed Toxicity TMDL should cover all new listings in the watershed for pyrethroids and organophosphate pesticides (e.g., malathion), if they are not removed as requested in the first comment. The Toxicity TMDL includes a trigger for additional investigation if ongoing toxicity is identified in the watershed. The toxicity trigger has resulted in the identification of pyrethroids as a potential cause of toxicity, and the Conditional Waiver includes a bifenthrin water quality benchmark triggering management practice implementation in response to exceedances, in addition to the organophosphate pesticides included in the TMDL. Additionally, the structure of the TMDL is designed to proactively prevent toxicity and therefore it is not necessary to develop another TMDL for these constituents. As a result, if the waterbodies are placed on the 303(d) list as new listings, we request that the waterbodies in Table 4 be moved from 5A to 5B. Table 4. Pyrethroid and Organophosphate listings covered by the existing Toxicity TMDL (see comment letter) **Requested Action:** **• Change all pollutant-waterbody segment combinations in Table 3 and Table 4 from 5A to 5B or 4A based on coverage by an existing USEPA approved TMDL.**	Also see responses to comments 7.30, 7.31, and 7.32. The list and the factsheets have been updated to reflect the Calleguas Creek Reach 9A nitrate listing is being addressed by a TMDL The list and the factsheets have been updated to reflect the Calleguas Creek Reach 12 Chlorpyrifos and diazinon listing are being addressed by a TMDL. The list and the factsheets have been updated to reflect the Honda Barranca DDT listing is being addressed by a TMDL. The list and the factsheets have been updated to reflect the Fox Barranca DDE listing is being addressed by a TMDL. The list and the factsheets have been updated to reflect the La Vista Drain and Santa Clara Drain listings which are being addressed.
7.97	***9. Remove waterbody-pollutant combinations for agricultural drains listed***	The decisions for the waterbody-pollutant

No.	Comment	Response
	as Category 2. Two new agricultural drains were included inappropriately on the Category 2 list (i.e., assessed for listing) and should be removed: Drain Along Gerry Road to Calleguas Creek Reach 9, and Oxnard Drain. The Gerry Road agricultural drain is a small drainage ditch with intermittent flows that exists solely to collect non-potable water from the adjacent agricultural lands before it drains into Calleguas Creek Reach 9; it is not a tributary to Calleguas Creek Reach 9. A VCAILG monitoring site was selected on this drain to be representative of agricultural discharges to Calleguas Creek Reach 9 and is not representative of receiving water conditions. Accordingly, neither the MUN beneficial use nor the MAR beneficial uses apply to this agricultural drain. The new listing for Oxnard Drain also should be removed from the Draft Category 2 list. The monitoring site indicated for this drain is located in the Ormond Beach Wetlands area where flows from the Hueneme Drain, the J St. Drain (now "Chumash Creek"), and the Oxnard Industrial Drain (formerly known as the Oxnard Drain but now known as the "Ormond Lagoon Waterway") commingle. In order to list the "Ormond Lagoon Waterway" (formerly the Oxnard Industrial Drain), a monitoring station would have to be established on that channel upstream of the wetlands area to ascertain water quality in that waterbody.	combinations associated with "Drain along Gerry Road" and "Oxnard Drain" have been changed to "do not list" due to insufficient information at this time to determine whether the Drain along Gerry Road and Oxnard Drain should be included in the region's water quality assessment pursuant to sections 305(b) and 303(d) of the Clean Water Act. Once such a determination is made by the Los Angeles Water Board, necessary changes, if any, will be transmitted to the State Water Board, so that the GIS mapping component of CalWQA can be updated. Additionally, the Los Angeles Water Board will re-evaluate the LOE(s), as appropriate.
7.98	**IV. ADDRESS ALL OTHER INCONSISTENCIES AND ERRORS IN LIST** FBVC's staff and consultants have identified a large number of inconsistencies and issues in the list that should all be addressed prior to adoption. The summary below provides examples of issues identified. The list is not comprehensive, because in many cases the information provided made it difficult or impossible to conduct a proper analysis. **10.** ***Correct Appendix G fact sheets.*** The Appendix G fact sheets often include incorrect information and discussion.	Los Angeles Water Board staff intends to make the necessary corrections in the CalWQA database and make the appropriate listing/delisting decisions as the State Board staff prepare the Integrated Report and 303(d) list for State Board approval later this year or prior to the next Listing Cycle that includes the Los Angeles Region.

No.	Comment	Response
	While most of the identified issues do not appear to impact the listing decisions, they make the review of information difficult. Examples of errors found include: • Incorrect Evaluation Guideline and Guideline Reference. For example, the Evaluation Guideline (i.e., criterion) provided for cyfluthrin (a pyrethroid) in LOEs 84065, 83200 and 88712 actually is for the chlorinated herbicide 2,4,5-TP. The stated criterion (29 mg/L) was not found in the cited Guideline Reference. Many additional instances were noted in LOEs for phorate, dimethoate, disulfoton, endosulfan sulfate, and many other LOEs. Because the numeric guidelines (and reference documents from which these are obtained) form the basis for any listing, it is critical that these be carefully reviewed and verified prior to issuing the final fact sheets and 303(d) list. • Incorrect beneficial uses assigned to objectives. For example, MUN beneficial uses listed when aquatic life objectives are presented in the fact sheet. • Incorrect beneficial uses assigned to a waterbody. For example, MUN beneficial uses assigned to a tidally influenced waterbody (e.g., Duck Ponds Agricultural Drain), and MAR and EST beneficial uses assigned to a waterbody that is too far upstream to be tidally influenced (e.g., Wheeler Canyon/Todd Barranca). • Incorrect TMDLs assigned to a pollutant. For example, for chlordane in Calleguas Creek Reach 2, the applicable TMDL is listed as the Calleguas Creek Metals TMDL. It should be the Organochlorine Pesticides, PCBs, and Siltation TMDL. • Incorrect QAPPs identified. For example, the VCAILG QAPP is often referenced for the Ventura County MS4 monitoring data set. • Incorrect number of samples evaluated and incorrect number of criteria exceedances. For example, the number of samples evaluated for toxaphene on the Rio de Santa Clara/Oxnard Drain No. 3 and on Wheeler Canyon/Todd Barranca is identified as 2 samples, whereas data files obtained from the Regional Board website contain 5 samples for the date range indicated in fact sheets, including 3 samples with results of “ND”. Stating in fact sheets that a pollutant exceeds criteria in 100% of samples, instead of the true figure of 40%, conveys an inflated impression of the degree of impairment by that pollutant in a waterbody. The inclusion of J-flagged data when enumerating exceedances (e.g., for chlordane in the same waterbodies) further exacerbates these numbering inaccuracies.	

No.	Comment	Response
	Requested Action: **• Correct the Appendix G fact sheets for errors such as incorrectly assigned beneficial uses, existing TMDLs, QAPPs, and number of samples / number of exceedances.**	
7.99	**11.** ***Correct the Appendices and Fact Sheet Categories*****.** Appendix A, Appendix B, Appendix C, and Appendix G are inconsistent, which makes the analysis of new additions very difficult since it is unclear which segment-pollutant combinations actually are new listings. Following are examples of a number of identified issues that need to be corrected to allow FBVC to fully vet and understand the proposed listings. A number of proposed "name changes" in Appendix A are not shown in Appendix B and there are no associated fact sheets describing the name change (e.g., Reach 4 listings for chlorpyrifos and total DDT). This makes it very challenging to assess the validity or basis for the name change. In other instances, listed name changes are found in Appendix B or C but not supported by an explanation for the name change in Appendix G. The fact sheets for the following name changes should provide justification or explanation for the name change, as many appear to be switching tissue or sediment listings to water listings. If this is in fact the change being made, justification for the water listing needs to be provided in the fact sheet. It is not appropriate to characterize changing the medium that is the basis for the listing as a name change. Table 5. Listed as Name Changes in Appendix A (see comment letter) There are a number of inconsistencies where Appendix A does not include all of the new 2014 listings found in Appendix B. Below are a few examples of such inconsistencies. Table 6. Incorrectly listed waterbody segment-pollutant combinations (see comment letter)	Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data. The 303(d) list is being revised to no longer include separate listings for different environmental media, that is, water, sediment and tissue may be considered in one assessment for waterbodies that have data for all three environmental media.

No.	Comment	Response
	There are also a number of instances where existing waterbody-pollutant listings from the 2010 303(d) list were not stated as delisted in Appendix A and do not appear in Appendix B, C, or G under the waterbodies to delist. We request clarification as to whether these waterbody-pollutant combinations are, in fact, being delisted, as some align with the assessment provided by the Stakeholders Implementing TMDLs in the Calleguas Creek Watershed. Table 7. Not described as delisted in Appendix A but not found Appendix B or C (see comment letter) **Requested Action:** **• Correct the numerous inconsistencies described above in Table 5, Table 6, and Table 7 and ensure that all of the proposed 303(d) list appendices are internally consistent.**	
7.100	12. ***Correct the waterbody assigned Hydrologic Unit (HUCs) and Calwater numbers to reflect those listed in the Basin Plan*.** There are multiple instances of what appear to be incorrect Hydrologic Unit numbers (HUCs) and Calwater numbers assigned to the various waterways. For instance, a comparison of the 8 digit HUCs listed in Appendix B of the 303(d) list to the 12 digit HUCs listed in Appendix I of the Basin Plan indicate a number of inconsistencies such that waterbodies present in the Santa Clara River Watershed (e.g., Santa Clara River Reach 1, 2, and 3) are listed with a Calleguas watershed HUC (18070103) while the same reaches are listed as 18070102 in the Basin Plan. This makes identifying the location of unknown waterbodies not previously listed or described in the Basin Plan to assess if they are receiving waters that should be assessed especially difficult. A full review of the 303(d) List HUCs should be completed to correct all errors. **Requested Action:** **• Perform a full review of HUCs and Calwater numbers listed in Appendix B through F and correct any inconsistencies with the Basin Plan.**	It is the intention of the Los Angeles Water Board staff to work with State Board staff to resolve mapping issues including HUCs for those reaches, as appropriate, prior to the State Board approval of the 2016 303(d) list, or at the next Listing Cycle that includes the Los Angeles Region.

No.	Comment	Response
7.101	**13.** ***Correct or clarify inconsistencies in the staff report.*** There is inconsistent discussion about some proposed listings in the staff report, which should be clarified to avoid confusion. For instance, on page 10 of the Staff Report there is a discussion about existing TMDLs covering newly proposed pollutants: "*For example, the proposed new listings for DDE and DDD in Calleguas Creek Reach 3 … are being addressed by the Calleguas Creek Organochlorine Pesticides, PCBs and Siltation TMDL … and would then be in Category 4A.*" However, we could find no listings of DDE and DDD for Reach 3 in any Appendix of the report including Appendix C – Category 4A Waterbody Segments. Furthermore, the Fact Sheets in Appendix G state that DDE and DDD should not be listed for Reach 3. We ask the RWQCB to either clarify or remove the above referenced statement, and clarify any other inconsistencies between the staff report and the list. **Requested Action:** **• Correct or remove language cited on page 10 of the staff report regarding DDE and DDD listing of Calleguas Creek Reach 3 and clarify any other identified inconsistencies within the staff report.**	The Staff Report has been corrected.
7.102	**14.** ***Ensure that all thresholds being used for assessment are consistent and valid under the Listing Policy.*** In many cases, the same pollutant is assessed using different thresholds without any explanation for the basis of the threshold. Additionally, in several cases, an LC50 or threshold for individual species were used for the assessment. This is inconsistent with the Listing Policy, which states that it must be demonstrated that an evaluation guideline is "applicable to the beneficial use, protective of the beneficial use, scientifically based and peer reviewed, and well described." Because it has not been demonstrated that the individual species' response to these pollutants is applicable and protective of the beneficial use, these guidelines should not be used to make a listing. The Regional Board should review all assessments for consistency, especially for the pesticides (bifenthrin, cyfluthrin, cypermethrin, malathion, permethrin), as well as applicability to the beneficial use	As the State Water Board staff and Los Angeles Water Board staff review waterbody pollutant data for this and future listing cycles, they will continue to review the appropriateness of the guidelines and thresholds.

No.	Comment	Response
	as described in the listing policy. Table 8. 303(d) Pollutants Using Thresholds for Interpreting Narrative Objectives (See comment letter) The 303(d) list includes new listings for bifenthrin, cyfluthrin, cypermethrin, malathion, and permethrin in Ventura County watersheds. Currently no water quality objectives have been promulgated by USEPA or the State of California for these pollutants and so the criteria listed are from a variety of studies. Some issues with these criteria include the following (this list is by no means inclusive; a thorough review of all listings for these pollutants should be undertaken): • The criterion used for listing bifenthrin on Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2 is 0.00397 μg/L based on the CDFG criteria. The selective use of a saltwater genus mean acute value is inappropriate when the CDFG study clearly states in the "Conclusions and Recommendations" section that "insufficient freshwater and saltwater acute toxicity data were available to calculate CMC values for bifenthrin." The same use of a criterion unsupported by the study author(s) applies to cypermethrin on the Santa Clara Drain. • Use of LC50 for listing of cyfluthrin for CCW Reach 4 and Santa Clara River Reach 3 is inappropriate. LC50s do not meet the standard set forth in the listing policy as stated on page 20: *" the evaluation guideline… identifies a range above which impacts occur and below which no or few impacts are predicted.*" By definition an LC50 is simply the concentration at which half of the population of the tested species has died. The LC50 should not be used as the evaluation guideline. • The criterion used for listing permethrin for Calleguas Creek Reach 4 is 0.0002μg/L based on the UC Davis criteria. However, upon reviewing the UC Davis source, we found the listed chronic standard for permethrin is 2 ng/L (page 92), which is 0.002μg/L not 0.0002μg/L as listed in the 303(d) list. **Requested Action:** **• Review the guidelines used for interpreting narrative objectives and ensure that they are consistently applied and use correct unit conversions.** **• Remove all guidelines that do not comply with the stated listing policy as**	

No.	Comment	Response
	described above.	
8.	Castaic Lake Water Agency, March 30, 2017	
8.1	One of the subject proposed revisions would add polychlorinated biphenyls (PCBs) to the 303(d) listing for Castaic Lake and Lagoon. The data referenced in the proposed PCB listing is from a relatively small number of fish tissue samples analyzed in 2007. The Agency samples and analyzes water from the lake prior to treatment. Our data does not indicate that PCBs are present in the lake water. Because of this, and the limited data described above, we believe additional study should be conducted to look at longer term trends in PCB concentrations in fish tissue, and PCB source determination.	As indicated by the commenter, Castaic Lake is proposed for inclusion on 303(d) list for PCBs. This listing decision is based on 3 LOEs and supported by LOE 94733. In LOE 94733, a total of 4 fish tissue composites were generated from largemouth bass (1 composite - 5 fish per composite) and common carp (1 composite - 5 fish per composite) from 2 sampling locations (20 fish, total). All four composite samples were found in exceedance of the criterion for PCB. The commenter is encouraged to submit the additional PCB water column data into CEDEN so that it can be assessed during future listing cycles. The longer-term trends in PCB concentrations in fish tissue, and PCB source determination are important determinations, which would take place if a TMDL or other regulatory program is developed to address PCBs in the Lake.
9.	City of Azusa, March 30, 2017	
9.1	**Summary** Of the 22 metals reported for all San Gabriel River water quality segments, 19 (84.3%) of them fall under the "de-list" and "do not list" categories. The City believes that 3 additional metals (15.7%) should be de-listed, which would raise the total to 22 (100%), for reasons more particularly described below. Based on the de-listing of these metals, the City contends that the Regional Board should remove the San Gabriel Metals TMDL from the Los Angeles Basin Plan.	Specific comments on the 303(d) list are addressed below; comments on the San Gabriel Metals and Selenium TMDL are outside the scope of this action. Adjustments to the 303(d) list do not alter TMDLs. The revision of a TMDL, when warranted, is a separate Board action. The listing for copper in the San Gabriel River

No.	Comment	Response
	I. San Gabriel River: Estuary As the table below illustrates, copper for the estuary is listed on the 2010 303(d) list but was not carried over to the 2016 303(d) list. It must be assumed that the Regional Board did not intend to place copper on this list. Whether or not this was an oversight on the part of the Regional Board, there is ample justification for not listing copper for the estuary. As is the case with most metals and toxics referenced in TMDLs and in the MS4 Permit, the Regional Board did not comply with the federal California Toxic Rule (CTR) to the following extent: 1. The Regional Board did not calculate the numeric limitation for lead properly. CTR establishes water quality standards (including TMDLs), based only on ambient (dry) weather sampling and analysis. However, the Regional Board calculated a wet weather numeric limitation for lead based on stormwater sampled from receiving waters. Further, CTR requires a "real time" hardness parameter (using calcium carbonate) as an adjustment factor in establishing water quality standards for metals and toxics. The Regional Board apparently used a default hardness factor of 100 mg/l. CTR states clearly that the 100 mg/I for hardness is only intended to be an example in calculating CTR water quality standards. It is important that the actual hardness value be applied (which must be sampled and analyzed as the same toxics and metals are sampled). Too low of a hardness value will set a lower numeric limit. The higher the limit is, the less difficult it is to meet it. 2. Regional Board also did not follow the Water Quality Control Policy for California's Clean Water Act Section 303(d) List (Listing Policy). The Listing Policy requires a binomial distribution based on a null hypothesis) to determine if the number of the samples that resulted in exceedances (of CTR) are statistically sufficient to warrant placement on lead on the 303(d) list. There is no evidence that this task was completed. It is possible that it was not completed because the Listing Policy was not adopted until 2004. The copper was added to the 303(d) list in 1998 and carried over to the 2000 303(d) list. Based on the San Gabriel River Metals TMDL, it appears that the copper data was based on water quality samples conducted in 1998.	Estuary is carried over to the 2016 303(d) list. See Appendix A as well as Appendix G. The decision to “do not delist” copper is supported by data in CalWQA. Copper was first listed for the San Gabriel River Estuary in 2006 and has remained on the list in 2010, 2012 and 2016. For the 2016 303(d) list, the copper listing was “carried over” and new LOEs were added with new data for this listing cycle. The LOEs in the factsheet for the San Gabriel River Estuary copper listing do not support delisting copper. The decisions to “do not list” lead, selenium and zinc are supported by the data in CalWQA. The commenter may be assuming that a default hardness value was used, but the factsheet states, “***If no hardness data were available***, a value of 100 mg/L was used” (emphasis added). In this case, site-specific hardness data were available and were used as indicated in the data set “Data for Various Pollutants in Various Water Bodies in Sanitation Districts of Los Angeles County, 2005-2010.” See response to comment 3.3 for the use of listing decisions made prior to the adoption of the Listing Policy. Comments on TMDL and the Los Angeles County MS4 Permit and the provisions therein are outside

No.	Comment	Response
	3. The Regional Board's Surface Water Ambient Monitoring Program (SWAMP) performed water quality samples for metals in the estuary in June of 2005. Copper, after properly adjusted for hardness, resulted in 3.23 micrograms per liter (ug/1). The limit is 9.4 ug/1. In other words, no exceedance was detected. Table I. San Gabriel River: Estuary **[See the comment letter for Table I]** Placing copper on the 2016 303(d) list "do not list" category should effectively eliminate the need for impacted MS4 Permittees to comply with the estuary's copper limitation of 3.7 ug/1 (see Table I(a) below). Table I(a) from Attachment P of the Los Angeles MS4 Permit **[See the comment letter for Table I(a)]** **Recommendation to Regional Board**: (1) approve staff's recommendation not to list lead, selenium, and zinc for the estuary; (2) grant the City's request to de-list copper for the estuary; and (3) use the de-list and do not list justification for this and other metals to remove the San Gabriel River Metals TMDL from the Los Angeles Basin Plan.	the scope of this action.
9.2	**II. San Gabriel River: Reach 1 (Estuary to Firestone)** Metals for San Gabriel River, Reach 1 from the Estuary to Firestone were not placed on the 2010 303(d) List and not placed on the "do not list" category of the 2016 303(d) List. It is unclear, however, why the MS4 Permit requires compliance with the copper limitation of 18 ug/1 (shown above in Table I(a), despite the fact that copper was not listed on the 2010 303(d) list in the first place. Table II. San Gabriel River: Reach 1 (Estuary to Firestone) **[See the comment letter for Table II]** **Recommendation to Regional Board**: (1) approve staff's recommendation not to list copper, lead, selenium, and zinc for Reach 1; and (2) use the do not list	The decisions to "do not list" copper, lead, selenium and zinc are supported by the data in CalWQA. Comments on MS4 permit requirements and the San Gabriel River Metals and Selenium TMDL are outside the scope of this action.

No.	Comment	Response
	justification for this and other metals to remove the San Gabriel River Metals TMDL from the Los Angeles Basin Plan.	
9.3	**III. San Gabriel River: Reach 2 (Firestone to Whitter Narrows Dam)** As shown on Table III below, the 2016 303(d) list rolls-over lead from the 2010 303(d) list. Lead, however, should be de-listed for the following reasons: 1. Lead is a legacy pollutant (lead content in fuels have been significantly reduced). 2. The 303(d) lists for 1998 and 2000 placed lead on the "list" category, but failed to comply with the California Toxic Rule (CTR) as explained above. 3. The Regional Board did not follow the State's 303(d) Listing Policy. More specifically, according to the San Gabriel River Metals TMDL (Table 2-7), Reach 2 was sampled during dry weather (ambient) for dissolved lead by the Los Angeles County Department of Public Works (LACDPW), in accordance with CTR using the correct hardness adjustment. The 10 samples taken resulted in zero exceedances. If this result were applied to the 303(d) Listing Policy, it would not be sufficient to place lead on the 303(d) List. For a sample size between 2 and 24, 2 exceedances are required for 303(d) list placement. 4. Regional Board's Surface Water Ambient Monitoring Program (SWAMP) performed water quality samples for metals in the estuary in June of 2005. Lead, after properly adjusted for hardness, resulted in 0.81 micrograms per liter (ug/1). The limit is 3.8 ug/1. In other words, no exceedance was detected. Table III. San Gabriel River: Reach 2 (Firestone to Whittier Narrows Dam) **[See the comment letter for Table III]** **Recommendation to Regional Board**: (1) do not approve staff's recommendation not to de-list lead; and (2) use the do not list justification for this and other metals	The decisions to "do not delist" lead is supported by the data in CalWQA. Lead is not a "legacy" pollutant; there are current uses and sources of lead in the watershed. Comments on the TMDLs and the MS4 permits are outside the scope of this action. There are three LOEs for lead in the San Gabriel River Estuary Reach 2 including data collected under the MS4 permit and a County of Sanitation District of Los Angeles County permit.

No.	Comment	Response
	to remove the San Gabriel River Metals TMDL from the Los Angeles Basin Plan.	
9.4	**IV. San Gabriel River: Reach 3 (Whittier Narrows Dam to Ramona)** As shown on Table IV below, San Gabriel River Reach 3 was not placed on the 2010 303(d) list and, therefore, it is easy to see why it is placed on the 2016 303(d) "do not list" category. What is difficult to understand is why the Los Angeles MS4 Permit requires compliance with copper, lead, and zinc. The answer lies on MS4 Permit Attachment P: TMDLs in San Gabriel River Watershed Management Area. It states: *Permittees shall comply with grouped wet WLAs ... expressed as total recoverable metals discharged to all upstream reaches and tributaries of the San Gabriel River Reach 2 and Coyote Creek* (see Table l(b) below). In other words, even though San Gabriel River Reach 3 is not on the 2010 303(d) list for metals, the MS4 Permit requires compliance with them nevertheless. It does this by applying TMDL numeric targets for copper, lead, and zinc because: (1) San Gabriel River Reach 2 lists a lead TMDL number target of 81.34 ug/1; and (2) Coyote Creek lists copper target of 24. 71 ug/1 and zinc at 144.57 ug/1. The rationale for applying downstream numeric targets for copper, lead, and zinc is at best murky. How can metals as pollutants associated with downstream reaches be applied to upstream Reach 3 of the San Gabriel River? Pollutants cannot travel upstream against gravity. Table IV. San Gabriel River: Reach 3 (Whittier Narrows to Ramona) **[See the comment letter for Table IV]** Table I(b) from Attachment P of the Los Angeles MS4 Permit **[See the comment letter for Table I(b)]** **Recommendation to Regional Board**: (1) approve staff's recommendation not to list copper, lead, and zinc; and (2) use the de-list for these metals to remove the San Gabriel River Metals TMDL from the Los Angeles Basin Plan.	The decisions to "do not list" copper, lead, and zinc are supported by the data in CalWQA. Comments on TMDLs and MS4 permits are outside the scope of this action.
9.5	**V. San Gabriel River: Coyote Creek**	

No.	Comment	Response
	The 2016 303(d) List correctly de-lists lead and zinc but does not de-list copper. Copper should be de-listed for the following reasons: 1. The San Gabriel River Metals TMDL contains ambient sample data for Coyote Creek correctly applying CTR. Under Table 2-7, 8 samples are listed with 0 exceedances. If this result were applied to the 303(d) listing policy, it would not qualify for 303(d) placement. A sample size between 2 and 24 would require exceedances equal to and greater than 2. 2. Wet weather water quality data was used to justify placing copper on the 303(d) list. Listing support information cites that CTR relative to copper was applied to wet weather. As mentioned above, wet weather and CTR requirements are mutually exclusive. Wet weather limitations for San Gabriel River and other receiving water bodies in Los Angeles County are intended to be applied - incorrectly -- to MS4s and other NPDES permittees. Table V. Coyote Creek **[See the comment letter for Table V]** **Recommendation to Regional Board**: (1) approve staff's recommendation not to list lead and zinc; (2) approve the City's request to de-list copper; and (3) use the de-list and do not list justification for this and other metals to remove the San Gabriel River Metals TMDL from the Los Angeles Basin Plan.	The decision to "do not delist" for copper is supported by data in CalWQA. Comments on the TMDLs and the MS4 permits are outside the scope of this action. The Listing Policy does not indicate that data from wet and dry weather must be assessed separately, CTR criteria apply to water quality in both dry and wet weather.
9.6	**VI. San Jose Creek Reach 1 (SG Confluence to Temple St.)** Regional Board staff recommends that: (1) selenium be de-listed; and (2) copper, lead, and zinc not be listed (see Table VI below). Table VI: San Jose Creek Reach 1 **[See the comment letter for Table VI]** **Recommendation to Regional Board**: (1) approve staff's recommendation to de-list selenium and not list copper, lead, and zinc; and (2) use the de-list and do not	Comments on the TMDLs and the MS4 permits are outside the scope of this action.

<tr><td>9.7</td><td>VII. South San Jose Creek (Los Angeles County)

This is Reach is a new listing under the 2016 303(d) List.

VII. South San Jose Creek (Los Angeles County) [See the posted letter for Table VII]

Recommendation to Regional Board: (1) approve staff's recommendation not list to selenium copper, lead, and zinc; and (2) use the de-list and do not list justification for these and other metals to remove the San Gabriel River Metals TMDL from the Los Angeles Basin Plan.</td><td>Comments on the TMDLs and the MS4 permits are outside the scope of this action.</td></tr>
<tr><td>10.</td><td colspan="2">City of Gardena, March 30, 2017</td></tr>
<tr><td>10.1</td><td>The City of Gardena (City) appreciates the opportunity to comment on the revised 2016 303(d) Integrated Report for the Dominguez Channel. The City also welcomes the proposed "de-list" and "do not list" of pollutants, particularly metals and toxics. These pollutants are the basis for the Dominguez Channel Harbor Toxics TMDL (DCHT-TMDL), which is derived from the 2010 303(d) list. The elimination of these pollutants should effectively eliminate the need for the DCHT-TMDL, which the Dominguez Channel Watershed Management Program was created to comply with.

I. 2010 303(d)/2016 303(d) List Dominguez Channel, Reaches 1 and 2

This list, on which the DCHT-TMDL was developed, contains the following toxics for Reach 1 and 2 as shown in the tables presented below. The tables also show the status of toxic pollutants, including metals, which the 2016 303(d) list revises in terms of the following categories: (1) list; (2) de-list; and (3) don't de-list.

II. Reach 1 Dominguez Channel (unlined portion below Vermont)</td><td>Adjustments to the 303(d) list do not alter TMDLs. The revision of a TMDL, when warranted, is a separate Board action.

In regards to PAHs, while PAHs is delisted, the data in CalWQA support the listing of the individual PAHs of Pyrene, Phenanthrene, Chrysene, and Benzo (a) pyrene.
The fact sheet for the PAH delisting states:
Based on the readily available data and information, the weight of evidence indicates that there is sufficient justification in favor of removing the PAH sediment-pollutant combination and replacing this general PAH listing with the individually listings of Pyrene, Phenanthrene, Chrysene, and Benzo (a) pyrene on the section 303(d) list in the Water Quality</td></tr>
</table>

Response to Comments on the Draft 2016 303(d) List
Comment Deadline: March 30, 2017

No.	Comment	Response
	[See the posted letter for Table] In sum, the 2016 303(d) list for toxics and metals proposes to de-list PAHs and zinc (in sediment) and not list Methylnaphthalene 2. However, because PAHs are to be de-listed, Chryslene, Phenanthrene, and Pyrene must also be de-listed because they are specific types of PAHs. Thus, the total number of toxics to be eliminated from the 2016 303(d) list is 8. Copper should be delisted as well because: (1) it was not listed on the 2010 303(d) Integrated Report for toxics and metals for Reach 1 of the Dominguez Channel; (2) the 2012 303(d) list recommended that copper not be listed;" and (4) SWAMP data (2003) for all reaches of the Dominguez Channel resulted in only a few slight exceedances for dissolved copper (but not for total recoverable copper, which is the California Toxics Rule (CTR) compliance standard). Should the Regional Board insist on retaining copper on the 2016 303(d) list, it should provide sampling data based on the CTR for establishing ambient water quality standards. Excluding the aforementioned metals and toxics from the 2016 303(d) list eliminates 9 of them - 56% of the total. On this basis alone, the DCHT-TMDL should be voided.	*Limited Segments category.* The decision to "do not list" Naphthalene is based on one LOE in the CalWQA database that shows no exceedances of 15 samples. The decision to "de-list" zinc is based on three LOEs in the CalWQA database that show no exceedances. In regards to copper, the decision to "list' copper is supported by the data in CalWQA. This is a new "list" decision based on data added to the CalWQA database this listing cycle from both water and sediment. Both dissolved and total water column data (and sediment data) are used for metals assessments. See response to 3.3 regarding assessments based on readily available data.
10.2	As discussed below the metals and toxics on the proposed 2016 303(d) list that have not been de-listed for Reach 1 of the Dominguez Channel should be de-listed. **1. *Chlordane*** This toxic should be de-listed for the following reasons: (1) no justification to list chlordane was provided in Decision ID 20199 of the proposed 2016 303(d) Integrated Report in keeping with 303(d) Listing Policy; (2) the 2016 303(d) list proposes that chlordane be de-listed for Reach 2 of the Dominguez Channel ();	Chlordane was listed for the Dominguez Channel Estuary in 1998 or prior; data assessed prior to 2006 is not in the CalWQA database. There is insufficient data in the CalWQA database to justify a decision to "delist." Los Angeles Water Board staff encourages the commenter to enter all the relevant data into CEDEN in preparation for the next listing cycle

No.	Comment	Response
	and (3) SWAMP data (2003), based on multiple grab samples for both reaches, resulted in non-detects for chlordane.	that includes the Los Angeles Region.
10.3	**2. *DDT (tissue/sediment)*** This toxic should be de-listed for the following reasons: (1) no justification was provided in Decision ID 19790 of the proposed 2016 303(d) list to list DDT in keeping with 303(d) Listing Policy; (2) DDT is de-listed for Reach 2 of the Dominguez Channel; (3) SWAMP data (2003), based on multiple grab samples for both reaches, resulted in non-detects for DDT; and (4) DDT is a legacy pollutant that has been banned for several decades.	Decision ID 19790 is the reference to the 2012 303(d) list which did not consider new data for the Los Angeles Region (the 2012 303(d) list considered data from Regions 1, 6 and 7); the decision simply "carried over" a previous decision. Decision ID 34076 is the relevant 2016 decision. Decision ID 34076 includes six LOEs and supports a decision to "do not delist." The decision for Reach 1 of the Dominguez Channel is based, appropriately, on data from that reach. Whether or not another reach is listed is not a consideration in the data analysis. Reaches may be influenced by different sources. In regards to "legacy" pollutants, see response to comment 17.7.
10.4	**3. *Dieldrin (tissue)*** Dieldrin (tissue) should be de-listed for the following reasons: (1) no 303(d) listing policy justification for was provided in Decision ID 34645 of the proposed 2016 303(d) list to list dieldrin; (2) the proposed 2016 303(d) list recommends that dieldrin be de-listed for Reach 2 of the Dominguez Channel (despite the fact that the two reaches are connected); (3) dieldrin is a legacy pollutant; and (4) SWAMP data (2003) based on multiple grab samples for both Dominguez Channel reaches resulted in non-detects for dieldrin.	Dieldrin was listed for the Dominguez Channel Estuary in 1998 or prior; data assessed prior to 2006 is not in the CalWQA database. There is insufficient data in the CalWQA database to justify a decision to "delist." The decision for Reach 1 of the Dominguez Channel is based, appropriately, on data from that reach. Whether or not another reach is listed is

No.	Comment	Response
		not a consideration in the data analysis. The reaches may be influenced by different sources. In regards to “legacy” pollutants, see response to comment 17.7. Los Angeles Water Board staff encourages the commenter to enter all the relevant data into CEDEN in preparation for the next listing cycle that includes the Los Angeles Region.
10.5	**4. *Lead (including tissue)*** Lead (tissue) should be de-listed for the following reasons: (1) no justification to list lead was provided in Decision ID 34645 of the proposed 2016 303(d) Integrated Report in keeping with 303(d) Listing Policy; (2) SWAMP data (2003), based on multiple grab samples for both reaches, resulted in no exceedances for dissolved lead in Reach 1 of the Dominguez Channel; (3) according to the DCHT-TMDL, the samples taken for lead do not comply with the federal California Toxic Rule (CTR), in that they were not based exclusively on ambient samples and incorrectly used a hardness default value of 49 mg/13); and (4) lead as legacy pollutant has been significantly reduced in the environment as a result of de-leaded fuels).	It is clear from the context of the comment that commenter is actually referring to Decision ID 34613 for lead and not Decision ID 34645 which is for dieldrin. Decision ID 34613 includes six LOEs and supports a decision to “do not delist.” Comments on the Dominguez Channel and Greater Harbor Waters Toxic Pollutants TMDL are outside the scope of this action. Lead is not a “legacy” pollutant; there are current uses and sources of lead in the watershed.
10.6	**5. *Polychlorinated Bi-phenyls (PCBs)*** PCBs should be de-listed for the following reasons: (1) no justification to list was provided in Decision ID 33063 of the proposed 2016 303(d) Integrated Report in keeping with 303(d) Listing Policy (does not conform to the binomial distribution requirement contained in Section 3.1 of the policy); (2) PCBs are de-listed for	Decision ID 33063 includes five LOEs, which were all analyzed with respect to the binomial distribution per the Listing Policy. The decision for Reach 1 of the Dominguez Channel is based, appropriately, on data from that

No.	Comment	Response
	Reach 2 of the Dominguez Channel; (3) PCBs are legacy pollutants that have been banned for decades; and (4) SWAMP data (2003) based on multiple grab samples for both reaches resulted in non-detects for PCBs.	reach. Whether or not another reach is listed is not a consideration in the data analysis. The reaches may be influenced by different sources. In regards to "legacy" pollutants, see response to comment 17.7. Los Angeles Water Board staff encourages the commenter to enter all the relevant data into CEDEN in preparation for the next listing cycle that includes the Los Angeles Region.
10.7	**6. *Toxicity*** Toxicity should be de-listed for the following reasons: (1) no justification to list was provided in Decision ID 43000 of the proposed 2016 303(d) Integrated Report in keeping with 303(d) Listing Policy (does not conform to the binomial distribution requirement contained in Section 3.1 of the policy)4 ; (2) SWAMP data (2003) based on multiple grab samples for both reaches resulted in nondetects for most toxics (both Dominguez Channel reaches); and a few detects but no exceedances; and a very few exceedances for metals; and (3) the 2016 303(d) list proposes to de-list toxics affecting Dominguez Channel R1 and R2 that contribute to toxicity5 (there can be no toxicity if many of the toxics are to be de-listed).	Decision ID 43000 includes two LOEs both of which assessed data using the binomial distribution per the Listing Policy. Decision ID 43000 refers to Dominguez Channel (lined portion above Vermont). Los Angeles Water Board staff encourages the commenter to enter all the relevant data into CEDEN in preparation for the next listing cycle that includes the Los Angeles Region. There can be toxicity even when the cause of the toxicity is undetermined. Section 3.6 of the Listing Policy states, *"Waters may also be placed on the section 303(d) list for toxicity alone."*
10.8	**7. *Sediment Toxicity*** Sediment toxicity cannot be commented on because it is not addressed in the 2016 303(d) listing report, although it is listed in both the 2010 and 2012 303(d) reports.	Sediment toxicity data for Dominguez Channel Estuary (unlined portion below Vermont) is included as part of the toxicity listing. The decision to "do not delist" toxicity include two

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td></td><td>It is not certain if the Regional Board intended to de-list sediment toxicity or to carry it over. Against this background it is recommended the all of following toxics and metals be eliminated from the proposed 2016 303(d) Integrated Report for Reach 1 of the Dominguez Channel:

1. Benzo(a)pyrene (PAH)
2. Benzo(a)anthracene (PAH)
3. Chlordane (tissue)
4. Chryslene (PAH)
5. Copper
6. DDT(tissue and sediment)
7. Dieldrin (tissue)
8. Lead (tissue)
9. Methylnaphthlene 2
10. Polychlorinated Bi-phenyls (PCBs)
11. Polyaromatic-Hydrocarbons (PAHs)
12. Phenanthrene (PAH)
13. Pyrene (PAH)
14. Sediment Toxicity
15. Toxicity
16.Zinc (sediment)

Eliminating all of these toxics/metals should be sufficient justification for eliminating or significantly revising the DCHT-TMDL.</td><td>LOEs.

For PAHs, see response to comment 10.1.
For chlordane, see response to comment 10.2.
For copper, see response to comment 10.1.
For DDT, see response to comment 10.3.
For Dieldrin, see response to comment 10.4.
For lead, see response to comment 10.5.
For Methylnaphthlene 2, see response to comment 10.1.
For PCBs, see response to comment 10.6.
For toxicity, also see response to comment 10.6 and 10.7.
For zinc, see response to comment 10.1.</td></tr>
<tr><td>10.9</td><td>III. Reach 2 Dominguez Channel (lined portion above Vermont)

[See the posted letter for Table]

The 2016 303(d) list proposes to carry-over from the 2010 303(d) all of the toxics except diazinon, which is de-listed. Copper, lead, zinc, and toxicity should be de-listed for the same reasons for de-listing Dominguez Channel R1 metals and toxics.</td><td>See response to comment 10.1 to 10.7 regarding to metals and toxics listings.

The Benthic Community Effects listings are associated with other pollutant listings so waterbodies with Benthic Community Effects listings are appropriately in Category 5 or 4a. See response to comment 11.19.</td></tr>
</table>

No.	Comment	Response
	The 2016 (303d) list also adds "Benthic-Macroinvertebrate Bioassessment" (8MB), which should not be listed for the following reasons: • BMB is not a pollutant. • BMB is used to evaluate the health of wadeable streams using a scoring system. Reach 1 of the Dominguez Channel is not wadeable. The Los Angeles County Flood Control District forbids entry into this and other flood control channels. • The Index of Biotic Integrity (IBI) score of 40, on which the BMB is justified, is considered to be on the edge of "poor" to "fair." But it was based only on 3 samples, taken in 2006, 2007, and 2008. Not only is the sample size not statistically significant, and therefore not in keeping with the 303(d) Listing Policy, but the data is not current. • BMB decision ID, 83960, also uses as lines of evidence toxicity, which is associated with copper, lead, zinc, and diazinon. However, copper, lead, zinc, and toxicity should not be listed on the proposed 2016 303(d) list for the same reasons they should not be listed for Reach 2 of the Dominguez Channel. Further, the 2016 303(d) list proposes to de-list diazinon, a toxic. • According to the Southern California Coastal Water Research Project (SCCWRP), Technical Report 88, which is a bioassessment study concluded in 2015, metals, toxicity, and pyrethroids were only weakly or rarely associated with poor stream health in the Southern region. • Biota, including fish, located in Reach 1 or Reach 2 of the Dominguez Channel has not been specifically identified as being impaired by metals or toxics. The Regional Board has not been able to demonstrate that fish and other wildlife have been impaired. Admittedly, this would be difficult given that Dominguez Channel is a non-perennial stream; it only flows when it rains. There are no studies that have identified the number and species of fish in the Dominguez Channel during storm events. If there were any fish in the channel traveling from up-stream they would probably perish when moving from a freshwater to a saltwater	Benthic Community Listings for channels that are lined entirely with concrete, which includes Dominguez Channel (above Vermont), have been reassigned to Category 3 (insufficient information to assess beneficial use support but some uses may be threatened) until such time as benthic community condition scores have been more specifically calibrated for concrete-lined channels. See response to comment 11.24. For sample size, see response to comment 11.24. For copper, lead and zinc see response to comment 10.3, 10.5 and 10.1. Commenter may mean Technical Report 844 *"Bioassessment of Perennial Streams in Southern California: A Report on the First Five Years of the Stormwater Monitoring Coalition's Regional Stream Survey."* Dominguez Channel was not assessed in this Report. Fish are not part of a Benthic Macroinvertebrate bioassessment.

No.	Comment	Response
	environment.	
10.10	**III. Conclusions** In the final analysis, each of the metals and toxic pollutants on the proposed 2016 303(d) list for Reaches 1 and 2 of the Dominguez Channel should be de-listed. The bases for the delistings are, in the aggregate, defective because: 1. The data supporting the listings are out-dated (in some cases by almost 15 years). It is unclear why more current water quality data is not available, especially given that each MS4 in the State is required to pay an annual SWAMP surcharge along with its regular annual MS4 Permit fee to the State. Unlike most non-SWAMP monitoring (sampling and analysis), the Regional Board's SWAMP unit conducts monitoring in accordance with USEPA guidance and State policy. The data SWAMP generates is accurate, objective, and extremely useful. Had SWAMP been allowed to conduct monitoring on a regular basis, the DCHT-TMDL may not have been necessary. 2. Over the past two decades, water quality undoubtedly has improved. Many toxic pollutants are no longer in the environment (e.g., DDT, various pesticides, cleaning solvents, lead in gasoline, etc.). Substantial credit should also be given to municipalities. Since the Los Angeles County MS4 program began in the nineties, cities have dutifully implemented best management practices (BMPs) that have been effective in source-controlling pollutants and reducing them from outfalls through post-construction runoff pollution mitigation controls. Community sensitivity to mitigating runoff pollution is another factor attributable to MS4 public education and outreach programs. 3. The pollutant listings claim to be based on water quality standards developed in conformance with CTR, but they are not. CTR standards for metals and toxics are intended to be ambient standards, derived from dry weather sampling and analysis from receiving water. Instead, they were derived from wet weather conditions. Further, CTR requires an actual hardness value to calculate water quality standards. Many of the 303(d) pollutants were CTR calculated using average	For a discussion of readily available data, see response to comment 32.3. The Dominguez Channel and Greater Los Angeles and Long Beach Harbor Waters Toxics TMDL was based on a thorough review of data that confirmed impairments for the pollutants addressed by the TMDL; it did not solely rely on past 303(d) listings. As noted earlier, adjustments to the 303(d) list do not alter TMDLs. The revision of a TMDL, when warranted, is a separate Board action. Additionally, while the Los Angeles Water Board acknowledges the efforts of MS4 permittees, comments on MS4 permits are outside the scope of this action. The Listing Policy does not indicate that data from wet and dry weather must be assessed separately; additionally, CTR criteria apply to water quality in both dry and wet weather. For these data assessments, when hardness data was available, the hardness was used in the calculation of the criterion, per CTR. When hardness was not available, the default value of

No.	Comment	Response
	hardness values or in some cases the hardness factor of 100 mg/L. According to CTR, this factor was intended only to be used for illustrative purposes when calculating ambient standards for metals and toxics. 4. The pollutant listings, with the exception of those based on the Regional Board's Surface Water Ambient Monitoring Program (SWAMP), do not comply with the State's 303(d) Listing Policy's requirement of meeting the statistical frequency test using a binomial distribution in accordance with a null hypothesis. It should be noted that the DCHT-TMDL was based on faulty 303(d) metals and toxic pollutant listings. What is regrettable is that the costly Dominguez Channel EWMP is based on the DCHT-TMDL.	100 mg/L was used, per CTR. In regards to the binomial distribution see response to comments 10.6 and 10.7.
11.	City of Los Angeles, Bureau of Sanitation (LASAN), March 30, 2017	
11.1	It is crucial that the 303(d) List be revised based on sound science and methodologies following the requirements of the State's Listing Policy. Revisions to the 303(d) List may result in changes to our Enhanced Watershed Management Programs, Coordinated Integrated Monitoring Programs, as well as affecting requirements for the four Water Reclamation Plants operated by LASAN. As such, we feel it is imperative that the listings reflect our understanding of the watersheds to the best of our abilities given the available data.	Comment noted.
11.2	Attachment 1: Detailed Technical Comments on the 2016 Revisions to the Los Angeles Region 303(d) List **Water Body / Pollutant**: Wilmington Drain / Zinc **Technical Comment:** The Fact Sheet for Decision ID 63330 states that one line of evidence is available to assess zinc in Wilmington Drain (90159). LOE 90159 includes data collected by Heal the Bay's, "Compton Creek Monitoring Program" where 3 of 5 samples exceeded the evaluation guideline (i.e., the CTR). However, data collected by Heal the Bay's, "Compton Creek Monitoring Program", were collected from Compton Creek in the Los Angeles River watershed, not in Wilmington Drain. It	Los Angeles Water Board staff intends to correct the LOEs and the decision, as appropriate, as the State Board staff prepare the Integrated Report and 303(d) list for State Board approval. These changes are in process at this time.

No.	Comment	Response
	appears as if the source of confusion is that the samples were collected from a site located at Cressy Street Drain—Williamington Drain (note the difference between Williamington and Wilmington). As such, LOE 90159 consists of data that should not be included when assessing whether or not a zinc impairment exists in Wilmington Drain. Excluding LOE 90159 results in no data available to assess the waterbody pollutant combination. ***Requested Action: Remove Decision ID 63330 for the zinc listing for Wilmington Drain as there are no data to assess the waterbody pollutant combination.***	
11.3	Wilmington Drain / Copper Although the Fact Sheet for Decision ID 44676 states that only two lines of evidence are available in the administrative record to assess the pollutant, Appendix G shows three distinct lines of evidence (4280, 90131, and 90473). LOE 4280 is a placeholder LOE to support a 303(d) listing decision made prior to 2006. As such, no data are included within this LOE. LOE 90131 includes data collected by the City of Los Angeles where 2 of 33 samples exceeded the evaluation guideline (i.e., the CTR). LOE 90473 includes data collected by Heal the Bay's, "Compton Creek Monitoring Program" where 2 of 5 samples exceeded the evaluation guideline (i.e., the CTR). The Fact Sheet for Decision ID 44676 combines these three LOEs to state that 4 of 38 samples exceed the CRITERIA and this exceeds the allowable frequency listed in Table 4.1 of the Listing Policy. However, as previously noted, the third LOE includes data collected by Heal the Bay's, "Compton Creek Monitoring Program", which was focused on Compton Creek in the Los Angeles River watershed, not in Wilmington Drain. It appears as if the source of confusion is that the samples were collected from a site located at Cressy Street Drain—Williamington Drain (note the difference between Williamington and Wilmington). As such, LOE 90473 consists of data that should not be included when assessing whether or not a copper impairment exists in Wilmington Drain. Excluding LOE 90473 results in the sample exceedance frequency being 2 of 33 samples, which meets the allowable frequency listed in Table 4.1 of the Listing Policy.	Los Angeles Water Board staff intends to correct the LOEs and the decision, as appropriate, as the State Board staff prepare the Integrated Report and 303(d) list for State Board approval. These changes are in process at this time.

No.	Comment	Response
	Requested Action: Revise Decision ID 44676 for the copper listing for Wilmington Drain to Delist from 303(d) list and remove from Category 5 (Appendix B) because the total number of exceedances is equal to or less than the number of exceedances allowed to delist per the Listing Policy.	
11.4	Los Angeles River Estuary (Queensway Bay) / Copper The Fact Sheet for Decision ID 64264 presents one line of evidence related to copper in the Los Angeles River Estuary (85965). LOE 85965 presents information from a State of California program that sampled marinas throughout California and assess the data provided as follows: *"A total of six grab samples were collected during each sampling event. Four separate grab samples were collected from inside the marina basin (Sites 1, 2, 3, & 4) and two separate grab samples were collected from outside the marina basin (Sites 5 & 6). Sample results for sites inside the marina basin and sites outside the marina basin were averaged per sample event, resulting in two sample results per sampling event."* Per the LOE, the Regional Board utilized data collected from inside the Downtown Shoreline Marina (Sites 1, 2, 3, & 4) and data collected outside the marina basin (Sites 5 & 6) to make a determination that 3 of 6 samples exceeded the copper criterion. No site location information is provided specific to these sites (GPS locations are provided in the associated documents, but no sites are specifically named Sites 1, 2, 3, 4, 5, & 6) so it is not possible to verify the locations. Regardless, data from inside the Marina should not be combined with data from the Estuary to assess the Estuary. These are two distinct bodies of water with differing inputs and water quality conditions. Dissolved copper data collected inside the Marina shows an average concentration of 7 ug/L and represents three of the three exceedances identified in the Fact Sheet. Dissolved copper data collected outside of the Marina (presumably in the Estuary) shows an average concentration of 0.72 ug/L and represents zero of three exceedances. The dissolved copper data collected from inside and outside of the Marina are	Site locations in longitude, latitude are given in the "LocationsSamplesDetails" file included in the Data Reference link on the factsheet *"Data for Various Pollutants in California Marinas, 2006."* However, the sites 1, 2, 3, and 4 are within the Marina and should be included with the "San Pedro Bay Near/Off Shore Zones." Los Angeles Water Board staff intend to correct the LOEs and the decision, as appropriate, as the State Board staff prepare the Integrated Report and 303(d) list for State Board approval. These changes are in process at this time.

No.	Comment	Response
	significantly different from one another, as is to be expected, given that they are separate waterbodies and one is a marina and the other is an estuary. ***Requested Action: Either 1) remove Decision ID 64264 and the corresponding 303(d) listing in Attachment B or 2) revise Decision ID 64264 to reflect the waterbody is the Downtown Shoreline Marina rather than the Los Angeles River Estuary and remove the copper listing for the Los Angeles River Estuary from the 303(d) list (Attachment B).***	
11.5	Ballona Creek / Toxicity The Fact Sheet for Decision ID 34253 presents two lines of evidence that indicate the presence of sediment toxicity (83019 and 83020). LOE 83019 references a Statewide Stream Pollution Trends Study 2008 and LOE 83020 references Statewide Project Urban Pyrethroid Status Monitoring. When reviewing the station locations (404SUP093 and 404BLNAxx) associated with these two LOEs in an August 2012 Surface Water Ambient Monitoring (SWAMP) report titled "Toxicity in California Waters: Los Angeles Region", the sampling locations are identified as (page 11) "approximately one kilometer downstream from the confluence with Sepulveda Channel." In a 2014 SWAMP report titled "Trends in Chemical Contamination, Toxicity and Land Use in California Watersheds: Stream Pollution Trends (SPoT) Monitoring Program Third Report - Five-Year Trends 2008-2012", the site 404BLNAxx is identified as Ballona Creek Downstream of Centinela (33.986 -118.417). In the Ballona Creek Toxics TMDL Staff Report, Ballona Creek Reach 2 and Estuary are defined as follows (page 5): Ballona Creek to Estuary (Reach 2) is the longest segment of the creek (approximately 4 miles) continuing on from National Boulevard and ending at Centinela Avenue where the Estuary begins. As such, the sites identified in LOEs 83019 and 83020 are in the Ballona Creek Estuary rather than in Ballona Creek and the Estuary already has a toxics TMDL. ***Requested Action: Remove Decision ID 34253 for toxicity for Ballona Creek as there are no data to assess the waterbody pollutant combination.***	The Ballona Creek Estuary Toxics TMDL Staff Report identifies the downstream end of Ballona Creek Reach 2 correctly when it states, *"Centinela Creek drains directly to "Ballona Creek Estuary" just below the boundary with Reach 2"*; however, Ballona Creek Reach 2 does not end at Centinela Ave., as stated. Ballona Creek Reach 2 ends just above the confluence with Centinela Creek as shown in the Los Angeles Region Basin Plan. However, a review of the sampling location is in process at this time.

No.	Comment	Response
11.6	Dominguez Channel (lined portion above Vermont Ave) / Ammonia The Fact Sheet for Decision ID 35134 states that two lines of evidence are available in the administrative record to assess pollutant (4098 and 83962). LOE 4098 is a placeholder to support a 303(d) listing decision made prior to 2006. As such, no data are included within this LOE. LOE 83962 includes data collected by the City of Los Angeles (City) and states that samples were collected at 3 locations: Artesia Blvd. @ Western Ave., Manhattan Beach Blvd., and El Segundo Blvd. where 2 of the 21 samples exceeded the Water Quality Objective/Criterion. However, the data included within the Data Reference for LOE 83962 includes eight additional results that did not exceed the Water Quality Objective/Criterion (including samples collected at Vermont Ave., which was not identified within the LOE Spatial Representation). Given that the Basin Plan indicates that Vermont Ave. represents the reach break between Dominguez Channel and the Dominguez Channel Estuary, samples collected at Vermont Ave. are representative of the upstream water body (i.e., Dominguez Channel lined portion above Vermont Ave). Including all of the applicable data included within the Data Reference for LOE 83962 results in the sample exceedance frequency being 2 of 29 samples, which meets the allowable frequency listed in Table 4.1 of the Listing Policy. ***Requested Action: Revise Decision ID 35134 for the ammonia listing for Dominguez Channel to Delist from 303(d) list and remove from Category 5 (Appendix B) because the total number of exceedances is equal to or less than the number of exceedances allowed to delist per the Listing Policy.***	The sample collected at Vermont Ave. was collected just downstream of the Vermont Ave. reach break, so it was not included in the listing decision. That sampling location represents water quality of the downstream reach.
11.7	Dominguez Channel Estuary (unlined portion below Vermont Ave) / Ammonia As presented in LOE 83995, ammonia, pH, and temperature data were collected by the City of Los Angeles at four stations in Dominguez Channel Estuary during July 2009 and August 2009. The following table summarizes the number of samples and exceedances.	The decision has been updated to “DELIST.”

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td></td><td>

Summary of data for Dominguez Channel Estuary (unlined portion below Vermont Ave)

Waterbody	# of Samples	# of Exceedances of 4-Day Criteria	Delist if the # of exceedances equal or is less than[1]
Dominguez Channel Estuary (unlined portion below Vermont Ave)	28	0	2

1 For toxicants, the maximum number of exceedances allowed for delisting is shown in Table 4.1 (Page 14) of the Listing Policy.

COMPARISON OF EXCEEDANCES TO LISTING POLICY

As shown in the table above, the total number of exceedances is below the maximum number of exceedances allowed to delist per the Listing Policy. As a result, the available data demonstrates that Dominguez Channel Estuary meets the water quality objectives for ammonia (un-ionized) and should be delisted from the 303(d) list. This decision would be consistent with Decision ID 62240 (which treated the listing as a new listing despite an existing listing being present), which finds that ammonia in the Dominguez Channel Estuary should not be listed and states the following (emphasis added): "Based on the readily available data and information, the weight of evidence indicates that *there is sufficient justification against placing this water segment-pollutant combination on the CWA section 303(d) List in the Water Quality Limited Segments category*. This conclusion is based on the staff findings that:

1. The data used satisfies the data quality requirements of section 6.1.4 of the Policy.

2. The data used satisfies the data quantity requirements of section 6.1.5 of the Policy.

3. 0 of 28 samples exceeded the CRITERIA and this does not exceed the allowable frequency listed in Table 3.1 of the Listing Policy.

4. Pursuant to section 3.11 of the Listing Policy, no additional data and information are available indicating that standards are not met.

Regional Board Staff Decision Recommendation: After review of the available data and information, *RWQCB staff concludes that the water body-pollutant combination should not be placed on the section 303(d) list* because applicable water quality standards are not being exceeded."

</td><td></td></tr>
</table>

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td></td><td>Requested Action: Revise Decision ID 34669 for the ammonia listing for Dominguez Channel Estuary to Delist from 303(d) list and remove from Category 5 (Appendix B) based on Decision ID 62240 (for the ammonia [un-ionized] listing for Dominguez Channel Estuary) and the data reference provided in LOE 83995.</td><td></td></tr>
<tr><td>11.8</td><td>Compton Creek / Iron

The Fact Sheet for Decision ID 62052 states that one LOE (83798) is available in the administrative record to assess iron in Compton Creek. LOE 83798 lists the following as the Evaluation Guideline used as the basis for the listing: “National Recommended Water Quality Criteria Continuous Concentrations are intended to protect freshwater aquatic organisms from chronic exposures and are expressed as 4-day average concentrations. The City has several concerns with this listing:
The only two exceedances are associated with wet-weather samples collected on October 13, 2009. The Evaluation Guideline used as the basis is Criteria Continuous Concentrations (i.e., chronic criterion). It is inappropriate to use a chronic criterion as it is meant to protect aquatic life against chronic exposure and the samples were taken during a wet-weather event not representative of chronic conditions. USEPA does not recommend a Criteria Maximum Concentration (acute criterion) for iron within its National Recommended Water Quality Criteria.
The National Recommended Water Quality Criteria Continuous Concentration for iron does not specify whether the criterion applies to the total recoverable or dissolved fraction. None of the dissolved iron results associated with the samples used to assess the water body exceeded the criterion.
Section 6.1.5.3 of the Listing Policy states that “Samples used in the assessment must be temporally independent. If the majority of samples were collected on a single day or during a single short-term natural event (e.g., a storm, flood, or wildfire), the data shall not be used as the primary data set supporting the listing decision.” However, multiple samples were collected on the same day during the same storms and each was considered separately.</td><td>The review of the decision for Compton Creek iron is in process at this time.</td></tr>
</table>

No.	Comment	Response
	Samples collected on the same day during the same storm (as was the case with the two exceedances) should not be considered independently from one another as they are clearly not temporally independent and do not meet the Listing Policy requirements. Averaging samples collected on the same day results in 1 of 5 exceedances, which does not meet the requirements of the Listing Policy for placing a water body segment on the 303(d) list. ***Requested Action: Revise the decision for Decision ID 62052 for the iron listing for Compton Creek to Do Not List on 303(d) list (TMDL required list) and remove from Category 5 (Appendix B) due to an inappropriate evaluation guideline being used as the basis for the listing, the observed exceedances were not temporally independent, and none of the dissolved results exceeded the evaluation guideline.***	
11.9	Ballona Creek Estuary / Silver The Fact Sheet for Decision ID 34520 states "Silver has not been specifically listed on the 303(d) list." Furthermore, the single Line of Evidence (LOE) does not indicate that any data were analyzed (i.e., the number of samples listed is zero). As such, the listing should be removed. ***Requested Action: Revise Decision ID 34520 for the silver listing for Ballona Creek Estuary to Delist from 303(d) list and remove from Category 4 (Appendix C) to be consistent with the Fact Sheet.***	During the development of the Ballona Creek Estuary Toxics TMDL, USEPA and the Los Angeles Region found that the Ballona Creek listings for sediments (cadmium, copper, lead and silver) were made in error and should be applied to the Estuary. The original listing (for Ballona Creek) was made in 1998 or prior; LOE 2408 is a "placeholder" to support a previous listing decision. Data for these "placeholder" LOEs are not included in the CalWQA database. The factsheet has been revised for clarity.
11.10	Dominguez Channel Estuary (unlined portion below Vermont Ave) / Copper The Fact Sheet for Decision ID 33751 states that five LOEs are available to assess copper in the Dominguez Channel Estuary, four of which correspond to sediment and one of which corresponds to water. The sole LOE that presents water data	The review of the decision for Dominguez Channel Estuary (unlined portion below Vermont Ave) Copper is in process at this time. In addition, copper is included on the list as "being addressed by a TMDL," the Dominguez Channel

No.	Comment	Response
	states that 3 of 3 samples exceeded the dissolved California Toxics Rule (CTR) saltwater chronic criterion. However, these sample results were all collected on the same day and appear to be for total copper associated with a wet-weather event. When using the total copper CTR acute criterion (rather than the dissolved CTR chronic criterion), the samples do not exceed. As such, all LOEs that support a listing correspond to the sediment matrix. ***Requested Action: Revise the pollutant for Decision ID 33751 for the copper listing for Dominguez Channel Estuary to "Copper <u>(sediment)</u>" given that the LOEs supporting a listing correspond to the sediment matrix and move the listing to Category 4a (Appendix C).***	and Greater Los Angeles and Long Beach Harbor Waters Toxics TMDL.
11.11	Various waterbodies / Various pollutants For a number of existing listings, it appears as if a significant number of readily available data were not considered when making the Final Listing Decision. These data are from NPDES Permit monitoring programs (both wastewater and stormwater). When these data are considered, the number of measured exceedances supports rejection of the null hypothesis as presented in Table 4.1 of the *Water Quality Control Policy for Developing California's Clean Water Act Section 303(d) List* (Listing Policy). As such, these listings should be removed from the section 303(d) list. Furthermore, with regards to the cyanide listing for Ballona Creek, it appears as if Los Angeles (LA) Regional Water Quality Control Board (Regional Board or LARWQCB) staff applied the chronic CTR criterion to the entire dataset instead of applying the chronic CTR criterion during dry-weather and the acute CTR criterion during wet-weather.	See response to comment 32.3 for a discussion of the "readily available" data considered for this Integrated Report and 303(d) list. While, in TMDLs, targets and allocations may be developed separately for dry weather and wet weather and may apply chronic criteria to dry weather and acute criteria to wet weather, that is not the procedure used in 303(d) listing decisions. The Listing Policy does not indicate that data from wet and dry weather must be assessed separately, and the more conservative chronic criteria from CTR applies, appropriately, to water quality assessments.

No.	Comment	Response
11.13	Los Angeles River Reach 1 (Estuary to Carson Street) / Cadmium The Fact Sheet for Decision ID 32639 finds that cadmium in the Los Angeles River Reach 1 should not be listed and states (emphasis added): "Three lines of evidence are available in the administrative record to assess this pollutant. The CTR criterion for cadmium for the protection of aquatic life was exceeded three out of forty-two samples from data collected between 1996 and 2002 and no samples exceeded CCR Title 22 MCL guidelines for the protection of MUN beneficial uses in data collected between 2000 and 2003. Based on the readily available data and information, the weight of evidence indicates that *there is sufficient justification for removing this water segment pollutant combination from the section 303(d) list.*" In addition, the analysis conducted as part of the ULAR EWMP did not identify any exceedances from February 2001 through December 2010. ***Requested Action: Revise Decision ID 32639 for the cadmium listing for Los Angeles River Reach 1 to Delist from 303(d) list and remove from Category 5 (Appendix B) to be consistent with the Fact Sheet and because there have not been any observed exceedances since 2001.***	In the 2002 303(d) list, a cadmium listing was added for Reach 1 of the Los Angeles River based on stormwater data. Data for listings prior to 2006 are not included in the CalWQA database. In addition, the USEPA final decision for the 2006 303(d) list added this listing to the 'being addressed by USEPA approved TMDL' portion of the 303(d) List on this basis of the data review and the targets and allocations for cadmium included in the Los Angeles River Metals TMDL. The factsheet has been revised for clarity.
11.14	Echo Park Lake / Ammonia Decision ID 34696 proposes to change the ammonia listing for Echo Park Lake from List on 303(d) list (TMDL required list) to list on the 303(d) list (being addressed by United States Environmental Protection Agency [USEPA] approved TMDL). However, the TMDL report made a finding of nonimpairment for ammonia, as outlined in the following excerpt from Section 6.2.3.2 of the TMDL report (emphasis added): "Echo Park Lake was listed as impaired for ammonia in 1996 based on an assessment in the Regional Board's Water Quality Assessment and Documentation Report (LARWQCB, 1996). Consistent with project plan recommendations provided in California's Impaired Waters Guidance (SWRCB, 2005), EPA and	The 303(d) list and the factsheet has been updated to "DELIST."

No.	Comment	Response
	local agencies collected 35 additional samples (7 wet-weather) between May 2003 and February 2010 to evaluate current water quality conditions. There was one ammonia exceedance in 35 samples (Appendix G, Monitoring Data). Therefore, Echo Park Lake meets ammonia water quality standards and USEPA concludes that preparing a TMDL for ammonia is unwarranted at this time. *USEPA recommends that Echo Park Lake not be identified as impaired for ammonia in California's next 303(d) listing*."[1] ***Requested Action: Revise Decision ID 34696 for the ammonia listing for Echo Park Lake to Delist from 303(d) list and remove from Category 4 (Appendix C) based on USEPA's recommendation.*** 1 U.S. Environmental Protection Agency, Los Angeles Area Lakes TMDLs, Section 6.2.3.2 Summary of Ammonia Non-Impairment, March 2012, p.6-13.	
11.15	Lincoln Park Lake / Lead Decision ID 34817 proposes to change the lead listing for Lincoln Park Lake from List on 303(d) list (TMDL-required list) to list on the 303(d) list (being addressed by USEPA approved TMDL). However, the TMDL report made a finding of nonimpairment for lead, as outlined in the following excerpt from Section 5.3 of the TMDL report (emphasis added): "Lincoln Park Lake was listed as impaired for lead in 1996 based on an assessment in the Regional Board's Water Quality Assessment and Documentation Report (LARWQCB, 1996). Consistent with project plan recommendations provided in California's Impaired Waters Guidance (SWRCB, 2005), EPA and local agencies collected 40 additional samples (11 wet-weather) between October 2008 and December 2010 to evaluate current water quality conditions. There were zero dissolved lead exceedances in 40 samples (Appendix G, Monitoring Data). USEPA also collected one sediment sample in September 2010 to further evaluate lake conditions. There were zero sediment lead exceedances of the 128 ppm freshwater (Probable Effect Concentrations) sediment target (Appendix G, Monitoring Data). Therefore, Lincoln Park Lake meets lead water quality standards and USEPA concludes that preparing a TMDL for lead is unwarranted	The 303(d) list and the factsheet has been updated to "DELIST."

No.	Comment	Response
	at this time. *USEPA recommends that Lincoln Park Lake not be identified as impaired by lead in California's next 303(d) list*." ***Requested Action: Revise Decision ID 34817 for the lead listing for Lincoln Park Lake to Delist from 303(d) list and remove from Category 5 (Appendix B) based on USEPA's recommendation.*** U.S. Environmental Protection Agency, Los Angeles Area Lakes TMDLs, Section 5.3 Lead Impairment, March 2012, p.5-18	
11.16	Lincoln Park Lake / Ammonia The data utilized to develop the original listing in 1998 are not available (these data were requested from USEPA and the Regional Board during development of the TMDL in 2010. Based on USEPA's TMDL report, data collected prior to 2009 were reported as ammonium, without corresponding ammonia, pH, or temperature measurements making it impossible to compare these data to ammonia criteria. Only ammonia data collected with corresponding pH and temperature data can be used to determine if criteria were exceeded. In 2008, the Regional Board collected eight ammonia samples all of which were below the reporting limit of 0.1 mg/L and chronic criterion. In 2009, the City of Los Angeles and USEPA/Regional Board conducted monitoring and collected 15 and three samples, respectively, all of which were below the chronic criterion. As stated in the TMDL report (pg. 5-10): *"There were no exceedances of the acute or chronic ammonia criteria during any recent sampling events with associated pH and temperature measurements."* In summary, there are no ammonia data with corresponding pH and temperature measurements available to support the original listing and all available recent data demonstrate there are no exceedances. ***Requested Action: Revise Decision ID 35004 for the ammonia listing for Lincoln Park Lake to Delist from 303(d) list and remove from Category 5 (Appendix B).***	The Water Quality Assessment Report (LARWQCB, 1996) includes ammonia as not supporting beneficial uses. Twenty-eight ammonium samples were reported ranging from non-detect to 1.14 mg-N /L which is less than the acute target, but greater than the chronic target for total ammonia N (assuming the analytical method converted all ammonia to ammonium). Data from lines of evidence developed prior to 2006 are not included in the CalWQA database. While the EPA TMDL for the Los Angeles Area Lakes did review data from 2008 and 2009, which did not exceed criteria, unlike for lead, the EPA TMDL for the Los Angeles Area Lakes did not make a finding of non-impairment for ammonia and instead established targets.

No.	Comment	Response
11.17	Los Angeles River Reach 2 (Carson to Figueroa Street) and Los Angeles River Reach 5 (within Sepulveda Basin) / Oil The source of oil seeping into the River was found to be naturally-occurring crude oil. This conclusion is supported by the results of investigations completed by various agencies, which are summarized as follows: An investigation was conducted following seeps of petroleum hydrocarbons into the LA River in June 2001. Based on lab results and borings, it was concluded that the source of the LA River channel oil seeps is naturally-occurring crude oil from Puente formation sands. Oil was visible in Puente formation seams, partings and fractures, as well as sand lenses, and appeared to have migrated upward into sandy alluvial soils. Gasses encountered included hydrogen sulfide, commonly sources from crude oil reservoirs. The hydrocarbon seeps appeared to be concentrated where the Puente formation contacts with younger, less permeable units or layers. The USEPA On-Scene Coordinator (OSC) conducted subsurface investigations of the oil seeps in the LA River during August and September 2001. The OSC found that the oil did not discharge as a result of a spill, leak, or discharge from any facility and that the oil has been discharging to the river since at least 1943 and there is no practical means of preventing this oil seep from discharging to the River. On April 19, 2002, an email was sent to Steven Pedersen of City of Los Angeles /Watershed Protection Division (WPD) by Steven Poole of the US Coast Guard/National Pollution Funds Center (USGC/NPFC). Mr. Poole stated that City of Los Angeles cannot submit to USGC/NPFC a claim for reimbursement for cost incurred by the City associated with May 2001 oil clean-up efforts in the LA River because Title 1 of the Oil Pollution Act does not allow for reimbursement for **naturally-occurring oil** (natural seepage). In summary, the reports and correspondence discussed herein, indicate that multiple agencies believe that the oil found in the listed reaches of the LA River is associated with naturally-occurring seepage suggesting that a 303(d) listing is not	The State and Regional Water Boards are currently exploring options to address pollutants that may be naturally elevated in water bodies. Until the natural sources of pollutants are addressed by either an exclusion policy as adopted by the State Water Board or a natural sources exclusion (or other site-specific objective) is developed by the Los Angeles Water Board, oil in the Los Angeles River is an impairment and appropriately on the 303(d) list. There is no alternative regulatory program identified that will reduce oil in the Los Angeles River so the category cannot be 4b. However, the factsheet has been updated to include “natural sources” as the source.

No.	Comment	Response
	warranted. **Studies Used in the Analysis** The following studies/correspondences were used in the analysis: • Pollution Report (2002), USEPA Region IX • Correspondence (2002) from Michael P. Brown, Manager, Geotechnical Engineering Division, Bureau of Engineering, City of Los Angeles • Correspondence (2002) from Steven Poole, Claims Manager, USGC/NPFC Despite repeated efforts by WPD to obtain the historical information utilized to develop the original listing, the Regional Board has not provided the information for inclusion in the analysis. Therefore, the analysis is based solely on recent information available to WPD. **Summary of Findings** The source of oil seeping into the River was found to be naturally-occurring crude oil. This conclusion is supported by the results of investigations completed by various agencies, which are summarized below. **Investigations of the Geotechnical Engineering Division, Bureau of Engineering, City of Los Angeles – June 2001** An investigation was conducted following seeps of petroleum hydrocarbons into the engineered channel of the LA River across from the Piper Technical Center in June 2001. This study concluded that the source of the LA River channel oil seeps is naturally-occurring crude oil from Puente formation sands, based on lab results and borings. The samples of the oil seeps and associated bacterial-growth scums revealed that the seeps were predominantly in the oil or heavy-hydrocarbon range. This supports the conclusion that the LA River oil seeps are natural crude oil as opposed to fuel leaks.	

No.	Comment	Response
	Drilling of wells along Mission St. (east of the river channel) confirmed that oil-bearing Puente formation sands and fractures are the source of crude oil and gases that migrate into the shallow alluvial soils. The hydrocarbons, visible oil and PID readings generally increased with depth toward the Puente formation. Oil was visible in Puente formation seams, partings, and fractures, as well as sand lenses, and appeared to have migrated upward into sandy alluvial soils. Gasses encountered included hydrogen sulfide, commonly sources from crude oil reservoirs. The hydrocarbon seeps appeared to be concentrated where the Puente formation contacts younger, less permeable units or layers. **Pollution Report, EPA – January 2002** The USEPA OSC conducted extensive subsurface investigations of the oil seeps in the LA River during August and September 2001. The OSC found that the oil did not discharge to the River as a result of a spill, leak, or discharge from any facility based on the investigation. The oil has been discharging to the river since the least 1943 and there is no practical means of preventing this oil seep from discharging to the LA River. The OSC also evaluated the use of epoxy or urethane sealants on the seeps to reduce the flow of oil. However, it was concluded that the use of sealants on the seeps would cause the oil to get into the subdrain system and eventually enter the LA River. In summary, WPD attempted to evaluate the original listing information in light of the currently available information. Although the Regional Board did not provide the information, the reports and correspondence discussed herein, and attached to this letter, indicate that multiple agencies believe that the oil found in the listed reaches of the Los Angeles River is associated with naturally-occurring seepage. ***Requested Action: Revise Decision IDs 34118 and 34203 for the oil listings for Los Angeles River Reaches 2 and 5 to Delist from 303(d) list and remove from Category 5 (Appendix B) given that the oil found in the listed reaches of the Los Angeles River is associated with naturally-occurring seepage. Alternatively, move the listing to Category 4b as other regulatory programs are reasonably***

11.20	Lincoln Park Lake / PCBs Decision ID 64083 proposes to list PCBs in fish tissue for Lincoln Lake Park. However, this Lake is annually stocked with fish and therefore the lake population	The minimum requirement to justify a listing is exceedances of the relevant criteria or guideline per the Listing Policy. Fish in Lincoln Park Lake exceeded the relevant guideline, the OEHHA fish contaminant goal for PCBs. The identification of

No.	Comment	Response
	does not spend its lifespan in Lincoln Park Lake and may have accumulated PCBs from another waterbody. A number of studies have indicated that farmed salmon accumulate PCBs from the fish meal they are fed. In order to determine the source of the exceedance, fish from the State's stocking system need to be tested prior to introduction and the duration of time they spend in the Lake needs to be determined by a tagging program. The current analysis makes the assumption that fish are introduced to the Lake free of PCBs and subsequently bioaccumulate PCBs from Lake sediments. In addition, the Lake is restocked every year in April which suggests that all fish stocked are immediately removed and consumed. Both of these assumptions need to be fully evaluated prior to determining the source of the exceedance and therefore Lincoln Park Lake does not meet the minimum requirements to justify a listing. ***Requested Action: Remove Decision ID 64083 from Category 5 (Appendix B) or revise from Category 5 to Category 3 so that further evaluation of whether or not the lake itself is actually impaired.***	fish exceeding the OEHHA fish contaminant goals is important for the protection of human health and it is appropriate to identify the impairment on the 303(d) list. The analysis did not make the assumption that fish are introduced to the Lake free of PCBs and subsequently bioaccumulate PCBs from Lake sediments, because a source analysis has not been completed.
11.21	Santa Monica Bay Offshore/ Nearshore / Arsenic The Fact Sheet for Decision ID 67208 presents two lines of evidence related to arsenic in Santa Monica Bay (88949 and 88950). LOE 88949 presents information related to sediment and found that 0 of 32 samples exceeded the sediment goals utilized in the assessment. LOE 88950 presents information related to fish tissue and indicates that 19 of 19 samples collected as part of Hyperion Water Reclamation Plan NPDES Permit during August of 2006, and August, September, October, and November of 2007 exceeded the evaluation guideline with the presumption that results were reported on a wet-weight basis and 10% of the total arsenic result represented the amount of inorganic arsenic in the sample for comparison to the guideline. In reviewing LOE 88950, no information/citation can be found supporting the assumption that 10% of the total arsenic result represented the amount of inorganic arsenic in the sample. It is appropriate to utilize inorganic arsenic in assessing potential risk; however, either measured inorganic arsenic or a conversion factor developed from actual measured ratios from Santa Monica Bay should be utilized. In USEPA's 2000 Guidance for Assessing Chemical	A review of the decision to list arsenic is in process at this time in order to re-examine the assumption of the ratio of organic to inorganic arsenic. 10% is a conservative assumption for amount of inorganic arsenic in the sample, though a locally developed conversion factor could be better and could be used in future assessment. Note, the San Diego listing only used 2 samples of shellfish leading to greater uncertainty than this assessment which used 19 samples and all 19 samples exceeded the guideline by a wide margin. The data were collected on several different days in several different zones. Data from different species cannot be aggregated from different species. Composites of different species will have different age profiles, different species occupy different trophic levels and will accumulate

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td></td><td>Contaminant Data for Use in Fish Advisories Volume 1 Fish Sampling and Analysis Third Edition (EPA 823-B-00-007), USEPA recommends that, in both screening and intensive studies, total inorganic arsenic tissue concentrations be determined for comparison with the recommended screening value for chronic oral exposure. Scientific literature demonstrates that a range of total to inorganic arsenic ratios exist. For example, a 2008 study specifically looking at arsenic speciation in 383 samples of marine fish and shellfish, showed that the inorganic fraction of arsenic is typically <0.5% with a few of the highest samples ranging from 1-5% The City's concern with the approach has been expressed in other regions of California as well. The Port of San Diego in an August 11, 2016 comment letter to the San Diego Regional Water Quality Control Board regarding a 303(d) arsenic listing, noted the high level of variability of the proportion of inorganic arsenic across species (typically <10%) as measured in a number of other studies, as well as a methodology that could be used to ground truth the applied proportion through actual sample data. In response to the Port of San Diego's comment the San Diego Regional Board removed an arsenic listing from their draft 303(d) list and stated:

"… there is a high level of uncertainty in the levels of inorganic arsenic in shellfish tissue. The assumption regarding the percent of total arsenic in shellfish tissue is likely conservative, and the San Diego Water Board agrees that a listing based on those assumptions has a high probability of mischaracterizing the results as an impairment. The San Diego Water Board supports the Port's suggestion that future monitoring of shellfish incorporate a measurement of both total and inorganic arsenic."

The City also has concerns with the approach to utilizing the data in comparison to the guidelines. Section 6.1.5.3 of the Listing Policy states that "Samples used in the assessment must be temporally independent." However, each individual sample was considered on its own without consideration for temporal representation. Samples collected on the same day (i.e., October 2007, November 2007, and September 2008) should not be considered independently from one another as they are clearly not temporally independent. Furthermore, given tissue concentrations represent the accumulation of pollutants over a time period of years</td><td>pollutants at different rates. These samples are independent and cannot be combined and considered as a single data point.

In addition, while the Listing Policy requires that samples be spatially and temporally independent, fish are not static; they move throughout a waterbody and accumulate pollutants in tissue over time. Therefore, the data are, by their nature, spatially and temporally independent.</td></tr>

No.	Comment	Response
	and the risk endpoint relates to a carcinogenic effect over a 30-year period, considering samples collected within months of each other (October and November 2007 and August and September 2008) also does not provide the required temporal independence. Data should be aggregated across appropriate temporal timeframes, which should be assessed on a case-by-case basis, but should be no less than annually. Lastly, in assessing tissue data, consideration should be given to the fact that multiple samples and species are collected and the range of concentrations within those samples and across species represents exposure and potential risk. Considering each individual sample separately from one another or across species results in an assumption that an individual sample is representative of the exposure condition. Data should not only be aggregated on an appropriate temporal scale, but also across species, potentially weighted based on likely consumption patterns. In summary, the lack of inorganic arsenic data and use of an unsupported conversion factor in combination with the approach to comparing tissue data that does not appropriately meet the requirements of temporal independence or reflect actual exposure conditions does support listing arsenic in Santa Monica Bay. The City welcomes the opportunity to discuss approaches to develop inorganic arsenic data for use in future evaluations, as well as an approach to consider tissue data to properly evaluate arsenic in Santa Monica Bay. ***Requested Action: Remove Decision ID 67208 from the 303(d) list. However, if the Regional Board feels it is necessary to categorize the information within the Integrated Report, place the waterbody pollutant combination in Category 3 as there is insufficient data and information to make a beneficial use support determination, but information and/or data indicates beneficial uses may be potentially threatened.*** [3]Peshut, P.J. et al., 2008. Arsenic speciation in marine fish and shellfish from American Samoa. Chemosphere 71 488-492. doi:10.1016/j.chemosphere.2007.10.014 [4]Port of San Diego comment letter to California Water Quality Control Board – San Diego Region. 11.22	Santa Monica Bay Offshore/ Nearshore / Mercury The Fact Sheet for Decision ID 67209 presents three lines of evidence related to mercury in Santa Monica Bay (4165, 88894, and 88891). LOE 4165 and 88891 presents information related to sediment toxicity and sediment chemistry, respectively. LOE 88894 presents information related to fish tissue and indicates that 2 of 19 samples collected as part of Hyperion Water Reclamation Plan NPDES Permit during August of 2006, and August, September, October, and November of 2007 exceeded the evaluation guideline with the presumption that results were reported on a wet-weight basis. Section 6.1.5.3 of the Listing Policy states that "Samples used in the assessment must be temporally independent." However, each individual sample was considered on its own without consideration for temporal representation. Samples collected on the same day (i.e., October 2007, November 2007, and September 2008) should not be considered independently from one another as they are clearly not temporally independent. Furthermore, given tissue concentrations represent the accumulation of pollutants over a time period of years, considering samples collected within months of each other (October and November 2007 and August and September 2008) also does not provide the required temporal independence. Data should be aggregated across appropriate temporal timeframes that should be assessed on a case-by-case basis, but should be no less than annually. Lastly, in assessing tissue data, consideration should be given to the fact that multiple samples and species are collected and the range of concentrations within those samples and across species represents exposure and potential risk. Considering each individual sample separately from one another or across species results in an assumption that an individual sample is representative of the exposure condition. Data should not only be aggregated on an appropriate temporal scale, but also across species, potentially weighted based on likely consumption patterns.	Fish collected on the same day, in the same zone, and of the same species, could be aggregated, but this data set represents fish collected on different days or in different zones or they are different species and therefore cannot be aggregated.. In addition, the fact that tissue concentrations represent the accumulation of pollutants over a time period of years, and each fish is a different age and will have moved differently through the environment, provides independence of the tissue sample. However, a review of this decision is in process at this time to confirm the number of exceedances.

	The City welcomes the opportunity to discuss an approach to appropriately consider tissue data to properly evaluate mercury in Santa Monica Bay. ***Requested Action: Remove Decision ID 67209 from the 303(d) list. However, if the Regional Board feels it is necessary to categorize the information within the Integrated Report, place the waterbody pollutant combination in Category 3 as there is insufficient data and information to make a beneficial use support determination, but information and/or data indicates beneficial uses may be potentially threatened.***	
11.23	Echo Park Lake and Machado Lake (Harbor Park Lake) / Various pollutants Echo Park Lake and Machado Lake (Harbor Park Lake) are two waterbodies located in Los Angeles County which have both been included on the 303(d) impaired waters list since 2006. Because of their water quality impairments, the City invested significant resources to rehabilitate the water quality of the lakes. The $45 million Echo Park Lake Rehabilitation Project was completed in 2015 and included extensive changes to the lake hydrology (e.g., storm drain upgrades, inlet and outlet upgrades, removal of contaminated lake sediments, and installation of lake aeration system) and immediately surrounding areas, including best management practices (BMPs) to reduce the loads of targeted pollutants including trash, metals, coliform, pesticides, and nutrients. The Machado Lake Ecosystem Rehabilitation Project involved dredging and capping the lake bottom, constructing an oxygenation system, adding new storm drain systems, as well as a number of other BMPs to improve water quality. These award-winning projects have been very successful and produced significant water quality improvements; however, these improvements are not reflected in the Regional Board's proposed 303(d) list. The proposed changes for Echo Park Lake includes two delistings for copper and lead, which the City supports; however, two new listings were added for chlordane (tissue) and dieldrin. The other legacy listings for Echo Park Lake and Machado Lakes remain on the proposed 303(d) list (see following table). The City maintains that these legacy listings are inappropriately categorized and should	Echo Park Lake: Chlordane and Dieldrin in Echo Park Lake are addressed by the Los Angeles Area Lakes TMDL for Nitrogen, Phosphorus, Mercury, Trash, OC Pesticides and PCBs. The Los Angeles Area Lakes TMDL included chlordane and reviewed chlordane data from several sources. The Chlordane data included as the LOE in the CalWQA database is from a SWAMP study, *"Contaminants in Fish from California Lakes and Reservoirs: Technical Report on Year One of a Two-Year Screening Study"* (SWAMP, 2009). Inclusion of this listing is in accordance with the Listing Policy. The Los Angeles Area Lakes TMDL included dieldrin and reviewed dieldrin data from an organics study by UCLA. The dieldrin data included as the LOE in the CalWQA database is from a SWAMP study, "*Contaminants in Fish from California Lakes and Reservoirs: Technical Report on Year One of a Two-Year Screening Study"* (SWAMP, 2009). Inclusion of this listing is

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td></td><td>instead be listed as Category 3 based on the significant restoration efforts conducted since the last update to the 303(d) list. The USEPA 2010 Integrated Report Guidance uses the following definition for Category 3 listings:

“The existing and readily available data and information is not representative of current conditions of the water body. This rationale might include a determination that: significant land use changes have occurred in the watershed changing the hydrology and nonpoint source loadings; point source discharges were removed; new discharges are now operating; or the locations of sampling stations did not reflect the character of the segment (e.g., limited to locations near discharge outfalls).”

The extensive restoration projects have entirely changed not only the chemical and physical conditions of the lakes themselves, but have also completely transformed the nonpoint source loadings, and hydrology of the system. Any data collected prior to the restoration efforts (i.e., all of the data used for the current listings) are not representative of the current condition of the lakes; therefore, both of these waterbodies are excellent candidates for a Category 3 listing and should be categorized as such until enough data exists to establish their current condition. It is likely that as a result of both of these restoration efforts, the lakes could be entirely delisted. However, until that time, a Category 3 listing would represent the most conservative listing on the part of the Regional Board.

The City appreciates the time and effort that goes into maintaining the 303(d) list and notes that these award-winning restoration projects were facilitated in part by the Regional Board’s historical listing actions. The City hopes that the extensive resources put into restoring the beneficial use of these waterbodies can be recognized by assigning the proper Category 3 listing to Echo Park and Machado Lake pollutants.

<table><tr><th>Decision ID</th><th>Water Body Segment</th><th>Listing</th></tr><tr><td>34030</td><td>Echo Park Lake</td><td>Algae</td></tr><tr><td>34696</td><td>Echo Park Lake</td><td>Ammonia</td></tr></table></td><td>in accordance with the Listing Policy.

The data available supports listing chlordane and dieldrin for Echo Park Lake in Category 4a per the Listing Policy. A conclusion that new data would support delisting or even be significantly different from existing data is speculative. See response to comment 32.3 for a discussion of “readily available” data for this listing cycle.

Machado Park Lake:
The Machado Park Lake impairments due to Algae, Ammonia, Eutrophic Conditions and Odor are being addressed by the Machado Lake Nutrient TMDL. The Machado Lake impairments due to Chem A, DDT, Chlordane and Dieldrin are being addressed by the Machado Lake Toxics TMDL. The data available supports listing all these listings in Category 4a per the Listing Policy. A conclusion that new data would support delisting or even be significantly different from existing data (and a movement to Category 3) is speculative.

The inconsistences noted by the commenter for Echo Park Lake and Machado Lake in the 303(d) list have been addressed and all the listings are in category 4a.

The significant restoration efforts are expected to be reflected in new data collected after the restoration efforts and submitted to CEDEN to</td></tr>

	<table><tr><td>62679</td><td>Echo Park Lake</td><td>Chlordane</td></tr><tr><td>62680</td><td>Echo Park Lake</td><td>Dieldrin</td></tr><tr><td>34698</td><td>Echo Park Lake</td><td>Eutrophic</td></tr><tr><td>34756</td><td>Echo Park Lake</td><td>Odor</td></tr><tr><td>33999</td><td>Echo Park Lake</td><td>PCBs (Polychlorinated biphenyls)</td></tr><tr><td>44748</td><td>Echo Park Lake</td><td>pH</td></tr><tr><td>32435</td><td>Echo Park Lake</td><td>Trash</td></tr><tr><td>34305</td><td>Machado Lake (Harbor Park Lake)</td><td>Algae</td></tr><tr><td>42416</td><td>Machado Lake (Harbor Park Lake)</td><td>Ammonia</td></tr><tr><td>34362</td><td>Machado Lake (Harbor Park Lake)</td><td>ChemA (tissue)</td></tr><tr><td>42417</td><td>Machado Lake (Harbor Park Lake)</td><td>Eutrophic</td></tr><tr><td>42262</td><td>Machado Lake (Harbor Park Lake)</td><td>Odor</td></tr><tr><td>35181</td><td>Machado Lake (Harbor Park Lake)</td><td>Trash</td></tr></table> In reviewing the proposed listings for the 303(d) list for Echo Park and Machado Lakes a number of inconsistencies were noted. They have been identified below: • Echo Park Lake PCB (tissue) (Decision ID 33999) is listed as a new 4A listing in Appendix C, but the change is not noted in Appendix A. • Machado Lake Chlordane (tissue) (Decision ID 33013), Dieldrin (tissue) (Decision ID 33643), and PCBs (tissue) (Decision ID 33285) are not listed	support the next listing cycle for the Los Angeles Region. The Los Angeles Water Board looks forward to the review of that data.

No.	Comment	Response
	as changes in Appendix A, do not appear in Appendix B or C, but are listed in Appendix G. • Machado Lake DDT (tissue) (Decision ID 33211) is not listed as a change in Appendix A and does not appear in Appendix B or C, but is listed in Appendix G, although incorrectly, as requiring a TMDL despite the fact that DDT is covered by an existing TMDL. • Machado Lake algae, ammonia, ChemA (tissue), eutrophication, odor and trash are included in Appendix G Fact Sheets as already being addressed by a USEPA-approved TMDL, which is expected to result in attainment of the standard; however, they are all listed as Category 5B in Appendix B and as unchanged in Appendix A in the proposed 303(d) List. The Regional Board should clarify if these omissions and inconsistencies equate to a delisting of the pollutants. As explained above, the City supports the delisting of the pollutants due to the extensive restoration projects that have been completed. If, for some reason, these listing were omitted in error and the RWQCB disagrees with the City's comment to include them as Category 3, then all of the listings should, at a minimum, be included as Category 4A. Category 4A is defined as "*A TMDL has been developed and approved by USEPA and the approved implementation plan is expected to result in full attainment of the water quality standard within a specified time frame."* Category 4A is supported by the approved TMDLs covering Echo Lake Chlordane and PCB listings, as well as the Machado Lake Chlordane, DDT, Dieldrin, PCB, algae, ammonia, ChemA(tissue), eutrophication, odor, and trash listings. ***Requested Actions:*** ***(1) Move all segments listed in the preceding table to Category 3 based on the completion of extensive restoration projects, and include the following text to explain the category change: "Due to recent extensive restoration efforts, data from 2010 and prior is not representative of current conditions of the water body. Available data are insufficient to determine attainment status."***	

No.	Comment	Response
	(2) If Category 3 listing of suggested pollutants does not occur, ensure that all pollutants listed in the preceding table are correctly categorized as Category 4A based on the existence of USEPA approved TMDLs. ***(3) Correct and/or clarify inconsistent listings in Appendices for consistency throughout the entire proposed 303(d) document.***	
11.24	Various waterbodies / Benthic Community Effects Notwithstanding the City's comments related to removing all listings that do not identify either toxicity or a pollutant as the impairment, the City identified the following listings for Benthic Community Effects (summarized in the following table) that are inappropriate: • Ballona Creek: Decision ID 65656 • Dominguez Channel (lined portion above Vermont Ave): Decision ID 66165 • LA River Reach 3 (Figueroa St. to Riverside Dr.): Decision ID 66229 • LA River Reach 4 (Sepulveda Dr. to Sepulveda Dam): Decision ID 66232 • Arroyo Seco Reach 1 (LA River to West Holly Ave.): Decision ID 44553 • Arroyo Seco Reach 2 (West Holly Ave to Devils Gate Dam): Decision ID 65548 • Compton Creek: Decision ID 44498 The City believes the listings are inappropriate, based on the following issues that are described in more detail below: • <u>Impairment of the reaches was not demonstrated using an appropriate metric for benthic community condition.</u> The listing decisions were based on Southern California Coastal Index of Biotic Integrity (SCIBI). The State Water Board has rejected use of the SCIBI in favor of the California Stream Condition Index (CSCI). The Regional Board Staff Conclusions	Listings based on both the SCIBI and CSCI scores are consistent with State policy and have been assessed relative to appropriate reference sites. See response to comment 26.4 for a discussion of the appropriate metrics for benthic community condition. See response to comment 26.5 for a discussion of the established water quality criteria. Benthic Community Listings for waterbodies that are lined entirely with concrete have been assessed as "insufficient information" until such time as benthic community condition scores have been more specifically calibrated for concrete-lined channels. The **Ballona Creek** samples were taken from a fully concrete-lined section and now Ballona Creek benthic community condition has been assessed as "insufficient information". The **Dominguez Channel above Vermont** samples were taken from a fully concrete-lined section and now Dominguez Channel above Vermont benthic community condition has been assessed as "insufficient information".

No.	Comment	Response
	(Staff Conclusions) for the listing decisions do not acknowledge that the data used to support the decisions were SCIBI scores, not CSCI scores. Instead, the Staff Conclusions imply that the decisions are based on CSCI scores. • <u>There is no established water quality criteria for benthic community condition.</u> Use of a SCIBI score of 40 (or other "cutoffs" promulgated by the authors of the SCIBI) as a listing threshold is not consistent with the State Board's current approach for identifying impairment thresholds for benthic community data. The Regional Board use of a CSCI score of 0.79 in other listing decisions (and implied to be appropriate for Ballona Creek) is also not consistent with the State Board's current approach for identifying impairment thresholds for benthic community data. • <u>Listings for concrete-lined channels using current metrics are inappropriate.</u> Reference reaches for concrete-lined channels in highly urbanized catchments are lacking. Physical habitat conditions were apparently not considered during data evaluation. The State Board is planning to develop expectations for benthic community condition for developed landscapes using the CSCI and a new Algal Stream Condition Index (ASCI). TMDL development for benthic community effects in concrete-lined channels based on unofficial IBI thresholds is premature. • <u>Insufficient data are available to meet the listing requirements.</u> Notwithstanding the previous issues, several of the listings rely on a single site for data as a basis of the listing inconsistent with the Listing Policy.	**LA River Reach 3** samples were taken from a fully concrete-lined section and now LA River Reach 3 benthic community condition has been assessed as "insufficient information". Benthic Community Listings which were based on samples taken from un-lined sections of reaches were appropriately assessed. **Arroyo Seco Reach 1** was listed in 2010 for benthic macroinvertebrate assessment (2 out of 2 samples not meeting the standard) in an *unlined* section of the channel. The additional assessment added this listing cycle appears to be from a lined section of the Arroyo Seco and that LOE is classified as "insufficient information." **Compton Creek** was listed in 2010 for benthic macroinvertebrate assessment in an *unlined* section of Compton Creek. Additional assessments were added for this listing cycle also in the unlined section of Compton Creek. **Arroyo Seco Reach 2** is not fully lined; three out of three IBI scores from 2006, 2007 and 2008 exceeded the standard. The Benthic Macroinvertebrate data included in the CalWQA database for LA River Reach 4 should be associated with Reach 5. Additionally, this section is not fully-lined. Los Angeles Water Board staff's intention will be to correct the reach in the CalWQA database and make the appropriate listing/delisting decisions as the State Board staff prepare the Integrated Report and 303(d) list for State Board approval or prior to the next Listing Cycle that includes the Los Angeles Region.

No.	Comment	Response

Type of Decision	Segment / Station	Cited Benthic Community Data				
		Line of Evidence (LOE) ID	Data Source	Metric used in Data Source	Time Frame	Scores[a]
New Listing	Ballona Creek (Station 14)	82971	Bioassessment Monitoring Report in LA County, 2006-2008	SCIBI	2006, 07, 08	3/3 scores were below 40
New Listing	Dominguez Channel (Station 19)	83960		SCIBI	2006, 07, 08	3/3 scores were below 40
New Listing	LA River Reach 3 (Stations 11 and 12)	85994		SCIBI	2006, 07	4/4 scores were below 40
New Listing	LA River Reach 4 (Station 13)	86097		SCIBI	2006, 07	2/2 scores were below 40
Do Not Delist	Compton Creek (Station 8)	83829		SCIBI	2006, 07, 08	3/3 scores were below 40
		30224	LA County 1994-2005 Integrated Receiving Water Impacts Report. Section 5, LA River Watershed Management Area, pp 5.1 - 5.40	SCIBI	2003, 04	2/2 scores were "very poor"
Previous Listing	Arroyo Seco Reach 1 (Station LALT501)	30223		SCIBI	2003, 04	2/2 scores were below 13
		82895	Bioassessment Monitoring Report in LA County, 2006-2008	SCIBI	2008	1/1 score was below 40
New Listing	Arroyo Seco Reach (Station 7)	82896		SCIBI	2006, 07, 08	3/3 scores were below 40

[a] Per Staff Conclusions, SCIBI scores were binned as very good (80-56), good (41-55), fair (27-40), poor (14-26) and very poor (0-13) habitat conditions; sites with scores below 26 are considered to have impaired conditions.

Impairment of the reaches was not demonstrated using an appropriate metric for benthic community condition.

SCIBI-based datasets should not be considered for listing decisions. Section 3.9 of the Listing Policy states:

> *"A water segment shall be placed on the section 303(d) list if the water segment exhibits significant degradation in biological populations and/or communities* ***as compared to reference site(s)*** *and is associated with water or sediment concentrations of pollutants including, but not limited to chemical concentrations, temperature, dissolved oxygen, and trash." [Emphasis added.]*

While it is commonly assumed that the SCIBI inherently accounted for reference conditions, the reference conditions used to develop the SCIBI were not representative of the low-elevation/low-gradient streams commonly found in the alluvial plains of the Los Angeles Region. It was developed using data from 275 sites, ranging from Monterey County to the Mexican border, but not a single reference location represented low-elevation and low-gradient streams. The reaches listed in the table above are extremely low gradient, low-elevation water

Response:

There are sufficient data in the waterbody segments listed to be representative of the water body segment in accordance with the Listing Policy Section 6.1.5.2 and 6.1.5.3. When single stations were re-sampled, they were sampled on different years.

See response to comments 26.4, 26.13 and 26.14 for a discussion of low elevation segments and the benthic community scores.

No.	Comment	Response
	bodies, and thus the SCIBI does not adequately define relevant reference conditions. Furthermore, the reference conditions used in the SCIBI represent a less restrictive definition of the reference condition than that which was deemed adequate as part of the State's Reference Condition Management Program[15]. The lead scientist for development of the SCIBI, Dr. Peter Ode, has acknowledged the limitations on application of the SCIBI. In a recently published paper regarding a study examining the SCIBI relative to other benthic macroinvertebrate bioassessments, he concluded that the SCIBI did not adequately address reference conditions in low-elevation sites, stating that the SCIBI was "not completely effective at controlling for an elevation gradient." Dr. Ode was also the coauthor of a March 2009 report on recommendations for development and maintenance of a network of reference sites to support biological assessment of California's wadeable streams. This report describes recommendations made by a technical panel of experts on bioassessment, including experts from the California Department of Fish and Wildlife, Southern California Coastal Water Research Project (SCCWRP), US EPA Region 9, and various universities. The technical panel laid out a number of steps that would be necessary to develop a network of adequate reference sites for implementation of criteria for bioassessments. They note that adequate reference sites have not been identified in southern California, stating, "human-dominated landscapes can be so pervasive in locations such as urban southern California and the agriculturally dominated Central Valley that no undisturbed reference sites may currently exist in these regions. A statewide framework for consistent selection of reference sites must account for this complexity." In 2010, as part of its project to develop a statewide Biointegrity Policy, the State Board abandoned use of the SCIBI and other regional IBIs, and funded development of the statewide CSCI (Mazor et al., 2016). The CSCI addressed at least some of the problems with the SCIBI through its use of a modeled reference condition as opposed to a regional reference pool. Starting in late 2016, the State Board began funding the development of a "companion" Algal Stream Condition Index (ASCI). The State Board is developing expectations for benthic community condition using both the CSCI and the ASCI which will be incorporated in a statewide Biointegrity Assessment Implementation Plan.	

No.	Comment	Response
	The Staff Conclusions associated with the new listings in the preceding table do not acknowledge that the data used to support the new listings were SCIBI scores. Further, the Staff Conclusions for all of the new listings imply that Regional Board staff based the listing decision on CSCI scores. The source of the BMI data for each of the new listings, and the new LOE for Compton Creek, ("Bioassessment Monitoring Report in Los Angeles County, 2006-2008") were appendices (Appendix H) of the Los Angeles County Stormwater Monitoring Reports for 2006, 2007, and 2008. *In these reports, BMI data were scored using the SCIBI (Ode et al. 2005), not the CSCI*. In two cases (Ballona Creek and Arroyo Seco Reach 2), the Staff Conclusions explicitly, but erroneously, state that the underlying BMI data were CSCI scores. In the other cases, the ambiguous acronym "IBI" is used where scores are cited, and then the narrative ends with a passage implying that the "IBI" scores were CSCI scores. The misleading information in the Staff Conclusion for each new listing recommendation is provided below. • Ballona Creek: "Based on the readily available data and information, the weight of evidence indicates that there is sufficient justification in favor of placing Benthic Community Effects on the CWA section 303(d) List. .... "**3 of 3 samples were below the California Stream Condition Index (CSCI) score of 0.79**, indicating poor water quality and that pollutant concentration and toxic effects are impacting aquatic life in this waterbody segment" ... "**The CSCI** is available statewide, accounts for a much wider range of natural variability, and provides equivalent scoring thresholds in all regions of the state. **The CSCI** will be used in the future for water quality assessment purposes statewide over the regional indices of biologic integrity." (Regional Board Staff Conclusion for Decision ID 65656, emphasis added) • Dominguez Channel (lined portion above Vermont Ave.): "Three of the three samples collected had IBI scores below 40 there are several other pollutants in this water body that are listed for impairment including ammonia, copper, diazinon, nitrogen, toxicity, and zinc." ... "**The CSCI** is applicable statewide, accounts for a much wider range of natural variability, and provides equivalent scoring thresholds in all regions of the state. **The CSCI** will be used in the future for water quality assessment	

No.	Comment	Response
	purposes statewide over the regional indices of biologic integrity (IBIs).” (Regional Board Staff Conclusion for Decision ID 66165, emphasis added) • Los Angeles River Reach 3 (Figueroa St. to Riverside Dr.): “Four of the four samples collected had IBI scores below 40.” ... “**The CSCI** is applicable statewide, accounts for a much wider range of natural variability, and provides equivalent scoring thresholds in all regions of the state. **The CSCI** will be used in the future for water quality assessment purposes statewide over the regional indices of biologic integrity (IBIs).” (Regional Board Staff Conclusion for Decision ID 66299, emphasis added) • Los Angeles River Reach 4 (Sepulveda Dr. to Sepulveda Dam): “Both of the two samples collected had IBI scores below 40.... Two of the two samples collected had IBI scores below 40. ... “**The CSCI** is applicable statewide, accounts for a much wider range of natural variability, and provides equivalent scoring thresholds in all regions of the state. **The CSCI** will be used in the future for water quality assessment purposes statewide over the regional indices of biologic integrity (IBIs).” (Regional Board Staff Conclusion for Decision ID 66232, emphasis added) • Arroyo Seco Reach 2 (West Holly Ave to Devils Gate Dam): “3 of 3 samples exceeded the GUIDELINE... **3 of 3 samples were below the California Stream Condition Index (CSCI) score of 0.79**. ... “**The CSCI** is applicable statewide, accounts for a much wider range of natural variability, and provides equivalent scoring thresholds in all regions of the state. **The CSCI** will be used in the future for water quality assessment purposes statewide over the regional indices of biologic integrity (IBIs).” (Regional Board Staff Conclusion for Decision ID 65548, emphasis added) ***There is no established water quality criteria.*** Regional Board staff utilized a SCIBI score of 40 as a listing threshold. However, this value is not an established water quality criteria, nor does it represent the type of threshold the State Board intends to use to identify community condition or levels of impairment in its Biointegrity Assessment Implementation Plan. A SCIBI	

No.	Comment	Response
	score of 39 was originally promulgated by the authors of the SCIBI (Ode et al. 2005) as an "impairment threshold" because it was equal to an arbitrary statistical criterion (two standard deviations below the mean reference site score). Although it was not used for the listings in the table above, Regional Board staff have also used a CSCI score of 0.79 as a listing threshold for other reaches (see also the statement regarding this threshold in the Staff Conclusions excerpt for Ballona Creek above). However, a CSCI threshold of 0.79 is also based on an arbitrary statistical criterion (10th percentile of the reference calibration site scores; Mazor et al. 2016), and is not an adopted water quality criteria. The State Board is not pursuing use of arbitrary statistical cutoffs, such as reference population percentiles, to identify benthic community impairment going forward. As outlined in the November 2016 Work Plan, the State Board is using a Biological Condition Gradient Expert Synthesis approach to relate ranges of biological condition scores to community condition. Using this approach, a team of experts uses taxonomic metrics to assign degrees of biological condition to test sites while being blind to the degree of anthropogenic stressors present at the sites. In addition, the analysis is blind to the relationship between site scores and statistical distributions of overall datasets or reference datasets. **Listings for concrete-lined channels using currently available metrics are inappropriate.** Application of the SCIBI to concrete-lined channels is especially inappropriate given the lack of a reference population for low-gradient streams in coastal southern California, in general, much less for modified channels, in specific. Section 6.1.5.8 of the listing policy states: *"When evaluating biological data and information, RWQCBs shall evaluate all readily available data and information and shall evaluate bioassessment data from other sites, and compare to reference condition. Evaluate physical habitat data and other water quality data, when available, to support conclusions about the status of the water segment."* EPA's causal assessment manual cites physical habitat as a leading cause of impairment in streams on 303(d) lists and recommends that, in all cases where	

No.	Comment	Response
	physical habitat is evaluated, stream size and channel dimensions, channel gradient, channel substrate size and type, habitat complexity and cover, vegetation cover and structure, and channel-riparian interactions should all be considered before making a decision.[19] Physical habitat conditions are not referenced in the Lines of Evidence for the benthic community effects listings in the preceding table, although physical habitat data collection is a standard part of bioassessment monitoring and reporting. Ultimately, benthic community impairments in concrete-lined channels should be evaluated for potential listing in Category 4c of the 305(b) integrated report, instead of on the 303(d) list of segments requiring a TMDL. The USEPA Guidance for 2006 Assessment, Listing and Reporting Requirements Pursuant to Sections 303(d), 305(b) and 314 of the Clean Water Act (IRG) states: *"Circumstances where an impaired segment may be placed in Category 4c include segments impaired solely due to lack of adequate flow or to stream channelization."* As part of its statewide Biostimulatory-Biointegrity Project, in recognition that it may not be appropriate or productive to apply a single set of benthic community condition expectations to streams in pristine and developed landscapes, the State Board is currently employing SCCWRP and CDFW to developing expectations for benthic community condition for developed landscapes using the CSCI and the Algal Stream Condition Index (ASCI).[20] The probability that concrete-lined channels in highly urbanized settings will be candidates for alternative benthic community endpoints is illustrated by language from the Work Plan: *"**In some streams, direct channel modifications (e.g., bank armoring) may also limit opportunities to sustain high-quality ecological conditions for aquatic life**. In these highly developed settings, the large number of linked stressors may prevent a stream from supporting its beneficial uses or attaining high scores on indices of biological condition. **Often, these stressors are difficult to mitigate or remove under the traditional mechanisms available to the Water Boards**. In these circumstances, the range of CSCI and/or ASCI scores may be constrained, but targeted restoration could improve conditions. Key technical questions underpinning*	

No.	Comment	Response
	the range of options and prioritization of management actions for wadeable streams along the continuum from undeveloped to highly developed landscapes found within California are: For which streams is biological integrity constrained by development in the catchment? How can they be identified and mapped? What are the ranges of biological conditions these developed landscapes can support?" (Mazor et al. 2017; emphasis added) Triggering TMDL development for benthic community effects in concrete-lined channels using unofficial impairment thresholds derived from statistical distributions of IBIs from unarmored reference reaches is unwarranted. **Insufficient data are available to meet the listing requirements** Notwithstanding the previous issues, several of the listings rely on a single site for bioassessment data, which is inconsistent with the Listing Policy. Per section 3.9 (Degradation of Biological Populations and Communities) of the Listing Policy, "The analysis should rely on measurements from at least two stations." Only one site is referenced in the Fact Sheets for the following listing decisions: • Ballona Creek • Dominguez Channel (lined portion above Vermont Ave) • Los Angeles River Reach 4 (Sepulveda Dr. to Sepulveda Dam) [Also, note that the data associated with Los Angeles River Reach 4 was actually collected in Los Angeles River Reach 5.] • Arroyo Seco Reach 1 (LA River to West Holly Ave.) • Arroyo Seco Reach 2 (West Holly Ave to Devils Gate Dam) • Compton Creek Because data were only collected at one site within these waterbodies, the requirements of the Listing Policy are not met. ***Summary*** As described in detail above, the approach utilized to establish benthic community effects impairments are not demonstrated using an appropriate metric for benthic community condition. The listings rely on an unestablished water quality criteria based on metrics that are not appropriate for concrete-lined channels. Lastly, in all but one listing, there are not sufficient data to meet the listing requirements per the	

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td></td><td>Listing Policy as the data were only collected at a single site within a waterbody.

Requested Action: Remove the following Decision IDs from the 303(d) list:
Ballona Creek: Decision ID 65656
Dominguez Channel (lined portion above Vermont Ave): Decision ID 66165
LA River Reach 3 (Figueroa St. to Riverside Dr.): Decision ID 66229
LA River Reach 4 (Sepulveda Dr. to Sepulveda Dam): Decision ID 66232
Arroyo Seco Reach 1 (LA River to West Holly Ave.): Decision ID 44553
Arroyo Seco Reach 2 (West Holly Ave to Devils Gate Dam): Decision ID 65548
Compton Creek: Decision ID 44498</td><td></td></tr>
<tr><td>11.25</td><td>Los Angeles River Reach 3 (Figueroa St. to Riverside Dr.) / Temperature, water

The temperature listing for Los Angeles River Reach 3 uses an evaluation guideline of 13-21°C as the optimum growth range for rainbow trout. However, the beneficial use listed for Los Angeles River Reach 3 is WARM. Only the COLD beneficial use uses the rainbow trout growth range as a listing criteria. This guideline should be removed and the number of exceedances recalculated based on the Basin Plan criteria for WARM.

Notwithstanding that the evaluation guideline of 13-21°C is inappropriate for Los Angeles River Reach 3 given the water body’s beneficial uses, the manner in which the evaluation guideline is applied is also inappropriate. Line of Evidence (LOE) 85933 references Moyle 1976 as the source of the evaluation guideline. Moyle 1976 was revised and expanded by Moyle 2002. Moyle 2002 states: “Rainbows are found where daytime temperatures range from nearly 0°C in winter to 26-27°C in summer, although extremely low (<4°C) or extremely high (>23°C) temperatures can be lethal if the fish have not previously been gradually acclimated. Even when acclimation temperatures are high, temperatures of 24-27°C are invariably lethal to trout, except for very short exposures.” As such, while temperatures above 21°C may not be optimal according to Moyle 1976,</td><td>A review of the Los Angeles River Reach 3 temperature decision is in process at this time.</td></tr>
</table>

No.	Comment	Response
	Moyle 2002 clearly states that lethal temperatures are those greater than 23°C which indicates that the evaluation guideline of 21°C is more appropriately applied as a chronic guideline (necessitating the establishment of an averaging period) and 23°C is the more appropriate "not-to-exceed" guideline as used in the proposed listing. When utilizing 23°C, only 40 of the 542 samples exceed the guideline, which does not meet the *Water Quality Control Policy for Developing California's Clean Water Act Section 303(d) List* (Listing Policy) minimum number of measured exceedances needed to place a water segment on the Section 303(d) list for conventional or other pollutants (a minimum of 90 exceedances would be required). As such, even if the Los Angeles River Reach 3 was designated with a COLD beneficial use, applying the appropriate "not-to-exceed" guideline of 23°C results in a finding of nonimpairment for temperature in Los Angeles River Reach 3. Lastly, notwithstanding that the evaluation guideline of 13-21°C is inappropriate for Los Angeles River Reach 3 given the water body's beneficial uses and that 23°C is the more appropriate "not-to-exceed" guideline, when the average water temperature across Los Angeles River Reach 3 was above 21°C (69.8°F), with only one exception out of 33, the air temperature was also above 21°C (69.8°F). As such, ambient air temperature above 21°C is most likely cause of exceedances of the 21°C evaluation guideline. ***Requested Action: Revise Decision ID 64386 for the temperature water listing for Los Angeles River Reach 3 to Do Not List on 303(d) list and remove from Category 5 (Appendix B) because the beneficial use protected by the evaluation guideline is not an existing or potential beneficial use within Los Angeles River Reach 3; the number of measured exceedances does not meet the minimum number of measured exceedances needed to place a water segment on the Section 303(d) list for conventional or other pollutants if an appropriate evaluation guideline is applied; and ambient air temperature is the most likely cause of exceedances of the evaluation guideline.***	
11.26	Los Angeles River Reach 3 (Figueroa St. to Riverside Dr.), Los Angeles River Reach 5 (within Sepulveda Basin), Bull Creek, Wildlife Lake, and Balboa Lake / Ammonia	Los Angeles River Reach 3 includes three LOEs (85894, 86019, and 2507); 85894 and 86019 were grouped to make the assessment that there were 33

Response to Comments on the Draft 2016 303(d) List
Comment Deadline: March 30, 2017

No.	Comment	Response
	The Fact Sheet for Decision ID 32974 corresponds to the ammonia listing for Los Angeles River Reach 3 (Figueroa St. to Riverside Dr.) and states that two lines of evidence are available in the administrative record to assess the pollutant, although there are three lines of evidence present (85894, 86019, and 2507). LOE 2507 is a placeholder to support a 303(d) listing decision made prior to 2006. LOEs 85894 and 86019 each state that all of the exceedances in each dataset occurred prior to and in 2007. The City found that the last exceedance was July 2007, which is to be expected given that 2007 was the year that the nitrification/denitrification (NDN) treatment process as completed at both the Los Angeles-Glendale Water Reclamation Plant (LAGWRP) and Donald C. Tillman Water Reclamation Plant (DCTWRP). Both the LAGWRP and DCTWRP discharges travel through Los Angeles River Reach 3, and since the NDN processes to remove ammonia were completed in July 2007, no exceedances in this waterbody have been observed. The Fact Sheet for Decision ID 32567 corresponds to the ammonia listing for Los Angeles River Reach 5 (within Sepulveda Basin) and states that two lines of evidence are available in the administrative record to assess the pollutant, although there are three lines of evidence present (86205, 86204, and 2520). LOE 2520 is a placeholder to support a 303(d) listing decision made prior to 2006. LOEs 86205 and 86204 each state that all of the exceedances in each dataset occurred prior to March and August 2007, respectively. The DCTWRP discharge flows through part of Reach 5 and the NDN processes to remove ammonia were completed in 2007. The Fact Sheet for Decision ID 60597 corresponds to the ammonia listing for Bull Creek and states that two lines of evidence are available in the administrative record to assess the pollutant (83158 and 83154). LOE 83154 presents one data point collected in May 2008 that does not show an exceedance. LOE 83158 states that all of the exceedances occurred prior to August 2007. The DCTWRP discharge flows through Bull Creek and the NDN processes to remove ammonia were completed in 2007. The Fact Sheet for Decision ID 66374 corresponds to the ammonia listing for Wildlife Lake and states that one line of evidence is available in the administrative record to assess the pollutant (90174). LOE 90174 states that all of the exceedances occurred prior to August 2007. The DCTWRP discharge flows	exceedances out of 111 samples total. Los Angeles River Reach 3 and Los Angeles River Reach 5 are being addressed by the Los Angeles River Nutrient TMDL. Bull Creek, Wildlife Lake, and Balboa Lake have been updated in the CalWQA database to reflect that they are being addressed by the Los Angeles River Nutrient TMDL. Los Angeles River Reach 4 is meeting the criteria based on the available data. Data collected after the NDN processes were put in place may show that the water quality in these reaches has improved; this update to the 303(d) list is only considering data submitted by August 30, 2010. For a discussion of readily available data see response to comment 32.3. Los Angeles Water Board staff encourages the commenter to enter all the relevant data into CEDEN in preparation for the next listing cycle that includes the Los Angeles Region.

No.	Comment	Response
	through Wildlife Lake and the NDN processes to remove ammonia were completed in 2007. The Fact Sheet for Decision ID 60378 corresponds to the ammonia listing for Balboa Lake and states that one line of evidence is available in the administrative record to assess the pollutant (82930). LOE 82930 states that all of the exceedances occurred prior to August 2007. The DCTWRP discharge flows through Balboa Lake and the NDN processes to remove ammonia were completed in 2007. Furthermore, the Fact Sheet for Decision ID 32913 corresponds to the ammonia listing for Los Angeles River Reach 4 (Sepulveda Dr. to Sepulveda Dam) and includes the decision to Delist from 303(d) list (being addressed by USEPA approved TMDL) based on the following Regional Board Staff Decision Recommendation: “RWQCB staff concludes that the water body-pollutant combination should be removed from the section 303(d) list because applicable water quality standards for the pollutant are not being exceeded.” This decision is based on two LOEs (2513 and 86136). LOE 2513 states “A TMDL and implementation plan have been approved for this water segment-pollutant combination. The Los Angeles River Nitrogen TMDL was approved by RWQCB on August 19, 2003 and subsequently approved by USEPA on March 18, 2004.” LOE 86136 finds that 0 of 152 samples exceeded the site-specific basin plan objective for total ammonia as nitrogen and only includes samples collected from 2008 to 2010 (which is after the date when the WRPs added the NDN treatment process and is inconsistent with the dates used in the assessments conducted for Los Angeles River Reaches 3 and 5, Bull Creek, and Wildlife Lake). Through the installation and implementation of NDN treatment facilities and process optimization by the City of Los Angeles (and City of Burbank), which has spent approximately $75 million to construct advanced treatment facilities to address ammonia, and approximately $6 million per year to operate those facilities, the quality of the water in the Los Angeles River watershed has been demonstrated to be fully attaining the applicable water quality objectives for ammonia. The message from the City and the Regional Board should be that the cooperative process worked, and that the applicable water quality standards are now being attained. Instead, the 303(d) list does not reflect the water quality	

No.	Comment	Response
	improvement. Given that the addition of the NDN treatment process to the WRPs has eliminated exceedances, the timeframe used to evaluate impairments due to ammonia should be made consistent with the timeframe used in Los Angeles River Reach 4 which would result in the same listing decision for each water body (i.e., Delist from 303(d) list [being addressed by USEPA approved TMDL]). ***Requested Action: Revise the following Decision IDs to a finding of nonimpairment and remove listings for ammonia from Category 5 (Appendix B) because the data used to conclude that the applicable water quality standards for the pollutant were exceeded are no longer representative of ammonia concentrations observed within the water bodies due to the installation and operation of NDN:*** - ***Los Angeles River Reach 3 Decision ID 32947*** - ***Los Angeles River Reach 5 Decision ID 32567*** - ***Bull Creek Decision ID 60597*** - ***Wildlife Lake Decision ID 66374*** - ***Balboa Lake Decision ID 60378*** -	
11.27	Los Angeles River Reach 1 (Estuary to Carson Street) and Los Angeles River Reach 2 (Carson to Figueroa Street) / Ammonia The Fact Sheet for Decision ID 32973 corresponds to the ammonia listing for Los Angeles River Reach 1 (Estuary to Carson Street) and is based on one LOE (2319), which does not contain any data. As such, the decision previously approved by the State Water Resources Control Board and the USEPA has not changed. The Fact Sheet for Decision ID 32911 corresponds to the ammonia listing for Los Angeles River Reach 2 (Carson to Figueroa Street) and is based on one LOE (2465) which does not contain any data. As such, the decision previously approved by the State Water Resources Control Board and the USEPA has not changed. In light of the information presented in the previous comment, it can be expected that conditions in Los Angeles River Reaches 1 and 2 since NDN was fully	Each of those LOEs are “placeholder” LOEs to show a finding of impairment made prior to 2006. The CalWQA database does not include data from decisions made prior to 2006. There is no additional data in the CalWQA database that would support delisting. Los Angeles Water Board staff encourages the commenter to enter into CEDEN the ammonia data analyzed as part of the Upper Los Angeles River (ULAR) Enhanced Watershed Management Program (EWMP) development prior to the next Listing Cycle that includes the Los Angeles Region.

No.	Comment	Response
	implemented (mid-2007) are consistent with what has been observed in Los Angeles River Reaches 3, 4, and 5 (i.e., no exceedances). A review of the ammonia data analyzed as part of the Upper Los Angeles River (ULAR) Enhanced Watershed Management Program (EWMP) do not show any exceedances. ***Requested Action: Revise the following Decision IDs to a finding of nonimpairment and remove listings for ammonia from Category 5 (Appendix B) because the data used to conclude that the applicable water quality standards for the pollutant were exceeded are no longer representative of ammonia concentrations observed within the water bodies due to the installation and operation of NDN:*** - ***Los Angeles River Reach 1 Decision ID 32973*** - ***Los Angeles River Reach 2 Decision ID 3291*** -	
11.28	Tujunga Wash (LA River to Hansen Dam) / Ammonia The Fact Sheet for Decision ID 32873 corresponds to the ammonia listing for Tujunga Wash (LA River to Hansen Dam) and is based on one LOE (2554) which does not contain any data. Rather, the Fact Sheet states that “One line of evidence is available in the administrative record to assess this pollutant. A TMDL has been developed and approved by USEPA and an approved implementation plan is expected to result in attainment of the standard. The Los Angeles River Nitrogen TMDL was approved by RWQCB on August 19, 2003 and subsequently approved by USEPA on March 18, 2004. This listing will substitute for the previous listings for foam, floc, scum, and taste and odor.” As there are no data to support the listing, the ammonia listing for Tujunga Wash should be removed. Also, substituting the listing for foam, scum, and taste and odor is not necessary because the Regional Board removed those listings from the section 303(d) list because they are not pollutants or toxicity. ***Requested Action: Revise Decision ID 32873 for the ammonia listing for Tujunga Wash to Delist from 303(d) list and remove from Category 5 (Appendix B).***	This LOEs is a “placeholder” LOE to show a finding of impairment made prior to 2006. The CalWQA database does not include data from decisions made prior to 2006. There is no additional data in the CalWQA database that would support delisting. The listings for foam, scum, and taste and odor were removed even though they showed impairment of beneficial uses because the listing for ammonia could “substitute” or stand in for those non-pollutant impairments and the Los Angeles River Nitrogen TMDL addresses those impairments.

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td>11.29</td><td>Bull Creek, Los Angeles River Reach 3 (Figueroa St. to Riverside Dr.), Los Angeles River Reach 4 (Sepulveda Dr. to Sepulveda Dam), Los Angeles River Reach 5 (within Sepulveda Basin), Los Angeles River Reach 6 (Above Sepulveda Flood Control Basin), and Los Angeles/Long Beach Outer Harbor (inside breakwater) / Toxicity

The Fact Sheets for the following Decision IDs relate to toxicity in the water column:
- Decision ID 39159 Bull Creek
- Decision ID 64389 Los Angeles River Reach 3 (Figueroa St. to Riverside Dr.)
- Decision ID 64465 Los Angeles River Reach 4 (Sepulveda Dr. to Sepulveda Dam)
- Decision ID 64489 Los Angeles River Reach 5 (within Sepulveda Basin)
- Decision ID 64536 Los Angeles River Reach 6 (Above Sepulveda Flood Control Basin)
- Decision ID 33930 Los Angeles/Long Beach Outer Harbor (inside breakwater)

The City has several concerns with the proposed listings:

1. Section 6.1.5.3 of the Listing Policy states that “Samples used in the assessment must be temporally independent.” However, data collected on the same day within the same waterbody are considered as independent samples without consideration of the fact they represent the same condition. These samples should be evaluated as representative of a single day.
2. In developing the number of samples analyzed and exceeded, the Regional Board appears to count a sample collected as one sample, but count acute and chronic results separately. In certain situations the result is two exceedances for the same sample. However, the Regional Board does not consider it conversely when there are no exceedances of acute or chronic</td><td>Decision ID 39159 Bull Creek is DO NOT LIST for toxicity because Bull Creek is meeting the criteria based on the available data. Bull Creek, the waterbody, is on the list under 4a due to the indicator bacteria listing, which is being addressed by a TMDL.

Decision ID 64389 Los Angeles River Reach 3 (Figueroa St. to Riverside Dr.) is a decision to LIST for toxicity with 29 out of 75 samples exceeding.

Decision ID 64465 Los Angeles River Reach 4 (Sepulveda Dr. to Sepulveda Dam) is a decision to LIST for toxicity with 21 out of 48 samples exceeding.

Decision ID 64489 Los Angeles River Reach 5 (within Sepulveda Basin) is a decision to LIST for toxicity with 21 out of 53 samples exceeding.

Decision ID 64536 Los Angeles River Reach 6 (Above Sepulveda Flood Control Basin) is a decision to LIST for toxicity with 13 out of 19 samples exceeding.

Decision ID 33930 Los Angeles/Long Beach Outer Harbor (inside breakwater) is a decision to LIST for toxicity with two LOEs, 9 out of 37 and 32 out of 112 samples exceeding.

1. It is in accordance with the Listing Policy to collect samples on the same day if the samples are from different locations although the Listing</td></tr>
</table>

No.	Comment	Response
	end points there is only one sample that is identified as not exceeded. One sample should result in only one nonexceedance or one exceedance. 3. For Decision IDs associated with the Los Angeles River watershed, data are included that do not represent current conditions. As described previously, the LAGWRP and DCTWRP upgraded their treatment processes to remove ammonia. Since the NDN processes to remove ammonia were completed, no exceedances for ammonia have been observed since August 2007. All toxicity data prior to August 2007 should be removed from the analysis. 4. A number of the results are based on testing with *Ceriodaphnia dubia* (*C. dubia*). As discussed in the Stormwater Monitoring Coalition: Toxicity Testing Laboratory Guidance Document (SCCWRP Technical Report 956 December 2016), the report states (page 18) that during the intercalibration study, multiple laboratories observed *C. dubia* toxicity in laboratory dilution water (which should be non-toxic). Additionally, the report (page 16) found testing variability observed during the intercalibration study for *C. dubia* which had a response that ranged from 16 to 27% effect, and a standard deviation of 19 to 27% effect. The report further indicated that this large variability is not uncharacteristic of the variability observed by others. 5. Toxicity testing results were developed with a statistical approach that is no longer utilized in the NPDES monitoring programs. The LAGWRP, DCTWRP, HWRP and TIWRP NPDES permits require that toxicity endpoints be calculated using the Test of Significant Toxicity (TST) statistical approach. Future data will not be comparable to the listing data. As such, data used for listings should be assessed in a manner consistent with current regulations prior to making a determination of impairment. Given the issues associated with the data analysis and testing methods used as well as the implications of the listings, the City believes that additional efforts are needed to validate and assess whether or not an impairment exists. The City welcomes the opportunity to discuss an approach to properly evaluate toxicity in the affected waterbodies.	Policy does require consideration if the samples represent an unusual condition (see Listing Policy 6.1.5.3 "*If the majority of the samples were collected on a single day or during a short-term natural event (e.g. a storm, flood, or wildfire), the data should not be used as the primary data set*.") These samples were collected over several years. 2. The commenter states: *In certain situations the result is two exceedances for the same sample. However, the Regional Board does not consider it conversely when there are no exceedances of acute or chronic end points there is only one sample that is identified as not exceeded.* Los Angeles Water Board staff do not find where this happened. 3. See response to comment 32.6, and for a discussion of readily available data see response to comment 32.3. 4. See response to comment 17.3 5. Future data using the different method will be considered in separate LOEs. Water Board staff are open to discussions on approaches to properly evaluate toxicity in the affected waterbodies in order to ensure the most appropriate data is entered into CEDEN prior to the next Listing Cycle that includes the Los Angeles Region.

Response to Comments on the Draft 2016 303(d) List
Comment Deadline: March 30, 2017

No.	Comment	Response
	Requested Action: Revise Decision IDs 39159, 64389, 64465, 64489, 64536, and 33930 for toxicity listings from Category 5 to Category 3.	
12.	City of Manhattan Beach, March 30, 2017	
12.1	The City of Manhattan Beach is gratified that its beaches meet the criteria for delisting for indicator bacteria. However, the staff report states that even though the delisting is being proposed, "it is important to note that the Santa Monica Bay Bacteria TMDL remains in effect for those beaches even if the delistings are fully approved." Appendix A indicated that the beach will be removed entirely from listing rather than changing the status to *Category 4a - TMDL has been developed and the approved implementation plan is expected to result in full attainment of the water quality standard within a specified time frame.* The City is concerned that delisting during all weather conditions may adversely affect our ability to compete for grant funding for multi-benefit regional and green street projects identified in the Beach Cities EWMP to address the Santa Monica Bay Beaches Bacteria TMDL (SMBBB TMDL) during wet weather within the high priority 28th Street Storm Drain System. Since the SMBBB TMDL targets are set differently for wet and dry weather, it would seem logical for the Regional Board to distinguish these conditions in the 303d listing and we ask that the Board revise the proposed delisting Manhattan Beach for indicator bacteria to be specific to dry weather since final compliance is now in effect and the TMDL objectives are being met for dry weather at all three sites, and that the beach at the SMB 5-2 28th Street monitoring location remain on the list in Category 4a for wet weather conditions. This will enable the City to be more competitive when applying for grant funding to complete its implementation of the wet weather SMBBB TMDL. The Regional Board Notice of Extension of Comment Deadline notes that Regional Board staff are aware that "in several instances, Appendix A, the Proposed Updates to the 303(d) List has not fully captured all of the new listing and delisting decisions that are detailed in Appendix G, the Fact Sheets due to system and clerical errors". This has made review of the proposed listing changes quite challenging but we have done our best given the limited time available. The City of Manhattan Beach respectfully provides the attached comments on the proposed revisions to the 2016 Section 303(d) and 305(b) Integrated Report.	The beach meets the requirements for delisting per the Listing Policy. No provision of the Listing Policy allows for decisions to "list" or to "do not delist" based on funding considerations. However, as noted, the TMDL and the requirements of the TMDL contained in the Los Angeles County MS4 Permit remain in effect. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.

No.	Comment	Response
12.2	City of Manhattan Beach Comments on Proposed Revisions to 303(d) List **Water Body/Pollutant: Manhattan Beach/Indicator Bacteria** **Comment**: The staff report states that even though Manhattan Beach is being proposed for delisting for indicator bacteria, the Santa Monica Bay Bacteria TMDL remains in effect. Likewise, Appendix A indicated that the beach will be removed entirely from listing rather than changing the status to Category 4a (A TMDL has been developed and the approved implementation plan is expected to result in full attainment of the water quality standard within a specified time frame.) The City is concerned that delisting may adversely impact our ability to compete for grant funding for multi-benefit regional and green street projects to address the Santa Monica Bay Beaches Bacteria TMDL during wet weather. **Recommendation**: Consider delisting of Manhattan Beach for indicator bacteria only during dry weather since final compliance is now in effect and the TMDL objectives are being met for dry weather at all three sites, and that the SMB 5-2 28th Street beach remain on the list in Category 4a Street beach remain on the list in Category 4a Manhattan Beach for wet weather indicator bacteria should be considered once the final wet weather SMBBB TMDL compliance deadline has passed.	See response to comment 12.1.
12.3	**Santa Monica Bay Offshore - Nearshore/Arsenic and Mercury** **Comment**: Santa Monica Bay Offshore-Nearshore areas are being proposed for listing for Arsenic and Mercury based on sampling conducted for the City of Los Angeles Hyperion Wastewater Treatment Plant NPDES Permit. Samples were collected during August 2006, October and November 2007, and August through September of 2007. This data predates the last listing cycle and no data collected within the past decade is presented to support the listing. The SWRCB Listing Policy Section 1.1.2.1 states that “data and information previously submitted to the Regional Water Boards, such as Discharge Monitoring Reports, need not be solicited if the data and information remain available to the	See response to comment 32.3 for a discussion of readily available data. See also response to comments 11.21 and 11.22.

No.	Comment	Response
	Regional Boards." **Recommendation**: Before making such important new listings Regional Board staff should review all readily available data including data collected within the past decade from the Hyperion Wastewater Treatment Plant NPDES Permit.	
12.4	**Santa Monica Bay Offshore - Nearshore/ Sediment Toxicity** **Comment**: On March 26, 2012 USEPA issued a final TMDL for Santa Monica Bay DDT and PCBs which found that "Our evaluation of the data showed only 3 out of 116 samples exhibited toxicity. Following the California listing policy, Santa Monica Bay is meeting the toxicity objective and there is sufficient evidence to delist sediment toxicity. We therefore make a finding that there is no significant toxicity in Santa Monica Bay and recommend that Santa Monica Bay not be identified as impaired by toxicity in the California's next 303(d) list." Contrary to this recommendation the Regional Board has not proposed delisting sediment in Santa Monica Bay for toxicity. **Recommendation**: Appendix G Decision ID 34120 should be revised to delist Santa Monica Bay for sediment toxicity based on the review and recommendation by USEPA in developing the Santa Monica Bay DDT and PCBs TMDL. Appendix A should be revised to place a "Y" in the New Delistings column and the "Y" eliminated from the Pollutant Name Change column since there does not appear to be any name change being proposed.	The 303(d) list and the factsheet has been updated to "DELIST."
12.5	**Santa Monica Bay Offshore - Nearshore/ DDT and PCBs** **Comment**: The listing for Santa Monica Bay Offshore- Nearshore/DDT and PCBs is included in Attachment B Category 5 (a water segment where standards are not met and a TMDL is required but not yet completed) however this listing is being addressed by the USEPA developed and approved TMDL. This change is explained in Attachment A summary under "other revisions".	The 303(d) list has been updated to show the listing is "being addressed by a TMDL."

No.	Comment	Response
	Recommendation: The listings for DDT and PCBs should be moved to Category 4a in Attachment C.	
12.6	**Santa Monica Bay Offshore - Nearshore/ Chlordane** **Comment**: The revised Appendix G Fact Sheet associated with Decision ID 37492 recommending delisting Santa Monica Bay Offshore-Nearshore waters for chlordane is not reflected in the Appendix A summary of recommended changes. **Recommendation**: Revise Attachment A to place a "Y" in the New Delisting column for Santa Monica Bay Offshore/Nearshore line for Chlordane.	Los Angles Water Board staff has found several inconsistencies with Appendix A as released for public comment. Appendix G is correct and Appendix A has been revised.
12.7	**Santa Monica Bay Offshore - Nearshore/ Polycyclic Aromatic Hydrocarbons (PAHs)** **Comment**: The revised Appendix G Fact Sheet associated with Decision ID 32656 recommending delisting Santa Monica Bay Offshore-Nearshore waters for PAHs is not reflected in the Appendix A summary of recommended changes. **Recommendation**: Revise Attachment A to place a "Y" in the New Delisting column for Santa Monica Bay Offshore/Nearshore line for PAHs.	Los Angles Water Board staff has found several inconsistencies with Appendix A as released for public comment. Appendix G is correct and Appendix A has been revised.
12.8	**Dominguez Channel (lined portion above Vermont)/Benthic Community Effects** **Comment**: Appendix G Decision ID 66165 is proposing to list the Dominguez Channel concrete-lined section above Vermont Avenue due to degradation of biological populations and communities (Benthic Community Effects) as evidenced by IBI scores below 40, however use of IBI scoring methodologies does not provide a reference that takes into account that concrete lined channels do not typically provide benthic habitat that will support biological populations and communities. The listing policy states that to make this determination the water body must "exhibit significant degradation in biological populations and/or communities <u>as compared to reference sites</u>" .... "This condition requires diminished numbers of species or individuals of a single species or other metrics	See response to comment 11.19 and 11.24 for Benthic Macroinvertebrate listings.

No.	Comment	Response
	<u>when compared to reference sites</u>." Additionally the listing policy states that "The analysis should rely on measurements from at least two stations." Whereas the data presented to support Decision ID 66165 came from a single station. **Recommendation**: Do not list Dominguez Channel lined portion above Vermont for Benthic Community Effects because the analysis is not supported by data consistent with the SWRCB listing policy.	
12.9	**Dominguez Channel (lined portion above Vermont)/Lead** **Comment**: The quality of the data set used to support the original listing does not meet the data quality standards of the SWRCB's listing policy. The listing policy states that "when the sample value is less than the quantitation limit and the quantitation limit is greater than the water quality standard, objective, criterion, or evaluation guideline, the result shall not be used in the analysis." This listing was based on a data set more than a decade old with no actual detections of lead but where exceedances were presumed to have potentially occurred because the quantitation limit of 5 ug/L was not in all instances sufficiently low to determine compliance with the CTR dissolved lead criterion for continuous concentration in water (where the CTR value ranged from 0.23 to 7.27 ug/L, depending on the associated hardness of the water sample). The data set reviewed was for samples collected between January 2002 and April 2007 at the LACFCD Mass Emission Station S28 where Artesia Boulevard crosses Dominguez Channel and between 2000 and 2001 at S23 near LAX. Lead was not apparently detected in any of the samples above the quantitation limits, rather the identified exceedances of the lead standard were nondetections where the positive quantification limits 5 ug/L were too high to determine compliance with the standard when hardness caused depression of the standard below 5 ug/L. No measured exceedances of the standard were observed in the data set which is more than a decade old and for which more recent data sets exist. **Recommendation**: Decision Recommendation ID 37347 should be revised to state that the water body should be delisted due to inadequate data and because the data reviewed did not demonstrate that applicable water quality standards are	A review of the Dominguez Channel (lined portion above Vermont) lead decision is in process at this time.

No.	Comment	Response
	being exceeded. Alternatively, Regional Board staff could review the more recent readily available data collected at these same Mass Emission stations as part of the LA County MS4 NPDES Permit monitoring program Cl 6948 NPDES No. CAS004001 and the listing decision revised based on data of quality consistent with the SWRCB's listing policy.	
12.10	**Dominguez Channel (lined portion above Vermont)/ Copper and Zinc** **Comment**: Are listed in Appendix B as Category 5 needing a TMDL, when the Dominguez Channel Toxics TMDL is in affect and is addressing these pollutants. **Recommendation**: Recategorize Copper and Zinc as Category 4a being addressed by a TMDL and move to Appendix C.	The 303(d) list has been updated to show that copper and zinc are "being addressed by a TMDL."
12.11	**Dominguez Channel (lined portion above Vermont)/ Diazinon** **Comment**: We are supportive of the proposed delisting for Diazinon. **Recommendation**: Consider eliminating the statement in Attachment A under Other Revisions which states "TMDL status changed from TMDL still required to Being Addressed by Completed TMDL" since this pollutant is being proposed for delisting.	Appendix A wording is automatically generated by the CalWQA database. We are exploring ways to better display this data.
12.12	**Dominguez Channel (lined portion above Vermont)/ Nitrogen, ammonia (Total Ammonia)** **Comment**: The Appendix G Fact Sheet Decision ID 35134 continues to support a listing for ammonia. This listing does not appear to be based on all readily available data since Los Angeles County Mass Emissions Station Data on the Dominguez Channel is not included in the data set. Monitoring data from 55 samples collected between November 2006 and July 2013 at LACFCD mass emission station S28 located where the Dominguez Channel crosses Artesia Boulevard in the City of Torrance, show that all 55 samples met the freshwater Basin Plan objective for ammonia. An additional 24 samples collected at	See response to comment 32.3 for a discussion of readily available data.

No.	Comment	Response
	LACFCD mass emission station TS19 between November 2008 and April 2011 also met the freshwater Basin Plan objective in every instance. These data were readily available to Regional Board staff since they were reported as part of the LA County MS4 NPDES Permit monitoring program Cl 6948 NPDES No. CAS004001. **Recommendation**: Delist Dominguez Channel lined portion above Vermont for ammonia and include readily available data reported as part of the LA County MS4 NPDES Permit monitoring program Cl 6948 NPDES No. CAS004001 into Decision ID 35134 to support this delisting.	
12.13	**Dominguez Channel (lined portion above Vermont)/ Aldrin** **Comment**: Appendix G Fact Sheet Decision ID 34620 for Aldrin recommends delisting due to flaws in the original listing. **Recommendation**: Attachment A should be updated for Dominguez Channel lined portion above Vermont Avenue to include a "Y" in New Delistings column for Aldrin.	Aldrin was delisted in 2010. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
12.14	**Dominguez Channel (lined portion above Vermont)/ ChemA** **Comment**: Appendix G Fact Sheet Decision ID 34426 for ChemA recommends delisting due to flaws in the original listing because the data used for the original listing was not from this water body. **Recommendation**: Attachment A should be updated for Dominguez Channel lined portion above Vermont Avenue to include a "Y" in New Delistings column for ChemA.	ChemA was delisted in 2010. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
12.15	**Dominguez Channel (lined portion above Vermont)/ Chlordane** **Comment**: Appendix G Fact Sheet Decision ID 34427 for Chlordane recommends	Chlordane was delisted in 2010. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes

No.	Comment	Response
	delisting due to flaws in the original listing because the data used for the original listing was not from this water body. **Recommendation**: Attachment A should be updated for Dominguez Channel lined portion above Vermont Avenue to include a "Y" in New Delistings column for Chlordane.	and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
12.16	**Dominguez Channel (lined portion above Vermont)/ Chromium** **Comment**: Appendix G Fact Sheet Decision ID 34430 for Chromium recommends delisting due to flaws in the original listing because the data used for the original listing was not from this water body. **Recommendation**: Attachment A should be updated for Dominguez Channel lined portion above Vermont Avenue to include a "Y" in New Delistings column for Chromium and remove the "Y" from the Pollutant Name Change column.	Chromium was delisted in 2010. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
12.17	**Dominguez Channel (lined portion above Vermont)/ DDT** **Comment**: Appendix G Fact Sheet Decision ID 36720 for DDT recommends delisting due to flaws in the original listing because the data used for the original listing was not from this water body. **Recommendation**: Attachment A should be updated for Dominguez Channel lined portion above Vermont Avenue to include a "Y" in New Delistings column for DDT.	DDT was delisted in 2010. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
12.18	**Dominguez Channel (lined portion above Vermont)/ Dieldrin** Comment: Appendix G Fact Sheet Decision ID 42330 for Dieldrin recommends delisting due to flaws in the original listing because the data used for the original listing was from fish tissue collected in the soft-bottom estuary below Vermont and was incorrectly applied to the lined portion of Dominguez Channel above Vermont.	Dieldrin was delisted in 2010. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.

No.	Comment	Response
	Recommendation: Attachment A should be updated for Dominguez Channel lined portion above Vermont Avenue to include a "Y" in New Delistings column for Dieldrin and remove the "Y" from the Pollutant Name Change column.	
12.19	**Dominguez Channel (lined portion above Vermont)/ Polycyclic Aromatic Hydrocarbons (PAHs)** **Comment**: Appendix G Fact Sheet Decision ID 34431 for PAHs recommends delisting due to flaws in the original listing because the data used for the original listing was not from this water body. **Recommendation**: Attachment A should be updated for Dominguez Channel lined portion above Vermont Avenue to include a "Y" in New Delistings column for PAHs.	PAHs was delisted in 2010. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a “Y” or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
12.20	**Dominguez Channel (lined portion above Vermont)/ Polychlorinated Biphenyls (PCBs)** **Comment**: Appendix G Fact Sheet Decision ID 34429 for PCBs recommends delisting due to flaws in the original listing because the data used for the original listing was not from this water body. **Recommendation**: Attachment A should be updated for Dominguez Channel lined portion above Vermont Avenue to include a "Y" in New Delistings column for PCBs.	PCBs was delisted in 2010. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a “Y” or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
13.	City of Palos Verdes Estates, March 30, 2017	
13.1	Please see the City of Palos Verdes Estates’ specific comments on the proposed revisions to the 2016 Section 303(d) and 305(b) Integrated Report, included herewith as Attachment A. Appendix A – City of Palos Verdes Estates Comments on Proposed Revisions to 303(d) List	See response to comment 2.13.

No.	Comment	Response
	Water Body/Pollutant: Santa Monica Bay Offshore/Nearshore (Arsenic) **Comment**: Decision No. 67208 (located in Appendix G of the February 2017 integrated staff report for the Los Angeles region) proposes that the Santa Monica Bay Offshore/Nearshore areas be placed on the section 303(d) list because sampling conducted for the City of Los Angeles Hyperion Wastewater Treatment Plant NPDES Permit in areas of Santa Monica Bay north of Redondo Beach Pier influenced by the Hyperion WWTP outfall revealed the presence of arsenic. These samples were collected during August 2006, October and November 2007, and August through September of 2007 from nearfield and from Zones 4 & 5. **Recommendation**: While the Santa Monica Bay Offshore/Nearshore areas include the waters of the Palos Verdes Peninsula, this listing should be defined in geographic scope to exclude the Offshore/Nearshore waters of the Palos Verdes Peninsula. The data supporting Decision No. 67208 is not spatially representative of the Palos Verdes Peninsula waters; therefore this listing should be revised to clearly exclude areas of Santa Monica Bay south of Redondo Beach Pier from the listing.	
13.2	**Water Body/Pollutant: Santa Monica Bay Offshore/Nearshore (Mercury)** **Comment**: Decision No. 67209(located in Appendix G of the February 2017 integrated staff report for the Los Angeles region) proposes that the Santa Monica Bay Offshore/Nearshore areas be placed on the section 303(d) list because sampling conducted for the City of Los Angeles Hyperion Wastewater Treatment Plant NPDES Permit in areas of Santa Monica Bay north of Redondo Beach Pier influenced by the Hyperion WWTP outfall revealed the presence of mercury. These samples were collected during August 2006, October and November 2007, and August through September of 2007 from nearfield and from Zones 4 & 5. **Recommendation**: While the Santa Monica Bay Offshore/Nearshore areas include the waters of the Palos Verdes Peninsula, this listing should be defined in geographic scope to exclude the Offshore/Nearshore waters of the Palos Verdes Peninsula. The data supporting Decision No. 67209 is not spatially representative of the Palos Verdes Peninsula waters; therefore this listing should be revised to clearly exclude areas of Santa Monica Bay south of Redondo Beach Pier from the listing.	See response to comment 2.14.

No.	Comment	Response
13.3	**Water Body/Pollutant: Malaga Cove Beach/Indicator Bacteria** **Comment**: Decision No. 32565 (located in Appendix G of the February 2017 integrated staff report for the Los Angeles region) proposes delisting Malaga Cove Beach from the section 303(d) list for indicator bacteria due to the fact that applicable water quality standards for this pollutant are not being exceeded. The City agrees with the Regional Board Staff Decision Recommendation in Decision No. 32565. However, while Decision No. 32565 has been modified since the last listing cycle in order to make the recommendation to delist, it continues to appear in the list of “original fact sheets” in Appendix G of the February 2017 integrated staff report for the Los Angeles region. Additionally, it is unclear why there is a “Y” in the Pollutant Name Change column in Appendix A since the original fact sheet relating to Decision No. 32565 shows the pollutant name as “indicator bacteria”. **Recommendation**: Modify the Revision Status entry in Fact Sheet 32565 from “original” to “revised” and move the fact sheet into the revised fact sheet group.	The CalWQA database has been corrected to show the decision as “revised” and not to show that the name has been revised.
13.4	**Water Body/Pollutant: Lunada Bay Beach (Indicator Bacteria and Beach Closures)** **Comment**: The fact sheet for Decision No. 34394 (located in Appendix G of the February 2017 integrated staff report for the Los Angeles region) recommends that the original “beach closures” listing for Lunada Bay Beach should be revised to an “indicator bacteria” listing. No data is available to support a listing at this location as this is not an accessible beach but is in fact a rocky cove with steep bluff faces that cannot be safely accessed for monitoring. The original listing was for beach closures and Decision ID 34394 changed the pollutant name to indicator bacteria without any providing indicator bacteria data for evidence. **Recommendation**: Like the rest of the shoreline areas on the Palos Verdes Peninsula, Lunada Bay should be delisted for indicator bacteria and beach closures due to faulty listing by revising the recommendation in the Fact Sheet for Decision No. 34394 and place a “Y” in the New Delistings column of Appendix A to the February 2017 integrated staff report for the Los Angeles region. Also please eliminate the word “beach” from the waterbody because this is not an accessible beach, but rather a rocky cove with a steep bluff face that is not readily accessible to the public.	All indicator bacteria-related listings in the State of California’s 303(d) list including “beach closures,” “coliform,” “pathogens,” have or will be revised to “indicator bacteria” for statewide consistency. Lunada Bay Beach was listed in 1996 and data from prior to 2006 are not included in the CalWQA database and staff have no information that the original listing was faulty.

No.	Comment	Response
13.5	**Water Body/Pollutant: Flat Rock Point Beach Area (Indicator Bacteria and Beach Closures)** **Comment**: Flat Rock Point forms the northern point of Bluff Cove and is part of the same "beach" as Bluff Cove. The fact sheet for Decision ID No. 34628 (located in Appendix G to the February integrated staff report for the Los Angeles Region) is proposing to revise the listing for Flat Rock Point from "beach closures" to "indicator bacteria" however no data to support the listing is provided. Since there is no separate monitoring data set for Flat Rock Point and Flat Rock Point is contiguous with Bluff Cove, Decision ID 32848 and supporting lines of evidence for Bluff Cove should also be applied to Flat Rock Point. **Recommendation**: Flat Rock Point Beach Area should be included with Bluff Cove Beach in the fact sheet for Decision ID No. 32848 and delisted along with Bluff Cove Beach. Also please eliminate the word "beach" from the waterbody because this is not an accessible beach, but rather a rocky point that is not safely accessible for monitoring.	All indicator bacteria-related listings in the State of California's 303(d) list including "beach closures," "coliform," "pathogens," have or will be revised to "indicator bacteria" for statewide consistency. Flat Rock Point Beach was listed in 1996 and data from prior to 2006 are not included in the CalWQA database and staff have no information that the original listing was faulty. The requested change to combine Flat Rock Point with the adjacent Bluff Cove requires a change to the CalWQA underlying map, which is maintained by State Board. It is the intention of the Los Angeles Water Board staff to work with State Board staff to resolve mapping issues and reassess the LOEs and decisions for these reaches, as appropriate, prior to the State Board approval of the 2016 303(d) list, or prior to the next Listing Cycle that includes the Los Angeles Region.
13.6	**Water Body/Pollutant: Malaga Cove Beach (DDT and PCBs)** **Comment**: Appendix C to the February 2017 integrated staff report for the Los Angeles region states that Malaga Cove Beach is included on the 303d list for DDT and PCBs with "Source Unknown". The source of the DDT and PCB listings are known to be associated with the Palos Verdes Shelf Superfund Site because this source is well documented in the USEPA TMDL for these pollutants in Santa Monica Bay. **Recommendation**: Change "source unknown" to "source – Palos Verdes Shelf Superfund Site" for both DDT and PCBs.	The sources for DDT and PCBs have been changed to "See TMDL documentation." The Santa Monica Bay Total Maximum Daily Loads for DDTs and PCBs was established by EPA in March 2012 and, as noted by the commenter, the TMDL has a complete discussion of sources.
13.7	**Water Body/Pollutant: Bluff Cove Beach (DDT and PCBs)** **Comment**: Appendix C to the February 2017 integrated staff report for the Los	The sources for DDT and PCBs have been changed to "See TMDL documentation." The

No.	Comment	Response
	Angeles region states that Bluff Cove Beach is included on the 303d list for DDT and PCBs with "Source Unknown". The source of the DDT and PCB listings are known to be associated with the Palos Verdes Shelf Superfund Site because this source is well documented in the USEPA TMDL for these pollutants in Santa Monica Bay. **Recommendation**: Change "source unknown" to "source – Palos Verdes Shelf Superfund Site Palos Verdes Shelf Superfund Site" for DDT and PCBs.	Santa Monica Bay Total Maximum Daily Loads for DDTs and PCBs was established by EPA in March 2012 and, as noted by the commenter, the TMDL has a complete discussion of sources.
13.8	**Water Body/Pollutant: Santa Monica Bay Offshore/Nearshore (DDT and PCBs)** **Comment**: Category 5 of Appendix B to the February 2017 integrated staff report for the Los Angeles region includes DDT and PCBs in the listing for Santa Monica Bay Offshore/Nearshore (a water segment where standards are not met and a TMDL is required but not yet completed); however this listing is being addressed by the USEPA developed and approved TMDL. This change is explained in the "other revisions" summary in Appendix A to the February 2017 integrated staff report for the Los Angeles region. **Recommendation**: The listings for DDT and PCBs should be moved to Category 4a in Appendix C since there is a USEPA approved TMDL in effect addressing the listings.	The Santa Monica Bay Offshore/Nearshore listing for DDT and PCBs have been revised to show "being addressed by a TMDL."
13.9	**Water Body/Pollutant: Santa Monica Bay Offshore/Nearshore (Chlordane)** **Comment**: Decision No. 37492(located in Appendix G of the February 2017 integrated staff report for the Los Angeles region) has been revised to recommend delisting Santa Monica Bay Offshore/Nearshore waters for chlordane; this revision is not reflected in the summary of recommended changes in Appendix A of the February 2017 integrated staff report for the Los Angeles region. **Recommendation**: Revise Appendix A to place a "Y" in the New Delisting column for Santa Monica Bay Offshore/Nearshore row for Chlordane.	Santa Monica Bay Offshore/Nearshore Chlordane was delisted in 2010. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
13.10	**Water Body/Pollutant: Santa Monica Bay Offshore/Nearshore(Polycyclic Aromatic Hydrocarbons (PAHs))** **Comment**: Decision No. 32656 (located in Appendix G of the February 2017	Santa Monica Bay Offshore/Nearshore Chlordane was delisted in 2010. Appendix A includes proposed changes to the 303(d) list including new

No.	Comment	Response
	integrated staff report for the Los Angeles region) has been revised to recommend delisting Santa Monica Bay Offshore/Nearshore waters for PAHs; this revision is not reflected in the summary of recommended changes in Appendix A of the February 2017 integrated staff report for the Los Angeles region. **Recommendation**: Revise Appendix A to place a "Y" in the New Delisting column for Santa Monica Bay Offshore/Nearshore row for PAHs.	listings, delistings, name changes and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
13.11	**Water Body/Pollutant: Wilmington Drain (Lead)** **Comment**: Decision No. 35085 (located in Appendix G of the February 2017 integrated staff report for the Los Angeles region) recommends delisting the Wilmington Drain for lead based on the weight of evidence. The City agrees with this recommendation due to the fact that LOE No. 90133 describes data collected in Compton Creek, which is unrelated to the Wilmington Drain. **Recommendation**: Remove LOE No. 90133 from the Fact Sheet for Decision No. 35085, and revise the supporting evidence statement to the Regional Board Staff Conclusion to state that: "0 of 33 samples exceeded the CRITERIA."	Los Angeles Water Board staff intends to make the necessary corrections in the CalWQA database and make the appropriate listing/delisting decisions as the State Board staff prepare the Integrated Report and 303(d) list for State Board approval or prior to the next Listing Cycle that includes the Los Angeles Region.
13.12	**Water Body/Pollutant: Wilmington Drain/Copper** **Comment**: Decision ID 44676 (located in Appendix G of the February 2017 integrated staff report for the Los Angeles region) for copper in Wilmington Drain includes a data set that should not have been included: LOE ID 90473 describes data collected in Compton Creek which is unrelated to Wilmington Drain. Removal of this data set from Decision ID 44676 would still leave LOE ID 90131 which is described as 33 samples, only two (2) of which exceeded the criteria for copper. This revised data set now meets the SWRCB Delisting criteria because the number of exceedances is 2 or less in a data set size of 28-36 samples. **Recommendation**: Remove LOE No. 90473 from the Fact Sheet for Decision ID 44676 and revise the supporting evidence statement "2 of 33 samples exceeded the CRITERIA." Also revise the recommendation to Delist from 303(d) List.	Los Angeles Water Board staff intends to make the necessary corrections in the CalWQA database and make the appropriate listing/delisting decisions as the State Board staff prepare the Integrated Report and 303(d) list for State Board approval or prior to the next Listing Cycle that includes the Los Angeles Region.
13.13	**Water Body/Pollutant: Machado Lake (Algae, Ammonia, ChemA, Eutrophic, Odor, Trash)** **Comment**: Category 5 of Appendix B to the February 2017 integrated staff report	Machado Lake listings for Algae, Ammonia Eutrophic, Odor, and Trash were assessed as "being addressed by a TMDL" in 2010. The

No.	Comment	Response
	for the Los Angeles region includes listings for algae, ammonia, ChemA, eutrophic, odor and trash for Machado Lake (a water segment where standards are not met and a TMDL is required but not yet completed); however all of these pollutant listings are being addressed by USEPA-approved TMDLs. **Recommendation**: These listings should be moved to Category 4a in Appendix C to the February 2017 integrated staff report for the Los Angeles region. Additionally, Appendix A should include language under the column for "Other Revisions" for each of these pollutants explaining that: "TMDL status changed from TMDL still required to Being Addressed by Completed TMDL."	Machado Lake listings for**,** ChemA, Chlordane, DDT, Dieldrin, and PCBs were assessed as "being addressed by a TMDL" in this listing cycle. Appendix A includes proposed changes to the 303(d) list including new listings, delistings, name changes and TMDL status changes. Each of these is marked with a "Y" or an explanation. Appendix A also includes waterbody pollutant combinations which were previously listed or delisted. We are exploring ways to better display this data.
14.	City of Pomona , March 30, 2017	
14.1	**Summary** The 2016 303(d) revisions for the several reaches (water quality segments) of the San Gabriel River propose to de-list, do not de-list, and do not list metals-related pollutants including copper, lead, selenium and zinc. These pollutants are the subject of the Total Maximum Daily Loads for Metals and Selenium for the San Gabriel River and Impaired Tributaries (San Gabriel Metals TMDL) adopted by USEPA Region IX (USEPA) and the California Regional Water Quality Control Board, Los Angeles Region (Regional Board) in 2007. This TMDL has been incorporated into the current Los Angeles County MS4 Permit (MS4 Permit). The MS4 Permit enables compliance with its waste load allocations (WLAs) -- also referred to as numeric targets. The numeric targets are translated into water quality based effluent limitations (WQBELs) which are applied to MS4 outfall discharges and to receiving waters. To comply with both, the MS4 Permit coercively encourages compliance through Watershed Management Programs (E/WMPs). The City is appreciative of the several metals pollutants that Regional Board is proposing to de-list and not to list. A total of 22 metals are reported for all San Gabriel River water quality segments. 19 (84.3%) of them fall under the "de-list" and "do not list" categories. This result should be sufficient to void the San Gabriel River Metals TMDL. 3 additional metals (15.7%) should be de-listed,	Comments on the San Gabriel Metals and Selenium TMDL and the LA County MS4 Permit are outside the scope of this action. See response to comments 14.2 as well as 9.2 – 9.7 for detailed responses regarding individual listing decisions raised by the commenter.

No.	Comment	Response
	which would raise the total to 22 (100%), for reasons more particularly described below. The data here strongly demonstrates that that the San Gabriel Metals TMDL should be removed from the Los Angeles Basin Plan.	
14.2	**I. San Gabriel River: Estuary** As the table below illustrates, copper for the estuary is listed on the 2010 303(d) list but was not carried over to the 2016 303(d) list. It must be assumed that the Regional Board did not intend to place copper on this list. If this is an oversight on the part of the Regional Board there is, nevertheless, ample justification for not listing copper for the estuary. As is the case with most metals and toxics referenced in TMDLs and in the MS4 Permit, the Regional Board did not comply with the federal California Toxic Rule (CTR) to the following extent: 1. The Regional Board did not calculate the numeric limitation for lead properly. CTR establishes water quality standards (including TMDLs), based only on ambient (dry) weather sampling and analysis. However, the Regional Board calculated a wet weather numeric limitation for lead based on stormwater sampled from receiving waters. Further, CTR requires a "real time" hardness parameter (using calcium carbonate) as an adjustment factor in establishing water quality standards for metals and toxics. The Regional Board apparently used a default hardness factor of 100 mg/l. CTR states clearly that the 100 mg/l for hardness is only intended be an example in calculating CTR water quality standards. It is important that the actual hardness value be applied (which must be sampled and analyzed as the same toxics and metals are sampled). Too low of a hardness value will set a lower numeric limit. The higher the limit is, the less difficult it is to meet it. 2. Regional Board also did not follow the Water Quality Control Policy for California's Clean Water Act Section 303{d) List (Listing Policy). The Listing Policy requires a binomial distribution based on a null hypothesis) to determine if the number of the samples that resulted in exceedances (of CTR) are statistically	See response to comment 9.1 for the history of copper on the 303(d) list in the San Gabriel River Estuary as well as for a discussion of the CTR and the use of "real time" hardness in calculating limitations. Comments on the San Gabriel River Metals and Selenium TMDL and the provisions of the LA County MS4 Permit are outside the scope of this proposed action. See response to comment 3.3 for the use of listing decisions made prior to the adoption of the Listing Policy. Los Angeles Water Board staff encourages the commenter to enter all the relevant data into CEDEN in preparation for the next listing cycle that includes the Los Angeles Region.

No.	Comment	Response
	sufficient to warrant placement on lead on the 303(d) list. There is no evidence that this task was completed. It is possible that it was not completed because the Listing Policy was not adopted until 2004. The copper was added to the 303(d) list in 1998 and carried-over to the 2000 303(d) list. Based on the San Gabriel River Metals TMDL, it appears that the copper data was based on water quality samples conducted in 1998. 3. The Regional Board's Surface Water Ambient Monitoring Program (SWAMP) performed water quality samples for metals in the estuary in June of 2005. Copper, after properly adjusted for hardness, resulted in 3.23 micrograms per liter (ug/1). The limit is 9.4 ug/1. In other words, no exceedance was detected. Table I. San Gabriel River: Estuary **[See the posted letter for Table I]** Placing copper on the 2016 303(d) list "do not list" category should effectively eliminate the need for impacted MS4 Permittees to comply with the estuary's copper limitation of 3. 7 ug/1 (see Table I(a) below). Table I(a) from Attachment P of the Los Angeles MS4 Permit **[See the posted letter for Table I(a)]** **Recommendation to Regional Board**: (1) approve staff's recommendation not to list lead, selenium, and zinc for the estuary; (2) grant the City's request to de-list copper for the estuary; and (3) use the de-list and do not list justification for this and other metals to remove the San Gabriel River Metals TMDL from the Los Angeles Basin Plan.	
14.3	**II. San Gabriel River: Estuary to Firestone** Metals for San Gabriel River from the Estuary to Reach 1 were not placed on the 2010 303(d) List and not placed on the "do not list" category of the 2016 303(d) List. It is unclear, however, why the MS4 Permit requires compliance with the copper limitation of 18 ug/1 (shown above in Table 1 (a), despite the fact that copper was not listed on the 2010 303(d) list in the first place.	See response to comment 9.2.

No.	Comment	Response
	Table II. San Gabriel River: Estuary to Reach 1 **[See the posted letter for Table II]** **Recommendation to Regional Board**: (1) approve staff's recommendation not to list copper, lead, selenium, and zinc for Reach 1; and (2) use the do not list justification for this and other metals to remove the San Gabriel River Metals TMDL from the Los Angeles Basin Plan.	
14.4	**III. San Gabriel River: Reach 2 (Firestone to Whitter Narrows Dam)** As shown on Table III below, the 2016 303(d) list rolls-over lead from the 2010 303(d) list. Lead, however, should be de-listed for the following reasons: 1. Lead is a legacy pollutant (lead content in fuels have been significantly reduced). 2. The 303(d) lists for 1998 and 2000 placed lead on the "list" category, but failed to comply with the California Toxic Rule (CTR) as explained above. 3. The Regional Board did not follow the State's 303(d) Listing Policy. More specifically, according to the San Gabriel River Metals TMDL (Table 2-7), Reach 2 was sampled during dry weather (ambient) for dissolved lead by the Los Angeles County Department of Public Works (LACDPW), in accordance with CTR using the correct hardness adjustment. The 10 samples taken resulted in no exceedances. If this result were applied to the 303(d) Listing Policy, it would not be sufficient to place lead on the 303(d) List. For a sample size between 2 and 24, 2 exceedances are required for 303(d) list placement. 4. Regional Board's Surface Water Ambient Monitoring Program (SWAMP) performed water quality samples for metals in the estuary in June of 2005. Lead, after properly adjusted for hardness, resulted in 0.81 micrograms per liter (ug/1). The limit is 3.8 ug/1. In other words, no exceedance was detected.	See response to comment 9.3.

No.	Comment	Response
	Table III. San Gabriel River: Reach 2 (Firestone to Whittier Narrows Dam) **[See the posted letter for Table III]** **Recommendation to Regional Board**: (1) do not approve staff's recommendation not to de-list lead; and (2) use the do not list justification for this and other metals to remove the San Gabriel River Metals TMDL from the Los Angeles Basin Plan.	
14.5	**IV. San Gabriel River: Reach 3 (Whittier Narrows Dam to Ramona)** As shown on Table IV below, San Gabriel River Reach 3 was not placed on the 2010 303(d) list and, therefore, it is easy to see why it is placed on the 2016 303(d) "do not list" category. What is difficult to understand is why the Los Angeles MS4 Permit requires compliance with copper, lead, and zinc. The answer lies on MS4 Permit *Attachment P: TMDLs in San Gabriel River Watershed Management Area*. It states: *Permittees shall comply with grouped wet WLAs ... expressed as total recoverable metals discharged to all upstream reaches and tributaries of the San Gabriel River Reach 2 and Coyote Creek* (see Table I(b) below). In other words, even though San Gabriel River Reach 3 is not on the 2010 303(d) list for metals, the MS4 Permit requires compliance with them nevertheless. It does this by applying TMDL numeric targets for copper, lead, and zinc because: (1) San Gabriel River Reach 2 lists a lead TMDL number target of 81 /34 ug/1; and (2) Coyote Creek lists copper target of 24.71 ug/1 and zinc at 144.57 ug/1. The rationale for applying downstream numeric targets for copper, lead, and zinc is at best murky. How can metals as pollutants associated with downstream reaches be applied to upstream Reach 3 of the San Gabriel River? Pollutants cannot travel upstream against gravity. Table IV. San Gabriel River: Reach 3 (Whittier Narrows to Ramona) **[See the posted letter for Table IV]** Table I(b) from Attachment P of the Los Angeles MS4 Permit **[See the posted letter for Table I(b)]** **Recommendation to Regional Board**: (1) approve staff's recommendation not to	See response to comment 9.4.

No.	Comment	Response
	list copper, lead, and zinc; and (2) use the de-list for these metals to remove the San Gabriel River Metals TMDL from the Los Angeles Basin Plan.	
14.6	**V. San Gabriel River: Coyote Creek** The 2016 303(d) List correctly de-lists lead and zinc but does not de-list copper. Copper should be de-listed for the following reasons: 1. The San Gabriel River Metals TMDL contains ambient sample data for Coyote Creek correctly applying CTR. Under Table 2-7, 8 samples are listed with 0 exceedances. If this result were applied to the 303(d) listing policy, it would not qualify for 303(d) placement. A sample size between 2 and 24 would require exceedances equal to and greater than 2. 2. Wet weather water quality data was used to justify placing copper on the 303(d) list. Listing support information cites that CTR relative to copper was applied to wet weather. As mentioned above, wet weather and CTR requirements are mutually exclusive. Wet weather limitations for San Gabriel River and other receiving water bodies in Los Angeles County are intended to be applied - incorrectly -- to MS4s and other NPDES permittees. Table V. Coyote Creek**[See the posted letter for Table V]** **Recommendation to Regional Board**: (1) approve staff's recommendation not to list lead and zinc; (2) approve the City's request to de-list copper; and (3) use the de-list and do not list justification for this and other metals to remove the San Gabriel River Metals TMDL from the Los Angeles Basin Plan.	See response to comment 9.5.
14.7	**VI. San Jose Creek Reach 1 (SG Confluence to Temple St.)** Regional Board staff recommends that: (1) selenium be de-listed; and (2) copper, lead, and zinc not be listed (see Table VI below).	See response to comment 9.6.

<tr><td>15.</td><td colspan="2">City of San Fernando, March 30, 2017</td></tr>
<tr><td>15.1</td><td>I. Summary

The 2016 303(d) revisions for the several reaches (water quality segments) of the Los Angeles River and tributaries propose to de-list, do not de-list, and do not list metals-related pollutants including copper, lead, selenium and zinc. These pollutants are the subject of the Total Maximum Daily Loads for Metals for the Los Angeles River (LAR-MTMDL) adopted by Regional Board in 2007. This TMDL has been incorporated into the current Los Angeles County MS4 Permit MS4 Permit (MS4 Permit). The MS4 Permit enables compliance with TMDL waste load allocations (WLAs) -- also referred to as numeric targets. The numeric targets are translated into water quality based effluent limitations (WQBELs)</td><td>See response to comment 3.1, 3.2 and 3.3.</td></tr>
</table>

No.	Comment	Response
	which are applied to MS4 outfall discharges and to receiving waters as limitations. To comply with both, the MS4 Permit coercively encourages compliance through Watershed Management Programs (E/WMPs). Although many metals have either been placed on the "de-list" or "do not list" categories for Los Angeles River water quality segments, many also have been placed on the "list" and do not de-list categories. These listings should be voided because: 1. although the LAR-MTMDL claims to have developed water quality standards (includes TMDLs) in accordance with the federal California Toxic Rule (CTR) adopted in 2000, it actually has not; and 2. the LAR-MTMDL is based on water quality samples that were conducted before the Water Quality Control Policy for California's Clean Water Act Section 303(d) List (Listing Policy), which was adopted in 2004.	
15.2	• **California Toxic Rule** CTR was adopted to provide a mathematical method for establishing ambient (dry weather) water quality standards for toxics necessary to protect beneficial uses of receiving waters. The LAR-MTMDL, however, along with other TMDLs, does not comply with CTR in two significant respects. First, the TMDL calculates numeric water quality standards/TMDLs for both wet weather and ambient receiving water conditions instead of only on ambient. The LAR-TMDL misinterprets CTR by claiming EPA did not differentiate between wet and dry weather conditions when establishing metals and toxics limitations. There is nothing in CTR that supports that view. CTR makes it clear that its purpose is to establish ambient water quality standards: *This final rule establishes ambient water quality for priority toxic pollutants*. USEPA defines ambient as: *Natural concentration of water quality constituents prior to mixing of either point or nonpoint source load of contaminants. Reference ambient*	See response to comment 3.2.

No.	Comment	Response
	concentration is used to indicate the concentration of a chemical that will not cause adverse impact to human health. In other words, ambient is the normal reference condition of a receiving water. This is also the clear understanding of the Regional Board's Surface Water Ambient Monitoring Program (SWAMP). MS4 and other point source stormwater (wet weather) outfall discharges, using sampling and analysis results, are measured against the ambient target for a pollutant established by CTR. For example, suppose a copper limitation is set at 37 micrograms per liter for a given water body. This limit is required to protect fish. Persistent exceedances of the limit based on outfall monitoring would necessitate a revision to the MS4 Permittee's stormwater management program. Second, CTR requires a hardness parameter (calcium carbonate) to make chemical water quality analysis of toxics more accurate. Generally, the higher the hardness value the higher the toxic pollutant expressed as a numeric limit. The LAR-MTMDL calculates CTR for metals/toxics using a hardness value of 100 milligrams per liter (mg/l). It contends that this is the hardness value required by CTR. This is false. CTR requires actual hardness to be determined by water quality sampling and analysis at the same time a toxic pollutant is sampled. The Regional Board's SWAMP abides by this requirement. Therefore, the LAR-MTMDL establishes limitations for metals and toxics that are more stringent than necessary. This provides another reason for voiding the LAR-MTMDL and revising it with a recalculated limitation for each metal by using an actual hardness value based on future ambient water quality sampling and analysis.	
15.3	• **California 303(d) Listing Policy (Listing Policy)** The Listing Policy was adopted to provide a statistical method to determine how many water quality samples that exceed a water quality standard are required to place a pollutant on the 303(d) list. That method is a binomial distribution based on the rejection of a null hypothesis measured against sample sizes (see attachment #1). A review of the 2016 303(d) list fact sheets reveals that the metals placed on previous 303(d) lists did not conform to the Listing Policy. In fact, the	See response to comment 3.3.

No.	Comment	Response
	LAR-MTMDL is based on water quality data that was developed prior to the adoption of the Listing Policy in 2004. According to the LAR-MTMDL, the metals numeric targets were based on data that was limited to 2002. Based on this fact alone the LAR-MTMDL should be voided.	
15.4	II. Los Angeles River Reach/Tributary Specific Comments Presented below are specific justifications for removing metals that fall under either the "list" or "do not list" categories because they do not conform to CTR or the Listing Policy. Almost all of them fall into these categories. **1. Los Angeles River Reach 4** Copper and lead are placed on the "do not de-list" category. Selenium and zinc are placed on the "do not list." As noted on the table below there are no listing issues here. Table I. LAR Reach 4 **[See the posted letter for Table I]**	For comments related to the CTR, see response to comment 3.2, for those pertaining to the Listing Policy see response to comment 3.3. For Los Angeles River Reach 4, comment noted. Copper and lead, in fact, are on the on the "de-list" category.
15.5	**2. Los Angeles River Reach 5** Selenium and zinc are recommended for placement on the "do not list" category. Copper and lead, on the other hand, are recommended for placement on the "list" category. However, they should not. The justification reported on the fact sheet for both copper and lead is that *0 of the 12 samples and exceeded the criteria*. This must be in error. How can zero or "none" of the 12 samples have exceeded the criteria? Based on this information, copper and lead should be on the do not list category. Table II. LAR Reach 5 **[See the posted letter for Table II]**	The copper "DO NOT DELIST" decision was based on LOE 2527, which is a 'placeholder' LOE to support a 303(d) listing decision made prior to 2006. The additional LOE 86184 (0 out of 12 sediment samples exceeding) is insufficient to make a decision of "DELIST." Section 4.1 of the Listing Policy requires a minimum of 28 samples (and fewer exceedances than listed in Table 4.1) to delist. The lead "DO NOT DELIST" decision was based on LOE 2528, which is a 'placeholder' LOE to support a 303(d) listing decision made prior to 2006. The additional LOE 86197 (0 out of 12 sediment samples exceeding) is insufficient to

No.	Comment	Response
		make a decision of "DELIST." Section 4.1 of the Listing Policy requires a minimum of 28 samples (and fewer exceedances than listed in Table 4.1) to delist.
15.6	**3. Tujunga Wash (Los Angeles River to Hansen Dam)** The Tujunga Wash is only listed (in the "do not list" category) for copper, carried-over from the previous 303(d) list (2010). According to the 303(d) list fact sheet, no samples were taken to justify placement (viz., 0 of the 12 samples exceeded the criteria). Based on this information copper should be de-listed. Table III. Tujunga Wash **[See the posted letter for Table III]**	The copper "LIST" decision is a "carryover" decision (no new data was assessed) and was based on LOE 2558, which is a 'placeholder' LOE to support a 303(d) listing decision made prior to 2006. Section 4.1 of the Listing Policy requires a minimum of 28 samples (and fewer exceedances than listed in Table 4.1) to delist. There is no additional information to support a delisting decision.
16.	City of Ventura, March 30, 2017	
16.1	The City has several concerns regarding the Regional Board's proposed 303(d) list and feels that it requires significant review and modifications before adoption. The City requests that the issues identified in this letter be addressed and the revised, proposed 303(d) list be released for another 60-day comment period prior to adoption. Several of the issues identified herein have resulted in the inability of the proposed 303(d) list to be fully vetted and reviewed by the affected parties. The requested modifications fall into two general categories: 1. New Category 5 listings that should not be listed due to incorrect thresholds being applied for the beneficial use and/or incorrect interpretation of the data (e.g., lack of temporal representation). 2. Errors in the listing information that make it difficult to fully evaluate the listings. Examples include challenges in identifying the data sets and analysis methods used, inconsistencies between the Category 5 list (Appendix B) and the Proposed updates to the 303(d) list (Appendix A), incorrect HUC/Calwater designations, incorrect beneficial uses listed for the applicable water quality objectives, and inconsistent use of thresholds for interpreting narrative objectives.	It is the intent of Los Angeles Water Board staff to work to resolve issues identified by commenters, as appropriate, as the State Water Board staff prepares to bring the 2016 Integrated Report to the State Water Board for its consideration later this year. See response to comment 16.2-16.20 for specific responses.

No.	Comment	Response
	The remaining sections of this letter provide the detailed list of requested changes to the proposed 303(d) list and the rationale for the requests. In summary, the City requests that all waterbody pollutant combinations in Table 1 below not be listed on the 303(d) list and the errors and inconsistencies identified in the other letters cited above be addressed.	
16.2	l. REQUESTED MODIFICATIONS TO THE LISTING STATUS Based on a review of the proposed Category 5 waterbody pollutant combinations, the City has identified several waterbodies that should either be delisted based on available data or proposed listings that should not be listed based on errors in the evaluation. The requested modifications are shown in Table 1, below, with a summary of the justifications for the requested change. A detailed discussion of each of the justifications follows the table. Table 1. Waterbody-pollutant combinations that should not be listed **Waterbody Segment: Santa Clara River Estuary** **Pollutant**: pH **Justification**: "No demonstration high pH is a result of waste discharge. A listing is not warranted in light of reference conditions for pH within estuaries.	The 303(d) list appropriately identifies the pH impairments. Analysis of sources and causes or identification of implementation measures to resolve or correct the impairment are not completed as part of the Integrated Report or 303(d) listing process. LOE88249 was developed using 493 samples collected at dozens of sampling stations over a time period of a decade. As the data support a listing decision, the waterbody pollutant combination should be listed until more data supporting a delisting decision become available or information suggests the environmental conditions have changed. See, also, response to comment 32.5.
16.3	**Waterbody Segment: Santa Clara River Estuary** **Pollutant**: Ammonia **Justification**: Appropriate data not considered and current data does not meet Listing Policy criteria.	LOE 88237 shows 4 of the 42 samples exceeded the one-hour average contraction of un-ionized ammonia. Even though 18 of the 42 samples were reported as non-detects, there is enough evidence that supports a listing decision. See, also, response to comment 32.4.
16.4	**Waterbody Segment: Santa Clara River Estuary**	The “Nitrogen, Nitrate” “LIST” decision is a

No.	Comment	Response
	Pollutant: Nitrogen, Nitrate **Justification**: Appropriate data not considered and current data does not meet Listing Policy criteria.	"carryover" decision (no new data was assessed) and was based on LOE 7819, which is a 'placeholder' LOE to support a 303(d) listing decision made prior to 2006. Section 4.1 of the Listing Policy requires a minimum of 28 samples (and fewer exceedances than listed in Table 4.1) to delist. There is no additional information to support a delisting decision. See, also, response to comment 23.6.
16.5	**Waterbody Segment: Santa Clara River Reach 1 (Estuary to Hwy 101 Bridge)** **Pollutant**: pH **Justification**: No demonstration high pH is a result of waste discharge.	The 303(d) list appropriately identifies the pH impairments. Analysis of sources and causes or identification of implementation measures to resolve or correct the impairment are not completed as part of the Integrated Report or 303(d) listing process. LOE88328 was developed using 60 samples collected at three sampling stations over a time period of a decade. As the data support a listing decision, the waterbody pollutant combination should be listed until more data supporting a delisting decision become available or information suggests the environmental conditions have changed.
16.6	**Waterbody Segment: Ventura Harbor: Ventura Keys Bridge)** **Pollutant**: Arsenic **Justification**: Data does not include proper temporal representation.	Fish were collected from three sub-locations from two sites. The three samples per site were averaged prior to assessment. Because the data collected is spatially independent, it is still appropriate to assess the data as individual samples even though they were

No.	Comment	Response
		collected on the same date. As the data support a listing decision, the waterbody pollutant combination should be listed until more data supporting a delisting decision become available. In addition, fish are not static and move throughout a waterbody, accumulating pollutants in tissue over time. Therefore, the data are, by their nature, spatially and temporally independent. However, a review of the decision to list arsenic is in process at this time in order to re-examine the assumption of the ratio of organic to inorganic arsenic and the applicable evaluation guideline. See, also, response to comment 11.21.
16.7	**Waterbody Segment: Ventura Harbor: Ventura Keys Bridge)** **Pollutant**: Cadmium **Justification**: Data does not include proper temporal representation.	See response to comment 16.6.
16.8	**Waterbody Segment: Ventura Harbor: Ventura Keys Bridge)** **Pollutant**: Chlordane **Justification**: Data does not include proper temporal representation.	See response to comment 16.6.
16.9	**Waterbody Segment: Ventura Harbor: Ventura Keys** **Pollutant**: DDT **Justification**: Data does not include proper temporal representation.	See response to comment 16.6.
16.10	**Waterbody Segment: Ventura Harbor: Ventura Keys** **Pollutant**: Dieldrin **Justification**: Data does not include proper temporal representation.	See response to comment 16.6.

No.	Comment	Response
16.11	**Waterbody Segment: S Ventura Harbor: Ventura Keys** **Pollutant**: PCBs (Polychlorinated biphenyls) **Justification**: Data does not include proper temporal representation.	See response to comment 16.6.
16.12	**Waterbody Segment: Ventura River Reach 1 and 2 (Estuary to Weldon Canyon)** **Pollutant**: Benthic Community Effects **Justification**: • Benthic Community Effects listing is based on flawed analyses. • Data does not include proper temporal representation.	The CSCI is applicable statewide, accounts for a much wider range of natural variability, and provides equivalent scoring thresholds in all regions of the state. See, also, response to comment 16.17.
16.13	**Waterbody Segment: Ventura River Reach 1 and 2 (Estuary to Weldon Canyon)** **Pollutant**: Temperature, water **Justification**: Analysis does not demonstrate temperature is above natural temperature.	The designated beneficial use supports cold water ecosystems including, but not limited to, preservation or enhancement of aquatic habitats, vegetation, fish, or wildlife, including invertebrates. As stated by Moyle, 1976, the optimum range for Rainbow Trout's growth and completion of most life stages is 13-21 degrees Celsius. Therefore, it is appropriate to use this information as Evaluation Guideline, which does not conflict with the water quality objective for Cold Freshwater Habitat.
16.14	**Waterbody Segment: Ventura Harbor: Ventura Keys** **Pollutant**: Indicator Bacteria **Justification**: Data from mouth of Arundell Barranca used in listing assessment.	It is the intention of the Los Angeles Water Board staff to work with State Board staff to resolve this mapping issue and reassess the LOEs and decisions, as appropriate, prior to the State Board approval of the 2016 303(d) list, or at the next Listing Cycle that includes the Los Angeles Region.

No.	Comment	Response
16.15	***1. There is no demonstration that high pH is a result of waste discharge.*** The waterbodies listed for high pH do not appropriately demonstrate that the high pH was a result of waste discharge as required in the Los Angeles Region Basin Plan (Basin Plan).[3] The Santa Clara River Estuary and Santa Clara River Reach 1 are both listed for high pH. As stated in the Fact Sheets and according to the Basin Plan, "*The pH of inland surface waters shall not be depressed below 6.5 or raised above 8.5* ***as a result of waste discharges***."[4] However, it was not demonstrated for either of these waterbodies that the elevated pH levels were a result of waste discharge as opposed to natural causes. Therefore, the Regional Board should either provide evidence that the elevated pH was a result of waste discharge and detail that in the Fact Sheets or, if no such evidence exists, the Regional Board should remove this proposed listing.[5] **Requested Action:** **Remove the pH listings for Santa Clara River Estuary and Santa Clara River Reach 1 as these high pH values are not the· result of waste discharge.**	See response to comment 16.2 and 16.5. Also see response to comment 32.5.
16.16	***2. Listing data lacks proper temporal representation.*** There are many instances where the data to support the listed pollutant lacks proper temporal representation. Section 6.1.5 .3 of the Listing Policy states that: *"Samples should be representative of the critical timing that the pollutant is expected to impact the water body. Samples used in the assessment must be temporally independent. If the majority of samples were collected on a single day or during a single short-term natural event (e.g., a storm, flood, or wildfire), the data shall not be used as the primary data set supporting the listing decision."* Many of the pollutants listed in Table 1 included data collected from a single sampling date, which violates the Listing Policy. For instance, all of the newly proposed pollutants for the Ventura Harbor: Ventura Keys (i.e., arsenic, cadmium, chlordane, DDT, dieldrin, and PCBs) were collected on a single day - February 28,	See response to comment 16.6-16.11.

No.	Comment	Response
	2007. These pollutants should not be listed because there is no temporal resolution provided. **Requested Action:** **Remove all listings shown in Table 1 that were based on a single sample collection date.**	
16.17	***3. Benthic Community Effects listing is based on flawed analyses and should be removed.*** The benthic community effects listing is based on a metric which has since been deemed arbitrary and inappropriate. The Index of Biotic Integrity (IBI) stream assessment was a commonly used metric to determine benthic community effects where the threshold used to distinguish an impaired reach was identified as a value of 39 and below. However, this threshold value was arbitrarily assigned as a statistical cut-off value in the originating study. The State has since endorsed the use of the California Stream Condition Index (CSCI), as stated in the Appendix G Fact Sheets for numerous other benthic community effects listings (e.g., Decision ID 66264)v, "*The CSCI is applicable statewide, accounts for a much wider range of natural variability, and provides equivalent scoring thresholds in all regions of the state. The CSCI will be used in the fi1ture for water quality assessment purposes statewide over the regional indices of biologic integrity (IBIs).*" Despite this, the newly listed benthic community effects for Ventura River Reach 1 and 2 (Estuary to Weldon Canyon) utilizes the IBI to assess the waterbody. Therefore, the City requests that this flawed listing be removed until the waterbody can be assessed with a more representative metric such as the CSCI. In addition to use of an arbitrary metric, the proposed listing for benthic community effects for the Ventura River Reach 1 and 2 lacks proper spatial representation since only two samples were collected from the same sample site ("Station O Main Street Bridge, Mainstem Ventura River" according to the Fact Sheets). In addition, temperature is used as a line of evidence to support the benthic community effects listing, however, the temperature listing for this same waterbody segment is also flawed and should be removed as discussed in the	Listings based on both the SCIBI and CSCI scores are consistent with State policy and have been assessed relative to appropriate reference sites. See response to comment 26.4 for a discussion of the appropriate metrics for benthic community condition. See response to comment 26.5 for a discussion of the established water quality criteria. Because the data collected is temporally independent, it is still appropriate to assess the data as individual samples even though they were collected at the same site. See, also, response to comment 16.13 for temperature.

No.	Comment	Response
	comment below. **Requested Action:** **Remove the benthic community effects listing for Ventura River Reach 1 and 2 (Estuary to Weldon Canyon) due to use of an outdated metric, lack of spatial resolution, and lack of supporting evidence from the temperature listing.**	
16.18	***4. Correct the proposed temperature listings which are based on incorrect criteria.*** The temperature listing for Ventura River Reach 1 and 2 (Estuary to Weldon Canyon) uses an evaluation guideline of 13-21 °C as the optimum growth range for rainbow trout. However, the applicable Basin Plan objective for waterbodies designated as COLD is, "*For waters designated COLD, water temperature shall not be altered by more than 5°F above the natural temperature."* The fact sheets provide no discussion of natural temperatures or a demonstration that the temperature was raised above natural temperatures in order to exceed the objectives. Notwithstanding that a deviation from natural temperatures has not been demonstrated, the way the evaluation guideline is applied is also inappropriate. Moyle 1976 is referenced as the source of the evaluation guideline. Moyle 1976 was revised and expanded by Moyle 2002.[7] Moyle 2002 states: "Rainbows are found where daytime temperatures range from nearly 0°C in winter to 26-27°C in summer, although extremely low (<4°C) or extremely high (>23°C) temperatures can be lethal if the fish have not previously been gradually acclimated. Even when acclimation temperatures are high, temperatures of 24-27°C are invariably lethal to trout, except for very short exposures."[8] As such, while temperatures above 21 °C may not be optimal according to Moyle 1976, Moyle 2002 clearly states that lethal temperatures are those greater than 23°C, which indicates that the evaluation guideline of 21 °C is more appropriately applied as a chronic guideline (necessitating the establishment of an averaging period) and 23°C is the more appropriate "not-to-exceed" guideline if used for listing.	See response to comment 16.13.

No.	Comment	Response
	Using the threshold of 23°C, only 2 samples would exceed the threshold in Ventura River Reach 1 and 2, which would not be enough to meet the listing threshold. **Requested Action:** **Remove the temperature listing for Ventura River Reach 1 and 2 based on lack of exceedances.**	
16.19	***5. Data from Arundell Barranca mouth is inappropriate to assess Ventura Harbor.*** Based on a review of the data provided in the spreadsheet entitled: Peninsula Beach, Ventura Harbor-Keys, and Arundell Barranca Data, site K5 appears to have been included in the analysis of the Ventura Harbor: Ventura Keys assessment. Site K5 is located in the mouth of the Arundell Barranca and is not within Ventura Harbor. A review of the data shows that the indicator bacteria concentrations at this site are much more similar to Arundell Barranca and not representative of the data for the rest of Ventura Harbor. In 2009, as part of the review of the proposed Harbor Cove TMDL, the City conducted an analysis of indicator bacteria data from Ventura Harbor using what appears to be the same dataset as used in the Regional Board's assessment. While the dataset appears to be the same, the number of samples and exceedances did not match completely (e.g., 103 exceedances of the enterococcus geomean with 510 samples in the City's analysis as compared to 104 exceedances and 537 samples in the Regional Board's analysis). The City could not easily determine what the differences in the calculations were and requests that the Regional Board review the exceedance calculations to ensure that all geomeans were calculated using a minimum of 5 samples and that duplicate samples in the dataset were correctly handled in accordance with the Listing Policy. Regardless of the potential differences in the calculations, the clear majority of the exceedances are from site K5 (64 of the 103 exceedances in the City's analysis). If	It is the intention of the Los Angeles Water Board staff to work with State Board staff to resolve this mapping issue and reassess the LOEs and decisions, as appropriate, prior to the State Board approval of the 2016 303(d) list, or at the next Listing Cycle that includes the Los Angeles Region.

No.	Comment	Response
	site KS is removed from the Ventura Harbor analysis (and added to the Arundell Barranca analysis so it is in the correct waterbody), based on the City's calculations, insufficient samples exist to list Ventura Harbor: Ventura Keys for fecal coliform or enterococcus. A summary of the City's analysis is shown in Table 2. Table 2. Summary of City's Analysis Ventura Harbor Indicator Bacteria **[See the posted letter for Table 2]** **Requested Action:** **Revise the calculations for Ventura Harbor: Ventura Keys by removing site K-5 which is not located in the Harbor. Revise any Lines of Evidence that no longer support a listing for indicator bacteria and remove the listing if appropriate.**	
16.20	**II. CORRECT OTHER ERRORS AND INCONSISTENCIES IN APPENDICES AND FACT SHEETS** Appendix A, Appendix B, Appendix C, and Appendix G have many inconsistencies which make the analysis of new additions very difficult since it is unclear which segment-pollutant combinations are new listings. Additionally, in many cases, data and Quality Assurance Project Plan (QAPP) references in the fact sheets are inconsistent with the data provided for review and it is not always clear what data were used in the analysis presented in the fact sheets. Examples of these inconsistencies and errors are detailed in the Calleguas Creek Watershed Stakeholders, VCAILG, and County of Ventura comment letter. The City requests that the Regional Board do a thorough review of all appendices to ensure that the proposed 303(d) list is internally consistent, the correct data were used for the assessment, and the errors identified in the other comment letters are addressed. **Requested Action:** **Correct the numerous errors and inconsistencies in the report and ensure that all the proposed 303(d) list appendices are internally consistent.**	See response to comment 7.98 and 7.99.

I. Waterbodies With Water Quality Attainment Should Be Delisted As Requested By The Los Angeles County Flood Control District During The 2010 Data Solicitation Period And Pursuant to the 303d Listing Policy

In August 2010 in response to the State Water Resources Control Board's (State Water Board's) data solicitation for the 2012 Integrated Report for Clean Water Act Sections 303(d) and 305(b), the Los Angeles County Flood Control District (LACFCD) submitted all the data and information that it collected since the State’s previous data solicitation in 2007. As part of the 2010 data submission, the LACFCD conducted a detailed analysis of the new data and found 15 listed waterbody-pollutant combinations that had attained their water quality standards and met the delisting criteria set forth in Section 4 of the Water Quality Control Policy for Developing California’s Clean Water Act Section 303(d) List (303(d) Listing Policy). To this end, LACFCD provided a detailed analysis of this data and identified those waterbodies that should be delisted pursuant to the State's 303(d) Listing Policy. Those waterbody-pollutant combinations are listed below.

<table>

</table>

No.	Comment	Response
	As set forth in the above table, none of the identified waterbody-pollutant combinations are currently proposed for delisting as part of the 2016 303(d) list, except for the Dominguez Channel Diazinon, despite meeting the delisting criteria under the *State's Listing Policy*. Based on a review of the fact sheets for these waterbodies in Appendix G, it appears that the post-2007 data and analysis submitted by the LACFCD was not taken into consideration by the Los Angeles Regional Water Quality Control Board (Regional Board). The County and the LACFCD request that the Regional Board consider the data set forth in the LACFCD's 2010 submission. Attached is a copy of the LACFCD comment letter and technical report from the 2010 data solicitation for your review and consideration. The County and the LACFCD further request that the Regional Board delist these waterbodies as requested.	
17.2	**II. The Regional Board Should Wait For The Completion Of The State's Biointegrity Policy Development Before Listing Waterbodies For Benthic Community Effects** Currently, there is no officially established California water quality objective or guideline for listing waterbodies for benthic community effects. As such, the State Water Board is currently developing statewide biological objectives to assist in addressing this gap. The 2010 State Water Board's initial notice letter[1] for development of these biological objectives states the following: *"State and Regional Water Board plans and policies do not contain numeric objectives or guidance for using biological data in regulatory decision-making. Therefore, biological objectives are needed to provide the narrative or numeric benchmarks that describe conditions necessary to protect aquatic life beneficial uses. The initial effort will focus on wadeable perennial streams and rivers."* Similarly, the CEQA public scoping document[2] released in 2012 for this project states the following:	There are established California water quality guidelines for listing waterbodies for benthic community effects, the SCIBI and the CSCI, which are both appropriate for 303(d) listing. These evaluation guidelines meet the requirements in Section 6.1.3 of the Listing Policy and both are in use throughout the State. Use of the guidelines is not premature; per the Listing Policy, the guidelines are "scientifically based and peer reviewed" and have been used in previous Integrated Reports. With respect to the use of IBI and CSCI for 303(d) listing, see response to comment 26.4 for a discussion of the appropriate metrics for benthic community condition and response to comment 26.5 for a discussion of the established water quality criteria. At this time, the CSCI and IBI are the best

No.	Comment	Response
	"Benchmarks for identifying biological impairments and interpreting narrative water quality objectives are not formally adopted in Water Board plans or policies and, therefore, not readily used as enforceable requirements …" [Page 6 of the scoping document] "The State Water Board will develop [biological objectives and] program of implementation that describes how biological objectives will be incorporated into permits and other regulatory actions, such as assessing attainment of aquatic life beneficial uses for 303(d) listing." [Page 8 of the scoping document] Thus, there is no established objective in California for assessing biological data, such as benthic macroinvertebrate data, for regulatory decision-making. This includes 303(d) listings. The State Water Board is currently making progress on compiling available information and conducting necessary scientific studies to develop applicable objectives and implementation policy (also known as Biointegrity Policy). The State Water Board has hired the Southern California Coastal Water Research Project (SCCWRP) and the California Department of Fish and Wildlife to develop technical information to aid development of the policy. To ensure that a range of public interests are represented during the development process, the State Water Board has reached out to interested stakeholders. The County and LACFCD is actively participating in these meetings. Although the State Water Board is currently developing biological objectives for benthic communities, the Regional Board has listed multiple waterbodies for benthic community impairment prior to the development of those objectives and its implementation guideline. The following table summarizes the waterbodies being proposed for benthic community listings by the Regional Board in the County.	measure of biologic integrity in California streams and it is appropriate to use IBI and CSCI in 303(d) listing decisions. As the State Board continues the development of the science and policy, new methods may supplant older methods and the 303(d) list will be updated, as appropriate, as that occurs. As with any water quality objective, new science or policy may make necessary revisions to the 303(d) list, but this possibility is not a justification to delay making 303(d) listing decisions when appropriate guidelines are available. Benthic Community Listings for waterbodies that are lined entirely with concrete have been reassigned to Category 3 (insufficient information to assess beneficial use support but some uses may be threatened) until such time as benthic community condition scores have been more specifically calibrated for concrete-lined channels. See response to comment 11.24, for more detail.

No.	Comment	Response
	(see table and text below)	

WATERSHED	WATERBODY SEGMENT	CONCRETE CHANNEL?
Ballona Creek	Ballona Creek	Yes
Dominguez Channel	Dominguez Channel	Yes
Los Angeles River	Alhambra Wash	Yes
	Arroyo Seco Reach 3	No
	Los Angeles River Reach 3	Yes
	Los Angeles River Reach 4	Yes
Malibu Creek	Medea Creek Reach 1	No
	Triunfo Creek Reach 1	No
San Gabriel River	San Gabriel River – East Fork	No
Santa Clara River	Santa Clara River Reach 5	No

Adopting these benthic community impairment listings without first awaiting the State Water Board's development of water quality objectives and implementation guidance is premature. First, in assessing biological data and justifying the proposed listings, the Regional Board used the Index of Biological Integrity (IBI) and the California Stream Condition Index (CSCI). The benchmarks/thresholds used are 40 for IBI and 0.79 for CSCI. While IBI and CSCI are available tools for evaluating the relative biological condition of perennial wadeable streams, the associated benchmarks/thresholds used by Regional Board staff for justifying the listings have not been officially adopted by the State Water Board or the Regional Board for purposes of determining 303(d) listings. Thus, to ensure statewide consistency, the appropriate benchmarks should be set by the Biointegrity Policy being developed by the State Water Board.

Second, the CSCI was developed to replace the IBI and is expected to be used in the Biointegrity Policy. Thus, the IBI and its associated benchmark should not be used for assessing stream conditions for purposes of regulatory decisions, such as 303(d) listing.

Third, many of the listings set forth in the table above are for concrete/modified

No.	Comment	Response
	channels, which are being treated the same as natural channels. This is inconsistent with the approach that the State Water Board has been taking in developing the Biointegrity Policy, which provides that in highly altered conditions, the standard should be based on "best attainable conditions". In this regard, the State Water Board's 2012 CEQA Scoping document[3] for biological objectives states the following: *"One of the difficulties of defining reference conditions in California is that many waterbodies in the State have been severely altered from their natural condition. Some of these alterations are not a result of the controllable environmental factors…. In highly altered systems where biological conditions are limited by uncontrollable factors, the focus is on expectations for the 'best attainable' conditions."* Concrete/engineered flood control channels in urban environments are among the systems that the State Water Board considers highly altered. For those systems, the State's goal is to establish standards that are reasonably expected to be attainable, which is different than standards for natural channels. The State Water Board is using a gradient approach where the biological expectations for altered stream channels are based on the level of alteration. Since altered stream channels have limited habitat, it is improbable to expect a thriving benthic community in these channels the same way as in natural stream channels. This conclusion is well demonstrated in the stream survey report published in 2016 by the Southern California Stormwater Monitoring Coalition (SMC) – the *2015 Report on the SMC Regional Stream Survey4, with Special Study on Engineered Channels.* For the reasons described above, the Regional Board should not list waterbodies, and particularly those with concrete or engineered channels, for benthic impairments until the State Biointegrity Policy is developed and adopted. However, if the Regional Board lists any waterbody for benthic impairment, then the listings should be listed under Category 4c, and not under Category 5, since it is uncertain that these impairments are caused by pollutants.	
17.3	**III. Toxicity Listings Are Based On Unreliable Data and Should Be Removed**	All the toxicity data assessed met the required

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td></td><td>

Ten County waterbodies are newly listed for toxicity, nine of which are streams or rivers, and one is an estuary. The majority of toxicity data used in the listings are from water toxicity tests conducted using the *Ceriodaphnia dubia* or other species.

WATERSHED	WATERBODY SEGMENT	TEST SPECIES
Los Angeles River	Bull Creek	C. dubia, Fathead
	LA River Reach 4	
	LA River Reach 5	
	LA River Reach 6	C. dubia, Fathead, Hyalella
San Gabriel River	SG River Estuary	Topsmelt, Fathead
	SG River Reach 3	C. dubia, Fathead
	San Jose Creek Reach 2	
Santa Clara River	South San Jose Creek	
	Piru Creek	C. dubia
	SC River Reach 5	C. dubia

These toxicity tests, however, have recently been found to be unreliable by a laboratory intercalibration study conducted by SMC[5]. The study utilized 10 laboratories in Southern California that are certified by the State of California for toxicity testing. (Almost all toxicity tests in Southern California are conducted by these laboratories.) Although standard methods and protocols were followed by all the laboratories, the test results for the same sample varied significantly between laboratories.

The below chart summarizes the results of the study. Each symbol in the chart represents the result from a single laboratory. **[See the posted letter for chart]**

As can be seen from the chart, there is high variability in the toxicity results between different laboratories for all the test species despite the fact that analytical procedures were performed on identical samples. For example, the results for

</td><td>

quality assurance.

The SMC Toxicity Testing Laboratory Guidance study, 2016, conducted a laboratory intercalibration study focusing on four species *C. dubia*, *Hyalella*, *Strongylocentrus* and *Mytilus*. Fathead and topsmelt were not a part of the study. The study did not conclude or recommend that previously analyzed data should be disregarded. The study authors recommended all four species for future use as part of the Stormwater Monitoring Coalition monitoring programs. The authors also provided specific guidance for stormwater testing for potential variability-inducing steps including hardness of dilution water, feeding, sample handling and water renewals, and aging of organisms. The authors further concluded:

> *"Based on the scoring system developed for this study, the participating laboratories were comparable for most of the test endpoints (Table 10). Virtually all laboratories were able to meet test acceptability requirements, including internal positive and negative controls. Most laboratories tended to produce internally consistent results when given blind duplicate samples. Finally, most laboratories produced data consistent with non - toxic samples when exposed to laboratory dilution water."*

WATERBODY SEGMENT	Source of data	Number of exceedances/ number of samples

</td></tr>
</table>

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td></td><td>Ceriodaphnia survival vary between 0 percent and 100 percent for the same sample depending on the laboratory used. Also, a sample of lab dilution water, which is expected to be non-toxic was found to be toxic by many labs. Such high magnitudes of inconsistency and incomparability between the labs makes the existing toxicity data invalid or not useful. It is thus very probable that the proposed 303(d) listings for toxicity are the result of false positive toxicity tests, resulting in unimpaired waterbodies being wrongly listed for toxicity.

It is incumbent upon the State to ensure that the laboratories it certifies produce consistent and accurate toxicity test results. The uncertainties and variability reflected in testing results between laboratories, as shown in the SMC study, can have a profound effect on the regulatory actions placed on a waterbody.

For these reasons the proposed water toxicity listings are not supported by reliable data. The County and the LACFCD therefore request that all toxicity listing based off of water toxicity testing be removed from the list. We also request that the State continue to re-evaluate its laboratory certification protocols and address the problems identified by SMC.</td><td>

<tr><td>17.4</td><td>IV. The Proposed Temperature Listings Are Based On An Inapplicable Standard And Therefore Should Be Removed

The following four waterbodies in the County are proposed listings for temperature-related impairment: Los Angeles River Reach 3, San Gabriel River Reaches 1 and 2, and Santa Clara River Reach 6. These listings should not be adopted for the following reasons:

First, natural temperatures for waterbodies in the Los Angeles Region are not known. Chapter 3 of the Los Angeles Region Basin Plan states the following for temperature:

“For waters designated WARM, water temperature shall not be altered by more than 5ºF above the natural temperature. At no time shall these WARM-designated waters be raised above 80ºF as a result of waste discharges.”

“For waters designated as COLD, water temperature shall not be altered by more than 5ºF above the natural temperature.”

The current Basin Plan does not have an established "natural temperature" baseline for waterbodies, nor does it have guidance for estimating natural temperatures. This precludes the use of alteration of natural temperature as a basis for assessing waterbodies in the region.

The Regional Board therefore appears to have used the 80°F objective as the basis for the proposed temperature listings. This standard, however, is not appropriate for two reasons: (1) Under the Basin Plan, the 80°F threshold is to be used only when there is evidence that the temperature rise was "as a result of waste</td><td>The 303(d) list appropriately identifies the temperature impairments. Analysis of sources and causes are not completed as part of the Integrated Report or 303(d) listing process.

The 80°F temperature objective protects the aquatic life beneficial use of WARM in surface waters regardless of the ultimate source of the water in that reach of the river. The Los Angeles Water Board does not have different objectives for different seasons.

The 2014-2016 Triennial Review includes a review of temperature as a Basin Planning Priority Project. Los Angles Water Board staff may consider the development of numeric temperature objectives for various waterbody classes and aquatic life beneficial uses in the future.

Temperature is also discussed in response to comment 11.18.</td></tr>
</table>

No.	Comment	Response
	discharges." The Regional Board did not provide evidence that any of the temperatures above 80°F were caused by waste discharges. (2) The 80°F threshold was applied to all waterbodies without considering the physical attributes or the historical ambient air temperatures of the waterbodies, which are uncontrollable. In the Los Angeles Region, ambient air temperatures can vary drastically, which would easily alter or raise the temperature above 80°F, especially in concrete channels during warmer months. Concrete channels are very susceptible to fluctuations in temperature due the material's ability to absorb heat. Even if the water is at a reasonable temperature when it enters a concrete channel, the water temperature may naturally rise as it travels through the channel, and not as the result of waste discharges. Second, Basin Plans of other Southern California Regions, which have similar habitats as in the Los Angeles Region, do not use 80°F as a water quality objective for WARM-designated waters. For example, the Santa Ana Region Basin Plan[6] uses 90˚F during warmer months of the year (June through October) and 78˚F during the rest of the year. The San Diego Region does not have any temperature water quality objectives for WARM-designated waters. Therefore, the use of 80˚F for purposes of assessing temperature-related impairments and listing waterbodies is unreasonable and unsupported, especially in concrete channels during dry seasons. The Regional Board should not list waterbodies for temperature until applicable standards are established for the Region.	
17.5	**V. Alondra Park Lake Is Not A Water of the United States And Therefore Should Be Removed From The Proposed 303(d) List** Alondra Park Lake is a man-made lake that was created in the late 1940s as part of County's plan to establish Alondra Park. The lake does not receive any runoff discharge from areas outside of the park and is not connected to the Dominguez Channel or any other surface waterbody. The lake's source of water is entirely groundwater that is pumped from the West Coast Groundwater Basin. This water is used to irrigate the park and the nearby golf course.	Alondra Park Lake is an approximately 7.3 acre lake. Waterbodies not explicitly identified in the Basin Plan Chapter 2 may still be subject to the “tributary rule.” The Los Angeles Basin Plan, Chapter 2, states: *Under federal law, all surface waters must have water quality standards designated in the Basin Plans. Most of the inland surface waters*

No.	Comment	Response
	In addition, Alondra Lake is not identified in the Basin Plan and, thus, does not have any beneficial use designation assigned to it. This confirms that the lake is not a receiving waterbody. The Section 303(d) list applies only to waters of the United States. Alondra Park Lake is a man-made enclosed lake not connected to any other waterbody. Any listings associated with Alondra Park Lake should therefore be removed from the proposed 2016 303(d) list.	*in the Region have beneficial uses specifically designated for them. Those waters not specifically listed (generally smaller tributaries) are designated with the same beneficial uses as the streams, lakes, or reservoirs to which they are tributary. This is commonly referred to as the "tributary rule."* Alondra Park Lake overflows to the Dominguez Channel in large storm events. Therefore, a hydrologic connection exists between Alondra Park Lake and the Dominguez Channel, a water of the United States. In addition, because such intermittent flow is capable of moving pollutants from the Alondra Park Lake to Dominguez Channel, a significant nexus exists between Alondra Park Lake and the Dominguez Channel. The Dominguez Channel travels through a number of municipalities in Los Angeles County before emptying into the Los Angeles Harbor. In addition, fishing takes place at Alondra Lake. The California Department of Fish and Wildlife plants trout at the Lake. Tissue mercury data from fish from Alondra Lake are part of the Statewide dataset used in the OEHHA statewide advisory, *Statewide Health Advisory and Guidelines for Eating Fish from California's Lakes and Reservoirs, July 2013.* The identification of fish exceeding the OEHHA fish contaminant goals is important for the protection of human health and it is appropriate to identify the impairment on the 303(d) list.

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td>17.6</td><td>VI. Data Being Used For Legacy Pollutant Listings Do Not Satisfy The Temporal Representativeness Requirements of The State's Listing Policy

The data being used to support proposed listings of waterbody-pollutant combinations for legacy pollutants does not satisfy the temporal requirements of the State's 303(d) Listing Policy as described below. Thus, these proposed listings should be removed.

Section 6.1.5.3 of the State's 303(d) Listing Policy states:

“Samples used in the assessment must be temporally independent. If the majority of samples were collected on a single day or during a single short-term natural event (e.g., a storm, flood, or wildfire), the data shall not be used as the primary data set supporting the listing decision. Samples should be available from two or more seasons or from two or more events . . .”

Section 6.1.5.6 of the Listing Policy states:

“To be considered temporally independent, samples collected during the averaging period shall be combined and considered one sampling event. For data that is not temporally independent (e.g., when multiple samples are collected at a single location on the same day), the measurements shall be combined and represented by a single resultant value.”

Section 3.1 of the Listing Policy requires a minimum of two exceedances to place a waterbody on the 303(d) list for toxic pollutants.

The data used to support some of the new listings was collected only on a single day. Therefore, pursuant to Sections 6.1.5.3 and 6.1.5.6 of the Listing Policy, these samples are not temporally independent and should be combined and considered as a single data point. Moreover, under Section 3.1 of the Listing Policy, a minimum of two exceedances are needed to place a waterbody on a 303(d) list. Thus, the following listings do not meet these Listing Policy guidelines:</td><td>The data used to support the listings identified by the commenter were collected on a single day but from two species per waterbody. Multiple composites from each unique species were averaged, but it would be inappropriate to average composites from different species. Composites of different species will have different age profiles and different species occupy different trophic levels and will accumulate pollutants at different rates. These samples are independent and cannot be combined and considered as a single data point.

Most of the averaged composite samples supporting theses listings represent 10 individual fish.

In addition, fish are not static; they move throughout a lake or stream and accumulate pollutants in tissue over time. Therefore, the data are, by their nature, spatially and temporally independent even though they were collected at the same site on the same day.

<table><tr><th>WATER BODY SEGMENT</th><th>POLLUTANT</th><th>Number of fish in composites</th></tr><tr><td>Alondra Park Lake</td><td>PCBs</td><td>Composites were largemouth bass (2 composites - 5 fish per composite) and common carp (2 composites - 5 fish per composite). VII. Legacy Pollutants (PCBs, DDT, Dieldrin, Chlordane) Should be Listed As a Category 4b, Not as Category 5

Many of the pollutants that are being considered for incorporation into the 303(d) list are legacy pollutants that have been banned by the U.S. Environmental Protection Agency (EPA) decades ago and are no longer manufactured or used in the United States. These pollutants include PCBs, DDT, Dieldrin, and Chlordane. PCBs were banned in 1979, DDT in 1980, Dieldrin in 1987, and Chlordane in 1988.

The newly proposed listing includes several waterbodies in the County that are listed for impairments associated with these pollutants:

<table>
<tr><th>WATERSHED</th><th>WATERBODY SEGMENT</th><th>POLLUTANT(S)</th></tr>
<tr><td>Dominguez Channel</td><td>Alondra Park Lake</td><td>PCBs</td></tr>
<tr><td>Malibu Creek</td><td>Malibou Lake</td><td>Dieldrin</td></tr>
<tr><td rowspan="2">Los Angeles River</td><td>Echo Park Lake</td><td>Chlordane, Dieldrin</td></tr>
<tr><td>Lincoln Park Lake</td><td>PCBs</td></tr>
<tr><td rowspan="2">San Gabriel River</td><td>Legg Lakes</td><td>DDT, PCBs</td></tr>
<tr><td>Santa Fe Dam Park Lake</td><td>PCBs</td></tr>
<tr><td rowspan="4">Santa Clara River</td><td>Castaic Lagoon</td><td>PCBs</td></tr>
<tr><td>Castaic Lake</td><td>PCBs</td></tr>
<tr><td>Elderberry Forebay</td><td>Dieldrin, PCBs</td></tr>
<tr><td>Pyramid Lake</td><td>Chlordane, DDT, Dieldrin, PCBs</td></tr>
</table>

The complete ban on these pollutants three decades ago, which is the strongest regulatory action an agency can take, has effectively addressed the true sources of these pollutants in the environment. Since these chemicals are no longer

</td><td>

The definition of 4b is "*Evidence shows at least one use is not supported, but a TMDL is not needed as an existing regulatory program is reasonably expected to result in the attainment of the water quality standard within a reasonable, specified time frame*."

A ban, in and of itself, is not a regulatory program and no time frame has been specified by any authority for waterbodies impaired by DDT, PCBs, Chlordane, or Dieldrin to attain the water quality standard under the ban, therefore the appropriate category for these waterbodies is 4a or 5.

Several TMDLs address these legacy pollutants; these TMDLs have timeframes for attainment of the standard and identify potential implementation actions such as non-structural and structural BMPs, and/or diversion and treatment to reduce sediment transport from the watershed to the waterbody. Implementation may, in some cases, require the removal of 'hotspots' of high sediment contamination. When an approved TMDL is in place the waterbody may be placed in category 4a (or may remain in category 5 if there are additional pollutants that are not yet addressed by a TMDL or other regulatory program).

The Echo Park Lake waterbody pollutant combinations are already addressed by a TMDL,

</td></tr>
</table>

No.	Comment	Response
	manufactured or used, the regulatory program already in place by the U.S. EPA is reasonably expected to result in the attainment of the water quality standard for these pollutants over time. As indicated in comment VI, waterbodies that contain legacy pollutants should not be listed because the data used for their listing does not satisfy the Listing Policy. However, if the Regional Board does list these waterbodies, we request that they be listed as Category 4b, not Category 5, because a regulatory program is already in place to address them.	the Los Angeles Area Lakes Nitrogen, Phosphorus, Mercury, Trash, Organochlorine Pesticides and PCBs TMDL. Other TMDL for legacy pollutants include: Dominguez Channel and the Greater Los Angeles and Long Beach Harbor Waters Toxics TMDL; Colorado Lagoon Organochlorine Pesticides, PCBs, sediment toxicity, PAHs and metals TMDL; McGrath Lake PCBs, Pesticides and Sediment Toxicity TMDL; Ballona Creek Estuary Toxic Pollutants TMDL (including Chlordane, DDT and PCBs); Machado Lake Pesticides and PCBs TMDL; Marina del Rey Harbor Toxics TMDL (including Chlordane and PCBs); and Calleguas Creek OC Pesticides and PCBs TMDL.
17.8	**VIII. The State Should Rely On The Most Updated Guideline to List Waterbodies Based On Fish Tissue Contamination** In assessing waterbodies for fish tissue contamination, the Regional Board used the following two guidelines: a. The 2008 Office of Environmental Health Hazard Assessment (OEHHA) fish contaminant goal, and b. The 1972 National Academy of Sciences (NAS) guidelines. The OEHHA guideline, developed in 2008 is not only up-to-date but also specific to California and, thus, reasonable to use for this particular assessment. On the other hand, the NAS guideline is half a century old and out of date. In the absence of an up-to-date NAS guideline, the assessment should be based exclusively on the OEHHA standard's line of evidence.	The use of both guidelines is appropriate, each supports a different beneficial use. Two or three lines of evidence were developed for the evaluation of the data for each of these waterbody pollutant pairs. One or two LOEs were developed for each of these waterbody pollutant pairs in support of an aquatic life beneficial use (WARM, COLD or both), which compared the data to the NAS evaluation guideline developed to protect aquatic life from the accumulation of toxic substances. In only one case this guideline was exceeded. One LOE was developed for each of these waterbody pollutant pairs in support of the fishing

No.	Comment	Response
	Based on the OEHHA guideline, the following waterbodies meet water quality standards and, therefore, should be removed from the proposed listing: • Castaic Lagoon for PCBs • Elderberry Forebay for Dieldrin • Pyramid Lake for Chlordane, DDT, Dieldrin, PCBs • Alondra Park Lake for PCBs Echo Park Lake for Chlordane and Dieldrin • Legg Lakes for DDT and PCBs.	beneficial use, COMM, which compared the data to the OEHHA guideline developed to protect human health from consumption of toxic substances. For all of these waterbody pollutant pairs, this guideline was exceeded frequently enough to place the waterbody pollutant pair on the 303(d) list.
17.9	**IX. ADDITIONAL COMMENTS** **A. Wilmington Drain-Copper should be delisted** Per Appendix G fact sheets, two lines of evidences (LOE) were used to support the listing for copper in Wilmington Drain. However, the information used for the second LOE is data collected in Compton Creek, which is a different waterbody. This data should not be used to evaluate Wilmington Drain. Removal of this LOE would lead to only 2 exceedances out of 33 data points. This would satisfy the delisting criteria of the State's Listing Policy. Therefore, copper should be delisted for Wilmington Drain.	Los Angeles Water Board staff will correct the LOEs and the decision, as appropriate, as the State Board staff prepare the Integrated Report and 303(d) list for State Board approval.
17.10	**B. The listings in Appendix A should be corrected to reflect the listing and delisting decisions in Appendix G** As already acknowledged in the February 24 Regional Board notice letter, Appendix A does not accurately capture all the listing and delisting decisions detailed in the fact sheets in Appendix G. For example, for Ballona Creek, Chlordane, DDT, Dieldrin, and PCBs were delisted during the previous listing cycle. However, these listings continue to be identified in Appendix A as part of the 2016 303(d) list. This is true for many of the waterbodies summarized in Appendix A. This error should be corrected to avoid any confusion and misinterpretation of the information by the general public.	Los Angeles Water Board staff is aware of the inconsistencies and Appendix A has been revised.
17.11	**C. Waterbodies that are on the 303(d) list and being addressed by a USEPA approved TMDL should be moved to Category 4a from Category 5**	Each of these waterbody pollutant pairs are included in the 303(d) list as “being addressed by

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td></td><td>Many of 303(d)-listed waterbodies from the previous listing cycle now have TMDLs. This requires a change in their status from Category 5 (TMDL required list) to Category 4a (being addressed by US EPA approved TMDL). Some of these status changes are not reflected in the revised list and need correction.

Similarly, some of the newly proposed listings are already being addressed by an existing TMDL for that watershed. In those cases, it is appropriate to put them also under Category 4a as opposed to Category 5. Examples, include:

• LA River Reach 3 and Rio Hondo Reach 2 for Indicator Bacteria, which are being addressed by the Los Angeles River Watershed Bacteria TMDL
• LA River Reach 6 for Copper and Compton Creek for Zinc, which are being addressed by the Los Angeles River Metals TMDL.</td><td>USEPA approved TMDL.” However, each of these waterbodies remains on the list in Category 5 because there are other pollutants impairing those waterbodies that have yet to be addressed by a TMDL or other regulatory program.

For example, Rio Hondo Reach 2 has a TMDL for indicator bacteria (the Los Angeles River Watershed Bacteria TMDL); however, Rio Hondo Reach 2 also is listed for dissolved oxygen and toxicity, which are not being addressed by a TMDL. Therefore, the water body, as a whole, is in Category 5.

Nonetheless, in the Appendix for Category 5, waterbody pollutant combinations for which a TMDL is complete are shown as 5B and waterbody pollutant combinations for which there is no TMDL are shown as 5A.</td></tr>
<tr><td>18.</td><td colspan="2">County of Ventura Public Works Agency, March 30, 2017</td></tr>
<tr><td>18.1</td><td>The County has a number of concerns regarding the draft 2016 Los Angeles Water Board's proposed revisions to the 303(d) list of impaired waterbodies and believes that it requires significant review and modification before adoption. The County requests that the issues identified in this letter be addressed and the proposed 303(d) list be released for another 60-day comment period prior to adoption. Several of the issues identified herein have resulted in the inability of the proposed 303(d) list to be fully vetted and reviewed.</td><td>See response to comment 32.1 for additional discussion of additional comment periods.</td></tr>
<tr><td>18.2</td><td>Requested modifications fall into three broad categories:

1. New Category 5 listings should not be listed due to incorrect thresholds applied to the beneficial use, incorrect sample locations, and incorrect interpretation of the data (e.g., mismatched units or lack of temporal representation).</td><td>See response to comment 18.3-18.61 for specific responses.</td></tr>
</table>

No.	Comment	Response
	2. Delistings requested previously by the County that have not been incorporated. 3. Errors in the listing information that make it difficult to fully evaluate the listings. Examples include inconsistencies between the Category 5 list (Appendix B) and the proposed updates to the 303(d) list (Appendix A), incorrect HUC/Calwater designations, incorrect beneficial uses listed for the applicable water quality objectives <WQOs), and inconsistent use of thresholds for interpreting narrative objectives. The remaining sections of this letter provide a detailed summary of requested changes to the 303(d) list and the rationale for the requested actions. In summary, the County requests that all waterbody pollutant combinations in Table 1 not be listed on the 303(d) list, nitrogen compounds in Santa Clara River Reach 3 be delisted, and the errors and inconsistencies identified in the CCW TMDL Stakeholders Letter be addressed.	
18.3	**I. REQUESTED MODIFICATIONS TO THE LISTING STATUS** Based on a review of the proposed Category 5 waterbody segment-pollutant combinations, the County has identified a number of waterbodies that should be either delisted based on available data or for which proposed new listings should not be listed based on errors in the data evaluation. The requested modifications are shown in Table 1, below, with a summary of the justifications for the requested changes. A detailed discussion of each of the justifications follows the table. **Table 1. Waterbody-pollutant combinations that should not be listed** Waterbody Segment: **Boulder Creek (Ventura County)** Pollutant: Chlordane Justification for Not Listing: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.5.

No.	Comment	Response
	• J-flagged data incorrectly used in assessment (WARM).	
18.4	**Boulder Creek (Ventura County)** Pollutant: Nitrogen, Nitrate Justification for Not Listing: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.6.
18.5	**Boulder Creek (Ventura County)** Pollutant: Specific Conductivity Justification for Not Listing: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.7.
18.6	**Boulder Creek (Ventura County)** Pollutant: Toxicity Justification for Not Listing: • Data does not include proper temporal representation.	See response to comment 7.8.
18.7	Waterbody Segment: **Ellsworth Barranca** Pollutant: DDE Justification for Not Listing: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody. • J-flagged data incorrectly used in assessment.	See response to comment 7.43.
18.8	Waterbody Segment: **Javon Canyon** Pollutant: Benthic Community Effects Justification for Not Listing: • Data does not include proper temporal representation. • Benthic Community Effects listing is based on flawed analyses.	Listings based on both the SCIBI and CSCI scores are consistent with State policy and have been assessed relative to appropriate reference sites. See response to comment 26.4 for a discussion of the appropriate metrics for benthic community condition.

No.	Comment	Response
		See response to comment 26.5 for a discussion of the established water quality criteria. Because the data collected are temporally independent, it is appropriate to assess the data as individual samples even though they were collected at the same site.
18.9	Waterbody Segment: **Javon Canyon** Pollutant: Selenium Justification for Not Listing: • Data does not include proper temporal representation.	Fish were collected from two sites on a single day. Because the data collected is spatially independent, it is appropriate to assess the data as individual samples even though they were collected on the same date. As the data support a listing decision, the waterbody pollutant combination should be listed until more data supporting a delisting decision become available. In addition, fish are not static; they move throughout a waterbody and accumulate pollutants in tissue over time. Therefore, the data are, by their nature, spatially and temporally independent.
18.10	Waterbody Segment: **Los Sauces Creek** Pollutant: Selenium Justification for Not Listing: • Data does not include proper temporal representation.	Fish were collected from two sites on a single day. Because the data collected are spatially independent, it is appropriate to assess the data as individual samples even though they were collected on the same date. As the data support a listing decision, the waterbody pollutant combination should be listed until more data supporting a delisting decision become available. In addition, fish are not static; they move

No.	Comment	Response
		throughout a waterbody and accumulate pollutants in tissue over time. Therefore, the data are, by their nature, spatially and temporally independent.
18.11	Waterbody Segment: **Madranio Canyon** Pollutant: Benthic Community Effects Justification for Not Listing: • Data does not include proper temporal representation. • Benthic Community Effects listing is based on flawed analyses.	Listings based on both the SCIBI and CSCI scores are consistent with State policy and have been assessed relative to appropriate reference sites. See response to comment 26.4 for a discussion of the appropriate metrics for benthic community condition. See response to comment 26.5 for a discussion of the established water quality criteria. Because the data collected are spatially independent, it is appropriate to assess the data as individual samples even though they were collected on the same day.
18.12	Waterbody Segment: **Madranio Canyon** Pollutant: Copper Justification: • Data does not include proper temporal representation.	Because the data collected are spatially independent, it is appropriate to assess the data as individual samples even though they were collected on the same day.
18.13	Waterbody Segment: **Madranio Canyon** Pollutant: Selenium Justification for Not Listing: • Data does not include proper temporal representation.	Because the data collected are spatially independent, it is appropriate to assess the data as individual samples even though they were collected on the same day.
18.14	Waterbody Segment: **Medea Creek Reach 1 (Lake to Confl. with Lindero)** Pollutant: Benthic Community Effects Justification for Not Listing: • Benthic Community Effects listing is based on flawed analyses.	See response to comments 26.4 and 26.15.

No.	Comment	Response
	• Data does not include proper temporal representation.	
18.15	Waterbody Segment: **Padre Juan Canyon** Pollutant: Benthic Community Effects Justification for Not Listing: • Benthic Community Effects listing is based on flawed analyses. • Benthic Community Effects data do not support listing. • Data does not include proper temporal representation.	See response to comments 26.4 and 26.15. Because the data collected are spatially independent, it is appropriate to assess the data as individual samples even though they were collected on the same day.
18.16	Waterbody Segment: **Padre Juan Canyon** Pollutant: Selenium Justification for Not Listing: • Data does not include proper temporal representation.	Because the data collected are spatially independent, it is appropriate to assess the data as individual samples even though they were collected on the same day.
18.17	Waterbody Segment: **Port Hueneme Harbor (Back Basins)** Pollutant: Arsenic Justification for Not Listing: • Data does not include proper temporal representation.	Because the data collected are spatially independent, it is appropriate to assess the data as individual samples even though they were collected on the same day. In addition, fish are not static; they move throughout a waterbody and accumulate pollutants in tissue over time. Therefore, the data are, by their nature, spatially and temporally independent.
18.18	Waterbody Segment: **Port Hueneme Harbor (Back Basins)** Pollutant: Cadmium Justification for Not Listing: • Data does not include proper temporal representation.	Samples were collected from three sub-locations from two sites. The three samples per site were averaged prior to assessment. Because the data collected are spatially independent, it is appropriate to assess the data as individual samples even though they were collected on the same day. In addition, fish are not static; they move throughout a waterbody and accumulate pollutants

No.	Comment	Response
		in tissue over time. Therefore, the data are, by their nature, spatially and temporally independent.
18.19	Waterbody Segment: **Port Hueneme Harbor (Back Basins)** Pollutant: Dieldrin Justification for Not Listing: • Data does not include proper temporal representation.	Samples were collected from three sub-locations from two sites. The three samples per site were averaged prior to assessment. Because the data collected are spatially independent, it is appropriate to assess the data as individual samples even though they were collected on the same day. In addition, fish are not static; they move throughout a waterbody and accumulate pollutants in tissue over time. Therefore, the data are, by their nature, spatially and temporally independent.
18.20	Waterbody Segment: **Port Hueneme Harbor (Back Basins)** Pollutant: PAHs (Polycyclic Aromatic Hydrocarbons) Justification for Not Listing: • Data does not include proper temporal representation.	Samples were collected from three sub-locations from two sites. The three samples per site were averaged prior to assessment. Because the data collected are spatially independent, it is appropriate to assess the data as individual samples even though they were collected on the same day. In addition, fish are not static; they move throughout a waterbody and accumulate pollutants in tissue over time. Therefore, the data are, by their nature, spatially and temporally independent.
18.21	Water Segment: **Santa Clara River Estuary** Pollutant: pH Justification for Not Listing: • No demonstration high pH is a result of waste discharge.	See response to comments 16.2 and 32.5.

No.	Comment	Response
18.22	Water Segment: **Santa Clara River Reach 1 (Estuary to Hwy 101 Bridge)** Pollutant: pH Justification for Not Listing: • No demonstration high pH is a result of waste discharge.	The 303(d) list appropriately identifies the pH impairments. Analysis of sources and causes or identification of implementation measures to resolve or correct the impairment are not completed as part of the Integrated Report or 303(d) listing process. There are multiple sources of water to Santa Clara River Reach 1 including “waste discharge” from sources such as wastewater treatment plants and the MS4. Exceedances in pH may be caused in part by waste discharge. The relative contribution of the causes of pH exceedances is largely speculative, at this time. See, also, response to comment 16.5.
18.23	Water Segment: **Santa Clara River Reach 3 (Freeman Diversion to A Street)** Pollutant: Chlordane Justification for Not Listing: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.72.
18.24	Water Segment: **Santa Clara River Reach 3 (Freeman Diversion to A Street)** Pollutant: Chlorpyrifos Justification for Not Listing: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.73.
18.25	Water Segment: **Santa Clara River Reach 3 (Freeman Diversion to A Street)** Pollutant: Cyfluthrin Justification for Not Listing: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.74.

No.	Comment	Response
18.26	Water Segment: **Santa Clara River Reach 3 (Freeman Diversion to A Street)** Pollutant: Cypermethrin Justification for Not Listing: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.75.
18.27	Water Segment: **Santa Clara River Reach 3 (Freeman Diversion to A Street)** Pollutant: DDD Justification for Not Listing: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.76.
18.28	Water Segment: **Santa Clara River Reach 3 (Freeman Diversion to A Street)** Pollutant: DDE Justification for Not Listing: • Data from agricultural drain rather than waterbody used as basis for listing decision. • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.77.
18.29	Water Segment: **Santa Clara River Reach 3 (Freeman Diversion to A Street)** Pollutant: DDT Justification for Not Listing: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.78.
18.30	Water Segment: **Santa Clara River Reach 3 (Freeman Diversion to A Street)** Pollutant: Mercury Justification for Not Listing: • Data and objectives have different units (ng/L vs. µg/L); data do not exceed objectives.	See response to comment 7.79.

No.	Comment	Response
18.31	Waterbody Segment: **Tapo Canyon** Pollutant: DDD Justification for Not Listing: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody. • Includes LOE for toxicity to support the DDD listing. This LOE should be removed since there is a separate LOE specifically for toxicity.	See response to comment 7.81.
18.32	Waterbody Segment: **Tapo Canyon** Pollutant: DDE Justification for Not Listing: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody. • Includes LOE for toxicity to support the DDE listing. This LOE should be removed since there is a separate LOE specifically for toxicity.	See response to comment 7.82.
18.33	Waterbody Segment: **Tapo Canyon** Pollutant: Nitrogen, Nitrate Justification for Not Listing: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.83.
18.34	Waterbody Segment: **Tapo Canyon** Pollutant: Specific Conductivity Justification for Not Listing: • Incorrectly listed using guideline for MUN beneficial use that is not applicable to waterbody.	See response to comment 7.84.
18.35	Waterbody Segment: **Triunfo Canyon Creek Reach 1** Pollutant: Benthic Community Effects Justification for Not Listing: • Benthic Community Effects listing is based on flawed analyses.	Two LOEs with five bioassessment scores supported a listing decision. Though IBI scores will be replaced by CSCI in the future for water quality assessment purposes, it remains appropriate to use data on IBI scores for listing

No.	Comment	Response
		purposes. The waterbody pollutant combination should be listed until more data supporting a delisting decision become available or information suggests the environmental conditions have changed. See response to comments 26.4 and 26.15.
18.36	Waterbody Segment: **Ventura Harbor: Ventura Keys** Pollutant: Arsenic Justification for Not Listing: • Data does not include proper temporal representation.	See response to comment 16.6
18.37	Waterbody Segment: **Ventura Harbor: Ventura Keys** Pollutant: Cadmium Justification for Not Listing: • Data does not include proper temporal representation.	See response to comment 16.6
18.38	Waterbody Segment: **Ventura Harbor: Ventura Keys** Pollutant: Chlordane Justification for Not Listing: • Data does not include proper temporal representation.	See response to comment 16.6
18.39	Waterbody Segment: **Ventura Harbor: Ventura Keys** Pollutant: DDT Justification for Not Listing: • Data does not include proper temporal representation.	See response to comment 16.6
18.40	Waterbody Segment: **Ventura Harbor: Ventura Keys** Pollutant: Dieldrin Justification for Not Listing: • Data does not include proper temporal representation.	See response to comment 16.6
18.41	Waterbody Segment: **Ventura Harbor: Ventura Keys**	See response to comment 16.6

No.	Comment	Response
	Pollutant: PCBs (Polychlorinated biphenyls) Justification for Not Listing: • Data does not include proper temporal representation.	
18.42	Waterbody Segment: **Ventura River Reach 1 and 2 (Estuary to Weldon Canyon)** Pollutant: Benthic Community Effects Justification for Not Listing: • Benthic Community Effects listing is based on flawed analyses.	See response to comment 16.12.
18.43	Waterbody Segment: **Ventura River Reach 1 and 2 (Estuary to Weldon Canyon)** Pollutant: Temperature, water Justification for Not Listing: • Analysis does not demonstrate water temperature is above natural temperature.	See response to comment 16.13.
18.44	Waterbody Segment: **Ventura River Reach 3 (Weldon Canyon to Confl. w/Coyote Cr)** Pollutant: Benthic Community Effects Justification for Not Listing: • Benthic Community Effects listing is based on flawed analyses.	See response to comment 16.12.
18.45	Waterbody Segment: **Ventura River Reach 3 (Weldon Canyon to Confl. w/Coyote Cr)** Pollutant: Mercury Justification for Not Listing: • Data and objectives have different units (ng/L vs. µg/L); data do not exceed objectives.	See response to comment 7.87.
18.46	Waterbody Segment: **Ventura River Reach 3 (Weldon Canyon to Confl. w/Coyote Cr)** Pollutant: Toxicity Justification for Not Listing:	Of the 43 samples evaluated, eight samples were in exceedance, which supported a listing decision. The waterbody pollutant combination should be listed until more data supporting a delisting

No.	Comment	Response
	• Toxicity data from prior to pesticide use restrictions used for listings. More recent data does not show toxicity.	decision become available. Staff encourages commenter to submit data to CEDEN in preparation for the next listing cycle.
18.47	Waterbody Segment: **Ventura River Reach 4 (Coyote Creek to Camino Cielo Rd)** Pollutant: Benthic Community Effects Justification for Not Listing: • Benthic Community Effects listing is based on flawed analyses. • Data does not include proper temporal representation.	See response to comment 26.4 for a discussion of the appropriate metrics for benthic community condition. See response to comment 26.5 for a discussion of the established water quality criteria. Because the data collected are temporally independent, it is appropriate to assess the data as individual samples even though they were collected at the same site.
18.48	Waterbody Segment: **Ventura River Reach 4 (Coyote Creek to Camino Cielo Rd)** Pollutant: Temperature, water Justification for Not Listing: • Analysis does not demonstrate water temperature is above natural temperature.	The designated beneficial use supports cold water ecosystems including, but not limited to, preservation or enhancement of aquatic habitats, vegetation, fish, or wildlife, including invertebrates. As stated by Moyle, 1976, the optimum range for Rainbow Trout's growth and completion of most life stages is 13-21 degrees Celsius. Therefore, it is appropriate to use this information as Evaluation Guideline, which does not conflict with the water quality objective for Cold Freshwater Habitat.
18.49	Waterbody Segment: **Wheeler Canyon/Todd Barranca** Pollutant: Benthic Specific Conductivity Justification for Not Listing: • Incorrectly listed using guideline for MUN beneficial use that is not	See response to comment 7.87.

No.	Comment	Response
	applicable to waterbody.	
18.50	***Listing data lacks proper temporal representation.*** There are many instances where the data to support the listed pollutant lacks proper temporal representation. Section 6.1.5.3 of the State Water Resources Control Board (SWRCB) Listing Policy1 states that: "*Samples should be representative of the critical timing that the pollutant is expected to impact the water body. Samples used in the assessment must be temporally independent. If the majority of samples were collected on a single day or during a single short-term natural event (e.g., a storm, flood, or wildfire), the data shall not be used as the primary data set supporting the listing decision.*" Many of the pollutants listed in **Table 1** included data collected from a single sampling date. This violates the Listing Policy. For instance, all the newly proposed pollutants for the Ventura Harbor: Ventura Keys (i.e., arsenic, cadmium, chlordane, DDT, dieldrin, and PCBs) were collected on a single day- February 28, 2007. Because there is no temporal resolution provided for these pollutants they should not be listed. **Requested Action:** **Remove all listings shown in Table 1 that were based on a single sample collection date.**	See response to comment 18.3-18.49 for specific responses.
18.51	***1. Benthic Community Effects Listing are based on flawed analyses and should be removed.*** The benthic community effects listings are based on a metric which has since been deemed arbitrary and inappropriate. The Index of Biotic Integrity (IBI) stream assessment was a commonly used metric to determine benthic community effects. The threshold used to distinguish an impaired reach was a value of 39 and below. However, this threshold value was arbitrarily assigned as a statistical cut-off value. The state has since endorsed the use of the California Stream Condition Index (CSCI), as stated in the Appendix G Fact Sheets, "*The CSCI is applicable*	See response to comment 18.8, 18.11, 18.14, 18.15, 18.35, 18.42, 18.44, and 18.47

No.	Comment	Response
	statewide, accounts for a much wider range of natural variability, and provides equivalent scoring thresholds in all regions of the state. The CSCI will be used in the future for water quality assessment purposes statewide over the regional indices of biologic integrity (IBIs)." Despite this, all of the newly listed benthic community effects in Table 1 utilize the IBI to assess the waterbodies. Therefore, the County is requesting that these flawed listings be removed until the waterbodies can be assessed with a more representative metric such as the CSCI. In addition, a number of water segments are listed as an exceedance for benthic community effects citing a low CSCI score, however, the original data shows only IBI scores. The Water Board should clearly note whether a CSCI or IBI assessment was performed. For instance, the Fact Sheets show that Padre Juan Canyon has 2/2 samples which exceed for benthic community effects using a CSCI score of 0.35 and 0.52 which is below the 0. 79 CSCI threshold. However, the raw data shows that an IBI was performed resulting in scores of 40 and 39, which would only represent one exceedance which would not support listing the water body. The Water Board should clearly state where the CSCI scores are that they are referring to. This issue applies to all new benthic community effects listings. More detailed information can be provided upon request. In addition, many of the benthic community effects listings rely on a single day of sampling which does not provide proper temporal representation as discussed in the previous comment. **Requested Action:** **• Update the Appendix G Fact Sheets to clearly state that an IBI metric was used not the CSCI for all pollutants noted in Table 1.** **• Remove all listings shown in Table 1 for benthic community effect that use the IBI listing.**	
18.52	***2. There is no demonstration that high pH is a result of waste discharge.*** The waterbodies listed for high pH do not appropriately demonstrate that the high pH was a result of waste discharge as required in the Basin Plan. The Santa Clara	See response to comment 16.15.

No.	Comment	Response
	River Estuary and Santa Clara River Reach 1 are both listed for high pH. As stated in the Fact Sheet and according to the Los Angeles Region Basin Plan "*The pH of inland surface waters shall not be depressed below 6. 5 or raised above 8. 5* ***as a result of waste discharges***" [emphasis added]. However, it was not demonstrated for either of these waterbodies that the elevated pH levels were a result of waste discharge as opposed to natural causes. Therefore, the Los Angeles Water Board should either provide evidence that the elevated pH was a result of waste discharge and detail that in the Fact Sheets, or, if no such evidence exists, the Los Angeles Water Board should remove these proposed listings. **Requested Action:** **Remove the pH listings for Santa Clara River Estuary and Santa Clara River Reach 1 as there is no data provided in the Fact Sheet that demonstrate that these high pH values are the result of waste discharge.**	
18.53	***3. Remove any pollutant listing based on municipal drinking water objectives where the MUN beneficial use does not apply.*** Numerous listings were made using WQOs for the protection of the municipal drinking for waterbodies that do not have applicable municipal drinking water beneficial uses. Many of the waterbodies listed are waterbodies for which no beneficial uses are designated or waterbodies designated for the municipal beneficial use with an asterisk (i.e., P*) in the Basin Plan. The asterisked MUN beneficial use should not be used to propose new 303(d) listings. Fact Sheets for previous 303(d) listing cycles have clearly noted that the asterisked MUN beneficial uses should not be used for 303(d) listing purposes. State Board Resolution No. 88-63 (Sources of Drinking Water) and Regional Board Resolution 89-03 (Incorporation of Sources of Drinking Water Policy into the Water Quality Control Plans (Basin Plans)), state that "All surface and ground waters of the State are considered to be suitable, or potentially suitable, for municipal or domestic waters supply and should be so designated by Regional Boards [with certain exceptions which must be adopted by the Regional Board]." The Regional Board adopted a Water Quality Control Plan for the Los Angeles	See response to comment 7.89, 18.3, 18.4, 18.5, 18.7, 18.27, 18.28, 18.31, 18.32, 18.33, 18.34, and 18.49.

No.	Comment	Response
	Region (Basin Plan) on June 4, 1994, that included provisions to implement State Water Board Resolution 88-63. On May 26, 2000, the USEPA approved the revised Basin Plan except for the implementation plan for potential MUN-designated water bodies. On August 22, 2000, the City of Los Angeles, City of Burbank, City of Simi Valley, and the County Sanitation Districts of Los Angeles County challenged USEPA's water quality standards action in the U. S. District Court. On December 18, 2001, the court issued an order remanding the matter to USEPA to take further action on the 1994 Basin Plan consistent with the court's decision. On February 15, 2002, USEPA revised its decision and approved the 1994 Basin Plan in whole. In its February 15, 2002 letter, USEPA stated: *"EPA bases its approval on the court's finding that the Regional Board's identification of waters with an asterisk ("*') in conjunction with the implementation language at page 2-4 of the 1994 Basin Plan, was intended "to only conditionally designate and not finally designate as MUN those water bodies identified by an ('*) for the MUN use in Table 2-1 of the Basin Plan, without further action." Court Order at p. 4. Thus, the waters identified with an ("*') in Table 2-1 do not have MUN as a designated use until such time as the State undertakes additional study and modifies its Basin Plan. Because this conditional use designation has no legal effect, it does not constitute a new water quality standard subject to EPA review under section 303(c)(3) of the Clean Water Act ("CWA"). 33 U.S. C. § 1313(c)(3)."*[3] In addition to the above decision, the Basin Plan states that until the additional study is undertaken and the Basin Plan is modified "no new effluent limitations will be placed in Waste Discharge Requirements as a result of these designations". The Regional Board has also determined that WQOs applicable to the MUN beneficial use will not be used to assess impairments under the 303(d) listing programs. For constituents that only have objectives that are applicable to the MUN beneficial use, the decision Fact Sheets for the 303(d) listing process state that there are no applicable WQOs in waterbodies designated with an asterisk("*"). In the 2010 listing cycle, a number of 303(d) listings were actually removed based on this determination. Below is an example of the language from a	

No.	Comment	Response
	listing decision for Los Angeles River Reach 1 : *"The listing for aluminum in this water body was originally based on data assessed using the MCL for aluminum. Since MUN is a "potential" beneficial use, it is not appropriate to use the MCL to evaluate aluminum data from this reach. Thus, there is no aluminum objective for this reach and the original listing is faulty. "* Based on this evidence, it is clear that for waterbodies with a MUN designation that includes an asterisk ("*"), WQOs specific to the MUN beneficial use are not applicable. As such, water quality data collected in these receiving waters should not be compared to WQOs applicable to the MUN beneficial use. **Requested Action:** **Revise all the new listings in the Fact Sheets to ensure none are based on municipal drinking water objectives when the MUN beneficial use does not apply.**	
18.54	***4. Agricultural Drain and MS4 outfall monitoring data incorrectly used as basis for listing decisions.*** There are some instances where listing decisions are based on data from the Agricultural VCAILG Monitoring Program which include monitoring data from agricultural drains. Santa Clara River Reach 3 (Freeman Diversion to A Street) listings (i.e., chlordane, chlorpyrifos, cyfluthrin, cypermethrin, ODD, ODE, and DDT) were based on multiple lines of evidence, but were primarily listed based on exceedances at VCAILG sample site "S03D_Bards" which is an agricultural drain that drains to Santa Clara River Reach 3. This site was selected to be representative of agricultural discharges to Reach 3 and it is not representative of receiving water conditions. Therefore, any data collected from "S03D_Bard" and other agricultural drain sites cannot be used to list the downstream reach. All listings should be evaluated to ensure that the monitoring locations were in receiving waters rather than agricultural drains.	See response to comments 7.72 and 7.88.

No.	Comment	Response
	In some cases, other lines of evidence cite location "Santa Clara River at Freeman Diversion at 11th Street Drain (tributary to Santa Clara River) at sample location Santa Paula-1" ("Santa Paula-1"). This location is an MS4 outfall location that is designed to characterize urban discharges from City of Santa Paula and is not located in the Santa Clara River's receiving waters. As a result, the data from "Santa Paula-1" location should not be used for listing receiving waters. However, it should be noted that the data linked to the Fact Sheet did not include any data from "Santa Paula-1" so it is unclear what data were evaluated for these listings. Unless receiving water data contain exceedances, none of the constituents for Santa Clara River Reach 3 should be listed. **Requested Action:** **Remove all listings shown in Table 1 that were based on Agricultural and MS4 discharge monitoring data not representative of the listed waterbody and evaluate remaining listings to ensure no other listings are based on agricultural drain or MS4 outfall monitoring rather than receiving water monitoring.**	
18.55	***5. Remove toxicity Lines of Evidence (LOE) from pollutant Fact Sheets when a LOE specifically for toxicity already exists.*** Numerous pollutants listed for Tapo Canyon (chlordane, DDD, and DDE) include a toxicity LOE to support the pollutant listing, when a toxicity LOE already exists for the waterbody. These pollutant-specific toxicity LOEs include no scientific evidence that the specific pollutant was the cause of observed toxicity and so should be removed from the Fact Sheet. **Requested Action:** **Remove the Lines of Evidence for toxicity for Tapo Canyon in Table because no evidence was provided that these constituents were the cause of toxicity.**	See response to comment 18.31 and 18.32.
18.56	***6. Reassess mercury listings using correct objective and correct units.*** The data used to assess mercury for Santa Clara River Reach 3 and Ventura River Reach 3 are in ng/L (nanograms per liter) and the objective is µg/L (micrograms per liter). The data need to be converted into the same units as the objective before	See response to comment 7.90.

No.	Comment	Response
	an exceedance can be determined. The County expects that after this calculation has been performed the waterbodies will no longer meet the listing guidelines. Additionally, although a California Toxics Rule objective exists for mercury, an USEPA nationally recommended criteria was used for the assessment. An explanation for the use of a recommended criteria when an established WQO exists should be provided. **Requested Action:** **Repeat the mercury analysis after correcting the unit error and clarify the objective used.**	
18.57	***7. Correct the proposed temperature listings which are based on incorrect criteria.*** The temperature listing for Ventura River Reaches 1 and 2 (Estuary to Weldon Canyon) and Ventura River Reach 4 (Coyote Creek to Camino Cielo Rd) uses an evaluation guideline of 13-21 degrees Celsius (°C) as the optimum growth range for rainbow trout. However, the applicable Basin Plan objective for waterbodies designated as *COLD* is "For waters designated as COLD, water temperature shall not be altered by more than 5 degrees F above the natural temperature." The Fact Sheets provide no discussion of natural temperatures or a demonstration that the temperature was raised above natural temperatures in order to exceed the objectives. Notwithstanding that a deviation from natural temperatures has not been demonstrated, the manner in which the evaluation guideline is applied is also inappropriate. Moyle 1976 is referenced as the source of the evaluation guideline. Moyle 1976 was revised and expanded by Moyle 20024. Moyle 2002 states: "Rainbows are found where daytime temperatures range from nearly 0°C in winter to 26-27°C in summer", although extremely low (<4°C) or extremely high (>23°C) temperatures can be lethal if the fish have not previously been gradually acclimated. Even when acclimation temperatures are high, temperatures of 24-27°C are invariably lethal to trout, except for very short exposures (25, 26). " As such, while temperatures above 21 °C may not be optimal according to Moyle 1976, Moyle 2002 clearly states that lethal temperatures are those greater	See response to comment 18.43 and 18.48.

No.	Comment	Response
	than 23°C which indicates that the evaluation guideline of 21 °C is more appropriately applied as a chronic guideline (necessitating the establishment of an averaging period) and 23°C is the more appropriate "not-to-exceed" guideline if used for listing. Using the threshold of 23°C, no samples would exceed the threshold in Ventura River Reach 4 and only 2 samples would exceed the threshold in Ventura River Reaches 1 and 2. Neither of these number of exceedances would meet the listing thresholds. **Requested Action:** **Remove the temperature listing for Ventura River Reach 1 and 2 as well as Ventura River Reach 4.**	
18.58	***8. The toxicity listing for Ventura River Reach 3 (Weldon Canyon to Confl. With Coyote Cr) relies on outdated data*** Based on a review of the available data, all the observed toxic samples occurred prior to 2009. Of the 8 exceedances, 3 occurred in 2000/2001 and the rest were in 2006, 2007 and 2008. In the 2006-2008 time period, toxicity was commonly observed due to chlorpyrifos and diazinon which were subsequently restricted. Toxicity in many watersheds has been significantly reduced as a result of these use modifications. The available data shows that no samples exceeded after 2008, indicating that those pesticides or another cause that is no longer present, were the cause of the toxicity. Because of the transient nature of toxicity and the potential that the causes of the toxicity are no longer present, exceedances from prior to the pesticide use bans should not be used as the basis for a listing. The more recent samples since the pesticide use restrictions should be used as a basis for evaluation. **Requested Action:** **Do not list Ventura River Reach 3 for toxicity based on exceedances from outdated data.**	See response to comment 18.46.

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td>18.59</td><td>9. Ensure no J-flagged data were used in the assessment.
The listing policy specifically prohibits the use of J-flagged ("estimated") data that fall below the quantitation limit but above the water quality standard. Section 6.1.5.5 of the Listing Policy specifically states:

"When the sample value is less than the quantitation limit and the quantitation limit is greater than the water quality standard, objective, criterion, or evaluation guideline, the result shall not be used in the analysis. The quantitation limit includes the minimum level, practical quantitation level, or reporting limit. "

All listings based on the use of J-flagged data should, therefore, be removed from the draft 303(d) list. Specific instances are included in Table 1, but this list is by no means inclusive; this significant error will have to be addressed by a thorough review of all listing data to confirm that no J-flagged data were used to justify listings.

For example, the line of evidence for the Boulder Creek chlordane listing erroneously states that three out of five samples exceed the objectives. . A review of the data shows that only 1 out of 5 samples exceed indicated criteria. The remaining 4 results were (1) not detected and (2) "estimated" (J-flagged) by the laboratory because results were below the reporting limit. Because only 1 sample showed an exceedance, this listing should be removed as it does not meet the binomial test limits set forth in the Listing Policy. A similar situation also occurred in the Ellsworth Barranca DOE listing.

Both the Boulder Creek and Ellsworth Barranca listings should be removed based on the incorrect assignment of the beneficial use MUN (as discussed earlier) in addition to the use of J-flagged data.

Requested Action:
• Review all Fact Sheets and Lines of Evidence for the use of J-flagged data and remove any instances where J-flagged data were used.
• Delist chlordane for Boulder Creek and DDE for Ellsworth Barranca as</td><td>See response to comment 7.5.</td></tr>
</table>

No.	Comment	Response
	well as any other pollutants that lack the minimum number of exceedances required to justify a listing.	
18.60	**II. REQUESTED DELISTINGS** In June 2015, the County and the Cities of Fillmore and Santa Paula submitted a letter with data and analysis that supported delisting of the Santa Clara River for ammonia. In the November 10, 2016 letter, Los Angeles Water Board staff responded with plans to recommend delisting of ammonia from Santa Clara River Reach 3 in the 2016 California Integrated Report. The letter is provided as an attachment to this letter. The County requests that the delistings provided in the attached letter be included in the 303(d) list scheduled for adoption on May 4, 2017. **Requested Action:** **Delist Ammonia in Santa Clara River Reach 3.**	As stated in the November 10, 2016 letter, the Regional Board staff recommended delisting of Santa Clara River Reach 3 Ammonia from the 2016 California Integrated Report. Decision 32846 was revised to "Delist from 303(d) list (being addressed by USEPA approved TMDL)".
18.61	**III. CORRECT OTHER ERRORS AND INCONSISTENCIES IN APPENDICES AND FACT SHEETS** Appendix A, Appendix B, Appendix C, and Appendix G have many inconsistencies which make the analysis of new additions very difficult since it is unclear which segment-pollutant combinations actually are new listings. As a result, there is concern that not all changes to the 303(d) list that may be considered for adoption were identified in the review. The lack of clarity comes from the following inconsistencies: • Not all new listings are summarized in Appendix A. • Appendix B was found to be missing some new and old listings based on a comparison to Appendix G. • Appendix G has fact sheets for some listings noted as new in Appendix A or B identified as old fact sheets from the last listing cycle (e. g. benthic community listings in Javon Canyon). This indicates they were old listings, but a comparison to the 2010 303(d) list identified that they were in fact new listings and the fact sheets were incorrect or located in the wrong location.	See response to comment 7.98 and 7.99.

No.	Comment	Response
	Additionally, in many cases, data and Quality Assurance Project Plan references in the Fact Sheets are inconsistent with the data provided for review. Examples of these inconsistencies and errors were detailed in the CCW TMDL Stakeholders' comment letter. The County asks that the Los Angeles Water Board do a thorough review of all appendices to ensure that the Proposed 303(d) List is internally consistent, the correct data were used for the assessment, and the other errors identified in the CCW TMDL Stakeholders' comment letter are addressed. **Requested Action:** **Correct the numerous errors and inconsistencies in the report and ensure that all the proposed 303(d) list appendices are internally consistent.**	
19.	County of Ventura and the Cities of Fillmore and Santa Paula, March 30, 2017	
19.1	The proposed updates to the 303(d) list did not include delisting of the Santa Clara River Reach 3 for ammonia as recommended by the Los Angeles Regional Water Quality Control Board (Los Angeles Water Board) in the letter dated November 10, 2016 provided as an attachment to this letter. In June 2015, the County and the Cities submitted a letter with data and analysis that supported delisting of the Santa Clara River Reach 3 for ammonia. In the November 10, 2016 letter, Los Angeles Water Board staff responded: "Based on the findings described above, the requirements for delisting have been met. Therefore, Los Angeles Water Board staff plans to recommend delisting of ammonia from Santa Clara River Reach 3 in the 2016 California Integrated Report." (page 2 of the attached November 10, 2016 letter). The County and the Cities request that the ammonia delistings be included in the 303(d) list scheduled for adoption on May 4, 2017. Requested Action: Delist Ammonia in Santa Clara River Reach 3.	See response to comment 18.60.

No.	Comment	Response
20.	California Department of Water Resources (DWR), March 30, 2017	
20.1	The updates to the 303(d) list propose to add the following pollutants to the following State Water Project (SWP) affiliated locations: • Dieldrin, chlordane, DDT, and polychlorinated biphenyls (PCB) to Pyramid Lake • PCBs to Castaic Lake and Castaic Lagoon, and • Dieldrin and PCBs to Elderberry Forebay. DWR has the following comments: 1) The proposed pollutant listings lack a clear rationale that supports the recommended listings. A clear rationale, such as recommended food (i.e. fish) exposure levels (Food and Drug Administration for example), Fish Contaminant Goal (FCG), or Advisory Tissue Levels (ATL) for each pollutant should be provided so a clear comparison can be made. Some of the levels for these contaminants are above the FCG, they have not reached the ATL, and in fact, the report labels these contaminants as very low, as compared to the other higher priority contaminants. Absent such comparison, it is difficult to assess the appropriateness for such listings.	The Basin Plans contains narrative objectives for toxics pollutants that bioaccumulate within the biotic and result in adverse impacts to aquatic life or human health. Section 6.1.3 of the Listing Policy states that evaluation guidelines shall be used to interpret those objectives. Each LOE identifies the water quality objective/criterion and the evaluation guideline that was used in the assessment. Depending on the beneficial use being assessed, these evaluation guidelines are the National Academy of Science (NAS) guidelines for protection of aquatic life from bioaccumulation and Fish Contaminant Goals (FCGs). The policy allows for the use of evaluation guidelines published by the Office of Environmental Health Hazard Assessment (OEHHA) for the purposes of protection of human health from fish consumption. Water Board staff chose to use the FCGs values because they were the most protective values for fish consumption. There is no need to list a comparison of all three values rather than just selecting the most appropriate, protective, value. Furthermore, OEHHA screening values have been used as numeric targets in TMDLs within the Los Angeles region.
20.2	2) The PCB data in Table 11 (Summary Report) for Elderberry Forebay does not seem to match that of the proposed listing status. Elderberry Forebay is absent	Staff assumes the commenter is referring to Staff Report Appendix A: Summary of Regional Board

No.	Comment	Response
	from this Table.	Recommended Changes to the 2012 303(d) List. Elderberry Forebay dieldrin and PCBs are appropriately listed as new listings, which also matches the listing in Appendix B (Category 5).
20.3	3) Insufficient details are provided for dieldrin, chlordane and DDT. A more comprehensive effort that specifically focuses on these contaminants should be conducted before they are proposed for Pyramid Lake additions to the 303(d) list.	"LIST" is the appropriate recommendation for dieldrin, chlordane and DDT. Listed waterbodies are evaluated and listing decisions are made based on Section 3 of Listing Policy. Based on readily available data and Section 3.5 and Table 3.1 of the Listing Policy and there are sufficient samples to list based on the binomial distribution. Greater detail regarding those listings is provided in Decision 62840, 62841, and 65950 in Appendix G. Also see response to comment 32.3 regarding readily available data.
20.4	4) Further analysis, including statistical analysis, should be conducted to support this proposed listing. Given the proposed listing recommendations are based on sample analytical data, a statistical analysis to show that sufficient sample size has been obtained for each lake should be provided. Additional considerations for analysis should also include: • Increasing sampling locations. Were the samples obtained truly representative of the entirety of the lakes, especially those that are the subject of this letter? • Do the composite samples truly represent averages of the fish caught, or are they additive? Can composites identify anomalies? Can a lake-wide composite be skewed, as a result of one very high data point? • One-time study involving one year seems insufficient. Studies with longer duration are more appropriate to accurately determine the pollutant levels.	While the Listing Policy requires that samples be spatially and temporally independent, fish are not static; they move throughout a waterbody and accumulate pollutants in tissue over time. Therefore, the data are, by their nature, spatially and temporally independent. At the time a TMDL is developed, or other regulatory program is developed, a more refined geographic scope can be identified considering collection sites and fish movement. See response to comment 32.3 regarding readily available data.

21.	Earth Law Center (ELC) , March 30, 2017	
21.1	**<u>1. Full Compliance with Clean Water Act Sections 305(b) and 303(d) Requires Identification of All Hydrologically Impaired Waterways</u>** *a. CWA Section 303(d)* Clean Water Act (CWA) Section 303(d)(1)(A) requires California to "identify those waters within its boundaries for which the effluent limitations … are not stringent enough to implement any water quality standard applicable to such waters." This must be a robust listing, with sufficient details about the waterways (including flow) to allow the state to "establish a priority ranking" for the waterways, also required by Section 303(d)(1)(A). In other words, California's 303(d) list must provide a comprehensive list of all impairments. The state's Listing Policy provides some mixed direction, stating on the one hand that 303(d) list only covers impairments by "pollutants" (rather than also by "pollution," such as flow),[2] but on the other hand stating that Regional Water Board Fact Sheets supporting Section 303(d) listings "shall contain...Pollutant or *type of pollution* that appears to be responsible for standards exceedance."[3] The latter path is the appropriate course. No objection, further, can be made to including flow-impaired waterways on the Section 303(d) list on the basis that the state is not required to prepare TMDLs to address "pollution." First, Section 303(d)(1)(A) makes no mention of limiting the 303(d) list to those waterways requiring Total Maximum Daily Loads (TMDLs). In fact, no mention of TMDLs is made until Section 303(d)(1)(C), which sets requirements on how to manage impaired waterways. Moreover, the state itself does not take this position for waterways impaired by pollutants. Instead, the state lists in Category 5 (what it deems its Section 303(d) list) pollutant-impaired waterways that do, and do not, require TMDLs by state evaluation.[4] Accordingly, the state must include hydrologically impaired waterways, including those impaired by altered flow, on its 303(d) list. This is the path the Los Angeles RWQCB correctly took in listing the Ventura River (Reaches 3 & 4) for "pumping" and "water diversion" impairments.	The State Water Board has already addressed similar comments regarding flow-related impairments in their response to comments for their Proposed Clean Water Act Section 303(d) List of Water Quality Limited Segments (303(d) List) Portion of the 2012 California Integrated Report, posted March 3, 2015. The Los Angeles Water Board concurs with State Board's response to *American Rivers*. The State Water Board response is provided below: *Sufficient flow is necessary to protect water quality and beneficial uses of water. "Pollution," such as lack of adequate flow, may cause impairments to water quality standards. Specifically, reduced flows can cause or contribute to impaired water quality conditions, such as elevated water temperatures, increased pollutant concentrations, degraded recreational opportunities, and reduced habitat area and/or volumes.* *State law recognizes the connection between flow and water quality. The Legislature specifically identified its intention to "combine the water rights and water pollution and water quality functions of state government to provide for consideration of water pollution and water quality, and availability of unappropriated water whenever applications for appropriation of water are granted or waste discharge requirements or*

No.	Comment	Response
	However, rather than continuing to follow the clear intent of CWA Section 303(d), the Los Angeles RWQCB instead proposes to delist the Ventura River (Reach 3) for "pumping,"[5] despite this listing having been properly included on the 303(d) list since 1998. The primary reason given is that "[t]he listing is for a non-pollutant and therefore should be delisted."[6] However, as established above, the CWA requires the listing of both pollutants and pollution on the 303(d) list, regardless of whether a TMDL is required. Therefore, we ask that the Ventura River (Reach 3) remain on the 303(d) list.	*water quality objectives are established" when it created the State Water Resources Control Board. (Wat. Code, § 174.)* *The State Water Board has broad authority to consider water quality and pollution when it makes water allocation determinations. (Wat. Code, §1258.) The State Water Board has significant experience both setting and implementing flow criteria through water right actions, including its Bay-Delta Program and its Policy for Maintaining Instream Flows in Northern California Coastal Streams. The State Water Board also has experience setting flow requirements as part of its responsibility to certify that the operation of hydropower facilities subject to Federal Power Act licensing meet water quality standards. Those actions are always controversial and frequently involve differences of opinion among scientists, who testify under oath, as to appropriate flow criteria in those proceedings. The State Water Board has previously recognized that its major rivers are over-allocated and adversely impacted by flow alterations (see for instance Strategic Plan Update 2008-2012, State Water Resources Control Board, September 2, 2008, p.10). However, the extent of the impact on instream beneficial uses of a stream depends on the unique circumstances of each situation and requires knowledge of other factors impacting the physical and biological integrity of the watercourse, including physical impediments to fish passage and sediment recruitment (dams and culverts, in addition to natural impediments such*

No.	Comment	Response
		as waterfalls and landslides), the source of the water accreting to the stream (is it cool groundwater or is it warm runoff from open lands), the location and physical effect of diversions relative to habitat, and other factors that affect pollution. *Pursuant to the above-cited state law, the State Water Board is expressly required to consider water quality and pollution when making water rights determinations. The converse is not true, however, with regard to the federal law directly applicable to developing the Integrated Report. The federal statutory directives pursuant to CWA 303(d) and 305(b) require states to report on the water quality necessary to provide for fish, wildlife, and recreational opportunities and other beneficial uses. In fulfilling its reporting obligations pursuant to CWA 303(d) and 305(b), the federal statutes do not expressly require the states to consider flow, pollution, or allocation of water rights, when reporting on standards attainment. Clean Water Act (CWA) section 305(b), combined with the section 303(d) reporting requirements, comprises the California Integrated Report (Integrated Report). Those reporting requirements establish a process for states to use to develop information on the quality of their state's waters.* *CWA section 305(b) is the principle [sic] means by which U.S. EPA and the public assess whether waters meet water quality standards. The report is used by U.S. EPA to inform Congress on the*

		quality of navigable waters and their tributaries nationwide. *CWA section 305b requires states to report on:* *"[A] description of the water quality of all navigable waters in such State during the preceding year, with appropriate supplemental descriptions as shall be required to take into account seasonal, tidal, and other variations, correlated with the quality of water […]."[A]n analysis of the extent to which all navigable waters of such State provide for the protection and propagation of a balanced population of shellfish, fish, and wildlife, and allow recreational activities in and on the water."* *"[A]n analysis of the extent to which the elimination of the discharge of pollutants and a level of water quality which provides for the protection and propagation of a balanced population of shellfish, fish, and wildlife and allows recreations activities in and on the water, have been or will be achieved by the requirements of this chapter, together with recommendations as to additional action necessary to achieve such objectives and for what waters such additional action is necessary."*

No.	Comment	Response
		(CWA § 305(b)(1)(A)-(C); see id. at § 305(b)(1)(D) & (E) (describing economic and environmental reporting requirements).) U.S. EPA describes the section 305(b) reporting goals at: http://water.epa.gov/type/watersheds/monitoring/upload/2003_07_24_monitoring_305bguide_v1ch1.pdf , *and provides 2006 Integrated Report Guidance here:* *http://water.epa.gov/lawsregs/lawsguidance/cwa/tmdl/2006IRG_index.cfm.* *As provided in the above U.S. EPA reference material, the primary purpose of the 305(b) and 303(d) reporting requirements is to determine the extent waters are attaining standards, identify waters that are impaired and need to be added to the 303(d) list and placed in Category 5 for the development of a total maximum daily load (TMDL), and identify waters that can be removed from the list when standards are attained.* *The guidance U.S. EPA developed for states to implement the Integrated Report consistently provides that segments should be placed in Category 4c when "the [S]tates demonstrate[] that the failure to meet an applicable water quality standard is not caused by a pollutant, but instead is caused by other types of pollution" such as lack of adequate flow. (See Guidance for 2006 Assessment, Listing and Reporting Requirements*

No.	Comment	Response
		Pursuant to Section 303(d), 305(b) and 314 of the Clean Water Act (July 29, 2005). *In making decisions concerning standards assessment, it is imperative that the State Water Board undertakes a structured framework regarding its assessment and listing methodology and also provides information on the content of such methodologies.* *It may be appropriate to assess flow alteration pursuant to section 305(b) to the extent it could be used to support water quality decision-making. However, without a defined methodology for assessing non-pollutant related pollution, Water Board staff does not have a consistent and transparent approach to analyzing the extent to which flow-related alterations cause or impact water quality standards. The decisions made by the State and Regional Water Boards must be based on a methodology that provides all stakeholders with the opportunity to understand exactly how assessment decisions are made. The State Water Board's listing determinations must be supported by documentation that explains the analytical approaches used to infer true segment conditions. (See U.S. EPA's 2006 Guidance for Assessment and Listing, p. 29 (explaining what constitutes an assessment methodology and U.S. EPA's review of a state's methodology for consistency with the CWA and a state's water quality standards).) In addition to recognizing U.S. EPA's recommendation that segments be placed in Category 4c when the cause is solely*

No.	Comment	Response
		due to pollution, and given the uncertainties associated with determining appropriate flow criteria to be used as a threshold for determining impairment, the State Water Board does not believe that placing segments in Category 4c of the Integrated Report results is warranted. Neither is such a reporting format an appropriate use of its limited resources, particularly considering the State Water Board's broad authority to address flow issues through its other legal authorities, which unlike information provided in the Integrated Report, have the potential to result in flow improvements through voluntary or regulatory action. However, in this 303(d) list, the Los Angeles Water Board has assigned the Ventura watershed pumping and water diversions to "being addressed by a TMDL" (Category 4a). In EPA's approval letter for the Ventura River Algae, Eutrophic Conditions and Nutrients TMDL, EPA stated "Based on EPA's approval of the State' s TMDLs addressing the algae, eutrophic conditions and nutrient impairments, together with other available information regarding Reaches 3 and 4 of the Ventura River, EPA has determined that it is unnecessary at this time to establish separate actions for the pumping and water diversion in Reaches 3 and 4 of the Ventura River." Decision ID 33817 Ventura Reach 3, water diversion Decision ID 44534 Ventura Reach 4, water diversion

		Decision ID 34271 Ventura River Reach 3, pumping Decision ID 44793 Ventura Reach 4, pumping
21.2	*b. CWA Section 305(b)* The state must also include hydrologically impaired waters in its broader, CWA Section 305(b) report. Section 305(b) requires states to submit biennial reports[7] that "shall" describe the "water quality of all navigable waters," including an analysis of the extent to which the waters protect fish and wildlife, for compilation and submission to Congress.[8] Federal regulations describe this requirement and its purpose, stating that **the Section 305(b) report "serves as the primary assessment of State water quality" and the basis of states' water quality management plan elements, which "help direct all subsequent control activities."**[9] States must use the Section 305(b) report to develop their annual work program under Sections 106 and 205(j).[10] California's Integrated Report accordingly must include an adequate Section 305(b) report if the state is to develop meaningful water quality plans that appropriately direct staff and resources to the most important control activities. The Section 305(b) report must particularly include information regarding waterway flows to ensure that the fundamental purpose of Section 305(b) in guiding workplanning is met. The provision of information regarding waterway flow is also called for by CWA Section 101, which sets **the national objective of restoring and maintaining the "chemical, *physical*, and biological integrity of the Nation's waters."** (Emphasis added.) The U.S. Supreme Court itself explicitly affirmed the importance of addressing physical elements of waterway health such as flow, stating **that the distinction between water quality and quantity under the CWA is "artificial."**[11] The Staff Report runs afoul of the CWA by ignoring Category 4C entirely for inclusion in either its 303(d) list or its 305(b) report, reporting that *zero* water bodies in the Los Angeles Region are impaired due to altered hydrology under Category 4C.[12] As with other regional water boards, the Los Angeles RWQCB	The State Water Board has already address similar comments regarding flow-related impairments in their response to comments for their Proposed Clean Water Act Section 303(d) List of Water Quality Limited Segments (303(d) List) Portion of the 2012 California Integrated Report, posted March 3, 2015. The Los Angeles Water Board staff concurs with the State Water Board's response to *American Rivers*. The State Water Board response is provided below: *It is State Water Board staff's interpretation that waterbodies currently listed for pollutant based impairments should not be included for pollution based impairments as well. The pollution based impairments should be addressed via the TMDL or other regulatory process. If all pollutant based impairments are eventually addressed and the pollution impairments still exist, then placement into Category 4c could be appropriate.* In addition, the State Water Board states: *U.S. EPA tried to implement a flow TMDL for the Ventura River listings and abandoned the effort because it lacked authority to address nonpollutant impairments. Consequently, a Nutrient TMDL has been implemented that takes*

No.	Comment	Response
	appears to rely on the Listing Policy for this decision, which states that the 303(d) list only includes those water segments that require the development of a TMDL.[13] Here, again, the Staff Report assumes an illegally narrow definition of its requirements under the CWA. The Integrated Report is supposed to include *both* a robust and legally adequate 303(d) list *as well as* a robust and legally adequate 305(b) report. These requirements are combined; they are not the same (*see also* sec. 8). If the State Water Board and Regional Water Boards take the position that pollution-impaired waterways (including flow-impaired waters) cannot be included in the Section 303(d) list, then the Listing Policy – which by definition applies *only* to the Section 303(d) list – is irrelevant. It cannot be used as an excuse to ignore flow impairments entirely. The state in that case must then turn to its requirements under Section 305(b), which broadly require it to report on water quality, including as impacted by altered flow. Indeed, the Staff Report recognizes that it must consider flow-impaired waterways in its assessment, describing Category 4C as being applicable if "[t]he non-attainment of any applicable water quality standard for the waterbody is the result of pollution and is not caused by a pollutant."[14] No legitimate reason is given for failing to comply with this requirement, however. A legally adequate Section 305(b) report must include waterways impaired by pollution, including hydrologically impaired waterways, whether or not the waterways are also impaired by a pollutant. This information is also critical for the state to set waterway protection priorities properly. Proper identification of hydrologically impaired waterways is also important if the state is to fully comply not only with Section 305(b), but with CWA Section 303(d) as well. This section not only calls for identification of impaired and threatened waterways, but also requires the state to prepare a "*priority ranking*" of such waters, "taking into account the severity of the pollution" and waterway uses.[15] Flow and other hydrologic alteration data and information are critical to proper prioritization of impaired waters for further staff and resource attention. Specifically in regards to the Ventura River (Reach 3), in addition to misguidedly delisting this water segment from the 303(d) list for its impairment due to	*into account the flow impairments as a causative factor*. While these listings are not strictly flow-related, in this 303(d) list, the Los Angeles Water Board has assigned the Malibu Creek and the Matilija Creek fish barriers listing to Category 4c. However, the Los Angeles Water Board recognizes that the issue of Statewide consistency may become more important as the State Water Board approves the Los Angeles Region 303(d) list combined with lists for other Regions. See: Decision ID 34814 Malibu Creek fish barriers Decision ID 35724 Matilija Creek reach 1 Fish Barriers Decision ID 34162 Matilija Creek reach 2 Fish Barriers Decision ID 34241 Matilija Creek reservoir Fish Barriers Also, see response to comment 21.1.

No.	Comment	Response
	"pumping," the Los Angeles RWQCB staff also fails to reclassify this water segment under Category 4C, finding that "[t]here is no established method for determining impairment due to pollution like pumping so a Category 4C finding is also inappropriate."[16] Once again, this response is misguided, as the state must at minimum include hydrologically impaired waters in its broader, CWA Section 305(b) report, as described above, whether or not there are flow standards or a formal methodology to do so. See Sec. 6, below. Finally, we reiterate that because Section 303(d)(1)(A) broadly requires identification of impairments *regardless* of whether TMDLs are needed, the state's Section 303(d) list should include a robust Category 4C set of listings. State law cannot weaken the requirements of the CWA by artificially limiting the scope of this list.	
21.3	**2. U.S. EPA Guidance and Reports, and the State Water Board Itself, Have Called for Identification of Hydrologically Impaired Waterways in Category 4C of the Integrated Report** U.S. EPA issued formal Integrated Report Guidance (i.e., for the combined Sections 303(d) and 305(b) reports) to states and territories in August 2015; in it, EPA specifically addresses the topic of hydrological impairment.[17] The U.S. EPA Guidance clearly states that: > If States have data and/or information that a water is impaired due to pollution not caused by a pollutant (e.g., aquatic life[18] use is not supported due to hydrologic alteration or habitat alteration), those causes should be identified and that water should be assigned to Category 4C.[19] The Guidance specifically references hydrologic alteration as an example of a Category 4C listing.[20] It further references EPA Guidance going back at least to 2006, which similarly said that flow-impaired waters should be identified in the Integrated Report under Category 4C (the 2010 CCKA et al. Letter references this 2006 Guidance in support of flow listings; see attachment 3).	There is not clear evidence supporting the fact that beneficial uses are impaired solely due to the lack of or excess of perennial or ephemeral flows. The State Water Board has already address similar comments regarding flow-related impairments in their response to comments for their Proposed Clean Water Act Section 303(d) List of Water Quality Limited Segments (303(d) List) Portion of the 2012 California Integrated Report, posted March 3, 2015. The Los Angeles Water Board concurs with the State Water Board's response to *American Rivers*. The State Water Board response is provided below: *The State Water Board and North Coast Regional Water Board (North Coast Water Board) staff could not clearly determine if the beneficial uses*

No.	Comment	Response
	U.S. EPA and USGS reinforced this mandate in a joint report in February 2016 on flow, stating in part that "EPA recommends reporting impairments due to hydrologic alteration in Category 4c, which are those impairments due to pollution not requiring a TMDL."[21] Even more specifically, U.S. EPA Region 9 has directly told the State Water Board that the Board is "well aware of [EPA's] interest toward listing selected streams for 'flow impairments' (at least under 305(b)) where lines of evidence are strong."[22] Further, the State Water Board Executive Director himself decided that the state should identify flow-impaired waters in its Integrated Reports, stating that California "would now list for flow alterations" and that "[l]istings would be made under category 4C for impaired [sic] by pollution not a pollutant, and be based on staff's professional judgment as well as the evidence submitted by the data."[23] Again, no reason is given in the Staff Report for ignoring the clear flow impairments throughout the region in light of the CWA, guidance, and state direction.	*of a water quality segment were impaired solely due to stream flow or lack thereof. In many water segments, flow is seasonal resulting in dry periods during the summer months. If interpretive guidance or a clear methodology was developed to examine flow and other forms on non-pollutant related pollution, Water Board staff would have a transparent and consistent way to characterize beneficial use impairments caused by such pollution.* Also see response to comment to comment 21.1 and 21.2.
21.4	**<u>3. The San Diego RWQCB Has Adopted Numerous Listings for Hydrologic Impairment for Its Current Integrated Report</u>** The SD RWQCB recently adopted an Integrated Report and Staff Report[24] that **identified 30 waterway segments for listing in Category 4C, either with a Category 5 pollutant listing or alone**.[25] Consistent with U.S. EPA Guidance, the SD RWQCB recognized that identifying all pollutant and pollution impairments provides a far more accurate picture of the challenges before the state than ignoring key impairments. For example, the Staff Report found that "over 96 percent of streams that exhibited biological degradation had both an associated pollutant(s) and supporting information showing pollution from in-stream habitat/hydrologic alteration and/or watershed hydrologic alteration (hydromodification, Table 3)." If the Regional Board had ignored such pollution impairments, then virtually all of the impaired streams in the San Diego Region would have been under-assessed, likely resulting in misallocation of limited	As the commenter states and the San Diego Regional Board mentioned in their staff report, "*…streams that exhibited biological degradation had both an **associated pollutant**(s) and supporting information showing pollution from in-stream habitat/hydrologic alteration and/or watershed hydrologic alteration …*"

No.	Comment	Response
	resources and attention. ELC commented to the San Diego Board in support of these listings; these comments are attached.[26]	
21.5	**4. <u>California Has Identified Hydrologically Impaired Waterways in the Past</u>** In California, "pumping" and "water diversion" are currently listed as causes of impairment for Ventura River Reaches 3 and 4, in the Los Angeles Region. Additionally, Ballona Creek Wetlands is currently listed as impaired by "Hydromodification," among other impairments. All three water body segments are currently listed for these specific flow-related impairments in Category 5.[27] California's history of identifying flow-related impairments under Section 303(d) should be considered precedential. And as explained herein and by Santa Barbara Channelkeeper in its comment letter, there is no basis for delisting Reach 3 of the Ventura River.	The State Water Board has already addressed similar comments regarding flow-related impairments in their response to comments for their Proposed Clean Water Act Section 303(d) List of Water Quality Limited Segments (303(d) List) Portion of the 2012 California Integrated Report, posted March 3, 2015. The Los Angeles Water Board concurs with the State Water Board's response to *American Rivers*. The State Water Board response is provided below: *The Staff Report (at p. 9-10) states that the Water Boards have not considered the direct assessment of flow data since the adoption of the Listing Policy in 2004. The Staff Report acknowledges, however, that there were 4 listings on the existing 303(d) List related to flow-related alterations in the Ballona Creek and Ventura River watersheds (Region 4) but that those decisions were made prior to the adoption of the Listing Policy.* *The Listing Policy provides listing factors based solely on pollutant impairments. As a result, any section 303(d) listings related to flow alterations are contrary to the Listing Policy and U.S. EPA guidance and would be appropriate for reconsideration. Because the 4 segments were included on the 303(d) list due to pollution-related impairments, and not a pollutant, the Staff Report*

No.	Comment	Response
		explains that the 4 listings for flow will likely be proposed for delisting in the next listing cycle. *However, it is important to note that the 4 segments were also listed on the 303(d) List for pollutant impairments for which TMDLs have been developed: Ventura River Reaches 3 and 4 – are identified as impaired due to pumping and water Diversion. The Regional Water Board and U.S. EPA have found that those flow related impairments were addressed via the Ventura River Algae TMDL. Regarding the listings for Ballona Creek Wetlands, identified as impaired due to hydromodification and reduced tidal flushing, the Regional Water Board and U.S. EPA have found that the Ballona Creek Sediment and Exotic Vegetation TMDL are addressing the stressors involved with the hydromodification and reduced tidal flushing.* *U.S. EPA tried to implement a flow TMDL for the Ventura River listings and abandoned the effort because it lacked authority to address non-pollutant impairments. Consequently, a Nutrient TMDL has been implemented that takes into account the flow impairments as a causative factor.* However, as noted in response to comment 21.1, the Los Angeles Water Board has assigned the Ventura River watershed pumping and water diversions to “being addressed by a TMDL” (Category 4a).

No.	Comment	Response
21.6	**<u>5. Numerous Other States Have Identified Hydrologically Impaired Waterways in Categories 4C and 5</u>** Many states around the country have followed U.S. EPA Guidance and the CWA by properly identifying flow-impaired waterways in their Integrated Reports. These include, but are not limited to, Western states such as Idaho, Montana, Wyoming, Washington and New Mexico.[28] One listing methodology that may be of particular interest to the Los Angeles is that used by Ohio, which identifies waters impaired by flow alteration by linking biological community degradation with upstream dams. Notably, a number of these states regularly include flow-impaired waterways on their 303(d) list as well as their 305(b) Report. ELC has collected a significant amount of information on other states' hydrologic impairment listings and processes (and provided this to the State Water Board); this can be made readily available to the Los Angeles Board if desired.	See response to comment 21.1 and 21.2.
21.7	**<u>6. Flow Standards Are Not Required to Identify Hydrologically Impaired Waterways in Category 4C</u>** Most, if not all, of the states that identify hydrologic (including flow) impairments make those listing decisions based on best professional judgment and the information before them. Flow standards are not required to be developed first. Even the State Water Board has stated that flow listings could be done "based on staff's professional judgment as well as the evidence submitted by the data," and that they "would likely be mostly narrative...unless there are specific numeric targets for flow in place."[29] In other words, the state itself has recognized that flow criteria are not necessary for flow impairment listings. ELC has compiled significant information collected on various states' hydrologic impairment listing strategies and would be pleased to provide this additional information if desired. U.S. EPA addresses the process of identifying hydrologically impaired waters in its 2015 EPA Listing Guidance, stating that: If States have data and/or information that a water is impaired due to	See response to comment 21.1 to 21.4.

No.	Comment	Response
	pollution not caused by a pollutant (e.g., aquatic life use is not supported due to hydrologic alteration or habitat alteration), those causes should be identified and that water should be assigned to Category 4C. Examples of hydrologic alteration include: a perennial water is dry; no longer has flow; has low flow; has stand-alone pools; has extreme high flows; or has other significant alteration of the frequency, magnitude, duration or rate-of-change of natural flows in a water; or a water is characterized by entrenchment, bank destabilization, or channelization. Where circumstances such as unnatural low flow, no flow or stand-alone pools prevent sampling, it may be appropriate to place that water in Category 4C for impairment due to pollution not caused by a pollutant. In order to simplify and clarify the identification of waters impaired by pollution not caused by a pollutant, States may create further subcategories to distinguish such waters.[30] Note that this description of the process for identifying flow impairments does not require adoption of flow standards as a prerequisite for listing. The SD RWQCB Staff Report also addressed this topic in their just-approved Staff Report and Integrated Report, similarly stating that: where a water segment exhibited significant degradation in biological populations and/or communities as compared to reference site(s) the San Diego Water Board assessed the segment for inclusion in Category 4c using data and information as prescribed in USEPA's 2015 Guidance...Where in-stream data was lacking, stream segments were evaluated using desktop aerial reconnaissance for potential in-stream habitat and hydrologic alteration associated with channel modifications, stream diversion or augmentation, and to evaluate the level of associated development and use of best management practices to mitigate hydromodification.[31]	
21.8	**7. Sound Public Policy Dictates that Flow-Impaired Waterways Must Be Identified**	The Los Angeles Water Board agrees with the value of identifying waterbodies that are impacted

No.	Comment	Response
	States, including California, have identified and are identifying flow-impaired waterways in their Integrated Reports not only because the Clean Water Act calls for it and U.S. EPA Guidance reinforces it. They also do so because it makes smart policy sense. Why would a state limit the amount of information it releases, information that could help it make better decisions about how to prioritize its resources? If the main problem with a waterway is not temperature or dissolved oxygen but flow, for example, then that information should be available so the best permitting and resource allocation decisions can be made to protect affected waterways. Identification of flow-impaired waterways is also important because those listings help the public exercise their own responsibility to help improve waterway health. U.S. EPA agreed in its Guidance, stating that "a variety of watershed restoration tools and approaches to address the source(s) of the impairment" exist even in the absence of TMDLs, increasing the importance of full and complete identification for impaired waterways.[32] Hydrologic impairment listings also can and should be used in CEQA analyses of proposed projects that could further impact the flow of identified waterways, thus preventing additional damage to already-impacted waterways and fish. ELC has prepared and submitted extensive comments to the state on the numerous policy benefits of properly identifying flow-impaired waterways.[33]	by pollution, including flow alteration, that are not otherwise impaired by other pollutants. Given the complex characteristics of climate and hydrology in the Los Angeles region, determining natural baseline flow conditions that are necessary to support aquatic habitat based on comparable reference conditions that resemble the conditions within our region and finding a defensible methodology for applying that information to determine impairment is a challenging endeavor that may be pursued in subsequent assessments.
21.9	**<u>8. Water Bodies Can and Should Be Placed in All Relevant Categories of Identification</u>** The Staff Report states that "[t]o meet CWA section 305(b) requirements of reporting on water quality conditions, the Integrated Report places each assessed waterbody segment into one of five non-overlapping categories based on the overall beneficial use support of the water segment…."[34] This statement appears to limit the RWQCB to placing water bodies in only one category, an interpretation presumably reflected in the recommendation to include zero listings in Category 4C.	The State Water Board has already addressed similar comments regarding flow-related impairments in their response to comments for their Proposed Clean Water Act Section 303(d) List of Water Quality Limited Segments (303(d) List) Portion of the 2012 California Integrated Report, posted March 3, 2015. The Los Angeles Water Board concurs with the State Water Board's response to *American Rivers*.

Response to Comments on the Draft 2016 303(d) List
Comment Deadline: March 30, 2017

No.	Comment	Response
	This approach is simply incorrect. U.S. EPA has been quite clear that water bodies can be placed into multiple categories, and in fact should be in order to provide the best available information to U.S. EPA and Congress. As explained by the SD RWQCB in its Staff Report: It is important to note that USEPA recommended in its 2015 guidance that "States assign all of their surface water segments to ***<u>one or more of five reporting categories</u>***"....[35] U.S. EPA reiterated this point in its joint report with USGS, stating that "EPA's guidance has noted that **assessment categories *are not mutually exclusive*, and waters may be placed in more than one category (for example, categories 4C and 5)**."36 Accordingly, flow impairments should be reflected in Category 4C whether or not there is a pollutant present, the approach taken recently by the SD RWQCB. Otherwise, the state is conflating the Section 303(d) and 305(b) reports rather than combining them, ignoring its Section 305(b) responsibilities in the process.[37] Because the state must comply with both Sections 305(b) and 303(d), it must provide information relevant to all categories applicable to a single water body.[38] The Integrated Report does not meet these mandates.	The State Water Board response is provided below: *The State Water Board has not indicated that it is bound to U.S. EPA's guidance. Additionally, the State Water Board disagrees with the commenter's interpretation of U.S. EPA's <u>Guidance for 2006 Assessment, Listing, and Reporting Requirements Pursuant to Sections 303(d), 305(b), and 314 of the Clean Water Act</u>, which is excerpted in the Staff Report at page 10.* *U.S. EPA's guidance at section V.G.3 (pg. 56) states:* *Segments should be placed in Category 4c when the [S]tates demonstrate[] that the failure to meet an applicable water quality standard is **not caused by a pollutant**, but instead is caused by other types of pollution. Segments placed in Category 4c do not require the development of a TMDL. Pollution, as defined by the CWA is 'the man-made or man-induced alteration of the chemical, physical, biological, and radiological integrity of water' (section 502(19)). In some cases, the pollution is caused by the presence of a pollutant and a TMDL is required. In other cases, pollution does not result from a pollutant and a TMDL is not required. States should schedule these segments for monitoring to confirm that there continues to be no pollutant associated with the failure to meet the water quality standard*

No.	Comment	Response
		and to support water quality management actions necessary to address the cause(s) of the impairment. Examples of circumstances where an impaired segment may be placed in Category 4c include segments impaired ***solely*** *due to lack of adequate flow or to stream channelization.* *(Page 56, emphasis added.) In California waterbody-pollutant combinations are assessed consistent with the Water Quality Control Policy for developing the California's Clean Water Act Section 303(d) List (Listing Policy) to determine the overall use support rating. That overall use support rating is used by the California Water Quality Assessment Database (CalWQA) to determine the overall Integrated Report Category for the waterbody as a whole.* *The State Water Board interprets the U.S.EPA guidance to indicate that a waterbody should not be placed into Category 4c if there is a pollutant based impairment identified to be impairing water quality that requires a TMDL. The waters for which flow information has been submitted for inclusion into Category 4c are all identified in the Integrated Report as impaired due to pollutants under Category 5, 4a, or 4b. Waterbodies impaired by pollutants, such as temperature, and also by flow modifications will be addressed by TMDLs for the pollutant. To the extent that the pollutant is affected by flow, the Regional Water Boards will work with the State Water Board through its Division of Water Rights to determine*

No.	Comment	Response
		the extent to which a water right action can improve the pollution impairment and the appropriate implementation action. *Additionally, U.S. EPA submitted a comment letter regarding the State Water Board's consideration of the CWA 303(d) List stating:* *"EPA commends the Regional Board and State Board staff for the transparency of the process with respect to data used in the assessment and the applicable standards." U.S. EPA also explained that the purpose behind its substantive listing recommendations to the State Water Board was designed to ensure that U.S. EPA's approval of the CWA 303(d) list could occur without U.S. EPA making changes subsequent to the State Water Board's approval. Notably, while U.S. EPA noted disagreement with certain listings or delistings proposed in the Staff Report, U.S. EPA stated no disagreement with the Staff Report's assessment of flow related data and information. U.S. EPA has final review and approval authority of California's CWA 303(d) List before it becomes effective.* Also see response to comment 21.1 and 21.4.
21.10	**9. Readily Available Data Exist and Have Been Provided in Support of the Listing of Waterways as Hydrologically Impaired** As evident based on substantial, readily available information, the lines of evidence for hydrologic impairment are strong for numerous Los Angeles Region waterway segments, including but not limited to Reach 3 of the Ventura River	Also see response to comment 21.1, 21.2, and 32.3 regarding readily available data.

No.	Comment	Response
	(specifically for "pumping," as currently listed) as well as the Santa Clara River (particularly Reaches 1 and 2).[39] Federal regulations state that states must evaluate "all existing and readily available information" in developing their 303(d) lists and prioritizations.[40] The SWRCB's Executive Director reinforced the breadth of this requirement in a memorandum on the scope of listing regulations at 40 CFR § 130.7(b)(5).41 This information must include flow, a position recently reinforced by U.S. EPA, who stated that the integrated reporting format is key to "acknowledge the important role of flow in contributing to water-body impairments."[42] <u>Data Supporting Listing of the Ventura River (Reaches 3 and 4)</u> Excessive pumping contributes to the severe dewatering of the Ventura River (Reach 3), imperiling endangered steelhead trout and other aquatic species. Therefore, the Los Angeles RWQCB must not delist this waterway for "pumping" as is currently proposed. As support, ELC incorporates by reference those comments prepared by Santa Barbara Channelkeeper on the Los Angeles Region's 2012 Integrated Report[43] and 2016 Integrated Report,[44] both of which summarize the extensive body of evidence establishing the link between pumping on Reach 3 (as well as Reach 4) of the Ventura River and resulting negative biological impacts, including to steelhead trout. ELC also incorporates by reference numerous additional documents that highlight the negative effects of excessive pumping on Reach 3 (as well as Reach 4) of the Ventura River, including from U.S. EPA Region 9 (finding in its Draft TMDL for Reaches 3 and 4 of the Ventura River that "low flows due to pumping and diversion activities likely exacerbate the flow and water quality conditions in Reaches 3 and 4"),[45] the National Marine Fisheries Service (NMFS) (finding in a 2007 Draft Biological Opinion that "[w]ater withdrawals from surface diversions and subsurface pumping have affected the timing and magnitude of the Ventura River flows ... and has decreased the quantity and quality of critical habitat for steelhead")[46], and the Los Padres National Forest Ojai Ranger District (describing the historic impacts low flows have upon steelhead trout populations in the Ventura River watershed in a report on steelhead	

No.	Comment	Response
	restoration).[47] Together, this data demonstrates that pumping impairs beneficial uses in Reach 3 of the Ventura River, particularly those beneficial uses related to aquatic life and habitat. In accordance with Section 3.11 of the Listing Policy, when information indicates non-attainment of standards by a water body, the appropriate methodology for evaluation is weight of evidence to determine listing under Section 303(d). This recommendation is consistent as well with Section 3.9 of the Listing Policy, which supports listing if the water body exhibits degradation in biological populations and pollutants sufficient to impair, or threaten impairment of, beneficial uses. Reach 3 of the Ventura River has exhibited degradation in populations of fish (including steelhead trout) that rely upon adequate flows for survival. Based on the readily available data and information, the evidence is sufficient to support the continued listing of Reach 3 of the Ventura River on the 303(d) list due to "pumping." Thus, the proposed delisting of the "pumping" impairment on Reach 3 must not proceed. The Los Angeles RWQCB staff has not provided sufficient information to justify this delisting, nor have they addressed the above evidence that clearly validates the "pumping" listing as it originally occurred. Similarly, this evidence supports the continued listing (as currently proposed) of Reach 3 as impaired due to "water diversion," and of Reach 4 as impaired due to both "water diversion" and "pumping." **<u>Data Supporting Listing of the Santa Clara River</u>** Since at least 2013, ELC and partners have submitted detailed information establishing a clear impairment due to altered flows on the Santa Clara River (in particular Reaches 1 and 2, located downstream of the Vern Freeman Diversion Dam). In May 2013, we submitted a "shortlist" of ten California waterways being drained dry for inclusion on the 303(d) list, along with supporting evidence (see Attachment 2). The Santa Clara River was one of those waterways.	

No.	Comment	Response
	As described in the submitted evidence: The Santa Clara River is Southern California's last major free flowing waterway and is home to 17 species listed as threatened or endangered under the state and federal Endangered Species Acts. At River mile 10.5, United Water Conservation District (United) diverts almost all of the River's flows outside of large storm events. United, USGS, and local agency data show that water diverted at the Vern Freeman Diversion Dam for agricultural usage, groundwater recharge, and other uses, deprive migrating steelhead of sufficient flows and juvenile steelhead of healthy estuary rearing grounds.48 In addition to impacting beneficial uses associated with the provision of adequate steelhead habitat, surface water withdrawals also destroy downstream native riparian and endangered bird habitat, degrade the ecological integrity of the River's estuary, and impair a plethora of cultural and recreational beneficial uses downstream.[49] Additional readily available information further supports the imperative to list the Santa Clara River as impaired due to altered flows. This includes documents published by NMFS (describing in a Final Biological Opinion the negative biological impacts of the Vern Freeman Diversion Dam, which can deplete the Santa Clara River of all its flows and jeopardizes the existence of endangered Southern California steelhead trout),[50] the Santa Clara River Trustee Council and The Nature Conservancy (describing Santa Clara River flow reductions caused by water diversions and groundwater pumping and the resulting impact on steelhead trout),[51] the Los Angeles RWQCB (describing the historic decline of steelhead trout in the Santa Clara River, as well as flow impacts from water diversions and hydromodification in its "State of the Watershed" report),[52] and others. Together, this data demonstrates that reduced flows impair beneficial uses in the Santa Clara River, particularly those beneficial uses related to aquatic life and habitat. This is most clearly true in Reaches 1 and 2 of the Santa Clara River, where over-diversion and other flow impacts (due in large part to the Vern	

No.	Comment	Response
	Freeman Diversion Dam) can cause the waterway to go completely dry. In accordance with Section 3.11 of the Listing Policy, when information indicates non-attainment of standards by a water body, the appropriate methodology for evaluation is weight of evidence to determine listing under Section 303(d). This recommendation is consistent as well with Section 3.9 of the Listing Policy, which supports listing if the water body exhibits degradation in biological populations and pollutants sufficient to impair, or threaten impairment of, beneficial uses. The Santa Clara River has exhibited degradation in populations of fish (including steelhead trout) that rely upon adequate flows for survival. Based on the readily available data and information, the evidence is sufficient to support the listing of the Santa Clara River (particularly Reaches 1 and 2) on the 303(d) list for impairment caused by altered flow. This evidence also supports including Santa Clara River on the 305(b) report.	
21.11	In sum, we once again urge the Los Angles RWQCB to follow the lead of the SD RWQCB, as well as U.S. EPA and numerous other states, in identifying flow- and otherwise hydrologically-impaired waters in the region's Integrated Report. To do so, the staff report must be revised to support the continued listing of Reach 3 of the Ventura River as impaired due to pumping (as done in previous years), as well as by listing the Santa Clara River (particularly Reaches 1 and 2) as impaired due to altered flows.	See response to comment 21.1, 21.2, and 21.4.
22.	Heal the Bay (HtB) , March 30, 2017	
22.1	**Data/Information Collection and Timing Delay** In late 2014, Heal the Bay commented on the State Water Resources Control Board's (State Board's) *Proposed Amendment to the Water Quality Control Policy for Developing the Clean Water Act Section 303(d) List*. While we appreciated the chance to comment and the State Board's explanations in their Response to Comments, there are a few concerns that we continue to have regarding the new amendment and its effect on the Revised List. First, we understand that California is an expansive state and that the State	The State Water Board established what the commenter calls the "Rotating Basin Approach" in consideration of the large size of the State, the extensive amount of data to evaluate, and the increasing complexity of data analysis. Simply not delisting any waterbody ignores those areas where water quality may have improved albeit only as demonstrated with pre-2010 data. The Los Angeles Water Board anticipates that

No.	Comment	Response
	Board's resources are limited in comparison. In this sense we understand but are disappointed that California must implement the "Rotating Basin Approach," when coming into compliance with requests for biennial updates for the federal Clean Water Act's Section 303(d). This will effectively reduce regional updates on impaired waters from every two to every six years. Compounded on this is the surprising discovery that the State Board is discussing either listing or delisting bodies of water in Region 4 with information and data collected prior to *August 30, 2010* – almost seven years ago. This would be on par with a college admissions officer selecting a prospective student for a university based on their academic performance in 5th Grade. It would have seemed wiser to have at least updated and appended further data and information and possibly re-solicited water quality data from regional stakeholders during the years long interim with respect to whether water bodies are placed on or removed from the Revised List. Considering this discrepancy in timing from data submittal to listing and delisting proposals, we ask that the State Board and Environmental Protection Agency (EPA) not delist any bodies of water that are currently on the *2010 Integrated Report* until more current data is received. This will eliminate the possibility of delisting a water body that is currently impaired, as there is no way to know the condition of the waters in question using data solely from 2010 or before. To err on the side of caution when dealing with our state waters will be in the best interest of our water quality standards and beneficial uses. This seems like a reasonable, precautionary request and is supported by the State Board during the adoption of the policy. Taken from the State Board Hearing Transcript from Sept. 30, 2004, Board Member Nancy H. Sutley states, "If it's on the list . . . then you have to have some information that says that they [fish] are not dying now and the waterbody is not currently impaired . . .." Though Board Member Sutley is referring to listings that were made by mistake, the principle behind it should still hold true. The intent was to say that information and data on waters should currently show that water quality standards are met and that the body of water is not currently impaired	there may be waterbodies that are listed one listing cycle and delisted the next, perhaps to be re-listed in a later cycle. The Integrated Report and the 303(d) list should remain the State's best assessment based on water quality data evaluated, even as we recognize the limitations to the 303(d) list. In addition, beginning with the 2018 303(d) list, all data to be evaluated by the Water Boards for the Integrated Report and 303(d) list must be submitted to the California Environmental Data Exchange Database (CEDEN). See, also, response to comment 32.3.

No.	Comment	Response
	before being removed from the list. Board Member Sutley goes further to suggest that boards should affirm a lack of current impairment before delisting bodies of water by stating she was "Okay with not adding [additional] language [to the Listing Policy] as long as we're all in agreement and that's the direction of the regional boards that you have to look at the current conditions as well [before de-listing]." This very point is represented in the State Board's *Water Quality Control Policy for Developing California's Clean Water Act Section 303(d) List* (State Listing Policy)(Adopted Sept. 30, 2004 and Amended February 3, 2015) in Section 4.11, which states, "When making a delisting decision based on the situation-specific weight of evidence, the Regional Water Board must justify its recommendation by [Bullet 1] Providing any data or information including current conditions supporting the decision." We argue that there is no way to demonstrate current conditions with information and data that is aged seven years or more. Because of this it seems in line with State Listing Policy that no waterbodies be delisted for the current 303(d) List. During the next listing/delisting cycle, which will be in 2022, staff will be able to make a more accurate judgement on impairment simply because their information will be more up to date.	
22.2	**It is Misleading to Entitle this Current Edition the "2016" 303(d) List** It seems off-track and misleading to title this 303(d) list the *2016 Los Angeles Region Clean Water Act Section 303(d) List of Impaired Waters* (Integrated Report) when it only contains information from 2010. Since the State Water Board's original 2010 solicitation for data was intended for the 2012 list we think it would be much more constructive and accurate to have the current list in question labeled exactly as such and be called the *2012 Los Angeles Region Clean Water Act Section 303(d) List of Impaired Waters.* If any individual was filing their income taxes using tax information from a certain year, it would remain labeled as the tax return from the original time period, regardless of how long of an extension the individual received. Considering compliance with state and federal law, we could find no mention within the	The Los Angeles Water Board is complying with the naming convention as established by the State Water Board. The naming convention facilitates accounting of which Regions have updated listing decisions for that listing year. Also see response to comment 32.3.

No.	Comment	Response
	Federal Clean Water Act or the State Listing Policy of how the Integrated Report should be named, only how often it should submitted. Since the EPA is well aware of the new "rotating basin approach," and due to the fact that California has successfully amended its own State Listing Policy, we believe there to be no compliance issues for the more accurate renaming. In addition, it was made clear in the Integrated Report's "Staff Report" (February 2017) that the 303(d) List for Regions from Group 2 (Regions 3, 5, and 9), which was intended to be passed in 2014, has yet to be approved by the State Board or the EPA. If the State Board were to rename the 2014 Integrated Report the 2012 Integrated Report as well because it has yet to be approved, this would make clear to everyone exactly where the listing's value lies—by titling both lists from Basin Group 2 and 3, the revised 2012 Integrated Report. This would file nicely with California's Basin Group 1 (Regions 1, 6, and 7), which would identically be called the 2012 Integrated Report. This is also consistent with the original notice and request for data, titled "Notice of Public Solicitation of Water Quality Data and Information for 2012 California Integrated Report—Surface Water Quality Assessment and List of Impaired Waters." Further advantages of this titling would be that future inspection researchers unfamiliar with past reports would know that the listings would correspond much closer to the data from 2010. Looking towards the future, this more accurate labeling will help in clarifying reporting methods. It signifies when agencies made a clean break from when small windows of data were analyzed in favor of the current California Environmental Data Exchange Network (CEDEN) system, which uses a constant, up-to-date stream of information and allows for a more thorough and accurate 303(d) list for Region 4 in 2022. This would also make it crystal clear when the State of California "changed over" to the new "Rotating Basin Approach" in regards to fulfilling their obligations to Section 305(b) of the Clean Water Act.	
22.3	**The Optimistic Possibilities of CEDEN in 303(d) Listings** As mentioned above, the State Board does have an opportunity going forward with	The Los Angeles Water Board agrees and will work with State Board to provide workshops or other CEDEN training materials for Los Angeles

No.	Comment	Response
	CEDEN concerning water bodies in California. We are heartened to see that despite the fact that Region 4's 303(d) list will not be updated until 2022, that the list will be based on information up until 2021. This reduced lag time will only work to benefit the waters and beneficial uses of California's bodies of water. Further, as the State Board mentions in its *Comment Summary and Responses for the Proposed Amendment to the Water Quality Control Policy for Developing California's Clean Water Act Section 303(d) List* from January 26, 2015, "Requiring the use of CEDEN will ensure the data used for the 303(d) listing process is of a high quality and includes the necessary information for efficient assessments." It is true that the use of this database is likely to streamline the process for the staff of the Regional Boards, the State Board, the EPA, and any agency that wants to submit pertinent data. Heal the Bay noticed that the State Board scheduled CEDEN workshops in 2015 to "facilitate greater understanding of the needs of CEDEN users, develop tools to enhance the utility of CEDEN, and provide training on using the CEDEN system." We ask that the State Board provide more workshops now and in the coming years in anticipation of the current and future use of CEDEN by Region 4 Stakeholders. The people and water environment of California only stand to gain from thorough instruction given to invested stakeholders and the data they will provide.	Region stakeholders.
22.4	**Concerns with Individual Category 4a Delistings from the 303(d) List** *Delisting Hermosa Beach and Manhattan Beach for Indicator Bacteria* Beyond our concerns mentioned above with any impaired water delistings from the prior 2010 303(d) List, Heal the Bay feels strongly that both Hermosa and Manhattan Beach should remain on the 303(d) List and maintain their current TMDL for Indicator Bacteria. Looking at our past Beach Report Card data, even data solely from the supposed window ending on August 30, 2010 and before, we find it puzzling that either beach would be in consideration for delisting. In 2010 itself, our Hermosa Beach site by Herondo Street outfall was noted for single sample exceedances for *Enterococcus* for 17.6% of samples taken. Averaging	The delistings of Hermosa Beach and Manhattan Beach for Indicator Bacteria are in compliance with the Listing Policy. Although these beaches are being recommended for delisting, they are still subject to the Santa Monica Bay Beaches Bacteria TMDLs and 303(d) listing decisions do not change or eliminate effective TMDLs. The TMDL allocations that have been assigned to those beaches still apply and are incorporated into various NPDES permits/waste discharge requirements. In fact,

No.	Comment	Response
	exceedances from 2008 to present 2016, the Herondo storm drain outfall has shown *Enterococcus* exceedances 12% of the time. Concerning Manhattan Beach, their 28th Street outfall has shown *Enterococcus* exceedances 10% of the time since 2008. Both of these beaches are popular swimming and recreation areas and eliminating the TMDL would create the potential for impacts on human health and aquatic life. We would highly recommend waiting to remove both beaches from the 303(d) list until data from the past decade can be assessed. Like we discussed above, where uncertainty exists with regards to delisting bodies of water, decisions should be made in favor of protecting water quality, human health and the environment.	both beaches are classified as 'anti-degradation' beaches, which are subject to more stringent requirements compared to the reference beach. Also see response to comment 32.3 regarding readily available data.
23.	Los Angeles Department of Water and Power (LADWP) , March 30, 2017	
23.1	LADWP's detailed comments can be found below. **1.** Elderberry Forebay should not be listed for dieldrin or PCBs**.** LADWP's largest hydroelectric facility is the Castaic Power Plant, which is critical to the reliability of the electrical grid in the Los Angeles Basin. This facility along with the Elderberry Forebay was built in 1960 as part of a Federal Energy Regulatory Commission (FERC) project with the Department of Water Resources, and is operated under a FERC license. The Elderberry Forebay was built strictly for the operation of the plant as a storage component for the water that passes through the plant to generate electricity. This hydroelectric plant is known as a pass-through facility. Water from Pyramid Lake flows down a gradient through the Los Angeles Tunnel and seven penstocks to turn seven turbines in order to produce electricity. The water enters Elderberry Forebay after the turbines where it is then either discharged to Castaic Lake or pumped back to Pyramid Lake. LADWP has noted that the LARWQCB has proposed to add Elderberry Forebay to the revised 303(d) list for dieldrin and PCBs. However, activities at the plant do not use or add products that would contribute dieldrin or PCBs to its discharges into Elderberry. In fact, Elderberry Forebay is not open to the public and therefore does not have any beneficial uses beyond being an operating body of water for the	Elderberry Forebay is surface waterbody which is identified in Table 1 of Chapter 2 in the Los Angeles Region Basin Plan as having the beneficial uses of MUN, IND, PROC, AGR, GWR, FRSH, POW, WARM, COLD, WILD, RARE, and SPWN. Restricted access does not preclude a waterbody from possessing beneficial uses. For the 303(d) list, readily available water quality data are assessed for all beneficial uses that may be impaired by excess amounts of pollutants. No source analysis has been conducted and the 303(d) list identifies the source as "unknown." Source analysis, linkage, and allocations are typically determined during TMDL development or during the development of another regulatory program. See response to comment 32.3 regarding readily

No.	Comment	Response
	hydro plant. Its only use is for the pushing of the turbine blades to generate electricity. In 2008 the United States Environmental Protection Agency (USEPA) released its final version of its "National Pollutant Discharge Elimination System (NPDES) Water Transfers Rule" (Water Transfer Rule) codifying (40 CFR 122.3(i)) that water transfers are excluded from the regulation of the Clean Water Act (CWA). The 40 CFR 122.3 (i) expressly states "Water transfers mean an activity that conveys or connects waters of the United States without subjecting the transferred water to intervening industrial, municipal, or commercial use. USEPA's legal interpretation of the CWA concluded that Congress did not intend to subject water transfers where there is "no addition" of pollutants to the NPDES permit process because the pollutants were already in the waters being transferred and are not added. This ruling was put in place precisely for hydroelectric plants like the Castaic Power Plant that are considered pass-through facilities. Since this body of water is isolated from all public recreation and access and the water that passes through the Castaic Power Plant is used only to generate electricity, it seems inappropriate to include the Elderberry Forebay in the new 303(d) listing. With respect to Dieldrin, as stated in LADWP's Castaic Dieldrin Source Control Study sent to the LARWQCB in May 2010, LADWP contends that since the Castaic Power Plant has never used nor ever had a use for dieldrin, it cannot be the source of dieldrin in Elderberry Forebay. The source study points out that many of the tributaries that flow into the State Water Project, specifically those in the San Joaquin Valley, are agricultural areas where for years traditional pesticides (including dieldrin) have been used. Dieldrin was also an ingredient in several types of vector control measures used to mitigate vectors residing subsurface. These components, termed "legacy pesticides," primarily reside in the sediment/soil and are believed to be periodically liberated into the surrounding waterways. *Catskill Mountains Chapter of Trout Unlimited, Inc. v. EPA (Catskill III*) (2nd Cir. 2017), states that a water being transferred through a hydroelectric plant is not a discharge of a pollutant. In addition, as has been mentioned earlier, the Elderberry Forebay is only used for the operations of the plant, and therefore discharges from the Forebay would not be considered a discharge of a pollutant. Additionally, LADWP ceased the use of PCBs in the electrical equipment at	available data.

No.	Comment	Response
	Castaic Power Plant in the 1980s, and thus the hydroelectric plant is not a source. Furthermore, the NPDES Annual Monitoring Reports for Castaic Power Plant have shown "non- detect" for all PCB sampling over the last 20 years. Since the Elderberry Forebay is used and was built solely for the operation of the Castaic Power Plant hydroelectric facility, and since it is a pass-through that transfers water without any addition of pollutants, it would seem appropriate to remove the Elderberry Forebay from this 303(d) list. Therefore, LADWP respectfully requests that the Elderberry Forebay be removed from the current 303(d) list.	
23.2	2. The 303(d) listing recommendations should be updated to include current data and information. The LARWQCB Staff Report supporting the current listing recommendations notes that "Due to the volume of data received during the 2010 data solicitation period, the State Water Board determined that no additional data would be solicited or analyzed until all the 2010 data are assessed.[...] Los Angeles Water Board staff estimates that the 2022 303(d) list will include data submitted through 2021." (Staff Report at p. 6) LADWP is concerned that many of the data upon which proposed listings are based are more than ten (10) years old. However, some of the proposed listings are based on only two or three data points. Although LADWP understands and recognizes the resource limitations faced by the LARWQCB, we respectfully suggest that basing listings on datasets that do not include the most recent information, particularly when only a couple of samples are available to describe conditions in the region's water bodies, does not seem to be effective. Such limited data cannot be considered to describe current conditions appropriately.	See response to comment 32.3 regarding readily available data. Per the Listing Policy, waterbody-pollutant combinations are included on the 303(d) list with as few as two samples.
23.3	3. The proposed listings for "benthic community effects" are premature at this time, particularly for proposed listings in modified channels. LADWP notes that several of the proposed listings for "benthic community	See response to comment 11.19 and 11.24 regarding Benthic Macroinvertebrate listings.

No.	Comment	Response
	effects" are based upon limited data (2 or 3 samples) that were collected nine or more years ago, and that some of the proposed listings are based upon "index of biotic integrity" (IBI) scores. More importantly, many of the water bodies proposed for listing for benthic community effects are engineered or modified channels, and it is not scientifically or technically appropriate to expect that modified channels will achieve the CSCI or IBI scores that are observed in reference channels. The proposed listings do not consistently or clearly establish a link between the biological condition and the pollutant(s) that may be responsible for the biological condition; in fact, it is not clear that the pollutant measurements (available only for some proposed listings) were collected at the same time as the biological data. Finally, some of the samples upon which the proposed listings are based were collected downstream of and shortly after major wildfires; these data are likely representative of temporary disturbed conditions and may not be representative of typical conditions. State Water Board staff are currently working on developing a statewide policy or plan for biological integrity. This process has moved away from using the 181 and is now developing metrics for the California Stream Condition Index (CSCI) and an Algae Stream Condition Index (ASCI). This process has not reached consensus on how engineered or modified channels should be assessed, or what appropriate expectations for these channels should be. In fact, the State Water Board is currently convening a Science Advisory Panel to address this issue and many others, and the State Water Board's "Wadeable Stream Biostimulatory and Biointegrity Science Plan," dated February 2017, acknowledges that "Developed landscapes are associated with an increase of many stressors in streams, such as elevated contaminant and nutrient concentrations, altered flow regimes , sedimentation, and habitat degradation. Often, these stressors are difficult to mitigate or remove under the traditional mechanisms available to the Water Boards. In these circumstances, the range of CSCI or ASCI scores may be constrained in channels in developed landscapes." Because the State's policy is in development, no longer uses the IBI, has not clearly established a link between the presence of pollutant(s) and the biological condition, and has not produced direction regarding how benthic integrity should

“the natural receiving water temperature of all regional waters shall not be altered unless it can be demonstrated to the satisfaction of the Regional Board that such alteration in temperature does not adversely affect beneficial uses.”</td><td>See response to comment 17.4.</td></tr>
</table>

No.	Comment	Response
	Beginning upstream, Reach 2 is a 7-mile stretch from the outlet of the Whittier Narrows Dam and ends where the Sab Gabriel River crosses Firestone Blvd. Reach 2 is confined by engineered levees and rip-rap. The river remains a soft-bottom channel and during dry-weather has no measurable flow reaching Reach 1 due to having the most productive spreading grounds in Los Angeles County. Reach 1 is a 10-mile stretch beginning at Firestone Blvd in Downey and extends to the confluence of the San Gabriel River with Coyote Creek. It is a heavily urbanized reach with a concrete bottom. Two significant POTWs discharge into this Reach. During dry weather, these POTWs discharge vastly more water than enters the river channel though the combined MS4 outfalls. The volume of the POTW discharge will quickly render any potentially elevated temperature from discharges of MS4 outfalls as negligible. The Committee believes that a Water Quality Objective for Temperature in these Reaches is not applicable.	
25.2	In regards to Iron and Malathion in Coyote Creek; the LSGR Watershed Committee requests the Regional Board suspend the recommendation of Iron and Malathion due to monitoring data inconsistent with recent water body improvements. The LSGR Watershed has made a considerable effort in developing and implementing its Coordinated Integrated Monitoring Program (CIMP) and suggest monitoring data should reflect more recent and current outfall conditions and that any conclusions should be drawn from a more current and comprehensive data set. The LSGR believes this request is justified when considering that Iron and Malathion are derived from nationally Recommended Water Quality Standards and not based on an established EPA TMDL or conditions characteristic of Southern California waters.	See response to comment 24.1 and 32.3.
26.	Sanitation Districts of Los Angeles County (Sanitation Districts) , March 30, 2017	
26.1	The Sanitation Districts have concerns on some aspects of the Draft List, particularly where the listing thresholds used in the Staff Report appear to differ from receiving water quality objectives contained in the Basin Plan for the Coastal Watersheds of Los Angeles and Ventura Counties (Basin Plan) or other regulatory	See responses to comments 26.2 – 26.19.

No.	Comment	Response
	programs. Additionally, there appear to be data errors that impact some listing decisions. General comments relating to these concerns are provided below and detailed specific comments for each listing are provided in Attachment 1 and appendices to this letter.	
26.2	***1. Data Were Incorrectly Attributed to Some Reaches*** The Draft List contains a number of newly proposed listings based, in part, on data collected from incorrect reaches. Specific listings where this appears to have occurred include the benthic community and toxicity listings for Santa Clara River Reach 5; the temperature listing for Santa Clara River Reach 6; the toxicity, DO, and iron listings for Rio Hondo Reach 2; and the toxicity listing for San Jose Creek Reach 2.	Los Angeles Water Board and State Water Board staff are aware of these areas where the reach mapping that underlies the CalWQA database (which maps the 303(d) list) and the Los Angeles Basin Plan do not agree. It is the intention of the Los Angeles Water Board staff to work with State Board staff to resolve mapping issues and reassess the LOEs and decisions for those reaches, as appropriate, prior to the State Board approval of the 2016 303(d) list, or at the next Listing Cycle that includes the Los Angeles Region. For additional specific responses, see response to comment 26.10 and 26.19.
26.3	***2. Not All of the Data Submitted for Listing Consideration Were Used in Making the Listing Decision*** The Draft List contains a number of newly proposed listings where only a subset of the data submitted for listing consideration were evaluated; these data are included in the data files appended to the Staff Report but were not used in the listing analysis. Specific listings where this appears to have occurred include the toxicity listing for Santa Clara River Reach 5 and the temperature listing for Santa Clara River Reach 6.	See response to comment 26.12 for the Santa Clara River Reach 5 toxicity listing and response to comment 26.19 for the Santa Clara River Reach 6 temperature listing.
26.4	***3. The Draft List Includes Inappropriate Impairment Listings for "Benthic-Macroinvertebrate Bioassessments"*** The Draft February 2017 version of the 2016 303(d) List contains a number of	Listings based on the SCIBI and CSCI scores are consistent with State policy and have been assessed relative to appropriate reference sites.

No.	Comment	Response
	newly proposed listings for "Benthic-Macroinvertebrate Bioassessments." The proposed listings are based on application of the Southern California Coastal Index of Biological Integrity (SCIBI) and, in some cases, the California Stream Condition Index (CSCI). These include listings for Santa Clara River Reach 5, Los Angeles River Reach 3, and Medea Creek Reach 1. The Sanitation Districts believe these proposed listings should be removed, for the reasons listed below. <u>Listings Based on the SCIBI and CSCI Are Inconsistent With State Policy.</u> The Water Quality Control Policy for Developing California's Clean Water Act Section 303(d) List (Listing Policy) indicates that water bodies should only be listed for degradation of biological populations if they have significant degradation **<u>relative to reference sites</u>** [emphasis added]. Although the scientists that developed the SCIBI attempted to incorporate reference conditions into the index itself, the reference conditions used to develop the index did not include any low elevation, low gradient locations in Los Angeles County similar to the Los Angeles River and the Santa Clara River reaches of concern. Although the CSCI at least partially addresses some of the problems with the SCIBI by employing a modeled reference condition as opposed to the regional reference pool used by the SCIBI, the lack of any reference sites in large watersheds, low gradient, and low elevation systems still limits the identification of appropriate thresholds using the CSCI. Section 6.1.5.8 of the Listing Policy also states that when "evaluating biological data and information, RWQCBs shall evaluate all readily available data and information and shall…**<u>evaluate physical habitat data</u>** and other water quality data, when available, to support conclusions about the status of the water segment." [Emphasis added.] All of the reaches mentioned in this comment letter represent reaches that have undergone various levels of physical habitat modifications and there is no indication that an evaluation of the physical habitat was conducted. It is well recognized by the scientific community that a single standard or threshold is not applicable to all waterbodies of the State due to unmanageable non-pollutant physical habitat alterations that would preclude many streams from ever having biological assemblages similar to reference. The threshold used as the listing criterion for these reaches is therefore likely	Both the IBI and the CSCI assess benthic community relative to reference sites. The SCIBI was developed using data from 275 sites, ranging from Monterey County to the Mexican border. Eighty-eight sites were used as reference sites based on land use and local conditions. The CSCI employs a modeled reference condition as opposed to the regional reference pool used by the SCIBI. The proposed listings evaluate the physical habitat data in the determination of the reference and each listing decision includes associated water quality impairments. At this time, the CSCI (and IBI where CSCI is not available) is the best measure of biologic integrity in California streams and it is appropriate to use IBI and CSCI in 303(d) listing decisions. As the science progresses, improved methods may supplant older methods and the 303(d) list will be updated, as appropriate, as that occurs. The discussion of the strengths and weaknesses of scoring methods and additional areas needing additional research, are appreciated, but are not a justification to delay making 303(d) listing decisions. The use of the SCIBI and CSCI for 303(d) listing was done in accordance with Section 3.9 and 6.1.5.8 of the Listing Policy with biological data and impairment related to associated pollutants and/or pollution.

No.	Comment	Response
	inappropriate for these modified waterbodies.	Santa Clara River Reach 5, Los Angeles River Reach 3, and Medea Creek Reach 1 are discussed in more detail in response to comments 26.13, 26.14 and 26.15.
26.5	<u>Appropriate Thresholds for Interpretation of the CSCI Have Not Yet Been Determined</u>. The State Board has not yet developed any recommended thresholds for the CSCI. The proposed threshold of 0.79 used in the Draft List is the 10th percentile of the reference pool and was used as an arbitrary point of reference for a regional monitoring program with no regulatory vetting. Use of this threshold for impairment listings would result in 10% of the unimpaired reference streams being erroneously listed as impaired. Additionally, it is well recognized by the scientific community that a single standard or threshold will not be applicable to all waterbodies of the State since unmanageable non-pollutant features such as habitat condition/modifications are likely to preclude many streams from ever having biological assemblages similar to reference. The Sanitation Districts believe that it is inappropriate to make impairment decisions using the SCIBI and premature to rely on the improved, but still limited CSCI for making impairment decisions, particularly in reaches where surrounding development and instream physical habitat limitations are recognized. Therefore, the Sanitation Districts respectfully recommend that the Regional Board delay making decisions regarding benthic macroinvertebrate community impairments in this listing cycle, and instead continue to work with stakeholders, scientists, and the State Board that are currently engaged in efforts to address these and other issues as part of the Biointegrity/Bio-stimulatory Policy.	Selection of the 10th percentile of the reference distribution to indicate impairment was done by Mazor et al. (2016) and was independently peer-reviewed. The selection and identification of reference is done at the desktop scale, and likely includes some sites that may not be "reference" due to localized impacts not discernable on a desktop basis or by field crews when sampling. For example, known upstream illegal marijuana grow operations could remove a site from reference status due to impacts on water quality. However, accurately identifying active grow sites in the tributary watershed by desktop is largely infeasible. With the CSCI, any given test site gets matched to a subset of reference sites from the statewide pool that are most similar in terms of elevation, watershed size, annual precipitation, geology, etc., and those most-similar reference sites may come from other regions. The benthic macroinvertebrates that were observed in the most-similar group of reference sites are then used to predict what should be observed at the test site if it were in reference condition. Because the statewide reference pool adequately represents important environmental gradients, and because predictive modeling matches test sites to their most environmentally similar reference sites, the

No.	Comment	Response
		CSCI is appropriate for use.
26.6	***4. The Draft List Includes Inappropriate Impairment Listings for Temperature*** The Draft List contains a number of newly proposed listings for temperature. The Sanitation Districts believe the proposed temperature listings for San Gabriel River Reach 2, San Jose Creek Reach 1, and San Gabriel River Reach 1 should be removed because the impairment listings are inconsistent with the Basin Plan water quality objective for temperature, which states, "at no time shall these WARM-designated waters be raised above 80˚F **as a result of waste discharges**." [Emphasis added.] This water quality objective clearly distinguishes between exceedance of the 80˚F standard caused by "waste discharges" and those associated with other causes. Evidence indicates that summertime excursions greater than the 80˚F are not caused by wastes discharged but are likely due to elevated ambient air temperature, conductive and radiative heating associated with hardened landscapes, a lack of riparian cover, and increased ambient temperatures related to climate change. Additionally, the Draft List does not contain any analysis or evidence indicating that the elevated temperatures occurred as result of wastes discharged. Additionally, the Sanitation Districts believe that the proposed temperature listing for Santa Clara River Reach 6 is inappropriate. Measurements for this listing were taken immediately downstream of the Saugus Water Reclamation Plant (WRP), where tertiary treated effluent is discharged along one bank of the Santa Clara River bed. The flow remains isolated from the main channel of the Santa Clara River and percolates rapidly into the soil; groundwater resurfaces downstream near Reach 5 of the Santa Clara River. The predominant natural condition of this stretch of river is dry and would not be expected to support aquatic life without the Saugus WRP discharge; therefore, application of the 80˚F water quality objective is unnecessary and inappropriate. The only reasonable alternative for meeting the water quality objective would be to eliminate the discharge flows; however, the California Department of Fish and Wildlife would likely prohibit that option, due to the effluent's contribution to the groundwater and subsequent downstream flows. Upon resurfacing near Reach 5, the water temperature averages 69˚F,	The 303(d) list appropriately identifies temperature impairments. Analysis of sources and causes or identification of implementation measures to resolve or correct the impairment are not completed as part of the Integrated Report or 303(d) listing process. There are multiple sources of water to San Gabriel River Reach 2, San Jose Creek Reach 1, and San Gabriel River Reach 1 including "waste discharge" from sources such as wastewater treatment plants and the MS4. Exceedances in temperature may be caused in part by ambient temperatures or exacerbated by the lack of tree cover in some reaches; exceedances may also be caused in part by waste discharge. The relative contribution of the causes of temperature exceedances is largely speculative, at this time. The 80°F temperature objective protects the aquatic life beneficial use of WARM in surface waters regardless of the ultimate source of the water in that reach of the river. The Los Angeles Water Board does not have alternative objectives for effluent-dominated waters. The 2014-2016 Triennial Review includes a review of temperature as a Basin Planning Priority Project. Los Angles Water Board staff may consider the development of more specific numeric temperature objectives for various waterbody classes and aquatic life beneficial uses

No.	Comment	Response
	demonstrating that elevated temperatures in this isolated discharge area are not detrimental to beneficial uses in reaches where water occurs naturally in the river. Finally, elevated ambient temperatures regularly exceed 90˚F during the summer months, and heavily influence both the Saugus WRP discharge and the immediate downstream receiving water location. As indicated for the other temperature listings, the water quality objective for temperature in the Los Angeles Region Basin Plan clearly distinguishes between temperature exceedances caused by "waste discharges" and those associated with other causes. However, the Draft List does not contain any analysis to distinguish the relative contributions by the temperatures of the ambient air and wastes discharged on the receiving water.	in the future. See also responses to comments 26.16, 26.17, 26.18 and 26.19.
26.7	***5. Thresholds Used For Toxicity Impairment Listings Are Inconsistent With Basin Plan Objectives*** The Draft List contains a number of newly proposed listings for toxicity that include San Gabriel River Estuary, San Gabriel River Reach 3, Rio Hondo Reach 2, and Santa Clara River Reach 5. These listings should be removed for the reasons below. <u>The Acute Toxicity Impairment Criterion is Inconsistent With the Basin Plan Water Quality Objective for Acute Toxicity</u> The Staff Report fact sheets for the specific listings mentioned above state that "<100% survival (acute) was considered an exceedance." However, the Basin Plan states that "the acute toxicity objective for discharges dictates that the average survival in undiluted effluent for any three consecutive 96-hour static or continuous flow bioassay tests shall be at least 90%, with no single test having less than 70% survival when using an established USEPA, State Board, or other protocol authorized by the Regional Board." Therefore, a single-test threshold of less than 70% survival should be used to determine impairments; even a threshold of less than 90% survival would still be more conservative than Basin plan objective. <u>The Chronic Toxicity Impairment Criterion is Inconsistent With Water Quality Objective Interpretations Provided in NPDES Permits</u>	The acute toxicity and chronic toxicity data was included in the original data submission to State Board by the August 30, 2010 deadline. However, the necessary control data were not included. Los Angeles Water Board staff agrees that the existing evaluation guideline, *"Toxicity data was not reported with a control, therefore anything reported as <100 (chronic) or <100% survival (acute) was considered an exceedance"* for LOE 87842, LOE87970, LOE88019, and LOE87452 is not appropriate. For acute toxicity, the Los Angeles Water Board agrees that the use of the specific numeric target included in the Los Angeles Regional Basin Plan is appropriate. More specifically, "*there shall be no acute toxicity in ambient waters, including mixing zones. The acute toxicity objective for discharges dictates that the average survival in undiluted effluent for any three consecutive 96-hour static or continuous flow bioassay tests shall be at least 90%, with no single test having less*

No.	Comment	Response
	The Staff Report fact sheets for the specific listings mentioned above indicate that a single NOEC result of less than 100% receiving water represents an exceedance of the water quality objective. Although the Basin Plan provides no numeric chronic toxicity objectives, recently adopted Los Angeles Region NPDES permits do provide very specific direction on interpretation of the narrative water quality objectives for chronic toxicity. In a number of these permits, a footnote associated with the Receiving Water Monitoring Requirements Table of the Monitoring and Reporting Program states; "The **median monthly summary result is a threshold value** for a determination of meeting the narrative receiving water objective and shall be reported as 'Pass' or 'Fail'."[2] [Emphasis added.] In addition to aligning with the NPDES permit language, use of a monthly median will also address concerns regarding false positive error rates. The USEPA has determined that the expected false positive error rate for chronic toxicity testing using the NOEC is 5%. With this error rate, on average, one in 20 individual chronic toxicity tests will be erroneously identified as "toxic" using the NOEC, and there is a nearly 34% probability that 2 or more individual chronic toxicity test exceedances would be observed within a set of 24 discrete measurements in a completely non-toxic stream reach. When there are two or more exceedances out of 24 measurements, the Listing Policy specifies that a reach be listed as impaired. Therefore, using single chronic toxicity exceedances as the 303(d) criterion would eventually result in more and more non-toxic stream reaches being erroneously listed over time. However, using a monthly median chronic toxicity exceedance threshold would reduce the likelihood of inappropriate reach listings due to false positive chronic toxicity results to less than 1 %.	*than 70% survival when using an established USEPA, State Board, or other protocol authorized by the Regional Board.*" For chronic toxicity, as stated in the Basin Plan, "*there shall be no chronic toxicity in ambient waters outside mixing zones. To determine compliance with this objective, critical life stage tests for at least three species with approved testing protocols shall be used to screen for the most sensitive species. The test species used for screening shall include a vertebrate, an invertebrate, and an aquatic plant. The most sensitive species shall then be used for routine monitoring. Typical endpoints for chronic toxicity tests include hatchability, gross morphological abnormalities, survival, growth, and reproduction.*" However, there is no specific numeric target for chronic toxicity in the Basin Plan. In light of this, it may also be that the use of the monthly median of chronic toxicity to assess the chronic toxicity is appropriate since this method is used in recently adopted Los Angeles Region NPDES permits. As data was reassessed per the discussion above, the decision recommendations have been changed to "do not list" due to insufficient information (poor QAQC).
26.8	***6. Specific Comments on Individual Reach/pollutant Listing Decisions*** In addition to these general comments, the Sanitation Districts have comments on some specific listing decisions. As stated above, detailed comments are provided	LOE 87842 and Decision 66269 will be changed to reflect the changes in the evaluation guidelines discussed in response to comment 26.7.

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td></td><td>in the appendices to this letter. Because the implications of erroneous listings are substantial, the Sanitation Districts urge the Regional Board to consider this information in making the appropriate changes to the Draft List.

Fact Sheet #1
Water Body: San Gabriel River Estuary
Pollutant: Toxicity
Listing: List on 303(d) List (TMDL Required List)
Comment & Recommendation: Do Not List – Water Quality Objectives Being Achieved

The California Regional Water Quality Control Board, Los Angeles Region (Regional Board) is currently proposing that a new listing for toxicity be made to the 303(d) list for the San Gabriel River Estuary, based on one line of evidence: 14 of 113 samples exceeded the objective. The Districts believe this proposed listing is inappropriate and recommend not listing due to water quality objectives being achieved, for the reasons listed below; supporting evidence is provided in the sections that follow.

• Appendix A of this letter contains the full set of data applicable to this listing from Appendix G of the Regional Board Draft Staff Report. Using the temporal range indicated (June 2006 through May 2010), only six of 120 samples failed the thresholds specified in the fact sheet. According to Table 3.1 of the California Clean Water Act 303(d) Listing Policy (Listing Policy), an impairment listing is appropriate if 11 or more exceedances are observed when 120 samples are available.

• Although the Staff Report fact sheet states that “<100% survival (acute) was considered an exceedance,” the Basin Plan for the Coastal Watersheds of Los Angeles and Ventura Counties (Basin Plan) states that “the acute toxicity objective for discharges dictates that the average survival in undiluted effluent for any three consecutive 96-hour static or continuous flow bioassay tests shall be at least 90%, with no single test having less than 70% survival when using an established USEPA, State</td><td>The listing decision will be changed to “Do Not List” due to insufficient information as the control data was not submitted.

The review of the decision for San Gabriel River Reach 3 toxicity is in process at this time.</td></tr>

	Board, or other protocol authorized by the Regional Board." Therefore, a single-test threshold of less than 70% survival should be used to determine impairments; even a threshold of less than 90% survival would still be more conservative than Basin Plan objective. Applying a 90% threshold, none of the 120 samples would have exceeded the water quality objective. Therefore, this reach fails to meet the listing criteria for toxicity. • The full set of data appended to Appendix G of the Staff Report, including those that fell outside the indicated temporal range, contain a total 151 discrete toxicity tests. Sixteen failed the <100% acute survival threshold. Using a conservative 90% acute survival threshold, there are no toxicity exceedances, and the number of measured exceedances is insufficient to place this water segment on the section 303(d) list. • *Use of a <100% Survival Water Quality Objective Threshold Is Inappropriate and Unsupported.* • *Use of a <100% Survival Water Quality Objective Threshold Is Inconsistent with the Basin Plan and Other Documentation from the Regional Board.* • *Use of a <100% Survival Water Quality Objective Threshold Is Inconsistent with Criteria Used for Other Acute Toxicity Listings.* • *Use of a <100% Survival Water Quality Objective Threshold Is Inconsistent with the Results of Statistical Testing.* • *The Water Quality Objective/Threshold for Chronic Toxicity Should Be a Monthly Median.* *[See Sanitation District of Los Angeles County letter dated March 30, 2017 for complete text, figures and appendices.]*	
26.9	**Fact Sheet #2** **Water Body: San Gabriel River Reach 3** **Pollutant: Toxicity** **Listing: List on 303(d) List (TMDL Required List)** **Comment & Recommendation: Do Not List – Water Quality Objectives Being Achieved**	LOE 87970 and Decision 32521 will be changed to reflect the changes in the evaluation guidelines discussed in response to comment 26.7. The listing decision will be changed to "Do Not List" due to insufficient information as the control

No.	Comment	Response
	The California Regional Water Quality Control Board, Los Angeles Region (Regional Board) is proposing that a new listing for toxicity be made to the 303(d) list for Reach 3 of the San Gabriel River, based on one line of evidence using two datasets: 2 of 38 samples exceeded the objective in a dataset related to a previously conducted TMDL study and 13 of 75 samples exceeded the objective in a second dataset comprised of routine receiving water tests conducted as part of an NPDES permit. The Sanitation Districts of Los Angeles County (Sanitation Districts) believe this proposed listing is inappropriate and recommend not listing due to water quality objectives being achieved, for the reasons listed below; supporting evidence is provided in the sections that follow. Appendix A of this letter contains the full set of data applicable to this listing from Appendix G of the Regional Board Draft Staff Report. No data related to the TMDL study were provided; therefore, the number of tests and exceedances reported (2 of 38) could not be independently verified and were assumed to be accurate. For the dates indicated (June 2006 through May 2010), 13 exceedances were associated with only 66 samples. Combining the two datasets resulted seven acute and eight chronic toxicity exceedances out of 104 samples. • Although the Staff Report fact sheet states that “<100% survival (acute) was considered an exceedance,” the Basin Plan for the Coastal Watersheds of Los Angeles and Ventura Counties (Basin Plan) states that “the acute toxicity objective for discharges dictates that the average survival in undiluted effluent for any three consecutive 96-hour static or continuous flow bioassay tests shall be at least 90%, with no single test having less than 70% survival when using an established USEPA, State Board, or other protocol authorized by the Regional Board.” Therefore, a single-test threshold of less than 70% survival should be used to determine impairments; even a threshold of less than 90% survival would still be more conservative than Basin plan objective. Applying a 90% threshold, no acute toxicity samples in the dataset exceeded the water quality objective and 8 of 104 total samples exceeded the objective. According to Table 3.1 of the California Clean Water Act 303(d) Listing Policy (Listing Policy), an impairment listing is appropriate if 9 or more exceedances are observed when	data was not submitted. The review of the decision for San Gabriel River Reach 3 toxicity is in process at this time.

No.	Comment	Response
	104 samples are available. Therefore, this reach fails to meet the listing criteria for toxicity. • The Staff Report considered each chronic toxicity test result as an independent data point, even when multiple bioassays were conducted within a single month. However, the San Jose Creek (SJCWRP) and Whittier Narrows Water Reclamation Plant (WNWRP) permits state that the water quality objective for chronic toxicity is based on a monthly median; therefore, all tests within a single month should be considered part of a monthly median, rather than independent tests. Based on appropriate application of the monthly median as the chronic water quality objective (and a 90% acute toxicity threshold), there were 6 toxicity exceedances out of a total of 96 tests. According to Table 3.1 of the California Clean Water Act 303(d) Listing Policy (Listing Policy), an impairment listing is appropriate if 9 or more exceedances are observed when 96 samples are available. Therefore, this reach fails to meet the listing criteria for toxicity. • The full set of data (sets 1 and 2) appended to Appendix G of the Staff Report for all dates, including those outside the indicated temporal range, contain a total of 119 discrete toxicity tests. Using a conservative 90% acute survival threshold and appropriate monthly median chronic threshold, there are no acute exceedances and 6 chronic exceedances out of 110 results. This total does not meet the minimum number of measured exceedances needed to place a water segment on the section 303(d) list. • *Use of a <100% Survival Effect Water Quality Objective Threshold Is Inappropriate and Unsupported for Acute Toxicity Testing.* • *Use of a <100% Survival Water Quality Objective Threshold Is Inconsistent with the Basin Plan and Other Documentation from the Regional Board.* • *Use of a <100% Survival Water Quality Objective Threshold Is Inconsistent with Criteria Used for Other Acute Toxicity Listings.* • *Use of a <100% Survival Water Quality Objective Threshold Is Inconsistent with the Results of Statistical Testing.*	

No.	Comment	Response
	• *The Water Quality Objective/Threshold for Chronic Toxicity Should Be a Monthly Median.* *[See Sanitation District of Los Angeles County letter dated March 30, 2017 for complete text, figures and appendices.]*	
26.10	**Fact Sheet #3** **Water Body: San Jose Creek Reach 2** **Pollutant: Toxicity** **Listing: List on 303(d) List (TMDL Required List)** **Comment & Recommendation: Apply Data to Reach 1** The California Regional Water Quality Control Board, Los Angeles Region (Regional Board) is proposing that a new listing for toxicity be made to the 303(d) list for Reach 2 of the San Jose Creek, based on one line of evidence: 8 of 24 samples exceeded the objective. The Sanitation Districts believe this proposed listing is inappropriate and should be moved to Reach 1. All cited toxicity data is from receiving water station RC (N 34° 01' 8.6" W 117° 50' 27.7") for the Pomona Water Reclamation Plant, which is located in Reach 1 of San Jose Creek (Figure 1). This reach is already listed for toxicity under section 303(d). *Figure 1. Station Pom-RC (Blue Symbol) and San Jose Creek Reach 1 (Aqua Line)* *[See Sanitation District of Los Angeles County letter dated March 30, 2017 for complete text, figures and appendices.]*	Los Angeles Water Board and State Water Board staff are aware of several areas where the reach mapping that underlies the CalWQA database (which maps the 303(d) list) and the Los Angeles Basin Plan do not agree. It is the intention of the Los Angeles Water Board staff to work with State Board staff to resolve mapping issues and reassess the LOEs and decisions for those reaches, as appropriate, prior to the State Board approval of the 2016 303(d) list, or at the next Listing Cycle that includes the Los Angeles Region.
26.11	**Fact Sheet #4** **Water Body: Rio Hondo Reach 2** **Pollutant: Toxicity** **Listing: List on 303(d) List (TMDL Required List)** **Comment & Recommendation: Do Not List – Water Quality Objectives Being Achieved**	LOE 87452 and Decision 66146 will be changed to reflect the changes in the evaluation guidelines discussed in response to comment 26.7. The listing decision will be changed to “Do Not List” due to insufficient information as the control data was not submitted.

No.	Comment	Response
	The California Regional Water Quality Control Board, Los Angeles Region (Regional Board) is proposing that a new listing for toxicity be made to the 303(d) list for Reach 2 of the Rio Hondo, based on one line of evidence: 5 of 31 samples exceeded the objective. The Districts believe this proposed listing is inappropriate and recommend not listing due to water quality objectives being achieved, for the reasons listed below; supporting evidence is provided in the sections that follow. • Appendix A of this letter contains the full set of data applicable to this listing from Appendix G of the Regional Board Draft Staff Report. All cited toxicity data are from receiving water station RD1 for the Whittier Narrows Water Reclamation Plant (WNWRP). This sampling location (N 34° 02' 26.5" W 118° 04' 27") is in Reach 3 of the Rio Hondo, not Reach 2 (Figure 1). • Using the data for the temporal range indicated (June 2006 through May 2010), 7 of 33 samples failed the thresholds specified in the fact sheet. • Although the Staff Report fact sheet states that "<100% survival (acute) was considered an exceedance," the Basin Plan for the Coastal Watersheds of Los Angeles and Ventura Counties (Basin Plan) states that "the acute toxicity objective for discharges dictates that the average survival in undiluted effluent for any three consecutive 96-hour static or continuous flow bioassay tests shall be at least 90%, with no single test having less than 70% survival when using an established USEPA, State Board, or other protocol authorized by the Regional Board." Therefore, a single-test threshold of less than 70% survival should be used to determine impairments; even a threshold of less than 90% survival would still be more conservative than Basin plan objective. Applying a 90% threshold, no samples exceeded the acute toxicity water quality objective. • The Staff Report considered each chronic toxicity test result as independent data, even when multiple bioassays were conducted within a single month. However, the WNWRP permit states that the water quality objective for chronic toxicity is based on a monthly median; therefore, all tests within a single month should be considered part of a monthly median, rather than independent tests. Based on appropriate application of the monthly median as the chronic water	The review of the decision for Rio Hondo Reach 2 toxicity is in process at this time.

No.	Comment	Response
	quality objective (and a 90% acute toxicity threshold), there were 2 toxicity exceedances out of 31 tests. According to Table 3.1 of the California Clean Water Act 303(d) Listing Policy (Listing Policy), an impairment listing is appropriate if 3 or more exceedances are observed when 31 samples are available. Therefore, Reach 2 of the Rio Hondo fails to meet the listing criteria for toxicity. • The full set of data appended to Attachment G of the Staff Report, including those that fell outside the indicated temporal range, contains a total 38 discrete toxicity tests. Using a conservative 90% acute survival threshold and appropriate monthly median chronic threshold, there are no acute exceedances and 2 chronic exceedances out of 36 results. This total does not meet the minimum number of measured exceedances needed to place a water segment on the section 303(d) list. *Figure 1. Monitoring Station WN-RD1 (Blue Symbol) and Rio Hondo Reach 3 (Aqua Line)* • *Use of a <100% Survival Water Quality Objective Threshold Is Inappropriate and Unsupported.* • *Use of a <100% Survival Water Quality Objective Threshold Is Inconsistent with the Basin Plan and Other Documentation from the Regional Board.* • *Use of a <100% Survival Water Quality Objective Threshold Is Inconsistent with Criteria Used for Other Acute Toxicity Listings.* • *Use of a <100% Survival Water Quality Objective Threshold Is Inconsistent with the Results of Statistical Testing.* • *The Water Quality Objective/Threshold for Chronic Toxicity Should Be a Monthly Median.* *[See Sanitation District of Los Angeles County letter dated March 30, 2017 for complete text, figures and appendices.]*	
26.12	**Fact Sheet #5** **Water Body: Santa Clara River Reach 5**	Los Angeles Water Board staff will work with the State Board staff to address the issues related to

No.	Comment	Response
	Pollutant: Toxicity **Listing: List on 303(d) List (TMDL Required List)** **Comment & Recommendation: Do Not List – Water Quality Objectives Being Achieved** The California Regional Water Quality Control Board, Los Angeles Region (Regional Board) is proposing that a new listing for toxicity be made to the 303(d) list for Reach 5 of the Santa Clara River, based on one line of evidence: 2 of 2 samples exceeded the objective. The Sanitation Districts of Los Angeles County (Sanitation Districts) believe this proposed listing is inappropriate and recommend not listing due to water quality objectives being achieved, for the reasons listed below; supporting evidence is provided in the sections that follow. • Inappropriate data were utilized. Toxicity results were reported for sites SCR 1272 and SCR 14156. However, SCR 14156 is in Reach 6 of the Santa Clara River and should not be included in an evaluation of Reach 5 (Figure 1). • Incomplete data were utilized. The "Data for Various Pollutants in Various Water Bodies in Sanitation Districts of Los Angeles County 2005-2010" dataset should be included in this analysis as it was provided in response to the call for data, readily available, and used in other current listing recommendations. Appendix A of this letter contains the full set of data applicable to this listing from Appendix G of the Regional Board Draft Staff Report. • The Los Angeles Region Basin Plan states, "the acute toxicity objective for discharges dictates that the average survival in undiluted effluent for any three consecutive 96-hour static or continuous flow bioassay tests shall be at least 90%, with no single test having less than 70% survival when using an established USEPA, State Board, or other protocol authorized by the Regional Board." Therefore, a single-test threshold of less than 70% survival should be used to determine impairments. Applying this threshold (or even a more conservative 90% threshold) to the appropriate and complete dataset that excludes site SCR 14156 and includes Sanitation Districts data, there were five chronic toxicity exceedances out of 90 valid toxicity tests. This total does not	the spatial representation of samples. Los Angeles Water Board staff will also work with the State Board staff to address the missing data from the development of LOE 88730. LOE 88730 and Decision 67031 will be changed to reflect the changes in the evaluation guidelines discussed in response to comment 26.7. It is the intention of the Los Angeles Water Board staff to work with State Board staff to resolve mapping issues and reassess the LOEs and decisions for those reaches, as appropriate, prior to the State Board approval of the 2016 303(d) list, or at the next Listing Cycle that includes the Los Angeles Region.

No.	Comment	Response
	meet the minimum number of measured exceedances needed to place a water segment on the section 303(d) list. *Figure 1. Santa Clara River Reach 5 and RWB4 Stormwater Monitoring Council CY2008 CY2009 Sampling Locations* • *The Los Angeles Region Basin Plan Establishes Acute Toxicity Thresholds* • *The Water Quality Objective/Threshold for Chronic Toxicity Should Be a Monthly Median.* *[See Sanitation District of Los Angeles County letter dated March 30, 2017 for complete text, figures and appendices.]*	
26.13	**Fact Sheet #6** **Water Body: Santa Clara River Reach 5** **Pollutant: Benthic Community Effects** **Listing: List on 303(d) List (TMDL Required List)** **Comment & Recommendation: Do Not List – Water Quality Objectives Being Achieved** The California Regional Water Quality Control Board, Los Angeles Region (Regional Board) is currently proposing that a new listing for benthic community effects be made to the 303(d) list for Reach 5 of the Santa Clara River, based on two lines of evidence: Southern Coastal California Index of Biotic integrity (SCIBI) and California Stream Condition Index (CSCI) scores. The Districts believe this proposed listing is inappropriate and recommend not listing for the reasons listed below; supporting evidence is provided in the sections that follow. • The SCIBI-based analysis has been demonstrated to be inadequate for use in low gradient/low elevation watersheds similar to the reaches in the upper Santa Clara River. For this and other reasons, the State Water Resources Control Board (State Board) has rejected use of the SCIBI in favor of the technically superior CSCI scoring tool.	For additional discussion on the use of IBI and/or CSCI in listing decisions see response to comment 26.4. At this time, the CSCI (and IBI where CSCI is not available) is the best measure of biologic integrity in California streams and it is appropriate to use both IBI and CSCI scores in 303(d) listing decisions. The State Water Board has not ‘rejected’ the use of the SCIBI. The State is transitioning into using the CSCI because it is applicable statewide, accounts for a much wider range of natural variability, and provides equivalent scoring thresholds in all regions of the state. While, eventually, the State may assess waterbodies only by CSCI scores, it will take time to replace IBI scores with CSCI scores and this does not in any way mean that IBI scores (and assessments using them) are no longer valid. The commenter has provided several documents

	• Although the CSCI at least partially addresses some of the problems with the SCIBI by employing a modeled reference condition as opposed to the regional reference pool used by the SCIBI, the lack of any reference sites in large watersheds, low gradient, and low elevation systems still limits the identification of appropriate thresholds using the CSCI. Specifically, several Santa Clara River sites have been shown to fall outside the experience of the CSCI model. • Appropriate water quality thresholds for the CSCI have not been established. Although examples of approaches for developing CSCI thresholds have been published (e.g., by the Southern California Coastal Water Research Project), it is well recognized by the scientific community that a single standard should not be applicable to all water bodies because unmanageable nonpollutant features such as habitat condition are likely to preclude many streams from ever having biological assemblages similar to reference. The State Board is currently investing considerable resources to develop thresholds and should be allowed to complete the process before determination of impairment and listings. • The CSCI analysis for this listing used data from both Reach 5 and Reach 6 of the Santa Clara River. The CSCI analysis of the data collected from the Reach 5 location actually met the 0.79 threshold proposed by the Regional Board. • Physical habitat was not assessed, as required by the State Board Water Quality Control Board Quality Control Policy for Developing California's Clean Water Act Section 303(d) List (Listing Policy). Historically unmanaged or unmanageable stressors (e.g. channel/habitat modifications) are well documented as precluding sites from achieving reference conditions. • The proposed listing fails to associate the alleged impairment with other pollutants, namely toxicity and iron, which were listed as co-occurring. • *SCIBI Is an Inadequate Metric for Assessing Low Gradient, Low Elevation Streams.* • *CSCI Improves on the SCIBI But Some Limitations Remain*	that review and discuss the development of, and challenges with, aquatic life bio-criteria including IBI, CSCI and TALU (tiered aquatic life criteria). However, it appears that the principal evidence for the commenter's "inadequate for low elevation/lack of an appropriate reference site" argument is the CSCI Reference Density Cloud from a presentation of the California Bioassessment Workshop from 2012. The text accompanying the Reference Density Cloud in the presentation states, "*Could be used to establish exceptions for truly unique environmental settings.*" Nonetheless, it does not appear that any "truly unique environmental settings" have been established or are recognized by the State Bioassessment workgroup or other authority. The development of alternative thresholds via State Water Board efforts does not have a firm schedule to provide more useful guidance in the near future. It is appropriate to make listing decisions based on the best available data and science at this time. For the CSCI, the 10th percentile of reference pool is an appropriate evaluation guideline. Selection of the 10th percentile of the reference distribution to indicate impairment was done by Mazor et al. (2016) and was independently peer-reviewed. As previously noted, the selection and identification of reference is done at the desktop scale, and likely includes some sites that may not be "reference" due to localized impacts not discernable on a desktop basis or by field crews

	• *Appropriate Water Quality Standards (i.e. Biocriteria) Have Not Been Established* • *CSCI Data from Within Reach 5 of the Santa Clara River Show No Impairment* *Figure 1. CSCI Reference Density Cloud (Santa Clara River Sites Within Green Circle).* *Figure 2. Santa Clara River Reach 5 and Monitoring Stations Used in Listing* • *The Proposed Listing Fails to Evaluate Physical Habitat Data* • *The Proposed Listing Fails to Associate the Alleged Impairment with Other Pollutants* *[See Sanitation District of Los Angeles County letter dated March 30, 2017 for complete text, figures and appendices.]*	when sampling. The data considered in the LOE and for the listing decision for Reach 5 included IBI assessments from station Old Rd. on the west side of I-5 (three of three exceeding), and the site NR1 located 300 ft. upstream of the Los Angeles/Ventura County Line (one of two exceeding). The CSCI assessment was from the Santa Clara River Site 1272 and Santa Clara River Site 14156 (one out of one exceeding). The two sampling sites have now been "dis-aggregated" such that now, the data considered in the LOE and decision for Reach 5 includes IBI assessments from the Old Rd. station, on the west side of I-5 (three of three exceeding), and the site NR1 located 300 ft. upstream of the Los Angeles/Ventura County Line (one of two exceeding) and the CSCI assessments from the Santa Clara River Site 1272 and Santa Clara River Site 14156 (one out of two exceeding). Staff will review the inclusion of the second site (identified as SCR 14156) with State Water Board to determine whether it should be in Reach 5 or Reach 6, as part of resolving our mapping issues, see comment 26.2 The proposed listing evaluates the physical habitat data; physical habitat data is incorporated into the determination of reference sites. In addition, a Causal Assessment (Causal Assessment Evaluation and Guidance for California, K. Schiff,

No.	Comment	Response
		D. Gillett, A. Rehn and M. Paul, Southern California Coastal Water Research Project Technical Report 750, April 2015) concluded that elevated conductivity was the likely cause of biological conditions at the site and not the physical features of habitat simplification or river discontinuity. The proposed listing is associated with the documented impairments of other pollutants, including iron, toxicity and zinc. Furthermore, the Causal Assessment demonstrated that the impairment is associated with chloride. In summary, at this time, we know that the reach is impaired and that it is appropriate to list it per the Listing Policy. We anticipate further scientific work will be accomplished in upcoming years, which may make revisions and clarifications to the listing possible, including listing under 4c (impairment due to pollution, e.g. channelization) instead of 4b (impairment due to pollutants e.g. zinc, chloride, etc.).
26.14	**Fact Sheet #7** **Water Body: Los Angeles River Reach 3** **Pollutant: Benthic Community Effects** **Listing: List on 303(d) List (TMDL Required List)** **Comment & Recommendation: Do Not List – Water Quality Objectives Being Achieved** The California Regional Water Quality Control Board, Los Angeles Region (Regional Board) is proposing that a new listing for benthic community effects be made to the 303(d) list for Reach 3 of the Los Angeles River, based on a weight of	For the "inadequate for low elevation/lack of an appropriate reference site" argument, see response to comment 26.13. 26.16	**Fact Sheet #9** **Water Body: San Jose Creek Reach 1** **Pollutant: Temperature, Water** **Listing: List on 303(d) List (TMDL Required List)** **Comment & Recommendation: Do Not List – Meets Water Quality Objective** The California Regional Water Quality Control Board, Los Angeles Region (Regional Board) is proposing that a new listing for impairment due to water temperature be made to the 303(d) list for Reach 1 of San Jose Creek. The Sanitation Districts of Los Angeles County (Sanitation Districts) believe this proposed listing is inappropriate and recommend not listing due to water quality objectives being achieved. ***Failure to Meet Water Quality Objectives Has Not Been Demonstrated*** The Water Quality Control Plan: Los Angeles Region Basin Plan for the Coastal Watersheds of Los Angeles and Ventura Counties (Basin Plan) states that: "At no time shall these WARM-designated waters be raised above 80ºF **as a result of waste discharges**." [Emphasis added.] This water quality objective clearly distinguishes between exceedance of the 80ºF standard caused by "waste discharges" and those associated with other causes. Evidence indicates that summertime excursions greater than the 80ºF are not caused by waste discharges but are likely due to elevated ambient air temperature, conductive and radiative heating associated with hardened landscapes, a lack of riparian cover, and increased ambient temperatures related to climate change (details below). Additionally, the Draft List does not contain any analysis or evidence indicating that the elevated temperatures occurred as result of wastes discharged.	The water quality standard has been exceeded in 42 of 301 samples; even with the commenter's purported corrections to the database, 46 out of 339 or 32 out of 339 samples exceeded, in both cases, the data still exceed the allowable number of exceedances per the Listing Policy. Temperature, in some cases, may be because of pollution, e.g. habitat alteration, but may also be caused by discharges of waste, i.e. pollutants; therefore Category 5 is the appropriate category. Temperature is conventional pollutant with an objective defined in the Los Angeles Basin Plan, "*At no time shall these WARM designated waters be raised above 80 degrees F…"* See also response to comment 17.4 for additional discussion of temperature as a pollutant.

No.	Comment	Response
	The Regional Board Fact Sheet states that a single line of evidence was used in the assessment of temperature. Specifically, 42 of 301 samples from Pom-RD, Pom-RC, SJC-C1, and SJC-C2 exceeded the objective from July 2005 to November 2010 using the "Data for Various Pollutants in Various Water Bodies in Sanitation Districts of Los Angeles County, 2005-2010" dataset. Appendix A of this letter contains the full set of data applicable to this listing from Appendix G of the Regional Board Draft Staff Report. Based on a review of the dataset utilized for the listing evaluation, the Sanitation Districts identified 339 discrete temperature measurements, not 301. The dataset contains 368 results (Appendix 1); however, 29 samples were duplicates. Of the 339 unique temperature measurements, 46 exhibited a temperature that exceeded 80 ºF, not 42. However, 14 of the 46 temperature exceedances were demonstrably caused by conduction and radiation (details below), not waste discharges. Conduction and radiative heating likely also caused the remaining 32 exceedances out of 339 measurements; this total does not meet the minimum number of measured exceedances needed to place a water segment on the section 303(d) list. ***Pom-RC and Pom-RD Excursions Above 80 ºF Are Demonstrably Not a Result of Waste Discharges*** Tertiary treated water from the Pomona Water Reclamation Plant is discharged to the south fork of San Jose Creek and flows into Reach 1. Receiving water stations Pom-RC, Pom-RD, and SJC-C1 are located approximately 3, 12, and 12.5 miles from the upstream border of Reach 1, respectively. Reach 1 is fully lined in concrete from the upstream border to just upstream of SJC-C1 (Figure 1). As observed by Sanitation Districts staff and corroborated by EPA staff, groundwater exudes from relief structures distributed throughout the concrete-lined bottom, even in mid-summer (August) after several years of drought (Figure 2).[1] In the absence of discharge from the Pomona Water Reclamation Plant or other observed discharges, flows in SJC between Pom-RC and Pom-RD increase by 200% to greater than 400% (Figure 3) due to the release of this	

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td></td><td>groundwater, which has a localized average temperature of approximately 67 ºF.[2] As this groundwater-dominated flow travels downstream, the temperature naturally rises (Figure 4) due to heat conduction through the warm concrete lining and solar radiation exposure in the unshaded channel (Figure 5 shows ambient air temperature as a proxy for solar radiation[3]). When the concrete channel ends upstream of SJC-C1, the water leaves the heat source (concrete channel) and mixes with additional groundwater, resulting in consistently cooler temperatures. The observed spatial and temporal temperature profile, coupled with no identifiable waste discharges and substantial groundwater contributions, clearly demonstrates that the temperature excursions in Reach 1 of San Jose Creek are not a result of waste discharges.

	Failure to Meet Water Quality Objectives Has Not Been Demonstrated The Water Quality Control Plan: Los Angeles Region Basin Plan for the Coastal Watersheds of Los Angeles and Ventura Counties (Basin Plan) states that: "At no time shall these WARM-designated waters be raised above 80ºF **as a result of waste discharges**." [Emphasis added.] This water quality objective clearly distinguishes between exceedance of the 80ºF standard caused by "waste discharges" and those associated with other causes. Evidence indicates that summertime excursions greater than the 80 ºF are not caused by waste discharges but are likely due to elevated ambient air temperature, conductive and radiative heating associated with hardened landscapes, a lack of riparian cover, and increased ambient temperatures related to climate change (details below). Additionally, the Draft List does not contain any analysis or evidence indicating that the elevated temperatures occurred as result of wastes discharged. The Regional Board Fact Sheet states that a single line of evidence was used in the assessment of temperature. Specifically, 93 of 234 samples from LC-R4, R3-1, and R3-1b exceeded the objective from July 2005 to November 2009 using the "Data for Various Pollutants in Various Water Bodies in Sanitation Districts of Los Angeles County, 2005-2010" dataset. Based on a review of the entire dataset utilized for the listing evaluation,[1] the Sanitation Districts identified 288 discrete temperature measurements, 117 of which exhibited a temperature that exceeded 80ºF. However, these temperature exceedances were not as a result of waste discharges, but were directly associated with high elevated ambient air temperatures as well as conduction and radiation (details below). Therefore, under the definition in the Basin Plan, no exceedances of the water quality objective were observed. ***San Gabriel River Reach 1 Excursions Above 80 ºF Are a Result of Radiative***	temperature objectives for the different seasons. See, also, response to comment 17.4.

No.	Comment	Response
	and Conductive Heating Tertiary treated water from the San Jose Creek and Los Coyotes Water Reclamation Plants (WRPs) is discharged to the main stem of the San Gabriel River. Reach 1 is a fully lined concrete channel from approximately 0.25 miles downstream of the San Jose Creek WRP discharge point 001 to the San Gabriel River estuary. As explained in Fact Sheet #9, elevated temperatures in Reach 1 of San Jose Creek occurred even in the absence of observable waste discharges and were caused by conductive heating through the concrete lining and solar radiation exposure. Although a comprehensive assessment of flows, in the absence of WRP discharge, cannot be conducted along the San Gabriel River, the same conditions associated with the radiative and conductive heating exist in San Gabriel River Reach 1. This is supported by a significant correlation between ambient air temperature and receiving water temperature (R2 = 0.61) and the fact that 90% of excursions above 80ºF in the receiving water environment occurred during summer months, between June and September. The weight of evidence supports the contention that receiving water temperatures above 80ºF were a result of ambient and environmental conditions (i.e., summer weather and a concrete channel) and not waste discharges. *[See Sanitation District of Los Angeles County letter dated March 30, 2017 for complete text, figures and appendices.]*	
26.18	**Fact Sheet #11** **Water Body: San Gabriel River Reach 2** **Pollutant: Temperature, Water** **Listing: List on 303(d) List (TMDL Required List)** **Comment & Recommendation: Do Not List – Meets Water Quality Objective** The California Regional Water Quality Control Board, Los Angeles Region (Regional Board) is proposing that a new listing for impairment due to water temperature be made to the 303(d) list for Reach 2 of the San Gabriel River. The Sanitation Districts of Los Angeles County (Sanitation Districts) believe this proposed listing is inappropriate and recommend not listing due to water quality	The water quality standard has been exceeded in 81 of 224 samples; even given the commenter's purported corrections to the database, 81 of 232 samples exceeded, which still exceeds the allowable number of exceedances per the Listing Policy. See, also, response to comment 17.4.

No.	Comment	Response
	objectives being achieved. ***Failure to Meet Water Quality Objectives Has Not Been Demonstrated*** The Water Quality Control Plan: Los Angeles Region Basin Plan for the Coastal Watersheds of Los Angeles and Ventura Counties (Basin Plan) states that: "At no time shall these WARM-designated waters be raised above 80ºF **as a result of waste discharges**." [Emphasis added.] This water quality objective clearly distinguishes between exceedance of the 80ºF standard caused by "waste discharges" and those associated with other causes. Evidence indicates that summertime excursions greater than the 80 ºF are not caused by waste discharges but are likely due to elevated ambient air temperature, conductive and radiative heating associated with hardened landscapes, a lack of riparian cover, and increased ambient temperatures related to climate change (details below). Additionally, the Draft List does not contain any analysis or evidence indicating that the elevated temperatures occurred as result of wastes discharged. The Regional Board Fact Sheet states that a single line of evidence was used in the assessment of temperature. Specifically, 81 of 224 samples from SJC-R2 and SJC-R12 exceeded the objective from July 2005 to November 2009 using the "Data for Various Pollutants in Various Water Bodies in Sanitation Districts of Los Angeles County, 2005-2010" dataset. Based on a review of the entire dataset utilized for the listing evaluation,[1] the Sanitation Districts identified 81 excursions above 80 ºF out of 232 discrete temperature measurements, not 224. However, these temperature exceedances were not as a result of waste discharges, but were directly associated with high elevated ambient air temperatures as well as conduction and radiation (details below). Therefore, under the definition in the Basin Plan, no exceedances of the water quality objective were observed.	

No.	Comment	Response
	San Gabriel River Reach 2 Excursions Above 80 ºF Are a Result of Radiative and Conductive Heating Tertiary treated water from the San Jose Creek Water Reclamation Plant (WRP) is discharged to the main stem of the San Gabriel River. The uppermost ¼ mile of Reach 2 is a fully lined concrete channel, containing the R2 receiving water station. Data from this station represents 215 of 232 data points. As explained in Fact Sheet #9, elevated temperatures in Reach 1 of San Jose Creek occurred even in the absence of observable waste discharges and were caused by conductive heating through the concrete lining and solar radiation exposure. Although a comprehensive assessment of flows, in the absence of WRP discharge, cannot be conducted along the San Gabriel River, the same conditions associated with the radiative and conductive heating exist in San Gabriel River Reach 2. This is supported the fact that 99% of excursions above 80 ºF in the receiving water environment occurred during summer months, between June and October. The weight of evidence supports the contention that receiving water temperatures above 80 ºF were a result of ambient and environmental conditions (i.e., summer weather and a concrete channel) and not waste discharges. *[See Sanitation District of Los Angeles County letter dated March 30, 2017 for complete text, figures and appendices.]*	
26.19	**Fact Sheet #12** **Water Body: Santa Clara River Reach 6** **Pollutant: Temperature, Water** **Listing: List on 303(d) List (TMDL Required List)** **Comment & Recommendation: Do Not List** The California Regional Water Quality Control Board, Los Angeles Region (Regional Board) is proposing that a new listing for impairment due to water temperature be made to the 303(d) list for Reach 6 of Santa Clara River. The Sanitation Districts of Los Angeles County (Sanitation Districts) believe this proposed listing is inappropriate and recommend not listing.	Staff will review the inclusion of the site identified as SCR-14 with State Water Board staff to determine whether it should be in Santa Clara Reach 6 or Bouquet Canyon Creek, as part of resolving our mapping issues; see also comment 26.2. With respect to the sites identified as SA-RA and SA-RB, only the temporally overlapping samples from these stations have been averaged such as during extreme rainfall events when the sites were hydrologically connected. The commenter does

No.	Comment	Response
	Incorrect Datasets Were Used for Listing The Regional Board Fact Sheet states that a single line of evidence was used in the assessment of temperature. Specifically, 40 of 152 samples from Sa-RA, Sa-RB, and SCR-14 exceeded the objective from June 2005 to October 2010 using the "Data for Various Pollutants in Various Water Bodies in Sanitation Districts of Los Angeles County, 2005-2010" dataset. Temperature data from location SCR-14 (34.42833333N 118.5394444W) was evaluated as part of Reach 6 of the Santa Clara River. However, SCR-14 is located on Bouquet Canyon Creek, which is recognized as a distinct waterbody by the Region 4 Basin Plan. Figure 1 utilizes a reach delineation layer provided to the Sanitation Districts by Regional Board staff that clearly places SCR-14 in the Bouquet Canyon Creek Reach and not Reach 6. Therefore, temperature measurements from SCR-14 should not be included in the Reach 6 evaluation. *Figure 1. Stations Sa-RB (1), Sa-RA (2), SCR-14 (14), and Bouquet Canyon Creek (Aqua Line)* Locations Sa-RA and Sa-RB were correctly associated with Reach 6, but results were averaged in the listing evaluation based on the assessment that they were "not spatially independent." However, as highlighted in Figure 2, Sa-RA is located within the main channel of the Santa Clara River and is typically dry; all 25 temperature measurements at Sa-RA utilized in the Staff Report were associated with upstream dewatering activities or extreme storm events. Sa-RB is located in an isolated pool at the southern edge of the Reach 6 channel that receives recycled water discharges from the Saugus Water Reclamation Plant (WRP). Surface flows from this location travel less than a half-mile downstream in a disconnected side channel before percolating into the dry riverbed. Therefore, even though the two locations are relatively close to each other, Sa-RA is hydrologically isolated from Sa-RB except during extreme rainfall events. Consequently, the two locations would be expected to have very different temperature profiles and should therefore be considered spatially independent, with no averaging of results.	not adequately describe "upstream dewatering activities" for the Los Angeles Water Board staff to be able to discern the significance of these to the comment. The 80°F temperature objective protects the aquatic life beneficial use of WARM in surface waters regardless of the ultimate source of the water in that reach of the river. The Los Angeles Water Board does not have alternative objectives for effluent-dominated waters. See, also, response to comment 17.4.

No.	Comment	Response
	Figure 2. Satellite Imagery of Saugus WRP Ambient Monitoring Stations ***The 80ºF Water Quality Temperature Objective Is Unnecessary and Inappropriate for Santa Clara River Reach 6*** The only dry weather surface flows within this stretch of Reach 6 are associated with recycled water discharges from the Saugus WRP, which percolate into the dry riverbed and eventually resurface downstream near the Reach 5 boundary. At the point of resurfacing, the water temperature averages 69ºF and this perennial surface flow supports a diverse aquatic life community in Reach 5.1 However, the predominant natural condition of Reach 6 is dry and would not be expected to support any aquatic life without the Saugus WRP discharge. In addition, the cool temperatures in the water that resurfaces near the Reach 5 boundary demonstrate that elevated temperatures in the isolated discharge area are not detrimental to beneficial uses. Therefore, application of the 80ºF water quality objective in Santa Clara Reach 6 is unnecessary and inappropriate, as the presence of water exceeding the 80ºF water quality objective would not result in any impairment to naturally occurring aquatic life. ***Mitigating the Elevated Temperature at Sa-RB Is Not Feasible*** The only reasonable alternative to address the temperature water quality objective below the Saugus WRP at location Sa-RB during dry weather would be to eliminate the discharge. However, it is highly unlikely that the California Department of Fish and Wildlife would support any discharge reductions or elimination, because this action would remove all dry weather surface flows in that stretch of Santa Clara Reach 6 and could potentially reduce the amount of resurfacing groundwater flows that actually support a diverse aquatic community in Santa Clara River Reach 5. ***An Evaluation of the Relative Contribution of Radiative and Convective Heating Was Not Conducted*** Los Angeles Region Basin Plan for the Coastal Watersheds of Los Angeles and	

No.	Comment	Response
	Ventura Counties (Basin Plan) states that: “At no time shall these WARM-designated waters be raised above 80ºF **as a result of waste discharges**.” [Emphasis added.] This objective clearly distinguishes between temperature exceedances caused by “waste discharges” and those associated with other causes. Both the Saugus WRP discharge and the immediate downstream receiving water location (Sa-RB) are heavily influenced by ambient air temperature. Figure 3 includes a plot of the 15-day average values of the maximum air temperature along with the individual water temperature measurements collected at the Sa-RB location. Nearly all of the 80ºF temperature exceedances were associated with the higher summer time air temperatures and the two have a statistically significant correlation (R2 = 0.76). Because exceedances of the Basin Plan temperature objective are limited to those “as a result of waste discharges,” an evaluation of the contribution of ambient air temperature to the receiving water should have been conducted before identifying receiving water excursions above 80ºF as exceedances of the objective. *Figure 3. Sa-RB Temperature vs. Maximum Ambient Air Temperature (15-Day Average Value)* *[See Sanitation District of Los Angeles County letter dated March 30, 2017 for complete text, figures and appendices.]*	
27.	Santa Barbara Channelkeeper (SBC), March 30, 2017	
27.1	Please accept the following comments on the Los Angeles Regional Water Quality Control Board’s (Regional Board’s) 2016 Integrated Report, which are hereby submitted by Santa Barbara Channelkeeper. Santa Barbara Channelkeeper is a non-profit environmental organization dedicated to protecting and restoring the Santa Barbara Channel and its watersheds through science-based advocacy, education, field work and enforcement. We have been conducting water quality monitoring in watersheds from Gaviota to the Ventura River since 2001. We have engaged more than 1,200 volunteers in our monitoring	See response to comment 32.3.

No.	Comment	Response
	efforts and represent over 750 members. Our comments address the following concerns: • Procedural issues related to data solicitation gaps • Category 4C and Hydrologically Impaired Waterways • Inappropriate de-listing of the Ventura River Reach 3 Pumping Impairment Generally, Channelkeeper supports the Regional Board's ongoing efforts to document water quality impairments on the 303(d) List. Specific concerns regarding the Draft 2016 Integrated Report are summarized below. **<u>Procedural Concerns Related to Data Solicitation Gaps</u>** Channelkeeper is troubled that the Regional Board has fallen so far behind on data solicitations and review of 303(d) listings. 40 C.F.R. § 130.7(d)(1) mandates that: Each State shall submit biennially to the Regional Administrator beginning in 1992 the list of waters, pollutants causing impairment, and the priority ranking including waters targeted for TMDL development within the next two years as required under paragraph (b) of this section. The 2016 Integrated Report is based on data submitted in 2010 and will not be finalized until the middle of 2017. Based on EPA Guidance, the 2016 Integrated Report was due in April 2016. Clearly, the Regional Board has failed to achieve pertinent milestones and mandates related to the biennial review process. The lack of any recent data solicitation is particularly troubling as a fully accurate and current depiction of water quality is not available for the 2016 Integrated Report. The Regional Board has a mandate to "assemble and evaluate all existing and readily available water quality-related data and information to develop the list."[2] Accordingly, the Regional Board should base 2016 Integrated Report decisions based on "all existing and readily available" data, which includes data collected since the 2010 data solicitation. Six years of additional data is available	

No.	Comment	Response
	to the Board and should be appropriately utilized for the Region's listing, de-listing and planning purposes. Channelkeeper questions how such determinations can reasonably or legally be made without consideration of the last six years of existing and readily available data. It is additionally concerning that due to the State's new staged approach to 303(d) List review, further data solicitation will be delayed until the Los Angeles Regional Board's 2022 report, which will include data submitted through 2021. This means that the Regional Board will not have reviewed existing water quality data for our region for more than a decade. This is clearly unacceptable from a legal standpoint.	
27.2	**<u>Category 4C and Hydrologically Impaired Waterways</u>** Channelkeeper echoes and supports comments submitted to the Regional Board on March 30, 2017 by *Earth Law Center* regarding the necessity for evaluation and listing for hydrologically impaired waterways to fully comply with Clean Water Act Sections 305(b) and 303(d). Such evaluation and listing is clearly called for under the Clean Water Act, is supported by EPA Guidance, and paves the way for sound public policy and planning. Many other states around the country follow such Guidance to properly identify flow impaired waterways in their Integrated Reports. Recently, the San Diego Regional Water Quality Control Board notably identified 30 waterway segments for listing in Category 4C. Channelkeeper notes with concern that the Los Angeles Region has apparently forgone assessment of Category 4C impairments altogether in the Draft 2016 Integrated Report. We question the legality of such an oversight.	See response to comment 21.1, 21.2, 21.3, and 21.4.
27.3	**<u>Inappropriate de-listing of the Ventura River Reach 3 Pumping Impairment</u>** The Los Angeles Regional Board currently proposes to delist Reach 3 of the Ventura River for "Pumping" impairment. Channelkeeper strongly opposes this delisting decision. On February 5, 2015 Channelkeeper submitted detailed comments (Attachment 1) and data to the State Water Resources Control Board regarding its stated intent to delist Reaches 3 and 4 of the Ventura River for	See response to comment 21.1, 21.2, 21.3, and 21.4.

No.	Comment	Response
	pumping and diversion impairments. These comments were submitted in response to the State Water Board's Draft Staff Report for the 2012 Integrated Report dated December 31, 2014, which stated that the four listings on the existing 303(d) list due to flow related alterations in the Ballona Creek and Ventura River watersheds "will likely be proposed for delisting as part of the next Listing Cycle." Channelkeeper's submittal outlined in detail why Reaches 3 and 4 of the Ventura River may not be delisted from the 303(d) list as impaired for flow by pumping and diversion. The existing listings for Reaches 3 and 4 of the Ventura River accurately reflect the current diminished flows and resulting impairments to designated beneficial uses in those Reaches. The listings are legally valid, and consistent with the State Water Board's Listing Policy. In contrast, delisting Reaches 3 and 4 from the 303(d) list as impaired for flows due to excessive pumping and diversion is inconsistent with the Listing Policy, the Clean Water Act, and facts on the ground. We refer the Los Angeles Regional Board to our February 5, 2015 letter as its legal and technical merits remain unchanged. Channelkeeper additionally submitted multiple years of continuous monitoring data (submitted electronically via file "*MasterData_2013-2014.xls*") along with our 2015 comment letter. These data were summarized in tables as well as within an example "Listing Line of Evidence" provided with our 2015 letter. Lacking any formal data solicitation by the Los Angeles Regional Board since 2010, these submittals represent existing and readily available water quality-related data and information, which should have been used to develop the Draft 2016 Integrated Report. Since the submittal of our 2015 comment letter, Channelkeeper has collected additional water quality data that supports the existing listings for pumping and diversions in Reaches 3 and 4. We are submitting an updated data file ("*MasterData_2013-2016*") electronically along with this comment letter. **<u>Conclusion</u>** When Reaches 3 and 4 of the Ventura River were identified as flow-impaired by	

No.	Comment	Response
	pumping and diversions on California's 1998 303(d) list, the State Water Board took an important first step towards restoring the chemical, physical, and biological integrity of these waters. However, there is ongoing documentation that flow alterations from pumping and diversions continue to degrade Reaches 3 and 4 such that these waters cannot support their designated beneficial uses and water quality standards are not attained. Reaches 3 and 4 of the Ventura River are impaired for pumping and diversions based on the "Numeric Water Quality Objectives for Conventional or Other Pollutants in Water" listing factor, the "Situation-Specific Weight of Evidence" listing factor, as well as the "Degradation of Biological Populations and Communities" listing factor. Removing the pumping impairment listing for Reach 3 is not only illegal but will also impede existing and future efforts to remedy the ongoing flow impairments in the Ventura River. Channelkeeper strongly urges the Los Angeles Regional Board to comply with the Clean Water Act by continuing to identify Reach 3 on the 303(d) list as flow- impaired by pumping.	
28.	Sherwood Valley Homeowners Association, March 30, 2017	
28.1	We thank you for this opportunity to comment on the proposed changes to the 303(d) list prior to the upcoming public hearing on May 4, 2017. Representatives from the Lake Sherwood Joint Lake Advisory Committee plan to attend this meeting to discuss these important issues. We appreciate the proposed removal of the two pollutants, Ammonia and Organic Enrichment/Low Dissolved Oxygen. This is gratifying and recognizes the positive results produced by the time, effort and expense the Association has put forth over many years to mitigate these concerns. Respectfully, however, we are troubled to see that Algae and Eutrophic remain on the list. To help understand why these are still considered pollutants in Lake Sherwood, we reviewed the Los Angeles Water Board's website of the Draft 2016 303(d) List, and specifically Appendix G – Fact Sheets of the Draft. Here we see that the listing of Algae and Eutrophic are noted as "placeholders" to support decisions made prior to the 2006 Clean Water Act, and further that no evidentiary data	Lake Sherwood was as listed impaired for algae, ammonia, eutrophic conditions and organic enrichment/low dissolved oxygen in the 2010 Integrated Report. On the 2016 303(d) list, the Los Angeles Water Board has recommended delisting "organic enrichment/low dissolved oxygen" and ammonia, based on data showing there is not an impairment. "Placeholder" LOEs are those LOEs derived prior to the 2006; they are 'placeholder" in the sense that the raw data is not included in the CalWQA database. Per the Listing Policy, section 4.71.1, impairments are delisted when, based on all the readily

No.	Comment	Response
	samples were collected which could be used to assess these pollutants relative to the 2006 standards. Clearly there are zero measured exceedances of these standards at this point yet they remain on the list. It seems to us somewhat arbitrary to continue to consider these as "pollutants" in Lake Sherwood especially where there is a consistently good dissolved oxygen level, a continuous effort to remove excess plant growth via a special harvester with a full time crew, monthly monitoring of water chemistry, and special attention to and approved treatment of any algae that occurs as needed throughout the year. If sufficient justification does exist to continue to include these on the 303(d) list, we would appreciate having the reasons and rational detailed to us in writing so we may take any necessary actions to remove them in the future.	available data, there is sufficient evidence or data to justify a recommendation for delisting. The USEPA established a TMDL for the Malibu Creek watershed for nutrients to address these listings on March 21, 2003. The assessment of whether or not it is appropriate for the Lake to be removed from the 303(d) list for algae and eutrophic conditions must consider how those conditions interact with nitrogen and phosphorus levels, as discussed in the TMDL, and whether the TMDL targets are being met.
29.	Stakeholders Implementing TMDLs in the Calleguas Creek Watershed, March 30, 2017	
29.1	The development and implementation of TMDLs is a significant investment of resources and it is critical that the 303(d) List be based on sound science and methodologies. The Stakeholders understand that the Los Angeles Regional Water Board (Water Board) is proposing over 200 new waterbody-pollutant segment combination 303(d) listings, of which 95 changes fall within the Calleguas Creek Watershed (CCW). The Stakeholders have developed and implemented six effective TMDLs in the CCW and thus have extensive experience in the area. The Stakeholders have serious concerns with the Region's Proposed 303(d) List and feel that it requires significant review and modification before adoption. The Stakeholders request that the issues identified in this letter be addressed and the proposed 303(d) List be released for another 60-day comment period prior to adoption. Several of the issues identified herein have resulted in the inability of the proposed 303(d) List to be fully vetted and reviewed by the Stakeholders. The requested modifications fall into four general categories: 1. New Category 5 listings that should not be listed due to incorrect thresholds being applied for the beneficial use and incorrect interpretation of the data (e.g., mismatched units, incorrectly assigned sample locations) 2. Potential delistings that may exist if all watershed data were evaluated (e.g.,	The Los Angeles Water Board recognizes the significant implications of the 303(d) list and TMDLs. The 303(d) list is based on sound science and the readily available data. However, as the Los Angeles Water Board determines its priorities for TMDL development or other regulatory programs, it will not depend exclusively on the 303(d) list or the data contained therein (currently through 2010 only). Los Angeles Water Board staff intends to make the necessary corrections in the CalWQA database and revise, as appropriate, listing/delisting decisions as the State Board staff prepare the Integrated Report and 303(d) list for State Board approval later this year or prior to the next Listing Cycle that includes the Los Angeles Region. See response to comment 29.2-29.67 for specific

No.	Comment	Response
	TMDL monitoring program and all wastewater treatment plant NPDES monitoring). 3. New Category 5A listings that should be categorized as Category 5B because TMDLs already exist to address the pollutants. 4. Errors in the listing information that make it difficult to fully evaluate the listings. Examples include inconsistencies between the Category 5 list (Appendix B) and the Proposed updates to the 303(d) List (Appendix A), incorrect HUC/Calwater designations, incorrect beneficial uses listed for the applicable water quality objectives, and inconsistent use of thresholds for interpreting narrative objectives. The remaining sections of this letter provide the detailed list of requested changes to the 303(d) List and the rationale for the requests. In summary, the Stakeholders request that all waterbody-pollutant combinations in Table 1 not be listed on the 303(d) List, the waterbody-pollutant combinations in Table 3 be considered for delisting through analysis of all available watershed data, waterbody-pollutant combinations in Table 4 and Table 5 be designated as being addressed by a TMDL if they remain on the 303(d) List after the reassessment and the errors and inconsistencies identified in Comment IV be addressed for all waterbodies.	responses.
29.2	1. REQUESTED MODIFICATIONS TO THE LISTING STATUS Based on a review of the proposed Category 5 waterbody-pollutant combinations, the Stakeholders have identified a number of waterbodies that we feel should either be delisted based on available data or proposed listings that should not be listed based on errors in the evaluation. The requested modifications are shown in Table 1, below, with a summary of the justifications for the requested change. A detailed discussion of each of the justifications follows the table.	Comment noted. See detailed responses below and response to comment 29.1.
29.3	**Table 1. Waterbody-pollutant combinations that should not be listed** Waterbody segment: **Calleguas Creek Reach 2 (estuary to Potrero Rd)** Pollutant: DDD Justification:	See response to comment 7.14

29.53	**Santa Clara Drain** Pollutant: Toxaphene Justification: • Data from agricultural drain rather than waterbody used as basis for listing decision.	See response to comment 7.71.
29.54	**1. Agricultural Drain monitoring data incorrectly used as basis for listing decisions.** There are multiple instances where VCAILG monitoring data from agricultural drains that discharge to waterbody reaches were used to list these waterbody reaches. The drains are not listed tributaries or waterbodies in the Basin Plan and are not located within the waterbody that is being listed. As a result, the data should not be used for the listing decisions for these waterbodies. Calleguas Creek Reach 2 and Reach 4 were listed using data from the VCAILG monitoring sites 02D_BROOM (Reach 2) and 04D_ETTG and 04D_LAS (Reach 4), which are the locations of agricultural drains which drain to Reach 2 and 4. Santa Clara River Reach 3 was listed using data from the VCAILG sampling location S03D_BARDS, which is located on an agricultural drain that ultimately discharges into Santa Clara River Reach 3. These agricultural monitoring sites were selected to be representative of agricultural discharges to Calleguas Creek Reaches 2 and 4 and Santa Clara River Reach 3, and are not representative of receiving water conditions. Therefore, data collected from these sites cannot be used to list the downstream Calleguas Creek or Santa Clara River Reaches. All listings should be evaluated to ensure that the monitoring locations were in receiving waters rather than agricultural drains. In addition, La Vista Drain and Santa Clara Drain were listed as new waterbodies never before included in the previous 303(d) list, even though data has been	See response to comment 7.88.

No.	Comment	Response
	collected on both agricultural drains by the MS4 program since the early 1990s. These waterbodies are not designated in the Basin Plan or listed as tributaries in the Basin plan appendices. The La Vista Drain is an agricultural drain designed to convey excess agricultural irrigation water from agricultural lands, and as such, it is predominantly an open ditch that flows alongside W. Los Angeles Avenue and then along Santa Clara Avenue where it becomes the Santa Clara Drain. Additionally, inclusion of the COMM beneficial use for the Santa Clara Drain is inappropriate, as public access is prohibited because of fencing and locked gates maintained by the Ventura County Watershed Protection District. It is inappropriate to apply the MAR and EST beneficial uses to the Santa Clara Drain because the drain is located upstream of Highway 101 and is not tidally influenced. The monitoring location on each drain was selected to represent agricultural discharges for the Agricultural Waiver and was not designed to characterize receiving waters. Because these are agricultural drains and not tributaries, they should be removed from the Draft Category 5 list. **Requested Action:** • **Remove all listings shown in Table 1 that were based on Ag monitoring data from agricultural drains not representative of the listed waterbody and evaluate remaining listings to ensure no other listings are based on agricultural drain monitoring rather than receiving water monitoring.** • **Remove the La Vista Drain and the Santa Clara Drain from the List as they are agricultural drains and not waterbodies that fall under the jurisdiction of the 303(d) List.**	
29.55	***2. Remove any pollutant listing based on municipal drinking water objectives where the MUN beneficial use does not apply.*** Numerous listings were made using water quality objectives for the protection of the municipal drinking for waterbodies that do not have applicable municipal drinking water beneficial uses. Many of the waterbodies listed are brackish waterbodies for which no beneficial uses are designated or waterbodies designated for the municipal beneficial use with an asterisk (i.e., P*) in the Basin Plan. The asterisked MUN beneficial use should not be used to propose new 303(d) listings.	See response to comment 7.89.

No.	Comment	Response
	Fact Sheets for previous 303(d) listing cycles have clearly noted that the asterisked MUN beneficial uses should not be used for 303(d) listing purposes. State Board Resolution No. 88-63 (Sources of Drinking Water) and Regional Board Resolution 89-03 (Incorporation of Sources of Drinking Water Policy into the Water Quality Control Plans (Basin Plans)), state that "All surface and ground waters of the State are considered to be suitable, or potentially suitable, for municipal or domestic waters supply and should be so designated by Regional Boards... [with certain exceptions which must be adopted by the Regional Board]." The Regional Board adopted a Water Quality Control Plan for the Los Angeles Region (Basin Plan) on June 4, 1994, that included provisions to implement State Water Board Resolution 88-63. On May 26, 2000, the USEPA approved the revised Basin Plan except for the implementation plan for potential MUN-designated water bodies. On August 22, 2000, the City of Los Angeles, City of Burbank, City of Simi Valley, and the County Sanitation Districts of Los Angeles County challenged USEPA's water quality standards action in the U.S. District Court. On December 18, 2001, the court issued an order remanding the matter to USEPA to take further action on the 1994 Basin Plan consistent with the court's decision. On February 15, 2002, USEPA revised its decision and approved the 1994 Basin Plan in whole. In its February 15, 2002 letter, USEPA stated: *"EPA bases its approval on the court's finding that the Regional Board's identification of waters with an asterisk ("*'? in conjunction with the implementation language at page 2-4 of the 1994 Basin Plan, was intended "to only conditionally designate and not finally designate as MUN those water bodies identified by an ('*') for the MUN use in Table 2-1 of the Basin Plan, without further action." Court Order at p. 4. Thus, the waters identified with an ("*") in Table 2-1 do not have MUN as a designated use until such time as the State undertakes additional study and modifies its Basin Plan. Because this conditional use designation has no legal effect, it does not constitute a new water quality standard subject to EPA review under section 303(c)(3) of the Clean Water Act ("CWA"). 33 U.S.C. § 1313(c)(3)."*[1]	

No.	Comment	Response
	In addition to the above decision, the Basin Plan states that until the additional study is undertaken and the Basin Plan is modified "no new effluent limitations will be placed in Waste Discharge Requirements as a result of these designations". The Regional Board has also determined that water quality objectives applicable to the MUN beneficial use will not be used to assess impairments under the 303(d) listing programs. For constituents that only have objectives that are applicable to the MUN beneficial use, the decision Fact Sheets for the 303(d) listing process state that there are no applicable water quality objectives in waterbodies designated with an asterisk ("*"). In the 2010 listing cycle, a number of 303(d) listings were actually removed based on this determination. Below is an example of the language from a listing decision for Los Angeles River Reach 1: *"The listing for aluminum in this water body was originally based on data assessed using the MCL for aluminum. Since MUN is a "potential" beneficial use, it is not appropriate to use the MCL to evaluate aluminum data from this reach. Thus, there is no aluminum objective for this reach and the original listing is faulty."* Based on this evidence, it is clear that for waterbodies with a MUN designation that includes an asterisk ("*"), water quality objectives specific to the MUN beneficial use are not applicable. As such, water quality data collected in these receiving waters should not be compared to water quality objectives applicable to the MUN beneficial use. The listings of total dissolved solids, sulfates, and conductivity are all based on secondary maximum contaminant levels applied to protect the MUN beneficial use. In addition, Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2 and Rio De Santa Clara/Oxnard Drain No. 3 are maintained as fresh/brackish water via tide gates on both drains and do not have designated MUN beneficial uses. Therefore, the listing of TDS, sulfate, and specific conductivity is inappropriate as naturally occurring levels of these three constituents in groundwater entering both drains within the footprint of Naval Base Ventura County far exceed the secondary MCLs upon which these listings are based. USEPA validated this reasoning in its "TMDLs for Pesticides, PCBs and Sediment	

No.	Comment	Response
	Toxicity for Oxnard Drain 3",[2] where the MUN beneficial use was not considered to be "relevant to the impairments" addressed by the TMDL and so was not included in the TMDL. Additionally, Calleguas Creek Reach 2 and Reach 4 are considered brackish waterbodies according to the California Toxics Rule thresholds and are designated with an asterisked MUN beneficial use. Due to the brackish nature of these waterbodies, other Basin Plan objectives for TDS and sulfate are not considered to be applicable to Reach 2 or Reach 4 below Laguna Road. For all of these reasons, these proposed listings summarized in **Table 1** should not be listed. The proposed Calleguas Creek Reach 2 dimethoate listing was based on three lines of evidence which the Fact Sheet states all show no exceedances (this appears to be a typo). However, it appears that the only line of evidence that shows an exceedance is based on the potential (P*) MUN, which as described above, cannot be used to justify a listing. Furthermore, the Fact Sheet cites a guideline from the California Department of Health Services Notification Levels (1 µg/L) which has not yet gone through the formal MCL regulatory process and it is not clear that this threshold would meet the Listing Policy requirements. **Requested Action:** • **Revise all of the new listings in the Fact Sheets to ensure that none are based on municipal drinking water objectives when the MUN beneficial use does not apply.** • **Remove the segment-pollutant combinations for total dissolved solids, specific conductivity, sulfates, nitrogen, nitrate, dimethoate, and other MUN-based pollutants listed in Table 1 above from the 303(d) List.**	
29.56	***3. Reassess mercury listings using correct objective and correct units*** The data used to assess mercury for Calleguas Creek Reach 3, Reach 4, and La Vista Drain are in ng/L and the objective is µg/L. The data have to be converted to the same units as the objective before an exceedance can be determined. The Stakeholders expect that after this calculation has been performed the waterbodies will no longer meet the listing guidelines for mercury. Additionally, although a California Toxics Rule objective exists for mercury, an EPA nationally	See response to comment 7.90.

No.	Comment	Response
	recommended criterion was used for the assessment. An explanation for the use of a recommended criterion when an established water quality objective exists should be provided. **Requested Action:** • **Repeat the mercury analysis after correcting the units error.**	
29.57	***4. Incorrect location and data were used for listings in Reach 12*** The name of the monitoring site presented in the Fact Sheet for the chlorpyrifos, diazinon and malathion listings in Calleguas Creek Reach 12 is unclear. The University site is in Reach 3, not 12 and T01 is an MS4 discharge characterization site, not a receiving water monitoring location. Therefore, T01 should not be used for a 303(d) listing decision and University data is not from Reach 12. A review of the datasets provided in the link on the Fact Sheet only show data from University (ME-CC) and the number of samples appears to match up with the sample numbers shown in the Fact Sheet. As a result, it appears that the chlorpyrifos, diazinon and malathion listings do not apply to Reach 12. In addition, the Stakeholders request that only data collected after the implementation of applicable pesticide use restrictions were in place for these pesticides be considered in the listing decisions. Data from the Calleguas Creek TMDL watershed monitoring program that were not used in the assessment (see Comment II) demonstrates a marked reduction in these pesticides in receiving water since the use restrictions were implemented (approximately 2009 to present), particularly for receiving waters downstream of urban areas (e.g., Reach 12). Given the changed condition resulting from the pesticide use restrictions, monitoring data collected prior to 2009 is not representative of waterbody conditions for these constituents. Therefore, these constituents should not be listed unless data collected after the use restrictions were implemented demonstrates a continued impairment. **Requested Action:** • **Remove listings for Reach 12 that are not based on receiving water data from that reach.**	See response to comment 7.92

No.	Comment	Response
	• **Remove listings for chlorpyrifos, diazinon, and malathion based on historic data that are not representative of conditions after implementation of pesticide use restrictions.**	
29.58	***5. Correct the proposed temperature listing for Calleguas Creek Reach 12 (was Conejo Creek/Arroyo Conejo North Fork on 1998 303d list) which is based on incorrect criteria.*** The temperature listing for Reach 12 uses an evaluation guideline of 13-21°C as the optimum growth range for rainbow trout. However, the beneficial use listed for Reach 12 is WARM. The rainbow trout growth range threshold used for the listing is only applicable to the COLD beneficial use. This guideline should be removed and the number of exceedances recalculated based on the Basin Plan criteria for WARM. The basin plan criteria for WARM beneficial uses states the following: "For waters designated as WARM, water temperature shall not be altered more than 5 degrees F above the natural temperature. At no time shall these WARM designated waters be raised above 80 degrees F as a result of waste discharges." The Fact Sheet states that of 567 samples there were 3 instances of the downstream sample exceeding 80°F and in some cases a 30°F difference between upstream and downstream reaches. The Fact Sheet statement is unclear because Reach 12 is the upstream location and is not downstream of a waste discharge. Reach 12 drains a portion of the City of Thousand Oaks and open space areas and is located upstream of the Thousand Oaks Wastewater Treatment Plant. Therefore, it is unclear if the exceedances discussed in the Fact Sheet actually occur in Reach 12 and if exceedances do occur, whether they are a result of waste discharge or are a natural condition. The data provided for review was not compiled in a way that made it possible to easily review the assessment to determine if the exceedances were observed in Reach 12 (upstream) or Reach 10 (downstream). Regardless of the location of the samples, if there were 3 instances of temperature above 80°F and if they can be confirmed to be a result of waste discharge and not natural temperature conditions, according to the SWRCB 2015 303(d) Listing Policy three samples out of 567 would not meet the minimum number of measured	A review of the Calleguas Creek Reach 12 decision for temperature is in process at this time.

<table>
<tr><th>No.</th><th>Comment</th><th>Response</th></tr>
<tr><td></td><td>exceedances needed to place a water segment on the 303(d) List (see Listing Policy table 3.2). According to the binomial test, with a sample size of 500+ there would need to be well over 20 exceedances in order to be added to the 303(d) List, however, the Fact Sheet mentions only three exceedances of the Basin Plan criteria. According to the SWRCB's own guidance, this proposed listing should be removed.

Requested Action:
• Do not use the 13-21°C rainbow trout evaluation guideline which only applies to COLD beneficial use segments.
• Remove the temperature listing for Reach 12 as it does not meet the minimum listing requirements based on the binomial test described above and ensure that the analysis is applied to the correct reach.</td><td></td></tr>
<tr><td>29.59</td><td>6. Ensure no J-flagged data were used in the assessment.
The Listing Policy specifically prohibits the use of J-flagged ("estimated") data that fall below the quantitation limit but above the water quality standard. Section 6.1.5.5 of the Listing Policy specifically states:

"When the sample value is less than the quantitation limit and the quantitation limit is greater than the water quality standard, objective, criterion, or evaluation guideline, the result shall not be used in the analysis. The quantitation limit includes the minimum level, practical quantitation level, or reporting limit."

All listings based on the use of J-flagged data should, therefore, be removed from the draft 303(d) List. Specific instances are included in Table 1 and further explained in Table 2 below, but this list is by no means inclusive; this significant error will have to be addressed by a thorough review of all listing data to confirm that no J-flagged data were used to justify listings.

Table 2. Incorrect use of J-flagged data [See the posted letter for Table 2]

Requested Action:</td><td>See response to comment 7.93.</td></tr>
</table>

No.	Comment	Response
	• **Review all Fact Sheets and LOEs for the use of J-flagged data and remove any instances where J-flagged data were used.** • **Delist toxaphene for Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No. 2, chlordane for La Vista Drain, and any other pollutants listed in Tables 1 and 2 that lack the minimum number of exceedances required to justify a listing.**	
29.60	***7.*** **Remove listings where a waterbody assessment does not meet listing thresholds based on data provided.** Finally, the toxicity listing for Rio De Santa Clara/Oxnard Drain No. 3 does not meet the minimum requirements to be listed according to the Listing Policy (pg. 9). According to the Listing Policy, a waterbody can be listed only when the number of exceedances meets the binomial test; in the case of this waterbody, four samples were collected and only one sample showed an exceedance. However, two exceedances would be required for the waterbody to be added to the 303(d) List. Therefore, toxicity was incorrectly listed for this waterbody and should be removed entirely from the 303(d) List. **Requested Action:** **Remove the toxicity listing for Rio De Santa Clara/Oxnard Drain No. 3 based on meeting listing threshold requirements in the Listing Policy.**	See response to comment 7.52.
29.61	**II. REQUESTED REASSESSMENTS USING COMPLETE DATA SET** The assessments for the Calleguas Creek watershed do not appear to include any of the submitted Calleguas Creek Watershed TMDL monitoring data, monitoring data from the Camarillo Sanitary District, or monitoring data from the Simi Valley Wastewater Treatment Plant. All of this monitoring data has been provided to the Regional Board in annual monitoring reports and all data were collected using approved QAPPs. As a result, there is no reason why this data should not be included in the 303(d) listing process. In 2013, the Stakeholders did an assessment of the watershed using all watershed	See response to comment 32.3.

No.	Comment	Response
	data through 2012 and found that multiple waterbody-pollutant combinations could potentially be delisted as shown in Table 3. A summary of the assessment is included as an attachment to this letter and the datasets used in the analysis as well as all of the TMDL annual monitoring reports are available upon request. **[See the posted letter for Table 3]** While we recognize that this assessment uses two additional years of data than the current 303(d) listing analysis, a number of these waterbodies had many more samples than were necessary for delisting. As a result, we feel if all the watershed data were used in the assessment, a number of these waterbodies (particularly for metals) would be delisted. We also feel this assessment would demonstrate that several of the proposed listings, particularly for diazinon and chlorpyrifos and a number of organochlorine pesticides, are not warranted. A large number of new proposed listings are being added that are already covered by a TMDL. While the list acknowledges that a TMDL does not need to be developed by categorizing these new listings in Category 5B, in several cases, the watershed now has sufficient data to delist, whereas the listing is an artifact of old data being used to make the listing decision. These listings should not be added to the current list only to be removed during the next listing cycle as an artifact of the timing of the listing assessments. **Requested Action:** **Reassess all Calleguas Creek waterbodies using all available data.**	
29.62	**III. REQUESTED CATEGORY ASSIGNMENT CHANGES** ***8. Correct pollutants listed as Category 5A which should be 5B based on coverage by an existing TMDL.*** There are a number of proposed new listings for pollutants that are already covered by an existing TMDL and are incorrectly categorized as 5A. While the Stakeholders maintain that all of these listings should be removed entirely because of the issues detailed in Comment I, if they are not removed they should, at a minimum, be changed from 5A to 5B, as applicable.	See response to comment 7.96.

No.	Comment	Response
	A nutrient TMDL addressing nitrogen has been in effect since 2003, including for Reach 9A where a new 5A listing for nitrite is proposed. In 2006, the Toxicity and OC Pesticide and PCBs TMDLs for the Calleguas Creek watershed were established to address chlordane, chlorpyrifos, DDT, DOE, ODD, dieldrin, PCBs, sediment toxicity, and toxaphene. The La Vista Drain and Santa Clara Drain ultimately flow into Calleguas Creek Reach 4 (was Revolon Slough Main Branch), which is already addressed by an OC Pesticides and PCBs TMDL, the Toxicity TMDL, the Salts TMDL, and the Metals TMDL and therefore all of these proposed listings should be Category 5B. Furthermore, two other segments were listed for Chlorpyrifos - Honda Barranca and Duck Pond Agricultural Drains - but were correctly listed as Category 5B, citing the 2006 Toxicity TMDL. The Stakeholders request that any listings in **Table 4** and **Table 5** that are maintained after addressing the issues in Comment I should also be corrected to be designated as Category 5B. **[See the posted letter for Table 4]** In addition, we feel that the Toxicity TMDL should cover all new listings in the watershed for pyrethroids and organophosphate pesticides (e.g., malathion) if they are not removed as requested in the first comment. The Toxicity TMDL includes a trigger for additional investigation if ongoing toxicity is identified in the watershed. The toxicity trigger has resulted in the identification of pyrethroids as a potential cause of toxicity and the Stakeholders have already begun actions to address these pesticides in addition to the organophosphate pesticides included in the TMDL. The structure of the TMDL is designed to proactively prevent toxicity and therefore it is not necessary to develop another TMDL for these constituents. There are already sufficient controls in place through the agricultural waiver and MS4 permit. As a result, if the waterbodies are placed on the 303(d) List as new listings, we request that the waterbodies in Table 5 be changed from 5A to 5B. **[See the posted letter for Table 5]** **Requested Action:** • **Change all pollutant-waterbody segment combinations in Table 4 and**	

No.	Comment	Response
	Table 5 from SA to 5B or 4A based on coverage by an existing USEPA approved TMDL.	
29.63	**IV. ADDRESS ALL OTHER INCONSISTENCIES AND ERRORS IN LIST** In reviewing the list the Stakeholders identified a large number of inconsistencies and issues in the list that should all be addressed prior to adoption. The summary below provides examples of issues identified and is not a comprehensive list as in many cases the information provided made it challenging to provide comprehensive comments. **9.** ***Correct Appendix G Fact Sheets.*** The Appendix G Fact Sheets often include incorrect information and discussion. While most of the identified issues do not appear to impact the listing decisions, they make the review of information difficult. Examples of errors found include: • Incorrect beneficial uses assigned to a waterbody. For example, MUN beneficial uses assigned to a tidally-influenced waterbody (e.g., Duck Ponds Agricultural Drain). • Incorrect TMDLs assigned to a pollutant. For example, for chlordane in Calleguas Creek Reach 2, the applicable TMDL is listed as the Calleguas Creek Metals TMDL. It should be the Organochlorine Pesticides, PCBs, and Siltation TMDL. • Incorrect QAPPs identified. For example, the VCAILG QAPP is often referenced for the Ventura County MS4 monitoring data set. • Incorrect number of samples evaluated and incorrect number of criteria exceedances. For example, the number of samples evaluated for toxaphene on the Rio de Santa Clara/Oxnard Drain No. 3 is identified as 2 samples, whereas data files obtained from the Regional Board website contain 5 samples for the date range indicated in Fact Sheets, including 3 samples with results of "ND". Stating that a pollutant actually exceeds criteria in only 40% of samples, versus 100% exceedances as presented in Fact Sheets, provides a more accurate picture of the degree of impairment for that pollutant in a waterbody. The inclusion of J-flagged data when enumerating exceedances (e.g., for chlordane in the same waterbodies) further exacerbates these numbering inaccuracies.	See response to comment 7.98.

No.	Comment	Response
	Requested Action: **Correct the Appendix G Fact Sheets for errors such as incorrectly assigned beneficial uses, existing TMDLs, QAPPs, and number of samples/number of exceedances.**	
29.64	**10.** ***Correct the Appendices and Fact Sheet Categories.*** Appendix A, Appendix B, Appendix C, and Appendix G are inconsistent which makes the analysis of new additions very difficult since it is unclear which segment-pollutant combinations actually are new listings. Following are examples of a number of identified issues that need to be corrected to allow the Stakeholders to fully vet and understand the proposed listings. A number of proposed "name changes" in Appendix A are not shown in Appendix B and there are not associated Fact Sheets describing the name change (e.g., Reach 4 listings for chlorpyrifos and total DDT). This makes it very challenging to assess the validity or basis for the name change. In other instances, listed name changes are found in Appendix B or C but not supported by an explanation for the name change in Appendix G. The Fact Sheets for the following name changes should provide justification or explanation for the name change as many appear to be switching tissue or sediment listings to water listings. If this is, in fact, the change being made, the justification for the water listing needs to be provided in the Fact Sheet. It is not appropriate to modify the medium that is the basis for the listing as a name change. **[See the posted letter for Table 6]** There are a number of inconsistencies where Appendix A does not include all of the new 2014 listings found in Appendix B. Below are a few examples of such inconsistencies. **[See the posted letter for Table 7]** There are also a number of instances where existing waterbody-pollutant listings from the 2010 303(d) List were not stated as delisted in Appendix A and do not	See response to comment 7.99.

No.	Comment	Response
	appear in Appendix B, C, or G under the waterbodies to delist. The Stakeholders would like clarification if these listings are in fact being delisted as some align with the assessment shown in Table 3. **[See the posted letter for Table 8]** **Requested Action:** **Correct the numerous inconsistencies described above in Table 6, Table 7, and Table 8 and ensure that all of the proposed 303(d) List appendices are internally consistent.**	
29.65	**11**. ***Correct the waterbody assigned Hydrologic Unit (HUCs) and Ca/water numbers to reflect those listed in the Basin Plan.*** There are multiple instances of what appear to be incorrectly Hydrologic Unit numbers (HUCs) and Calwater numbers assigned to the various waterways. For instance, a comparison of the 8 digit HUCs listed in Appendix B of the 303(d) List to the 12 digit HUCs listed in Appendix I of the Basin Plan indicate a number of inconsistencies such that waterbodies present in the Santa Clara River Watershed (e.g., Santa Clara River Reach 1, 2, and 3) are listed with a Calleguas watershed HUC (18070103) while the same reaches are listed as 18070102 in the Basin Plan. This makes identifying the location of unknown waterbodies not previously listed or described in the Basin Plan to assess if they are receiving waters that should be assessed especially difficult. A full review of the 303(d) List HUCs should be completed to correct all errors. **Requested Action:** **Perform a full review of HUCs and Calwater numbers listed in Appendix B through F and correct any inconsistencies with the Basin Plan.**	See response to comment 7.100.
29.66	**12**. ***Correct or clarify inconsistencies in the staff report.*** There is inconsistent discussion in the staff report about some proposed listings that should be clarified to avoid confusion about the listings. For instance, on page 10 of the Staff Report there is a discussion about existing TMDLs covering newly proposed pollutants " For example, the proposed new listings for DOE and DOD in Calleguas Creek	See response to comment 7.101.

No.	Comment	Response
	Reach 3 ... are being addressed by the Calleguas Creek Organochlorine Pesticides, PCBs and Siltation TMDL ... and would then be in Category 4A." However , we could find no listings of ODE and ODD for Reach 3 in any Appendix of the report including Appendix C - Category 4A Waterbody Segments. Furthermore, the Fact Sheets in Appendix G state that ODE and DOD should not be listed for Reach 3. We ask the RWQCB to either clarify or remove the above referenced statement and clarify any other inconsistencies between the staff report and the list. **Requested Action:** **Correct or remove language cited on page 10 of the staff report regarding DOE and ODD listing of Calleguas Creek Reach 3 and clarify any other identified inconsistencies within the staff report.**	
29.67	**13**. ***Ensure that all thresholds being used for assessment are consistent and valid under the Listing Policy*.** In many cases, the same pollutant is assessed using different thresholds without any explanation for the basis of the threshold. Additionally, in several cases, an LC50 or threshold for individual species were used for the assessment, which is inconsistent with the Listing Policy which states that it must be demonstrated that an evaluation guideline is "applicable to the beneficial use, protective of the beneficial use, scientifically-based and peer reviewed, and well described". Because it has not been demonstrated that the individual species response to these pollutants is applicable and protective of the beneficial use these guidelines should not be used to make a listing. The Stakeholders ask that the Board review all assessments for consistency, especially for the pesticides (bifenthrin, cyfluthrin, cypermethrin, malathion, permethrin) as well as applicability to the beneficial use as described in the Listing Policy. **[See the posted letter for Table 9]** The 303(d) List includes new listings for bifenthrin, cyfluthrin, cypermethrin, malathion, and permethrin in CCW. Currently, no water quality objectives have been promulgated by USEPA or the State of California for these pollutants and so the criteria listed are from a variety of studies. Some issues with these criteria include the following (this list is by no means inclusive; a thorough review of all	See response to comment 7.102.

No.	Comment	Response
	listings for these pollutants should be undertaken): • The criterion used for listing bifenthrin on Duck Pond Agricultural Drains/Mugu Drain/Oxnard Drain No 2 is 0.00397 µg/L based on the CDFG criteria. The selective use of a saltwater genus mean acute value is inappropriate when the CDFG study clearly states in the "Conclusions and Recommendations" section that "insufficient freshwater and saltwater acute toxicity data were available to calculate CMC values for bifenthrin." The same use of a criterion unsupported by the study author(s) applies to cypermethrin on the Santa Clara Drain. • Use of LC50 for listing of cyfluthrin for CCW Reach 4 is inappropriate. LC50s do not meet the standard set forth in the Listing Policy as stated on page 20 *"the evaluation guideline ... identifies a range above which impacts occur and below which no or few impacts are predicted."* By definition, an LC50 is simply the concentration at which half of the population of the tested species has died. The LC50 should not be used as the evaluation guideline. • The criterion used for listing permethrin for Calleguas Creek Reach 4 is 0.0002µg/L based on the UC Davis[12] criteria. However, upon reviewing the UC Davis source the listed chronic standard for permethrin is 2 ng/L (page 92) which is 0.002µg/L, not 0.0002µg/L as listed in the 303(d) List. • In many instances the incorrect evaluation guideline and guideline reference are used. For example, the evaluation guideline (i.e., criterion) provided for cyfluthrin (a pyrethroid) in LOEs 84065, 83200, and 88712 is for the chlorinated herbicide 2,4,5-TP. The stated criterion (29 mg/L) was not found in the cited guideline reference. Many additional instances were noted in LOEs for phorate, dimethoate, disulfoton, endosulfan sulfate, and many other LOEs. Because the numeric guidelines (and reference documents from which these are obtained) form the basis for any listing, it is critical that these be carefully reviewed and verified prior to issuing the final Fact Sheets and 303(d) List. **Requested Action:** • **Review the guidelines used for interpreting narrative objectives and ensure that they are consistently applied and use correct unit**	

No.	Comment	Response
	conversions. • **Remove all guidelines that do not comply with the stated Listing Policy as described above.** **[See the posted letter for Attachment A]**	
30.	TECS Environmental Compliance Services, March 30, 2017	
30.1	TECS Environmental is pleased to comment on the Regional Board's proposed 2016 303(d) list revisions. Because there are almost 900 listing revisions for water quality segments in the Los Angeles County Basin, it would be impossible to address each one. Therefore, I will restrict my comments to general issues. To begin with, I am sure that a number of MS4 Permittees and industrial dischargers will be pleased to know that many of the pollutants proposed on the 303(d), which are current TMDLs or are scheduled to become ones, have been placed on the "de-list" or placed on the "do not list" category. Most conspicuous are metals for Reach 2 of the Rio Hondo and Reach 3 of the San Gabriel River. Although the 2010 303(d) list did not list any of these reaches for metals-related impairment, they were nevertheless required to comply with metals TMDLs (Los Angeles River Metals TMDL for Reach 2 of the Rio Hondo and the San Gabriel River Metals TMDL for Reach 3 of the San Gabriel River). The 2016 303(d) list proposes to rectify this mistake by placing both of these reaches under the "do not list" category for copper, lead, selenium and zinc, which form the basis for both of the TMDLs. However, the proposed 2016 303(d) list did not place any of the Arroyo Seco reaches on the "do not list." Like Reach 2 of the Rio Hondo and Reach 3 of the San Gabriel River, Arroyo Seco Reaches 1 and 2 were not on 2010 303(d) list, nor were they on the 2012 303(d) list, which did not make it to Los Angeles Basin Plan as an amendment. Nevertheless, the Los Angeles MS4 Permit subjects MS4 Permittees by extending the Los Angeles River Metals TMDL to Arroyo Seco reaches. The 2016 303(d) list should place these reaches on the "do not list" category for metals.	See response to comment 3.4.

No.	Comment	Response
	Recommendation: place Arroyo Seco Reaches 1 and 2 on the "do not list" for any metal.	
30.2	**I. CTR and 303(d) Listing Policy** Nevertheless, additional pollutants should be considered for exclusion because they were not established in accordance with the California Toxics Rule (CTR) adopted in 2000; and/or did comply with the *Wat*er *Quality Control Policy for California's Clean Water Act Section 303(d) List* (Listing Policy), which was adopted in 2004. • *California Toxic Rule* CTR was adopted to provide a mathematical method for establishing ambient (dry weather) water quality standards for toxics necessary to protect beneficial uses of receiving waters. The LAR-MTMDL, however, along with other TMDLs, does not comply with CTR in two significant respects. First, the TMDL calculates numeric water quality standards/TMDLs for both wet weather and ambient receiving water conditions instead of only on ambient. The LAR-TMDL misinterprets CTR by claiming EPA did not differentiate between wet and dry weather conditions when establishing metals and toxics limitations. There is nothing in CTR that supports that view. CTR makes it clear that its purpose is to establish <u>ambient</u> water quality standards: *This final rule establishes ambient water quality for priority toxic pollutants.* USEPA defines ambient as: *Natural concentration of water quality constituents prior to mixing of either point or nonpoint source load of contaminants. Reference ambient concentration is used to indicate the concentration of a chemical that will not cause adverse impact to human health.* In other words, ambient is the normal reference condition of a receiving water. This is also the clear understanding of the Regional Board's Surface Water Ambient Monitoring Program (SWAMP). MS4 and other point source stormwater (wet weather) outfall discharges, using sampling and analysis results, are measured	See response to comments 3.2.

No.	Comment	Response
	against the ambient target for a pollutant established by CTR. For example, suppose a copper limitation is set at 37 micrograms per liter for a given water body. This limit is required to protect fish. Persistent exceedances of the limit based on outfall monitoring would necessitate a revision to the MS4 Permittee's stormwater management program.	
30.3	Second, CTR requires a hardness parameter (calcium carbonate) to make chemical water quality analysis of metals and toxics more accurate. Generally, the higher the hardness value the higher the toxic/metal pollutant expressed as a numeric limit. And, the higher the limit there less difficult it is to meet. The metals and toxics TMDLs rely on differing hardness values. For the Dominguez Channel/Harbor Toxics TMDL an average hardness value of 50 mg/l is used. For Ballona Creek hardiness values for setting the wet weather TMDLs metals are varied, based on an average or median hardness that ranged from 77 mg/l to 108 mg/l. For dry weather, a median hardness value of 300 mg/l was applied. As mentioned, CTR is expressed exclusively as ambient and not wet weather standards. Thus the77 mg/l to 108 mg/l hardness values relative to wet weather are meaningless. For dry weather, a median value of 300 mg/l was used. For the Los Angeles River Metals TMDL variable hardness values were also used for wet and dry weather. The same is true to the San Gabriel River Metals TMDL. In any case, CTR requires actual hardness value to be determined at the time samples of metals/toxic pollutants are taken. Thus, in the final analysis, each of the metals/toxics pollutants that was placed on the "list" or "do not de-list" category should be placed on the "de-list" or "do not list" category because they were not established in ambient terms only and failed to use an actual hardness value.	Comments on TMDLs are outside the scope of this proposed action.
30.4	• 303(d) Listing Policy The Listing Policy was adopted to provide a statistical method to determine how many water quality samples that exceed a water quality standard are required to place a pollutant on the 303(d) list. That method is a binomial distribution based on the rejection of a null hypothesis measured against sample sizes (see	See response to comment 3.3.

No.	Comment	Response
	attachment #1). A review of the 2016 303(d) list fact sheets reveals that many of the metals and toxics placed on previous 303(d) lists did not conform to the Listing Policy. Those that do not should be placed on the "de-list" or "do not list" category.	
31.	Ventura Countywide Stormwater Quality Management Program, March 30, 2017	
31.1	On behalf of the Ventura Countywide Stormwater Quality Management Program (Program), which includes the Watershed Protection District, the County of Ventura and the incorporated cities of Camarillo, Fillmore, Moorpark, Ojai, Oxnard, Port Hueneme, Ventura, Santa Paula, Simi Valley, and Thousand Oaks, we thank you for the opportunity to provide input on the proposed revisions to the Clean Water Act Section 303(d) list of impaired waterbodies in the Los Angeles Region [hereinafter referred to as 303(d) list] which was distributed for public review on February 8, 2017. The Program has many concerns with the draft 2016 Los Angeles Water Board's proposed revisions to the 303(d) list of impaired waters. Several errors and inconsistencies hampered our ability to fully vet and review the proposed 303(d) list. It is our opinion that significant review and modifications must be made before adoption and additional public review after modifications will be necessary. Requested Action: After full consideration of all comments, revise draft 303(D) list, and allow for another 60-day comment period prior to adoption. It is critical that the Los Angeles Water Board's proposed revisions to the 303(d) list follow the State Water Resources Control Board (SWRCB) Listing Policy and be based on sound science and methodologies. The development and implementation of Total Maximum Daily Loads (TMDLs) is already a significant investment of resources, and the 303(d) list will drive pollutant waterbody prioritization under the potential Watershed Management Plan option in our next NPDES MS4 Permit.	See response to comment 32.1 and 7.2.
31.2	Data from a single point in time, or which is not representative of the receiving	It is in accordance with the Listing Policy to use

No.	Comment	Response
	water, should be excluded from this effort as should data with results reported below reporting limits (J-flagged). It appears the Program's outfall data was erroneously included for the Santa Clara River. This sampling location represents the runoff discharging from an MS4, not the receiving water quality, and is mostly from infrequent and short-term rain events. Of special concern is where the beneficial use MUN is driving 303(d) listings even though it should not be applied because it is identified as P* and is a conditionally applicable beneficial use. **Requested Action:** **Strictly comply with the State Water Resources Control Board (SWRCB) Listing Policy on identifying beneficial uses, impairments due to natural sources, and the appropriate data to support a listing.**	samples collected on the same day to assess waterbody condition if the samples are from different locations. The Listing Policy does provide for consideration of circumstances in which the samples represent an unusual condition (see Listing Policy, Section 6.1.5.3, *If the majority of the samples were collected on a single day or during a short-term natural event (e.g. a storm, flood, or wildfire), the data should not be used as the primary data set.)* LOEs and decisions which included “J-flagged” data are being reassessed, as identified. Decisions based on protection of a P*MUN beneficial use are being reassessed, as identified.
31.3	The Program supports the comments from the County of Ventura where a more detailed description of the issues identified here is discussed. The Program also supports the comments from the Calleguas Creek Watershed Stakeholders, as well as the Ventura County Irrigated Lands Group (VCAILG) who will be submitting separate comment letters regarding the proposed listing changes in the Calleguas Creek Watershed and VCAILG- affected waterbody segments. Significant resources are expended when a pollutant is included on the 303(d) list. Errors in this process, and the challenges of delisting a pollutant, divert our limited funding and staff time away from improving water quality. We greatly appreciate your attention to these requests and look forward to a 303(d) list that appropriately identifies the water quality issues within Ventura County.	Comment noted.
32.	Ventura Water Department of the City of San Buenaventura, March 30, 2017	
32.1	The specific focus of this comment letter by Ventura Water is on the Santa Clara River Estuary (SCRE) proposed listings. New constituents on the list for the SCRE include ammonia and pH. Constituents that are proposed to remain on the	See response to comments, below, for specific responses: 32.4 for ammonia,

No.	Comment	Response
	list of particular note include nitrate and toxicity. Ventura Water specifically requests the Los Angeles Regional Water Quality Control Board (Regional Board): • Reconsider proposed ammonia listing by recalculating the exceedances and using more recent data sets currently available to the Regional Board. • Reconsider the proposed pH listing based on consideration of reference conditions data, which indicate that substantial fluctuations in estuarine pH values are typical, and consistent pH values that comply with water quality objectives are not biologically attainable within estuaries. • Delist nitrate based on a recalculation using appropriate data and correct use of averaging periods for the data. • Reevaluate toxicity listing once the data is appropriately aggregated and averaged. • Reevaluate ChemA, Toxaphene, and Indicator Bacteria listings once more recent data is taken into consideration. • Address the issues identified in this letter and release a revised, proposed 303(d) list for another 60-day comment period prior to adoption.	32.5 for pH, 32.6 for nitrate, 32.7 for toxicity, 32.8 for ChemA, 32.9 for toxaphene, and 32.10 for indicator bacteria The public has had a 50-day comment period prior to the Los Angeles Water Board meeting. In addition, the State Water Board will provide an additional 30-day comment period so that the public may comment on the Los Angeles Region 303(d) list (in combination with five other Regional 303(d) lists) prior to bringing the list to the State Water Board for approval. Lastly, commenters will have an opportunity to comment to USEPA Region 9 regarding the California 303(d) List portion of the Integrated Report prior to final approval by USEPA.
32.2	**Relevant Background Information.** It is important to our overall comments on the 303(d) list to understand the context of the Santa Clara River and SCRE. Like many southern California rivers, the Santa Clara River has very minimal flows in the dry months leading to stagnant conditions in the SCRE that encourage algae growth and variations in both dissolved oxygen (DO) and pH due to the algae respiration cycles, as is the case to some extent even in more natural estuaries where conditions have not been modified. The river ends in the SCRE, which experiences both open and closed mouth periods due to beach berm formation and periodic, typically wet weather breaches. The SCRE is wind-mixed and mostly uniform in water quality, especially during closed mouth conditions. The Ventura Water Reclamation Facility (VWRF) discharges approximately 8 million gallons per day (mgd) of disinfected, tertiary effluent first to wildlife/water quality ponds, and then to the SCRE. During dry weather, the tertiary treated flows can be the	Comment noted.

No.	Comment	Response
	dominate supply of water to the SCRE to support wildlife species that utilize it. Species that utilize the SCRE include the following state and federally listed species: steelhead trout, tidewater goby, snowy plover, and California least tern. Ventura Water has spent many years studying the SCRE both independently, and pursuant to requirements of its NPDES permits. Ventura Water has invested more than $21,000,000 dollars in treatment process upgrades of the Ventura Water Reclamation Facility (VWRF) to improve the quality of the tertiary treated flows discharged to the SCRE. Ventura Water also currently recycles approximately 1 mgd for urban irrigation. Ventura Water is also currently working on implementing a potable reuse program that would divert up to 100% of its discharges to water reclamation uses, and identifying how much effluent can be diverted from the SCRE while still protecting its ecology and ecology-related beneficial uses and without "taking" (as that term is defined under the state and federal Endangered Species Acts, as applicable) any of the listed species that use or occupy the SCRE.	
32.3	**General Comments.** Of particular concern to Ventura Water with regard to the proposed 303(d) list is that much of the data used to determine water quality impairment for the SCRE is older data that is not representative of current conditions. The Staff report states, "Data used as part of the 2016 Integrated Report were received through August 30, 2010." The report then goes on to later say, "All readily available data and information in the administrative record was considered in the development of the 2016 Integrated Report." These statements are at odds with each other as by choosing to only rely on data collected through 2010; quite clearly the 303(d) list was not developed with all readily available data as required by the Listing Policy. Significant plant improvements have be implemented since 2010. VWRF monitoring data since the plant upgrades are readily available and should be included within the 303(d) list determination analyses. The SCRE has also been heavily regulated by the VWRF's NPDES permits. Many of those permit requirements have become more stringent since 2010, with the application of technology based limitations. By Ventura Water's estimation, many	The Los Angeles Water Board staff has developed the Integrated Report consistent with project plans and timelines established by the State Water Resources Control Board. Staff is working closely with the State Water Board to ensure that the remaining steps in the process for State Water Board approval go smoothly and meet the State Water Board's schedule. Los Angeles Water Board staff considered all readily available data and information in the administrative record in the development of the 2016 California Integrated Report. The State Water Board defined readily available data as those data submitted during the 2010 public data solicitation period, which began on January 14, 2010 and concluded on August 30, 2010. The

No.	Comment	Response
	of constituents on the proposed 303(d) list are not appropriate given recent water quality data. Lastly, based on current data and the State Water Resources Control Board's "Water Quality Control Policy For Developing California's Clean Water Act Section 303(d) List" ("Listing Policy") requirements to aggregate the data by appropriate reach or area and to use appropriate averaging periods, Ventura Water disagrees with some of the constituent listings and requests recalculation of exceedances. This letter addresses the proposed 303(d) listings and presents current data for each proposed SCRE impairment listing.	State Water Board issued a memo dated November 12, 2013, which explains the strategy of handling the data assessment for the 2014 Integrated Report as follows: Due to the volume of data received during the 2010 data solicitation period, the State Water Board will not solicit additional data until all of the current data is assessed and migrated to the California Water Quality Assessment Database (CalWQA) for Regional Water Board listing and delisting recommendations. Consequently, at the direction of the State Water Board and consistent with the other Regional Water Boards, Los Angeles Water Board staff did not include data after the 2010 solicitation period in the development of the 2016 Integrated Report for the Los Angeles Region. Further, the State Water Board adopted Resolution No. 2015-0005, to amend the Water Quality Control Policy for Developing California's Clean Water Act Section 303(d) List (Listing Policy) on February 3, 2015. The revisions to the Listing Policy were available for public comment prior to the public hearing to adopt those changes. Finding number eight in the Resolution states the following: State Water Board staff anticipates that next notice of solicitation will be sent out to solicit data and information for the 2018 Integrated Report (the CWA section 303(d) and 305(b)

No.	Comment	Response
		reporting requirements). For the upcoming 2012, 2014 and 2016 Integrated Reports, the data and information submitted in response to the 2010 notice of solicitation shall be assessed and considered. Notwithstanding the above information, Los Angeles Water Board staff appreciates the concern that data must be is as up-to-date as possible and reviewed frequently in order to implement our various programs. Staff reviews all types of water quality data on an ongoing, real-time basis separately from the Integrated Report process to develop TMDLs or other regulatory programs. Staff strives to increase its use and application of current data, and improving in this manner is one of our highest priorities. Staff encourages commenter to submit data to CEDEN in preparation for the next listing cycle.
32.4	**Ammonia Comments** The new ammonia listing cites that it is based on 4 exceedances out of 42 samples based on un-ionized ammonia concentrations using data collected from 1997 to 2010. While this meets the technical, formulaic requirements for number of exceedances set forth in the Listing Policy Table 3.1 for placing a waterbody on the 303(d) list, the methods and data used to calculate the exceedances are not clear. To calculate the concentration of un-ionized ammonia, total ammonia must be converted to un-ionized ammonia using site specific pH and temperature conditions within the SCRE at the time of the ammonia sampling. No conversion calculations for total ammonia were provided in the data set provided in the fact sheet; therefore, it is difficult to determine which pH and temperature data were used to correlate to corresponding total ammonia data. An accurate analysis	The data used to determine the listing can be found from a link on the factsheet “Decision ID 66589 Santa Clara River Estuary” for ammonia. The data is linked as <u>Data for Various Pollutants from the city of Ventura, 1997-2010.</u> Commenter does not explain why grab data would not reliable for purposes of determining the one-hour maximum values for temperature and pH. See response to comment 32.3 for a discussion of the “readily available” data considered for this

No.	Comment	Response
	should ideally connect pH, temperature, and ammonia data with a reasonable averaging criteria or statistical determination if multiple data points were used. Ventura Water requests recalculation of the exceedances based on current total ammonia data as well as proper calculations of un-ionized ammonia that take into account temperature and pH conditions that occurred, or should have been expected during the total ammonia sampling events. More specifically, closer inspection of the 1997 through 2010 data set used to determine the 4 exceedances indicates that the pH data used to calculate un-ionized ammonia was potentially data retrieved from a continuous monitoring, multiparameter Sondes (2009-2010) deployed for the City's Phase 1 Estuary Study (Stillwater Sciences 2011), among other data. The only total ammonia data collected as part of the Phase 1 study were collected on 6 days in 2009 and 2010. Corresponding pH and temperature were collected along with these samples. However, Ventura Water is concerned that these data do not represent the SCRE as a whole, specifically after the improvements to the VWRF (after November 2011). Moreover, only total ammonia is shown in that data set, and the data set does not include the calculation of un-ionized ammonia. Monthly grab sample temperature and pH data for the receiving water exists for some of the monitoring years cited (1997 - 2010), but grab data is not reliable for purposes of determining the one-hour maximum values for temperature and pH. In light of the aforementioned issues with the methods that appear to have been used to calculate unionized ammonia using a 1997 to 2010 data set, Ventura Water requests the Regional Board provide the calculation for the un-ionized ammonia, and update the calculation as appropriate to include more recent and more valid total ammonia, pH, and temperature assumptions from other data sets readily available to the Regional Board. Based on Ventura Water's more recent monitoring results, all of which constitute data readily available to the Regional Board, it does not appear that the SCRE un-ionized ammonia water quality objective is likely to have been exceeded a sufficient number of times to warrant a listing. Ventura Water requests the Regional Board utilize the data submitted to it by Ventura Water more recently than 2010 to assure that the evaluation of receiving water conditions in the SCRE is reasonably representative of current	Integrated Report and 303(d) list.

No.	Comment	Response
	conditions. The Regional Board imposed stringent ammonia limits and a time schedule to attain those limits on VWRF discharges of tertiary treated flows in both its 2008 and 2013 NP DES permits. To comply with these limits and to better control nitrates, Ventura Water invested more than $21 million in a VWRF plant improvement project to implement nutrient removal in its biological processes. This treatment upgrade project undertaken to meet the stringent NPDES permit ammonia effluent limits came online in November 2011. Since then, VWRF NPDES permit effluent limits for ammonia, including its water quality based effluent limits, have only been exceeded once, indicating that ammonia conditions in the SCRE have changed since November 2011, and the data relied upon in developing the proposed 303(d) list is not representative of conditions within the SCRE. The receiving water standards for the SCRE (used to establish the NPDES effluent limitation) are set based on un-ionized ammonia for saltwater criteria. The limits used to determine the 303(d) listing are the same criteria that are used to calculate limits in the NPDES permit (1999 Update of Ambient Water Quality Criteria for Ammonia): • One Hour Concentration = 0.233 mg/I unionized ammonia, based on fish spawning, and • 4 day average of 0.035 mg/L of unionized ammonia The total ammonia NPDES effluent limit calculated to meet this water quality objective is total ammonia of 1.07 mg/l average monthly and 1.17 mg/l max daily in the summer. Limits in the winter months are slightly higher. The limits were determined in accordance with EPA standards by considering the 50th and 90th percentile pH and temperature for considering chronic and acute toxicity. As shown in Figure 1 below, the total effluent ammonia from 2012 to 2016 only exceeded 1 mg/l once out of 59 samples, thus not exceeding the Listing Policy's binomial distribution null hypothesis Table 3.1 criteria for listing a constituent on	

No.	Comment	Response
	the 303(d) list (i.e., would need at least 5 exceedances). Similarly, the receiving water samples from 2012 to 2016 only exceeded 1 mg/l total ammonia twice out of 60 samples, so also not meeting the Table 3.1 criteria for listing a constituent on the 303(d) list. *Figure 1 Historical Effluent and Receiving Water Ammonia Monitoring* **[See the comment letter for Figure 1]** The effluent compliance point for all constituents except for flow in the 2013 NPDES permit for the VWRF is station MOOl, which is located at the Effluent Transfer Station (ETS) right before discharge into the wildlife ponds. Station MOOlA is located downstream of the wildlife ponds. It is only used for compliance with flow, but ammonia levels have been monitored there, starting in December 2013. Total ammonia actually drops from the compliance point to MOOlA as water passes through the wildlife ponds, likely due to a combination of volatilization and vegetative uptake. Therefore, the ammonia concentrations in the discharges into the SCRE are well below the permit standards that were set up to meet the ammonia receiving water quality objectives for saltwater, which are more stringent than freshwater standards. The comparison of ETS versus MOOlA data is shown in Figure 2. *Figure 2 Historical Effluent Ammonia Before and After Wildlife Ponds* **[See the comment letter for Figure 2]** **In light of the treatment plant upgrades implemented to reduce ammonia, and the fact that more recent data indicates only 1 exceedance in 59 samples, Ventura Water requests recalculation of the exceedances for ammonia and reconsideration of the listing decision based on the more recent data set currently available to the Regional Board.**	
32.5	pH Comments It is important to understand that many estuaries exhibit wide daily variations in pH mediated by algae as the result of daily photosynthesis and nighttime respiration (Park et al 1958). Beyond potential connections between algal	The 303(d) list appropriately identifies the pH impairments. Analysis of sources and causes or identification of implementation measures to resolve or correct the impairment are not

No.	Comment	Response
	productivity with the multiple nutrient sources to the SCRE (e.g., VWRF, agricultural runoff, groundwater, riverine, VWRF, ocean exchanges), algal growth and pH variations in the SCRE are exacerbated by physical factors as well (e.g., shallow waters, lack of consistent riverine flows, intermittent breaching and limited tidal exchange with the ocean). Consideration of the estuarine conditions likely to induce large pH swings is supported by recent monitoring data fully available to the Regional Board that shows that the VWRF plant tertiary treated flows are always in compliance with pH effluent limits (shown as a black dot on Figure 3). However, despite the very steady and compliant pH values for the tertiary treated flows, the receiving water does experience wide swings in pH as shown in Figure 3 below even when data collected from 2012 through 2016 is analyzed. However, it is important to note that the receiving water pH data is collected by grab samples (via boat) in the SCRE, likely at similar times of day and therefore does not necessarily reflect actual conditions in the estuary over the course of the day or the month. The receiving water data collected could theoretically meet the Listing Policy formulaic criteria. However, the determination whether to list should not be considered in a vacuum, but rather must also take into account the "type of waterbody (Bay and Harbors, Coastal Shoreline, *Estuary*, Lake/reservoir ...)" being considered for impairment. One way to take into account the type of waterbody considered for a 303(d) listing is to consider "reference conditions" as defined in Section 7 of the Listing Policy to understand the characteristics of estuarine water bodies that are least impaired by human activities to determine attainable biological conditions for such waterbodies in southern California. As discussed earlier, studies of pH variation in estuaries reveals that wide swings in pH due to the presence of algae constitute reference conditions for typical estuaries. The proposed listing does not appropriately demonstrate that the high pH was a result of waste discharge as required in the Los Angeles Region Basin Plan (Basin Plan). As stated in the Fact Sheets and according to the Basin Plan, "The pH of inland surface waters shall not be depressed below 6.5 or raised above 8.5 as a result of waste discharges." However, it was not demonstrated for the SCRE that	completed as part of the Integrated Report or 303(d) listing process. There are multiple sources of water to Santa Clara River Estuary including "waste discharge" from sources such as wastewater treatment plants and the MS4. Exceedances of pH may be caused in part by waste discharge. The relative contribution of the causes of pH exceedances is largely speculative, at this time. The way to "take into account" the type of waterbody, or reference conditions, or the interaction between pH and other factors such as algae, is during the development of a TMDL. See also, response to comment 16.2.

No.	Comment	Response
	the elevated pH levels were a result of waste discharge as opposed to natural causes. Therefore, the Regional Board should either provide evidence that the elevated pH was a result of waste discharge and detail that in the Fact Sheets or, if not such evidence exists, the Regional Board should remove this proposed listing. **Ventura Water requests reconsideration of the proposed pH listing for the SCRE based on consideration of reference conditions data, which indicate that substantial fluctuations in estuarine pH values are typical, and consistent pH values that comply with water quality objectives are not biologically attainable within estuaries.** *Figure 3 pH at VWRF and Receiving Water Locations* **[See the comment letter for Figure 3]**	
32.6	**Nitrogen and Nitrate Comments** Nitrogen/nitrate (collectively "nitrate") was originally listed on the 303(d) list adopted in 2012. The nitrate listing is based on receiving water samples collected between 2002 and 2007. Given that Ventura Water implemented a nitrification and denitrification project in November 2011, nitrate data collected before 2011 is no longer representative of SCRE conditions, and is therefore not reliable for determining current SCRE exceedance estimates. In reviewing receiving water data collected monthly from 2012 through 2016 (60 sample dates}, which is submitted to the Regional Board as part of NPDES reporting and is therefore readily available data under the Listing Policy, there were only 5 days during which SCRE water quality exceeded the nitrate receiving water quality objective of 10 mg/I . Because the SCRE is wind-mixed and fairly uniform (Phase 1 Estuary Subwatershed Study, Stillwater 2011}, we would argue that on any given day, sampling at a given location is strongly influenced by conditions at other nearby locations. The Listing Policy states: "Based on these evaluations of the water body setting, the Regional Water Boards should aggregate the data by appropriate reach or area . ... To be considered temporally independent, samples collected during the	The data used to list the Santa Clara River Estuary for Nitrogen Nitrate was NPDES receiving water monitoring from the City of San Buenaventura, Water Reclamation Plant (NPDES No. CA0053651) collected from 2002 to 2007. The commenter has presented additional data collected from 2012 to 2016. See response to comment 32.3 for a discussion of the "readily available" data considered for this Integrated Report and 303(d) list. The Listing Policy does allow for not using older data; Section 6.1.5.3 states, in part, "If the implementation of a management practice(s) has resulted in a change in the water body segment, only recently collected data {since the implementation of the management measure(s)) should be

No.	Comment	Response
	averaging period shall be combined and considered one sampling event. ... If the averaging period is not stated for the standard, objective, criterion, or evaluation guideline, then the samples collected less than 7 days apart shall be averaged." As shown in Figure 4 below, exceedances in multiple locations occurring in the SCRE on the same sampling date should be considered a single event because the multiple sampling results are designed to provide a spatial representation of the estuary during any particular event of exceedance. According to the binomial distribution null hypothesis (Listing Policy Table 3.1), the listing requirement for 60 to 71 data points is 6 exceedances, which is more than the current 5 exceedances demonstrated by the more recent data set developed after Ventura Water's implementation of treatment plant and treatment process upgrades. Section 4 of the Listing Policy states that a water segment shall be removed from a 303(d) listing if the water meets the water quality standards. Using Policy Table 4.1, the null hypothesis indicates that for 60 to 71 data points, if there are 5 exceedances or less, then the water segment can be delisted. **Based on current data, the number of exceedances (S) meets the delisting criteria, and given that VWRF already has an NPDES permit limit for nitrate, Ventura Water requests recalculation of the exceedances based on current data and correct use of averaging periods for the data (data collected on the same day to be averaged}. Ventura Water requests that based on this recalculation, nitrate be removed from the 303(d) list for the SCRE.** *Figure 4 Receiving Water Nitrate Levels* **[See the comment letter for Figure 4]**	considered…" In the next listing cycle, when Water Board staff is able to consider the more recent data, staff can consider the implementation of nitrification and denitrification in 2011 and the appropriateness of averaging the more recent data.
32.7	**Toxicity Comments** The City monitors chronic toxicity using Selanstrum for both effluent and receiving water. Using readily available data collected by Ventura Water from 2012 - 2016 and submitted to the Regional Board, the VWRF tertiary treated flows consistently met toxicity criteria of 1 TUc for the 60 samples, as shown in Figure 5. However, receiving water monitoring data does not similarly show consistent and full attainment of toxicity criteria. The receiving water monitoring	The data used to list the Santa Clara River Estuary for toxicity was NPDES receiving water monitoring from the City of San Buenaventura Ventura, Water Reclamation Plant (NPDES No. CA0053651) collected from 2002 to 2007. The commenter has presented additional data

No.	Comment	Response
	locations have a data set of 25 sample dates. **Using the argument presented above that the data should be aggregated and appropriate averaging should be used, Ventura Water requests that each sampling event (day) be considered separately and the data points be averaged.** To meet the Listing Policy Table 4.1 requirements for delisting, with 26 data points there would need to be 2 or fewer exceedances of toxicity objectives for the SCRE. Even considered as single events, there have been more than 2 exceedances of a 1 TUc, although those exceedances are unrelated to toxicity of tertiary treated flows, which did not show exceedances. Therefore, it does not appear that de listing the SCRE for toxicity would be appropriate at this time, even though toxicity exceedances are unrelated to VWRF tertiary treated flows. **However, Ventura Water requests this listing be reevaluated once the data is appropriately aggregated and averaged.** *Figure* 5 *Effluent and Receiving Water Toxicity* **[See the comment letter for Figure 5]**	collected from 2012 to 2016. See response to comment 32.3 for a discussion of the "readily available" data considered for this Integrated Report and 303(d) list.
32.8	**ChemA** ChemA is being included on the 303(d) list without any supporting data. The reasons for its listing are that the U.S. EPA approved a TMDL for the estuary in 2011. However, no data, historic or otherwise, were used to support the continued placement on this list. **Ventura Water requests that recent data be taken into consideration when assessing the placement of ChemA on the 303(d) list.**	ChemA is a suite of bio-accumulating pesticides that includes aldrin, dieldrin, chlordane, endrin, heptachlor, heptachlor epoxide, hexachlorocyclohexane (HCH) (including lindane), endosulfan, and toxaphene. ChemA was placed on the 303(d) list for the Santa Clara River estuary in 1998. Data used for listing or delisting decisions prior to 2006 are not included in the CalWQA database and this is reflected on the factsheets. The 1998 303(d) listing (and subsequent listings) for Chem A were predominately based on fish tissue concentrations of toxaphene. Los Angeles Water Board developed a TMDL for toxaphene in

No.	Comment	Response
		fish tissue in the Santa Clara River Estuary in 2010, which was approved by EPA in 2011. Source analysis showed that the source of toxaphene was irrigated agriculture and the TMDL was adopted as a single regulatory action through the renewal of the Conditional Waiver of Waste Discharge Requirements for Discharges from Irrigated Lands. The agricultural discharges regulated by the Conditional Waiver of Waste Discharge Requirements for Discharges from Irrigated Lands monitor for toxaphene and chlordane. During the next listing cycle, when Water Board staff is able to review this more recently collected monitoring data, staff may recommend revision of the 303(d) list including, potentially, a simplification of the list, by removing Chem A because the toxaphene and chlordane data more appropriately represent the impairment or non-impairment of the Estuary.
32.9	**Toxaphene** Similar to ChemA, toxaphene was included on the 303(d) list due to its TMDL status with the U.S. EPA, circa 2011. No new information or data was brought forward to support the status on the list. Based on data collected semiannually by the VWRF, toxaphene has not even been detected in either the effluent or the receiving water in recent memory. **Ventura Water requests that recent readily available data be taken into consideration when assessing the placement of toxaphene on the 303(d) list.**	Similar to ChemA, toxaphene was placed on the 303(d) list for the Santa Clara River estuary in 1998. Data used for listing or delisting decisions prior to 2006 are not included in the CalWQA database and this is reflected on the factsheets. Data more recent than 2010 will be considered in the next listing cycle for the Los Angeles Region. See response to comment 32.3 for a discussion of the "readily available" data considered for this Integrated Report and 303(d) list.
32.10	**Indicator Bacteria** Similar to ChemA and toxaphene, indicator bacteria was included in the 303(d)	Indicator Bacteria was placed on the 303(d) list for

No.	Comment	Response
	list due to its TMDL status with the U.S. EPA, circa 2011. No new information or data was brought forward to support the status on the list. **Ventura Water requests that recent data be taken into consideration when assessing the placement of indicator bacteria on the 303(d) list.**	the Santa Clara River estuary prior to 1998 (this impairment was originally called "coliform bacteria"). Data used for listing or delisting decisions prior to 2006 are not included in the CalWQA database and this is reflected on the factsheets. The Los Angeles Water Board developed a TMDL for indicator bacteria in 2010, which was approved by USEPA in 2012. Data more recent than 2010 will be considered in the next listing cycle for the Los Angeles Region. See response to comment 32.3 for a discussion of the "readily available" data considered for this Integrated Report and 303(d) list.
32.11	Summary/Conclusion Ventura Water appreciates the opportunity to comment on the proposed 303(d) list. Based on the analysis presented above using more recently collected, readily available data that properly represents existing conditions in the SCRE (2012 - 2016), our findings include: • Appropriate ammonia data were not considered in the proposed listing and current data do not meet the Listing Policy criteria for 303(d) listing. • A listing for pH is not warranted in light of reference conditions for pH within estuaries, which indicates that steady state pH values in compliance with water quality objectives are not biologically attainable even in high functioning estuaries. • Nitrate should be delisted based on relevant Listing Policy criteria. • Toxicity is unrelated to VWRF discharges of tertiary treated water to the SCRE, and the listing should be reevaluated once the data is appropriately aggregated and averaged.	Comments noted. See response to comment 32.4 for ammonia, 32.5 for pH, 32.6 for nitrate, 32.7 for toxicity, 32.8 for ChemA, 32.9 for toxaphene, and 32.10 for indicator bacteria. See response to comment 32.3 for a discussion of the "readily available" data considered for this Integrated Report and 303(d) list.

No.	Comment	Response
	• Chem A, Toxaphene, and Indicator Bacteria listings did not include recent data and should be reevaluated based on current data. It is important to note the City has been conducting studies on the SCRE since 2009 per the special studies requirements in the NPDES permits for the VWRF. These studies analyze the existing discharge impacts/benefits to aquatic habitat, and evaluate alternatives that include a reduction in discharge, improvement in discharge water quality, or a combination of both, for the purpose of improving aquatic habitat. These studies are site specific, taking into account the listed species using or occupying the SCRE, and the associated physical/chemical parameters that contribute to site specific aquatic habitat conditions. The results of the studies will be presented in the Phase 3 Estuary Studies Report (expected January 2018), and will provide a detailed understanding of the SCRE and information relevant to the 303(d) listing process.	

CALIFORNIA
Water Boards

EDMUND G. BROWN JR.
GOVERNOR

MATTHEW RODRIQUEZ
SECRETARY FOR
ENVIRONMENTAL PROTECTION

Los Angeles Regional Water Quality Control Board

To: Interested Persons

From: Renee Purdy, Section Chief
Regional Programs

Date: April 26, 2017

Subject: **Notice of change to Item 9, "Consideration of the proposed revisions to the Clean Water Act section 303(d) List of impaired waterbodies in the Los Angeles Region" on the May 4, 2017 Los Angeles Regional Water Quality Control Board meeting agenda**

Item 9, Consideration of the proposed revisions to the Clean Water Act section 303(d) List, was previously noticed as an action item on the May 4, 2017 Board agenda. The Los Angeles Water Board received a significant number of written comments in response to the public notice and comment period, which ended on March 30, 2017. Board staff is actively working to respond to these comments and revise the proposed 2016 303(d) list, where appropriate.

Due to the extensive number of listing decisions and associated lines of evidence involved, and in order to have sufficient time to make the appropriate revisions prior to a decision on the Los Angeles Region's 303(d) list, Item 9 has been changed to a Board workshop rather than an action item. The workshop format will allow Board staff to discuss the 303(d) listing process with the Board members and stakeholders as well as provide the status of Board staff's response to comments. The update provided on the response to comments will include a discussion of the types of revisions to the proposed 303(d) list that will be made in response to comments. Some of these revisions include correcting lines of evidence that addressed beneficial uses that should not have been assessed (for example, P* MUN use designations); creating and assessing new lines of evidence for data submitted by August 2010 that were not included in the State's assessment database; and correcting decisions where sampling data were misapplied to a waterbody.

The Los Angeles Water Board's goal is to forward to the State Water Resources Control Board (State Water Board) a regional 303(d) list that includes decisions based on all data submitted by the August 2010 deadline; complies with the State's Listing Policy; and adheres to the 2016 303(d) listing cycle guidelines provided by the State Water Board. The State Water Board has a goal of finalizing the 2014 and 2016 303(d) lists by early fall 2017. A Board workshop at the regional level will better allow for a thorough discussion of the issues and for the State Water Board and the Los Angeles Water Board to meet their goals.

After the May 4, 2017 Board workshop, Los Angeles Water Board staff will continue to revise the 303(d) list, as appropriate, per comments received and any direction provided by the Board during the workshop. Los Angeles Water Board staff will not bring the 2016 303(d) list back to the Los Angeles Water Board for action. Instead, Los Angeles Water Board management and staff will provide a recommendation to the State Water Board and the State Water Board will consider approval of the Los Angeles Region's 2016 303(d) list, along with the other remaining Regional Water Boards' 303(d) lists, at a future State Water Board meeting.

We also note that the notice of "Public Hearing and Opportunity to Comment on the Proposed Revisions to the Clean Water Act Section 303(d) List for the Los Angeles Region" dated February 8, 2017, included the following language:

> ***IV. FUTURE REVIEW BY STATE WATER BOARD***
>
> *To request the State Water Resources Control Board (State Water Board) or Executive Director of the State Water Board review specific listing recommendations approved by the Los Angeles Water Board, the request must be submitted to the State Water Board within 30 days after the Los Angeles Water Board approval…*

With this revised approach, a request within 30 days will not be necessary. Instead, stakeholders can respond directly to the State Water Board when it releases its combined 2014 and 2016 303(d) list for public comment. The Los Angeles Water Board will provide notice to stakeholders and post on its website revisions to the 303(d) list per the comments received prior to the State Water Board's release of the combined 2014 and 2016 303(d) list for public comment.

The workshop will be held at the Los Angeles Water Board's regularly scheduled board meeting on:

Date:	Thursday, May 4, 2017
Time:	9:30 a.m.
Place:	City of Pasadena Council Chambers 100 North Garfield Avenue Pasadena, California 91101

Please check the Los Angeles Water Board's website (http://www.waterboards.ca.gov/losangeles/) for the most up-to-date public meeting date and location as they are subject to change.

For additional information regarding this notice, please contact Dr. Jun Zhu at Jun.Zhu@waterboards.ca.gov or (213) 576-6681 or Dr. L.B. Nye, at LB.Nye@waterboards.ca.gov or at (213) 576-6785.

Lyris Name: 303(d)
