Flooding of the Yolo Bypass (CM2) would inundate 961–2,678 acres of nesting habitat and 368–2,678 acres of foraging habitat (Table 12-9-54). Based on hypothetical floodplain restoration, construction of setback levees for *CM5 Seasonally Inundated Floodplain Restoration* could result in periodic inundation of approximately 18 acres of nesting habitat and 2,701 acres of nonbreeding habitat (Table 12-9-54) resulting in the temporary loss of these habitats. Foraging yellow-headed blackbirds would be expected to move to adjacent suitable foraging habitat when the bypass is inundated, as they do under the current flooding regime. However, this inundation could reduce the availability of nesting habitat during years when flooding extends into the nesting season (past March). The periodic inundation of the Yolo Bypass (CM2) and of other floodplains (CM5) is expected to restore a more natural flood regime in support of wetland and riparian vegetation types that support nesting habitat.

NEPA Effects: Implementation of CM2 and CM5 would result in periodic inundation of nesting and foraging habitat for yellow-headed blackbird. Periodic inundation would have a less-than-significant impact on yellow-headed blackbird because inundation is expected to take place outside of the breeding season, and although foraging habitat may be temporarily unavailable, birds would be expected to move to adjacent foraging habitat.

CEQA Conclusion: Implementation of CM2 and CM5 would result in periodic inundation of nesting and foraging habitat for yellow-headed blackbird. Periodic inundation would have a less-than-significant impact on yellow-headed blackbird because inundation is expected to take place outside of the breeding season, and although foraging habitat would be temporarily unavailable, birds would be expected to move to adjacent foraging habitat.

Riparian Brush Rabbit

The habitat model used to assess effects on the riparian brush rabbit consists of 38 vegetation associations within the valley/foothill riparian natural community and adjacent grasslands. The vegetation associations were selected based on a review of understory and overstory composition from Hickson and Keeler-Wolf (2007) and species habitat requirements.

Just until recently, the only known naturally occurring populations of riparian brush rabbits were confined to Caswell Memorial State Park (MSP), a 258-acre park supporting riparian oak woodland on the Stanislaus River immediately southeast of the study area, and in the south Delta southwest of Lathrop, which is within the study area (Williams and Basey 1986; Williams et al. 2002) (Figure 12-46). On October 11, 2012 a single female riparian brush rabbit was captured near Durham Ferry Road in riparian habitat along the San Joaquin River between Caswell MSP and Lathrop (Bradbury pers. comm.). The is only the second naturally occurring population documented outside of Caswell MSP. Factors considered in assessing the value of adversely affected habitat for riparian brush rabbit, to the extent information was available, included size and degree of isolation of habitat patches, proximity to recorded species occurrences, and adjacency to conserved lands.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of riparian brush rabbit modeled habitat as indicated in Table 12-9-55. Full implementation of Alternative 9 would also include biological objectives over the term of the BDCP to benefit the riparian brush rabbit (BDCP Chapter 3, *Conservation Strategy*). The conservation strategy for the riparian brush rabbit, with conservation principles involves protecting, restoring or creating, and maintaining habitat and corridors near the largest remaining fragments of habitat and extant populations; providing high-water refugia from flooding; and managing feral predators (dogs and cats) in areas occupied by the species. The conservation measures that would be implemented to achieve the biological goals and objectives are summarized below.

- Provide a range of elevations in restored floodplains that transition from frequently flooded (e.g., every 1 to 2 years) to infrequently flooded (e.g., every 10 years or more) areas to provide a range of habitat conditions, upland habitat values, and refugia from flooding during most flood events (Objective L1.5, associated with CM3, CM5, and CM8).
- Increase the size and connectivity of the reserve system by acquiring lands adjacent to and between existing conservation lands (Objective L1.6, associated with CM3).
- Allow floods to promote fluvial processes, such that bare mineral soils are available for natural recolonization of vegetation, desirable natural community vegetation is regenerated, and structural diversity is promoted, or implement management actions that mimic those natural disturbances (Objective L2.1, associated with CM3, CM5, and CM11).
- Protect and improve habitat linkages that allow terrestrial covered and other native species to move between protected habitats within and adjacent to the Plan Area (Objective L3.1, associated with CM3–CM8, and CM11).
- Restore or create 5,000 acres of valley/foothill riparian natural community, with at least 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM3 and CM7).
- Protect 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).
- Maintain 1,000 acres of early- to mid-successional vegetation with a well-developed understory of dense shrubs on restored seasonally inundated floodplain (Objective VFRNC2.2, associated with CM5, CM7, and CM11).
- Of the 750 acres of protected valley/foothill riparian natural community protected under Objective VFRNC1.2, protect at least 200 acres of suitable riparian brush rabbit habitat (defined in CM7 Riparian Natural Community Restoration) that is occupied by the species or contiguous with occupied habitat (Objective RBR1.1, associated with 3).
- Of the 1,000 acres of early- to midsuccessional riparian habitat maintained under VFRNC2.2, maintain at least 800 acres within the range of the riparian brush rabbit (CZ 7), in areas that are adjacent to or that facilitate connectivity with occupied or potentially occupied habitat (Objective RBR1.2, associated with CM3, CM7, and CM11).
- Of the 5,000 acres of valley/foothill riparian natural community restored under Objective VFRNC1.1, restore/create and maintain at least 300 acres of early- to mid-successional riparian habitat that meets the ecological requirements of the riparian brush rabbit and that is within or adjacent to or that facilitates connectivity with existing occupied or potentially occupied habitat (Objective 1.3, associated with CM3, CM7, and CM11).
- Create and maintain high-water refugia in the 300 acres of restored riparian brush rabbit habitat and the 200 acres of protected riparian brush rabbit habitat, through the retention, construction and/or restoration of high-ground habitat on mounds, berms, or levees, so that refugia are no further apart than 66 feet (Objective RBR1.4, associated with CM7 and CM11).
- In protected riparian areas that are occupied by riparian brush rabbit, monitor for and control nonnative predators that are known to prey on riparian brush rabbit (Objective RBR1.5, associated with CM11).

- Of the 8,000 acres of grasslands protected under Objective GNC1.1 and the 2,000 acres of grasslands restored under Objective GNC1.2, protect or restore grasslands on the landward side of levees adjacent to restored floodplain to provide flood refugia and foraging habitat for riparian brush rabbit (Objective RBR1.6m, associated with CM3 and CM8).

As explained below, with the restoration and protection of these amounts of habitat, in addition to implementation of the AMMs to reduce potential effects, impacts on riparian brush rabbit would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-55. Changes in Riparian Brush Rabbit Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-152: Loss or Conversion of Habitat for and Direct Mortality of Riparian Brush Rabbit

- Alternative 9 conservation measures would result in the permanent loss of up to 111 acres of riparian habitat and 261 acres of associated grassland habitat for the riparian brush rabbit in the study area (Table 12-9-55). The hypothetical footprint for levee construction overlaps with one occurrence record for riparian brush rabbit, south of the Interstate 5/Interstate 205 interchange. Conservation measures resulting in permanent habitat loss include conveyance facilities construction (CM1), tidal natural communities restoration (CM4), and floodplain restoration (CM5). Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Development of Alternative 9 water conveyance facilities would result in the permanent removal of approximately 8 acres of riparian habitat and 58 acres of associated grassland habitat and in the temporary removal of 6 acres of riparian habitat and 139 acres of grassland habitat for riparian brush rabbit in CZ 8 (Table 12-9-55). The riparian habitat that would be removed is of low value for the riparian brush rabbit as is consists of several small, isolated patches surrounded by agricultural lands northeast of Clifton Court Forebay. The associated grasslands are also of low-quality for the species: They consist of long, linear strips that abut riparian habitat, but extend several miles from the riparian habitat and, therefore, provide few if any opportunities for adjacent cover. Trapping efforts conducted for the riparian brush rabbit in this area were negative (BDCP Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*). Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations.

- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove approximately 19 acres of riparian habitat and 18 acres of associated grassland habitat for the riparian brush rabbit in CZ 7 in the late long-term. The riparian habitat that would be removed consists of relatively small and isolated patches along canals and irrigation ditches surrounded by agricultural lands in the Union Island and Roberts Island areas, and several small patches along the San Joaquin River. The habitat that would be removed is not adjacent to any existing conserved lands, and is several miles north and northeast of the northernmost riparian brush rabbit record located northeast of Paradise Cut (Williams et al. 2002). Although the final footprint for tidal natural communities restoration would differ from the hypothetical footprint, compliance monitoring would be implemented to ensure that acreage limits are not exceeded, and the measures described in *AMM25 Riparian Woodrat and Riparian Brush Rabbit* require that tidal natural communities restoration avoid removal of any habitat occupied by the riparian brush rabbit.

- *CM5 Seasonally Inundated Floodplain Restoration*: Levee construction associated with floodplain restoration would result in the permanent removal of approximately 43 acres of riparian habitat and 26 acres of associated grassland habitat for the riparian brush rabbit in CZ 7 in the late long-term. Levee construction would also result in the temporary removal of 35 acre riparian habitat and 20 acres of grassland habitat for the riparian brush rabbit. Although the effects are considered temporary, 5 years to several decades may be required for ecological succession to occur and for restored riparian habitat to replace the function of habitat that has been affected.

  The value of this habitat for riparian brush rabbit is high: although it consists of small patches and narrow bands of riparian vegetation, these areas are in proximity to, or contiguous with, habitat with recorded occurrences of riparian brush rabbit. The hypothetical footprint for levee construction overlaps with one occurrence record for riparian brush rabbit, south of the Interstate 5/Interstate 205 interchange.

  Although the final floodplain restoration design would differ from the hypothetical footprint used for this effects analysis, restoration of the river floodplain in CZ 7 would be targeted in the general area of the riparian brush rabbit population. Implementation of adaptive management described in *AMM25* would ensure that riparian brush rabbit habitat permanently removed as a result of floodplain restoration does not exceed the maximum allowable habitat loss for this species.

- *CM11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in BDCP protected habitats may result in localized ground disturbances that could temporarily remove small amounts of riparian brush rabbit habitat. Enhancement and management actions in riparian brush rabbit habitat within the reserve system may include invasive plant removal, planting and maintaining vegetation to improve and sustain habitat characteristics for the species, and creating and maintaining flood refugia. These activities are expected to have minor adverse effects on available riparian brush rabbit habitat and are expected to result in overall improvements to and maintenance of riparian brush rabbit habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized through the AMMs listed below.

  Passive recreation in the reserve system could result in disturbance of individual riparian brush rabbits foraging in the ecotone between riparian and adjacent open habitats. However, *AMM37 Recreation* limits trail development adjacent to riparian corridors within the range of the riparian brush rabbit. With this minimization measure in place, recreation-related effects on the riparian brush rabbit are expected to be minimal.

- Operations and maintenance: Ongoing maintenance of BDCP facilities are not expected to adversely affect the riparian brush rabbit because the species is not expected to occur in the vicinity of proposed facilities.

- Injury and direct mortality: Water conveyance facility construction is not is not likely to result in injury or mortality of individual riparian brush rabbit because the species is not likely to be present in the areas that would be affected by this activity, based on live trapping results (BDCP Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*). Tidal natural communities restoration would not result in injury or mortality of the riparian brush rabbit because tidal natural communities restoration projects would be designed to avoid occupied riparian brush rabbit habitat and, if that is not possible, rabbits would be trapped and relocated as described in AMM25 (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Activities associated with construction of setback levees for floodplain restoration could result in injury or mortality of riparian brush rabbits: however, preconstruction surveys, construction monitoring, and other measures would be implemented to avoid and minimize injury or mortality of this species during construction (AMM25).

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA.

Alternative 9 would result in permanent and temporary effects combined on 14 acres of riparian habitat and 197 acres of grassland habitat for riparian brush rabbit in the near-term as a result of construction of the water conveyance facilities (CM1). The habitat would be lost in the valley/foothill riparian and grassland natural communities. Most of the near-term loss of riparian brush rabbit habitat would be in an area the species is unlikely to occupy in CZ 8. Habitat loss in CZ

7, in areas known or likely to be occupied, would occur during the early long-term and late long-term timeframes. Riparian restoration would be phased to minimize temporal habitat loss. There would be no near-term losses from CM2–CM18.

Typical NEPA project-level mitigation ratios for those natural communities that would be affected and that are identified in the biological goals and objectives for riparian brush rabbit in Chapter 3 of the BDCP would be 1:1 for restoration and protection of the valley/foothill riparian natural community, and 2:1 for protection of grassland. Using these ratios would indicate that 14 acres of riparian habitat should be restored, 14 acres of riparian habitat should protected, and 394 acres of grassland should be protected for riparian brush rabbit to mitigate near-term losses.

The BDCP has committed to near-term restoration of 800 acres of riparian(Objective VFRNC1.1) and an unknown number of associated acres of grassland and protection of 750 acres of riparian (Objective VFRNC1.2) with an unknown number of associated acres of grassland (Table 3-4 in Chapter 3, *Description of Alternatives*). In addition, the species-specific biological goals and objectives (Objectives RBR1.1–RBR1.6) would inform the near-term protection and restoration efforts. The natural community restoration and protection activities are expected to be concluded during the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for NEPA purposes. These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be not be adverse under NEPA, because the number of acres required to meet the typical ratios described above would be 14 acres of riparian habitat restored, 14 acres protected, and 394 acres of grassland protected.

The plan also contains commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM25 Riparian Woodrat and Riparian Brush Rabbit, and AMM37 Recreation*. These AMMs contain elements that avoid or minimize the risk of BDCP activities affecting habitats and species adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

There are 6,012 acres of modeled riparian brush rabbit habitat in the Plan Area, consisting of 2,909 acres of riparian habitat and 3,103 acres of associated grassland habitat. Alternative 9 a whole would result in permanent and temporary effects combined on 111 acres of modeled riparian habitat and 261 acres of modeled grassland habitat for riparian brush rabbit, representing 4% and 8% of the riparian and grassland modeled habitat. The BDCP would restore 5,000 acres and protect 750 acres of valley/foothill riparian natural community, a portion of which is expected to consist of suitable riparian brush rabbit habitat (Objectives VFRNC1.1 and VFRNC1.2). Objective RBR1.2 requires that at least 800 acres of early- to midsuccessional riparian natural community be conserved in CZ 7, in areas that are adjacent to or that facilitate connectivity with existing occupied or potentially occupied habitat. This would consist of 200 acres of protected habitat (Objective RBR1.1) and 600 acres of restored habitat. The 800 acres to be conserved would consist of early successional riparian vegetation suitable for riparian brush rabbit. The conserved habitat would also be part of a larger, more contiguous, and less patchy area of protected and restored riparian natural community than what currently exists in CZ 7 and would be contiguous with existing modeled riparian brush rabbit habitat. The species-specific objectives further require that the 200 acres of protected riparian habitat (Objective RBR1.4) and at least 300 acres of the restored riparian habitat (Objective RBR1.3) meet more specific ecological requirements of riparian brush rabbit, including large patches of dense riparian brush; ecotonal edges that transition from brush species to grasses and forbs, scaffolding plants to support vines that grow above flood levels; a tree canopy that is open, if present; and high-ground refugia from flooding. In protected riparian areas that are occupied by riparian brush rabbit, nonnative predators that are known to prey on riparian brush rabbit would be monitored and controlled (Objective RBR1.5).

In addition to restoration and protection of riparian habitat for the riparian brush rabbit, the BDCP would protect, and, if necessary, create or restore grasslands adjacent to suitable riparian vegetation in areas outside the floodplain levees (Objective RBR1.6). These grasslands are expected to provide additional foraging opportunities for the riparian brush rabbit and upland refugia during flood events. The actual acreage of grassland to be restored or protected for riparian brush rabbit would depend on site-specific needs adjacent to restored and protected riparian habitat (CM3). Grasslands on the landward side of levees adjacent to restored floodplain would be restored or protected as needed to provide flood refugia and foraging habitat for riparian brush rabbit (Objective RBR1.6).

In addition to grasslands protected and restored outside the levees for riparian brush rabbit as needed, the floodplains would transition from areas that flood frequently (e.g., every 1 to 2 years) to areas that flood infrequently (e.g., every 10 years or more) (Objective L1.5): these infrequently flooded areas would provide refuge for the riparian brush rabbit during most years. The BDCP would also create and maintain mounds, levee sections, or other high areas in restored and protected riparian areas (Objective RBR1.4) that are designed specifically to provide flood refugia for the riparian brush rabbit (BDCP Appendix 3.F, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*). Additionally, nonnative predators that are known to prey on riparian brush rabbit (e.g., feral dogs and cats) would be monitored in protected and restored riparian areas that are occupied by riparian brush rabbit (Objective RBR1.5), and controlled as needed (CM11).

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of valley/foothill riparian and grassland that could overlap with the species model, would result in the restoration of 800 acres of riparian and 79 acres of grassland modeled habitat for riparian brush rabbit. In addition, protection of valley/foothill riparian and grassland could overlap with the species model and would result in the protection of 200 acres of riparian and 317 acres of grassland riparian brush rabbit modeled habitat.

NEPA Effects: In the near-term, the loss of riparian brush rabbit habitat under Alternative 9 would not be adverse because there is little likelihood of riparian brush rabbits being present and the BDCP has committed to protecting and restoring the acreage required to meet the typical mitigation ratios described above. In the late long-term, the losses of riparian brush rabbit riparian and grassland habitat associated with Alternative 9, in the absence of other conservation actions, would represent an adverse effect as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection and restoration associated with the conservation components, guided by landscape-scale goals and objectives and by AMM1–AMM6, AMM10, AMM25, and AMM37, the effects of Alternative 9 as a whole on riparian brush rabbit would not be adverse.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA.

Alternative 9 would result in permanent and temporary effects combined on 14 acres of riparian habitat and 197 acres of grassland habitat for riparian brush rabbit in the near-term as a result of construction of the water conveyance facilities (CM1). The habitat would be lost in the valley/foothill riparian and grassland natural communities. Most of the near-term loss of riparian brush rabbit habitat would be in an area unlikely to be occupied by the species in CZ 8. Habitat loss in CZ 7, in areas known or likely to be occupied, would occur during the early long-term and late long-term timeframes. Riparian restoration would be phased to minimize temporal habitat loss. There would be no near-term losses resulting from CM2–CM18.

Typical CEQA project-level mitigation ratios for those natural communities that would be affected and that are identified in the biological goals and objectives for riparian brush rabbit in Chapter 3 of the BDCP would be 1:1 for restoration and protection of the valley/foothill riparian natural community, and 2:1 for protection of grassland. Using these ratios would indicate that 14 acres of riparian habitat should be restored, 14 acres of riparian habitat should protected, and 394 acres of grassland should be protected for riparian brush rabbit to mitigate CM1 losses.

The BDCP has committed to near-term restoration of 800 acres of riparian (Objective VFRNC1.1) and an unknown number of associated acres of grassland and protection of 750 acres of riparian (Objective VFRNC1.2) with an unknown number of associated acres of grassland (Table 3-4 in Chapter 3, *Description of Alternatives*). In addition, the species-specific biological goals and objectives (RBR1.1–RBR1.6) would inform the near-term protection and restoration efforts. The natural community restoration and protection activities are expected to be concluded during the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for CEQA purposes. These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be less than significant under CEQA, because the number of acres required to meet the typical ratios described above would be 14 acres or riparian habitat protected, 14 acres of riparian habitat restored, and 394 acres of grassland habitat protected.

The plan also contains commitments to implement AMM1–AMM7, AMM10, AMM25, and AMM37. These AMMs contain elements that avoid or minimize the risk of BDCP activities affecting habitats and species adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

There are 6,012 acres of modeled riparian brush rabbit habitat in the Plan Area, consisting of 2,909 acres of riparian habitat and 3,103 acres of associated grassland habitat. Alternative 9 would result in permanent and temporary effects combined on 111 acres of modeled riparian habitat and 261 acres of modeled grassland habitat for riparian brush rabbit, representing 4% and 8% of the riparian and grassland modeled habitat.

The BDCP would restore 5,000 acres and protect 750 acres of valley/foothill riparian natural community, a portion of which is expected to consist of suitable riparian brush rabbit habitat (Objectives VFRNC1.1 and VFRNC1.2). Objective RBR1.2 requires that at least 800 acres of early- to midsuccessional riparian natural community be conserved in CZ 7, in areas that are adjacent to or that facilitate connectivity with existing occupied or potentially occupied habitat. This would consist of 200 acres of protected habitat (Objective RBR1.1) and 600 acres of restored habitat. The 800 acres to be conserved would consist of early successional riparian vegetation suitable for riparian brush rabbit. The conserved habitat would also be part of a larger, more contiguous, and less patchy area of protected and restored riparian natural community than what currently exists in CZ 7 and would be contiguous with existing modeled riparian brush rabbit habitat. The species-specific objectives further require that the 200 acres of protected riparian habitat (Objective RBR1.4) and at least 300 acres of the restored riparian habitat (Objective RBR1.3) meet more specific ecological requirements of riparian brush rabbit, including large patches of dense riparian brush; ecotonal edges that transition from brush species to grasses and forbs, scaffolding plants to support vines that grow above flood levels; a tree canopy that is open, if present; and high-ground refugia from flooding. In protected riparian areas that are occupied by riparian brush rabbit, nonnative predators that are known to prey on riparian brush rabbit would be monitored and controlled (Objective RBR1.5).

In addition to restoration and protection of riparian habitat for the riparian brush rabbit, the BDCP would protect, and, if necessary, create or restore grasslands adjacent to suitable riparian vegetation in areas outside the floodplain levees (Objective RBR1.6). These grasslands are expected to provide additional foraging opportunities for the riparian brush rabbit and upland refugia during flood events. The actual acreage of grassland to be restored or protected for riparian brush rabbit would depend on site-specific needs adjacent to restored and protected riparian habitat (CM3). Grasslands on the landward side of levees adjacent to restored floodplain would be restored or protected as needed to provide flood refugia and foraging habitat for riparian brush rabbit (Objective RBR1.6).

In addition to grasslands protected and restored outside the levees for riparian brush rabbit as needed, the floodplains would transition from areas that flood frequently (e.g., every 1 to 2 years) to areas that flood infrequently (e.g., every 10 years or more) (Objective L1.5): these infrequently flooded areas would provide refuge for the riparian brush rabbit during most years. The BDCP would also create and maintain mounds, levee sections, or other high areas in restored and protected riparian areas (Objective RBR1.4) that are designed specifically to provide flood refugia for the riparian brush rabbit (BDCP Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*). Additionally, nonnative predators that are known to prey on riparian brush rabbit (e.g., feral dogs and cats) would be monitored in protected and restored riparian areas that are occupied by riparian brush rabbit (Objective RBR1.5), and controlled as needed (CM11).

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of valley/foothill riparian and grassland that could overlap with the species model, would result in the restoration of 800 acres of riparian and 79 acres of grassland modeled habitat for riparian brush rabbit. In addition, protection of valley/foothill riparian and grassland could overlap with the species model and would result in the protection of 200 acres of riparian and 317 acres of grassland riparian brush rabbit modeled habitat.

Only a small proportion of the lost habitat would be considered occupied and of high-value. Alternative 9 conservation measures provide for large acreages of riparian brush rabbit riparian and grassland habitat to be protected and restored, and the BDCP includes AMM1–AMM7, AMM10, AMM25, and AMM37, which are directed at minimizing or avoiding potential effects during construction and operation of the conservation measures. Overall, the BDCP would provide a substantial net benefit to the riparian brush rabbit through the increase in available habitat and habitat in protected status. These protected areas would be managed to support the species.

Considering the habitat restoration and protection associated with CM3, CM7, CM8 and CM11, guided by species-specific goals and objectives and by AMM1–AMM7, AMM10, AMM25, and AMM37, the temporary and permanent losses of riparian and grassland habitat and potential direct mortality of riparian brush rabbit as a result of implementing Alternative 9 would not represent a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. The loss of habitat and potential mortality of riparian brush rabbits would be a less-than-significant impact under CEQA.

Impact BIO-153: Indirect Effects of Plan Implementation on Riparian Brush Rabbit

Noise, lighting, and visual disturbance adjacent to construction activities could indirectly affect the use of modeled riparian brush rabbit riparian habitat and of associated grassland habitat in the study area. These construction activities would include water conveyance (including transmission line) construction in CZ 8, tidal natural communities restoration construction, and construction of setback levees. Water conveyance construction would potentially affect acres of adjacent riparian habitat and of associated grassland habitat: this construction would occur in CZ 8 where there is suitable habitat for the species but surveys by ESRP did not indicate the species is present in this area;; therefore, the potential for adverse noise and visual effects from conveyance facility construction would be minimal. Tidal natural communities restoration construction would also potentially affect adjacent riparian habitat and associated grassland habitat for this species: however, adverse effects on the species are unlikely because tidal natural communities restoration projects would be sited to avoid areas occupied by riparian brush rabbit. The activity most likely to result in noise, lighting, and visual disturbance to riparian brush rabbit is the construction of setback levees for floodplain restoration, which would take place in CZ 7, where the species is known to occur. The use of mechanical equipment during construction might cause the accidental release of petroleum or other contaminants that would affect the riparian brush rabbit in adjacent habitat, if the species is present.

NEPA Effects: Implementation of AMM1–AMM7, AMM10, AMM25, and AMM37 as part of implementing Alternative 9 would avoid the potential for substantial adverse effects on riparian brush rabbits, either indirectly or through habitat modifications or result in a substantial reduction in numbers or a restriction in the range of riparian brush rabbits. Therefore, indirect effects of Alternative 9 would not have an adverse effect on riparian brush rabbit.

CEQA Conclusion: Indirect effects from conservation measure operations and maintenance as well as construction-related noise, lighting, and visual disturbances could affect riparian brush rabbit in riparian and grassland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could affect riparian brush rabbit. The inadvertent discharge of sediment or excessive dust adjacent to riparian brush rabbit habitat could also have a negative effect on the species. With implementation of AMM1–AMM7, AMM10, AMM25, and AMM37 as part of Alternative 9, the BDCP would avoid the potential for substantial adverse effects on riparian brush rabbits, either indirectly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of riparian brush rabbits. Indirect effects of Alternative 9 would have a less-than-significant impact on riparian brush rabbit.

Impact BIO-154: Periodic Effects of Inundation of Riparian Brush Rabbit Habitat as a Result of Implementation of Conservation Components

CM5 Seasonally Inundated Floodplain Restoration is the only covered activity expected to result in periodic inundation of riparian brush rabbit habitat. This activity would periodically inundate approximately 264 acres of riparian habitat (9% of riparian habitat in the Plan Area) and 423 acres of associated grassland habitat (14% of associated grassland habitat in the Plan Area) for the riparian brush rabbit. The area between existing levees that would be breached and the newly constructed setback levees would be inundated through seasonal flooding. The potentially inundated areas consist of high-value habitat for the species: although they consist of small patches and narrow bands of riparian vegetation, many of these areas are in proximity to, or contiguous with, habitat with recorded occurrences of riparian brush rabbit. The restored floodplain would include a range of elevations from lower lying areas that flood frequently (e.g., every 1 to 2 years) to higher elevation areas that flood infrequently (e.g., every 10 years or more).

Seasonal flooding in restored floodplains can result in injury or mortality of individuals if riparian brush rabbits occupy these areas and cannot escape flood waters. One recorded occurrence of riparian brush rabbit (Williams et al. 2002), just west of Stewart Road in Mossdale, is in the area that would be seasonally flooded based on the hypothetical restoration footprint.

NEPA Effects: Floodplain restoration under CM5 would periodically affect only a small proportion of the modeled riparian brush rabbit habitat in the study area. The adverse effects of periodic inundation on the riparian brush rabbit would be minimized through construction and maintenance of flood refugia to allow riparian brush rabbits to escape inundation. Therefore, implementing Alternative 9, including AMM1–AMM7, AMM10, AMM25, and AMM37, would not be expected to result in substantial adverse effects on riparian brush rabbit, either directly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of riparian brush rabbits. Therefore, Alternative 9 would not adversely affect the species.

CEQA Conclusion: Floodplain restoration under CM5 would periodically affect only a small proportion of the modeled riparian brush rabbit habitat in the study area. The overall effect of seasonal inundation on existing riparian natural communities may instead be beneficial. Historically, flooding was the main natural disturbance regulating ecological processes in riparian areas, and flooding promotes the germination and establishment of many native riparian plants. In the late long-term, seasonal inundation in areas currently occupied by riparian vegetation may contribute to the establishment of high-value habitat for covered riparian species, such as the riparian brush rabbit. Long-term management of riparian areas would ensure that refugia also exist along the edges of seasonally inundated habitat.

The adverse effects of periodic inundation on the riparian brush rabbit would be minimized through construction and maintenance of flood refugia to allow riparian brush rabbits to escape inundation. Therefore, implementing Alternative 9, including AMM1–AMM7, AMM10, AMM25, and AMM37, would not be expected to result in substantial adverse effects on riparian brush rabbit, either directly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of riparian brush rabbits. Periodic inundation of riparian and grassland habitat for riparian brush rabbit under Alternative 9 would have a less-than-significant impact on the species.

Riparian Woodrat

The habitat model used to assess effects for the riparian woodrat consists of selected plant alliances from the valley/foothill riparian natural community, geographically constrained to the south Delta portion of the BDCP area in CZ 7, south of State Route 4 and Old River Pipeline along the Stanislaus, San Joaquin, Old, and Middle Rivers. Valley/foothill riparian areas along smaller drainages (Paradise Cut, Tom Paine Slough), and some larger streams in the northern portion of CZ 7 were excluded from the riparian woodrat habitat model due to a lack of trees or riparian corridors that were too narrow. Factors considered in assessing the value of affected habitat for the riparian woodrat, to the extent that information is available, include habitat patch size and connectivity.

The riparian woodrat is not known to occur in the study area. The only verified extant population of riparian woodrats rangewide is 2 miles east of the southern end of the study area in Caswell Memorial State Park along the Stanislaus River (Williams 1986:1–112; 1993). Riparian woodrat may occur in small patches of valley oak riparian forest along the San Joaquin River from the southern tip of the study area north to approximately the Interstate 5 overcrossing near Lathrop (Figure 12-47). Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of riparian woodrat modeled habitat as indicated in Table 12-9-56. Tidal habitat restoration, floodplain restoration, and protection and management of natural communities could affect modeled riparian woodrat habitat. However, because the species is not known to occur in the study area it is not expected to be affected by BDCP actions unless the species were to establish in the study area over the term of the BDCP. Full implementation of Alternative 9 would also include biological objectives over the term of the BDCP to benefit the riparian woodrat (BDCP Chapter 3, *Conservation Strategy*). The conservation strategy for the riparian woodrat involves providing opportunities for population expansion into the Plan Area from adjacent lands to the south and southeast. The strategy focuses on restoring and maintaining suitable habitat at the southernmost end of CZ 7, providing connectivity with existing populations to the south and southeast, and creating and maintaining flood refugia. This conservation approach is consistent with the recovery plan (U.S. Fish and Wildlife Service 1998) and conservation principles (BDCP Appendix 3.E). The conservation measures that would be implemented to achieve the biological goals and objectives are summarized below.

- Provide a range of elevations in restored floodplains that transition from frequently flooded (e.g., every 1 to 2 years) to infrequently flooded (e.g., every 10 years or more) areas to provide a range of habitat conditions, upland habitat values, and refugia from flooding during most flood events (Objective L1.5, associated with CM3, CM5, and CM8).
- Increase the size and connectivity of the reserve system by acquiring lands adjacent to and between existing conservation lands (Objective L1.6, associated with CM3).
- Protect and improve habitat linkages that allow terrestrial covered and other native species to move between protected habitats within and adjacent to the Plan Area (Objective L3.1, associated with CM3–CM8, and CM11).
- Restore or create 5,000 acres of valley/foothill riparian natural community, with 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM3 and CM7).
- Protect 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).

- Restore, maintain and enhance structural heterogeneity with adequate vertical and horizontal overlap among vegetation components and over adjacent riverine channels, freshwater emergent wetlands, and grasslands (Objective VFRNC2.1, associated with CM5, CM7, and CM11).
- Of the 5,000 acres of valley/foothill riparian natural community restored under Objective VFRNC1.1, restore/create and maintain 300 acres riparian habitat in CZ 7 that meets the ecological requirements of the riparian woodrat (i.e., dense willow understory and oak overstory) and that is adjacent to or facilitates connectivity with existing occupied or potentially occupied habitat (Objective RW1.1, associated with CM3, CM7, CM11).
- Provide and maintain high-water refugia in the 300 acres of riparian woodrat habitat restored under Objective RW1.1 through the retention, construction, and/or restoration of high-ground habitat on mounds, berms, or levees, so that refugia are no further apart than 67 feet (Objective RW1.2, associated with CM7 and CM11).

As explained below, with the restoration and protection of these amounts of habitat, in addition to implementation of the AMMs to reduce potential effects, impacts on riparian woodrat would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-56. Changes in Riparian Woodrat Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	Riparian	2	2	1	1	NA	NA
Total Impacts CM1		**2**	**2**	**1**	**1**	**NA**	**NA**
CM2–CM18	Riparian	0	51	0	33	0	203
Total Impacts CM2–CM18		**0**	**51**	**0**	**33**	**0**	**203**
TOTAL IMPACTS		**2**	**53**	**1**	**34**	**0**	**203**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-155: Loss or Conversion of Habitat for and Direct Mortality of Riparian Woodrat

Alternative 9 conservation measures would result in the permanent loss of up to 53 acres of habitat and temporary loss of up to 34 acres of habitat for riparian woodrat (Table 12-9-56). Construction of Alternative 9 water conveyance facilities (CM1) would not affect modeled habitat; however, tidal natural communities restoration (CM4) and seasonally inundated floodplain restoration (CM5) would remove habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Development of Alternative 9 water conveyance facilities would result in the permanent and temporary removal of approximately 3 acres of modeled habitat for riparian woodrat in CZ 8 (Table 12-9-56). The modeled habitat that would be removed is of low value for the riparian woodrat as it consists of several small, isolated patches surrounded by agricultural lands northeast of Clifton Court Forebay in CZ 8. Trapping efforts conducted for the riparian woodrat in this area were negative (BDCP Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*). Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations.
- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove approximately 10 acres of modeled habitat for the riparian woodrat in CZ 7. This habitat is of low value, consisting of a small, isolated patch surrounded by agricultural lands, and the species has a relatively low likelihood of being present in these areas. The measures described in *AMM25 Riparian Woodrat and Riparian Brush Rabbit*, require that tidal natural communities restoration avoid removal of any habitat occupied by the riparian woodrat as determined by presence/absence surveys. Because the estimates of habitat loss due to tidal inundation are based on projections of where restoration may occur, actual habitat loss is expected to be lower because sites would be selected to minimize effects on riparian woodrat.
- *CM5 Seasonally Inundated Floodplain Restoration*: Levee construction associated with floodplain restoration would result in the permanent removal of approximately 41 acres of modeled habitat for the riparian woodrat in CZ 7. The value of this habitat for riparian woodrat is moderate. Although the habitat consists of small patches and narrow bands of riparian vegetation and no riparian woodrats have detected in CZ 7, the riparian patches are in proximity to each other along the San Joaquin River. There are two species occurrences immediately south of CZ 7, one of which is less than 1.5 mile from the southernmost patch of riparian habitat potentially affected by levee construction.

  The final floodplain restoration design would differ from the hypothetical footprint used for this effects analysis. However, monitoring and adaptive management described in *CM11 Natural Communities Enhancement and Management a*nd AMM25 *Riparian Woodrat and Riparian Brush Rabbit* would ensure that riparian woodrat habitat permanently removed as a result of floodplain restoration does not exceed the amount estimated based on the hypothetical footprint. Habitat loss is expected to be lower than 41 acres because sites would be selected and restoration designed to minimize effects on the riparian woodrat. If natural flooding is insufficient to maintain appropriate riparian woodrat vegetation structure, the vegetation would be actively managed to provide suitable habitat structure as described in *CM11 Natural Communities Enhancement and Management.*

  Levee construction would also result in the temporary removal of 33 acres of modeled habitat for the riparian woodrat. Although the effects are considered temporary, 5 years to several decades may be required for ecological succession to occur and for restored riparian habitat to replace the function of habitat that has been affected.
- *CM11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in BDCP protected habitats may result in localized ground disturbances that could temporarily remove small

amounts of riparian woodrat habitat. Enhancement and management actions in riparian woodrat habitat within the reserve system may include invasive plant removal, planting and maintaining vegetation to improve and sustain habitat characteristics for the species, and creating and maintaining flood refugia. These activities are expected to have minor adverse effects on available riparian woodrat habitat and are expected to result in overall improvements to and maintenance of riparian woodrat habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized through the AMMs listed below.

- Operations and maintenance: The only ongoing effects on the riparian woodrat are those potentially resulting from habitat enhancement and management activities. Enhancement and management actions in riparian woodrat habitat within the reserve system may include invasive plant removal, planting and maintaining vegetation to improve and sustain habitat characteristics for the species, and creating and maintaining flood refugia. These activities may result in harassment of riparian woodrats through noise and visual disturbance which would be minimized with implementation of AMM1–AMM7, AMM10, and AMM25.

- Injury and direct mortality: Construction vehicle activity is not likely to result in injury or mortality of individual riparian woodrats because the species is not likely to be present in the areas that would be affected by this activity, based on live trapping results (BDCP Appendix 3.E, *Conservation Principles for the Riparian Woodrat and Riparian Brush Rabbit*). Tidal natural communities restoration would not result in injury or mortality of the riparian woodrats because under AMM25 tidal natural communities restoration projects would be designed to avoid occupied riparian woodrat habitat and if that is not possible to trap and relocate the species. Activities associated with construction of setback levees for floodplain restoration could result in injury or mortality of riparian woodrats; however, preconstruction surveys, construction monitoring, and other measures would be implemented under AMM25 to avoid and minimize injury or mortality of this species during construction, as described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*. If occupied riparian woodrat habitat cannot be avoided, mortality would be avoided through implementation of a trapping and relocation program. The program would be developed in coordination with USFWS, and relocation would be to a site approved by USFWS prior to construction activities.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

Near-Term Timeframe

Because water conveyance facilities construction is being evaluated at the project level, the near-term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction effects would not be adverse under NEPA.

Alternative 9 would result in permanent and temporary effects on 3 acres of modeled habitat for riparian woodrat in the near-term as a result of construction of the water conveyance facilities (CM1). The habitat would be lost in the valley/foothill riparian. All the near-term loss of riparian woodrat habitat would result from CM1 conveyance facility construction in CZ 8, and would occur in an area not likely to be occupied by the species. Habitat loss in CZ 7, in areas known or likely to be occupied, would occur during the early long-term and late long-term implementation periods.

Riparian restoration would be phased to minimize temporal habitat loss. There would be no near-term losses from CM2–CM18.

Typical NEPA project-level mitigation ratios for these natural communities that would be affected and that are identified in the biological goals and objectives for riparian woodrat in Chapter 3 of the BDCP would be 1:1 for restoration and 1:1 for protection of the valley/foothill riparian natural community. Using these ratios would indicate that 3 acres of riparian habitat should be restored and 3 acres of riparian habitat should be protected for riparian woodrat for near-term losses.

The BDCP has committed to near-term restoration of 800 acres of riparian (Objective VFRNC1.1) and protection of 750 acres of riparian (Objective VFRNC1.2) (Table 3-4 in Chapter 3, *Description of Alternatives*). In addition, the species-specific biological goals and objectives (RW1.1 and RW1.2) would inform the near-term protection and restoration efforts. The natural community restoration and protection activities are expected to be concluded during the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for NEPA purposes. These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be not be adverse under NEPA, because no riparian woodrat habitat would be lost and there is only limited potential for minor adverse effects on woodrats or its habitat from implementation of CM11.

These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized through the BDCP's commitment to *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM25 Riparian Woodrat and Riparian Brush Rabbit*. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The study area supports approximately 2,166 acres of modeled riparian woodrat habitat. Alternative 9 as a whole would result in the permanent loss of and temporary removal of 87 acres of modeled habitat for riparian woodrat habitat. None of this habitat is considered occupied.

The BDCP would restore 5,000 acres and protect 750 acres of valley/foothill riparian natural community, a portion of which is expected to consist of suitable riparian brush rabbit habitat (Objectives VFRNC1.1 and VFRNC1.2). Objective RW1.1 requires at least 300 acres of riparian habitat that meets the ecological requirements of the riparian woodrat (e.g., dense willow understory and oak overstory) and that is adjacent to or facilitates connectivity with existing occupied or potentially occupied habitat to be restored in CZ 7. The conserved habitat would also be part of a larger, more contiguous, and less patchy area of protected and restored riparian natural community than what currently exists in CZ 7 and would be contiguous with existing modeled riparian woodrat habitat. The species-specific objective further requires that the 300 acres of restored riparian habitat meet more specific ecological requirements of riparian woodrat (e.g., dense willow understory and oak overstory). Additionally, assuming the protected riparian natural community would provide riparian woodrat habitat proportional to the amount of modeled habitat in this natural community in the Plan Area (12% of the riparian natural community in the Plan Area is modeled riparian woodrat habitat), the protection of 750 acres of riparian natural community

(CM3) would provide an estimated 90 acres of protected riparian woodrat habitat that is comparable to or of higher value than existing modeled grassland habitat. All riparian protection would occur during the near-term period, to offset early riparian losses.

The BDCP would also create and maintain mounds, levee sections, or other high areas in restored and protected riparian areas (Objective RW1.2) that are designed specifically to provide flood refugia for the riparian woodrat (BDCP Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*). In addition, the restored floodplains would transition from areas that flood frequently (e.g., every 1 to 2 years) to areas that flood infrequently (e.g., every 10 years or more) (Objective L1.5): these infrequently flooded areas would provide refuge for the riparian woodrat during most years.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of valley/foothill riparian that could overlap with the species model, would result in the restoration of 300 acres of modeled habitat for riparian woodrat. In addition, protection of valley/foothill riparian could overlap with the species model and would result in the protection of 90 acres riparian woodrat modeled habitat.

Although there are no records of occurrences of the riparian woodrat in the study area, habitat restoration in CZ 7, in the vicinity of occurrences south of the study area, would increase opportunities for northward expansion of the species into the study area Implementation of Alternative 9 conservation measures is not expected to adversely affect the riparian woodrat for the following reasons.

- There are no riparian woodrat occurrences in the Plan Area.
- The habitat that would be removed consists of small patches that are of moderate value for the species.
- The habitat that would be removed permanently is a small proportion of the total habitat in the Plan Area (2%).
- Avoidance and minimization measures would be implemented to avoid injury or mortality of riparian woodrats, and to minimize loss of occupied habitat.
- Floodplain restoration would be designed to provide flood refugia so that flooding would not adversely affect any riparian woodrats that occupy restored floodplains.

NEPA Effects: Alternative 9 would provide a substantial benefit to the riparian woodrat through the net increase in available habitat and a net increase of habitat in protected status. These protected areas would be managed and monitored to support the species. The habitat that Alternative 9 would affect is currently unoccupied, and habitat removal is not expected to result in a discernible change in the abundance or distribution of riparian woodrats if they occupy study area habitats. Should the species be detected in the study area, implementation of AMM1–AMM7, AMM10, and AMM25 would avoid and minimize the effects of conservation component construction and implementation. Therefore, the loss of habitat and potential mortality of individuals would not have an adverse effect on riparian woodrat.

CEQA Conclusion:

Near-Term Timeframe

Because water conveyance facilities construction is being evaluated at the project level, the near-term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction impacts would be less than significant for CEQA purposes.

Alternative 9 would result in permanent and temporary effects on 3 acres of modeled habitat for riparian woodrat in the near-term as a result of construction of the water conveyance facilities (CM1). The habitat would be lost in the valley/foothill riparian. All the near-term loss of riparian woodrat habitat would result from CM1 conveyance facility construction in CZ 8, and would occur in an area not likely to be occupied by the species. Habitat loss in CZ 7, in areas known or likely to be occupied, would occur during the early long-term and late long-term implementation periods. Riparian restoration would be phased to minimize temporal habitat loss. There would be no near-term losses from CM2–CM18.

Typical CEQA project-level mitigation ratios for these natural communities that would be affected and that are identified in the biological goals and objectives for riparian woodrat in Chapter 3 of the BDCP would be 1:1 for restoration and 1:1 for protection of the valley/foothill riparian natural community. Using these ratios would indicate that 3 acres of riparian habitat should be restored and 3 acres of riparian habitat should be protected for riparian woodrat for near-term losses.

The BDCP has committed to near-term restoration of 800 acres of riparian (Objective VFRNC1.1) and protection of 750 acres of riparian (Objective VFRNC1.2) (Table 3-4 in Chapter 3, *Description of Alternatives*). In addition, the species-specific biological goals and objectives (RW1.1 and RW1.2) would inform the near-term protection and restoration efforts. The natural community restoration and protection activities are expected to be concluded during the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for CEQA purposes. The Plan also contains commitments to implement AMM1–AMM7, AMM10, and AMM25, which contain elements that avoid or minimize the risk of affected habitats and species adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be less than significant under CEQA, because no riparian woodrat habitat would be lost and there is only limited potential for minor adverse effects on woodrats or its habitat from implementation of CM11.

Late Long-Term Timeframe

The study area supports approximately 2,166 acres of modeled riparian woodrat habitat. Alternative 9 as a whole would result in the permanent loss of and temporary removal of 87 acres of modeled habitat for riparian woodrat habitat. None of this habitat is considered occupied.

The BDCP would restore 5,000 acres and protect 750 acres of valley/foothill riparian natural community, a portion of which is expected to consist of suitable riparian brush rabbit habitat (Objectives VFRNC1.1 and VFRNC1.2). Objective RW1.1 requires at least 300 acres of riparian habitat that meets the ecological requirements of the riparian woodrat (e.g., dense willow understory and oak overstory) and that is adjacent to or facilitates connectivity with existing occupied or potentially occupied habitat to be restored in CZ 7. The conserved habitat would also be part of a larger, more contiguous, and less patchy area of protected and restored riparian natural community than what currently exists in CZ 7 and would be contiguous with existing modeled riparian woodrat habitat. The species-specific objective further requires that the 300 acres of restored riparian habitat meet more specific ecological requirements of riparian woodrat (e.g., dense willow understory and oak overstory). Additionally, assuming the protected riparian natural community would provide riparian woodrat habitat proportional to the amount of modeled habitat in this natural community in the Plan Area (12% of the riparian natural community in the Plan Area is modeled riparian woodrat habitat), the protection of 750 acres of riparian natural community (CM3) would provide an estimated 90 acres of protected riparian woodrat habitat that is comparable to or of higher value than existing modeled grassland habitat. All riparian protection would occur during the near-term period, to offset early riparian losses.

The BDCP would also create and maintain mounds, levee sections, or other high areas in restored and protected riparian areas (Objective RW1.2) that are designed specifically to provide flood refugia for the riparian woodrat (BDCP Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*). In addition, the restored floodplains would transition from areas that flood frequently (e.g., every 1 to 2 years) to areas that flood infrequently (e.g., every 10 years or more) (Objective L1.5): these infrequently flooded areas would provide refuge for the riparian woodrat during most years.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of valley/foothill riparian that could overlap with the species model, would result in the restoration of 300 acres of modeled habitat for riparian woodrat. In addition, protection of valley/foothill riparian could overlap with the species model and would result in the protection of 90 acres riparian woodrat modeled habitat.

Although there are no records of occurrences of the riparian woodrat in the study area, habitat restoration in CZ 7, in the vicinity of occurrences south of the study area, would increase opportunities for northward expansion of the species into the study area Implementation of Alternative 9 conservation measures is not expected to adversely affect the riparian woodrat for the following reasons.

- There are no riparian woodrat occurrences in the Plan Area.
- The habitat that would be removed consists of small patches that are of moderate value for the species.
- The habitat that would be removed permanently is a small proportion of the total habitat in the Plan Area (2%).
- Avoidance and minimization measures would be implemented to avoid injury or mortality of riparian woodrats, and to minimize loss of occupied habitat.
- Floodplain restoration would be designed to provide flood refugia so that flooding would not adversely affect any riparian woodrats that occupy restored floodplains.

Alternative 9 would provide a substantial benefit to the riparian woodrat through the net increase in available habitat and a net increase of habitat in protected status. These protected areas would be managed and monitored to support the species. The affected habitat is currently unoccupied and habitat removal is not expected to result in a discernible change in the abundance or distribution of riparian woodrats if they occupy study area habitats. Should the species be detected in the study area, implementation of AMM1–AMM7, AMM10, and AMM25 would avoid and minimize the effects of conservation component construction and implementation. Therefore, the loss of habitat and potential mortality of individuals under Alternative 9 would not have a significant impact on riparian woodrat.

Impact BIO-156: Indirect Effects of Plan Implementation on Riparian Woodrat

Noise, lighting, and visual disturbance adjacent to construction activities could indirectly affect the use of modeled habitat for riparian woodrat. These effects are related construction activities associated with water conveyance construction, tidal natural communities restoration construction, and construction of setback levees. Indirect effects on the species from construction associated with tidal natural communities restoration are unlikely because tidal natural communities restoration projects would be sited to avoid areas occupied by riparian woodrat (AMM25). The activity most likely to result in noise, lighting, and visual disturbance to riparian woodrat would be the construction of setback levees. These adverse effects would be minimized through implementation of AMM1–AMM7, AMM10, and AMM25.

NEPA Effects: Implementation of the AMMs listed above as part of implementing Alternative 9 would avoid the potential for substantial adverse effects on riparian woodrats, either indirectly or through habitat modifications or result in a substantial reduction in numbers or a restriction in the range of riparian woodrats. Therefore, indirect effects of Alternative 9 would not have an adverse effect on riparian woodrat.

CEQA Conclusion: Should the species be detected in the study area, indirect effects of conservation measure construction and implementation could impact riparian woodrat and its habitat. AMM1–AMM7, AMM10, and AMM25 would avoid and minimize the impact.

Impact BIO-157: Periodic Effects of Inundation of Riparian Woodrat Habitat as a Result of Implementation of Conservation Components

CM5 Seasonally inundated floodplain restoration is the only covered activity expected to result in periodic inundation of riparian woodrat habitat. Floodplain restoration would result in periodic inundation of up to 203 acres of riparian woodrat habitat (9% of the riparian woodrat habitat in the Plan Area). The area between existing levees that would be breached and the newly constructed setback levees would be inundated through seasonal flooding. The potentially inundated areas consist of moderate-value habitat for the species. Although the habitat consists of small patches and narrow bands of riparian vegetation and no riparian woodrats have detected in CZ 7, the riparian patches are in proximity to each other along the San Joaquin River and there are two species occurrences immediately south of CZ 7, one of which is less than 1 mile from the southernmost patch of riparian habitat potentially affected by levee construction. The restored floodplains would transition from areas that flood frequently (e.g., every 1 to 2 years) to areas that flood infrequently (e.g., every 10 years or more).

***NEPA Effects*:** Alternative 9's periodic inundation of 203 acres of riparian habitat is not expected to result in substantial adverse effects on riparian woodrat, either directly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of riparian woodrat. The effects of periodic inundation on the riparian woodrat would be minimized through construction and maintenance of flood refugia to allow riparian woodrats to escape inundation. Therefore, the periodic inundation of riparian woodrat habitat would not adversely affect the species under Alternative 9.

CEQA Conclusion: Floodplain restoration under CM5 would periodically affect a total of 203 acres of riparian habitat for riparian woodrat, representing 9% of the 2,166 acres of modeled riparian woodrat habitat in the study area. The impact of periodic inundation on the riparian woodrat would be minimized through construction and maintenance of flood refugia to allow riparian woodrats to escape inundation, as described in AMM25. Implementation of CM5 would not be expected to result in significant impacts on riparian woodrat, either directly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of riparian woodrats. Periodic inundation of riparian woodrat habitat under Alternative 9 would have a less-than-significant impact.

Salt Marsh Harvest Mouse

The habitat model used to assess effects for the salt marsh harvest mouse includes six habitat types: primary tidal marsh habitat, secondary tidal marsh habitat (low marsh), secondary upland habitat adjacent to tidal marsh habitat, primary habitat within managed wetlands, secondary habitat within managed wetlands (dominated by plants characteristic of low marsh), and upland habitats within managed wetland boundaries. The tidal and managed wetland habitats were discriminated recognizing that regardless of habitat value, managed wetlands are at high risk of catastrophic flooding and have lower long-term conservation value than tidal wetlands.

Construction and restoration associated with Alternative 9 conservation measures would result in effects to modeled salt marsh harvest mouse habitat, which would include permanent losses and habitat conversions (i.e., existing habitat converted to greater or lesser valued habitat for the species post-restoration) as indicated in Table 12-9-57. All of the effects to the species would take place over an extended period of time as tidal marsh is restored in the Plan Area. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit salt marsh harvest mouse (BDCP Chapter 3, *Conservation Strategy*).

- Restore or create 6,000 acres of tidal brackish emergent wetland in CZ 11 to be consistent with the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (Objective TBEWNC1.1, associated with CM4)
- Within the 6,000 acres of tidal brackish emergent wetland restored or created, distribute 1,500 acres of middle and high marsh (primary salt marsh harvest mouse habitat) to contribute to total (existing and restored) acreage targets for each complex as specified in the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (Objective TBEWNC1.2, associated with CM4).
- Limit perennial pepperweed to no more than 10% cover in the tidal brackish emergent wetland natural community within the reserve system (Objective TBEWNC2.1).
- Protect and enhance at least 1,500 acres of managed wetland in Grizzly Island Marsh Complex for the benefit of salt marsh harvest mouse (Objective MWNC1.1, associated with CM3).
- Protect or restore grasslands adjacent to restored tidal brackish emergent wetlands to provide at least 200 feet of adjacent grasslands beyond the sea level rise accommodation area (Objective GNC1.4, associated with CM3 and CM8).

- Provide viable habitat areas for salt marsh harvest mouse within the 1,500 acres of restored or created middle and high marsh as defined in the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (Objective SMHM1.1).
- Provide viable habitat areas for salt marsh harvest mouse within the 1,500 acres of managed wetland protected and enhanced in the Grizzly Island Marsh Complex as defined in the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California, and increase population levels above the current baseline (Objective SMHM1.2).

As explained below, with the restoration or protection of these amounts of habitat, impacts on the salt marsh harvest mouse would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-57. Changes in Salt Marsh Harvest Mouse Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only.

TBEW = tidal brackish emergent wetland
MW = managed wetland
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-158: Loss or Conversion of Habitat for and Direct Mortality of Salt Marsh Harvest Mouse

BDCP tidal restoration (CM4) would be the only conservation measure resulting in effects on salt marsh harvest mouse habitat. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. Each of these activities is described in detail below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM4 Tidal Natural Communities Restoration* would result in effects to 6,968 acres of salt marsh harvest mouse modeled habitat, which would include 5,376 acres of permanent losses and 1,592acres of habitat conversions. Salt marsh harvest mouse may be displaced temporarily from areas of converted habitat but these areas would ultimately provide suitable habitat for the species. However, 1,058 of these acres would be downgraded from primary habitat (67 acres of primary tidal brackish emergent wetland and 991 acres of primary managed wetland) to secondary tidal brackish emergent wetland. The hypothetical restoration footprints in Suisun Marsh overlap with 13 CNDDB records for salt marsh harvest mouse (California Department of Fish and Wildlife 2013); however, the BDCP's conservation actions assume that all suitable habitat in Suisun Marsh is occupied by the species.
- *CM11 Natural Communities Enhancement and Management:* As described in the BDCP, the restoration of at least 1,500 acres of tidal brackish emergent wetland would be managed to provide viable habitat for salt marsh harvest mouse and the protection of 1,500 acres of managed wetland specifically to be managed for salt marsh harvest mouse. A variety of habitat management actions included in *CM11 Natural Communities Enhancement and Management* that are designed to enhance and manage these areas for salt marsh harvest mouse and may result in localized ground disturbances that could temporarily remove small amounts of salt marsh harvest mouse habitat. The restoration of tidal brackish emergent wetlands, the protection of managed wetlands, and the protection and/or restoration of grasslands within 200 feet of restored salt marsh harvest mouse habitat would also have enhancement and management actions that would include invasive species control, nonnative wildlife control, and vegetation management. Ground-disturbing activities, such as removal of nonnative vegetation are expected to have minor effects on habitat and are expected to result in overall improvements to and maintenance of salt marsh harvest mouse habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.
- Injury and Direct Mortality: The use of heavy equipment and handtools may result in injury or mortality to salt marsh harvest mouse during restoration, enhancement, and management activities. However, preconstruction surveys, construction monitoring, and other measures would be implemented to avoid and minimize injury or mortality of this species during these activities, as required by the AMMs listed below.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

The near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of near-term covered activities would not be adverse under NEPA. Alternative 9 would affect 2,465 acres of salt marsh harvest mouse modeled habitat in the study area in the near-term. These effects include 1,517 acres of permanent loss and 948 acres of converted habitat. Most of the habitat converted would be from primary habitats (599 acres consisting of 64 acres of tidal brackish emergent wetland and 534 acres of managed wetland) to secondary tidal brackish emergent wetland.

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal brackish emergent wetland, the protection and/or restoration of grasslands within 200 feet of restored tidal wetlands, and the protection and enhancement of 1,500 acres of managed wetlands for salt marsh harvest mouse. Though there would be a net loss of modeled habitat, nearly all of these losses (97%) are to managed wetlands, which according to the U.S. Fish and Wildlife Service are at high risk of catastrophic flooding (U.S. Fish and Wildlife Service 2010) and have lower long-term conservation value than tidal wetlands. The species-specific biological goals and objectives would inform the near-term protection and restoration efforts. These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of protection and restoration contained in the near-term Plan goals would keep pace with the loss of habitat and effects to salt marsh harvest mouse.

Other factors relevant to effects on salt marsh harvest mouse are listed here.

- Tidal restoration actions would not immediately displace salt marsh harvest mouse in managed wetlands as noted in the specie's draft recovery plan because the conversion of managed wetland to tidal marsh would be gradual. Tidal marsh restoration is often accomplished by breaching levees and converting diked nontidal marsh currently occupied by salt marsh harvest mouse populations to tidal wetlands, their historic condition. Conversion of these subsided areas requires sedimentation and accretion over time to restore marsh plains, resulting in a prolonged period (sometimes a decade or more) in which resident mice populations are displaced by uninhabitable aquatic areas (U.S. Fish and Wildlife Service 2010). Despite these temporary adverse effects, the draft recovery plan and Suisun Marsh Plan advocate strongly for restoration of tidal wetlands through the conversion of managed wetlands. These plans are based on the premise that managed wetlands are at high risk of loss of salt marsh harvest mouse habitat from a variety of factors, including flooding from levee failure and cessation of active management (which is often necessary to maintain habitat values in managed wetlands). Therefore, the temporary effects under BDCP would be consistent with those deemed acceptable in the draft recovery plan for salt marsh harvest mouse and the Suisun Marsh Plan. Restoration in Suisun Marsh would be carefully phased over time to offset adverse effects of restoration as it occurs. This phasing would ensure that temporal loss as a result of tidal natural communities restoration does not adversely affect the salt marsh harvest mouse population, ensure that short-term population loss is relatively small and incremental, and maintain local source populations to recolonize newly restored areas. The tidal restoration projects in Suisun Marsh would be implemented in 150-acre or greater patches that provide viable habitat areas for the salt marsh harvest mouse habitat consistent with the draft tidal marsh recovery plan (U.S. Fish and Wildlife Service 2010).

- The salt marsh harvest mouse population would be monitored during the phasing process (see BDCP Chapter 3, Section 3.4.4.3.4,), and adaptive management would be applied to ensure maintenance of the population as described in the BDCP (BDCP Chapter 3, Section 3.4.4.4 and Section 3.6).

- The BDCP commits to manage reserve areas so that perennial pepperweed cover is no more than 10% in tidal brackish emergent wetlands (Objective TBEWNC2.1), which would benefit pickleweed production in the marsh. Salt marsh harvest mouse depends on pickleweed for forage and cover.

Because there would be no project-level impacts on salt marsh harvest mouse resulting from CM1, the analysis of the effects and conservation actions does not include a comparison with standard ratios used for project-level NEPA analyses.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan*, and *AMM26 Salt Marsh Harvest Mouse and Suisun Shrew*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 35,588 acres of salt marsh harvest mouse modeled habitat. Alternative 9 as a whole would result in effects to 6,968 acres of saltmarsh harvest mouse modeled habitat over the term of the Plan, which would include 5,376 acres of permanent losses and 1,592 acres of habitat conversions. These effects (loss and conversion) would be on 20% of the modeled habitat in the study area. Most of these effects (99%) would be to managed wetlands, which though are known to be occupied by salt marsh harvest mouse are at high risk of catastrophic flooding and have a lower long-term conservation value than tidal wetlands (U.S. Fish and Wildlife Service 2010). Effects on up to 20% of the species' habitat in the Plan Area may diminish the salt marsh harvest mouse population in the Plan Area and result in reduced genetic diversity, thereby putting the local population at risk of local extirpation due to random environmental fluctuations or catastrophic events. This effect is expected to be greatest if large amounts of habitat are removed at one time in Suisun Marsh and are not effectively restored for many years, and if there are no adjacent lands with salt marsh harvest mouse populations to recolonize restored areas.

The Plan includes a commitment to restore or create 6,000 acres of tidal brackish emergent wetland, 1,500 acres of which would target middle and high marsh habitat (primary habitat for salt marsh harvest mouse) (TBEWNC1.1, TBEWNC1.2, SMHM1.1, associated with CM4), the protection of 6,500 acres of managed wetlands, 1,500 acres of which would be specifically managed for salt marsh harvest mouse (SMHM1.2 and MWNC1.1, associated with CM3), and the protection and/or restoration of grassland adjacent to tidal restoration (areas within 200 feet of tidal restoration) to provide upland refugia for salt marsh harvest mouse (GNC1.4, associated with CM3 and CM8). Other factors relevant to effects on salt marsh harvest mouse include:

- Tidal restoration actions would not immediately displace salt marsh harvest mouse in managed wetlands as noted in the draft recovery plan for salt marsh harvest mouse because the conversion of managed wetland to tidal marsh would be gradual. Tidal marsh restoration is often accomplished by breaching levees and converting diked nontidal marsh currently occupied by salt marsh harvest mouse populations to tidal wetlands, their historic condition. Conversion of these subsided areas requires sedimentation and accretion over time to restore marsh plains, resulting in a prolonged period (sometimes a decade or more) in which resident mice populations are displaced by uninhabitable aquatic areas (U.S. Fish and Wildlife Service 2010). Despite these temporary adverse effects, the draft recovery plan and Suisun Marsh Plan advocate strongly for restoration of tidal wetlands through the conversion of managed wetlands. These plans are based on the premise that managed wetlands are at high risk of loss of salt marsh harvest mouse habitat from a variety of factors, including flooding from levee failure and cessation of active management (which is often necessary to maintain habitat values in managed wetlands). Therefore, the temporary effects under BDCP are consistent with those deemed acceptable in the draft recovery plan for salt marsh harvest mouse and the Suisun Marsh Plan.

- In order to ensure that temporal loss as a result of tidal natural communities restoration does not adversely affect the salt marsh harvest mouse population, restoration in Suisun Marsh would be carefully phased over time to offset adverse effects of restoration as it occurs, ensure that short-term population loss is relatively small and incremental, and maintain local source populations to recolonize newly restored areas. The tidal restoration projects in Suisun Marsh would be implemented in 150-acre or greater patches that provide viable habitat areas for the salt marsh harvest mouse habitat consistent with the draft tidal marsh recovery plan (U.S. Fish and Wildlife Service 2010).
- The salt marsh harvest mouse population would be monitored during the phasing process (see BDCP Chapter 3, Section 3.4.4.3.4,), and adaptive management would be applied to ensure maintenance of the population as described in the BDCP (BDCP Chapter 3, Section 3.4.4.4 and Section 3.6).
- The BDCP commits to manage reserve areas so that perennial pepperweed cover is no more than 10% in tidal brackish emergent wetlands (Objective TBEWNC2.1), which would benefit pickleweed production in the marsh. Salt marsh harvest mouse depends on pickleweed for forage and cover.
- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value, which is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 6,046 acres and the protection of 1,550 acres of modeled habitat for salt marsh harvest mouse.

NEPA Effects: In the absence of other conservation actions, the effects on salt marsh harvest mouse habitat from Alternative 9 would represent an adverse effect as a result of habitat modification and potential direct mortality of a special-status species. However, the BDCP has committed to habitat protection, restoration, management, and enhancement associated with CM3, CM4, CM8, and CM11. This habitat protection, restoration, management, and enhancement would be guided by species-specific goals and objectives and by AMM1–AMM5 and AMM26, which would be in place throughout the construction period. Considering these commitments, losses and conversions of salt marsh harvest mouse habitat and potential mortality of individuals in the near-term and late long-term under Alternative 9 would not be an adverse effect.

CEQA Conclusion:

Near-Term Timeframe

The near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of near-term covered activities would be less than significant under CEQA. Alternative 9 would affect 2,465 acres of salt marsh harvest mouse modeled habitat in the study area in the near-term. These effects include 1,517 acres of permanent loss and 948 acres of converted habitat. Most of the habitat converted would be to primary habitats (599 acres consisting of 64 acres of tidal brackish emergent wetland and 534 acres of managed wetland) to secondary tidal brackish emergent wetland.

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal brackish emergent wetland, the protection and/or restoration of grasslands within 200 feet of restored tidal wetlands, and the protection and enhancement of 3,200 acres of managed wetlands for salt marsh harvest mouse. Though there would be a net loss of modeled habitat, nearly all of these losses (97%) are to managed wetlands, which according to the U.S. Fish and Wildlife Service are at high risk of catastrophic flooding (U.S. Fish and Wildlife Service 2010) and have lower long-term conservation value than tidal wetlands. The species-specific biological goals and objectives would inform the near-term protection and restoration efforts. These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of protection and restoration contained in the near-term Plan goals would keep pace with the loss of habitat and effects to salt marsh harvest mouse habitat.

Other factors relevant to effects on salt marsh harvest mouse are listed here.

- Tidal restoration actions would not immediately displace salt marsh harvest mouse in managed wetlands as noted in the specie's draft recovery plan because the conversion of managed wetland to tidal marsh occurs be gradual. Tidal marsh restoration is often accomplished by breaching levees and converting diked nontidal marsh currently occupied by salt marsh harvest mouse populations to tidal wetlands, their historic condition. Conversion of these subsided areas requires sedimentation and accretion over time to restore marsh plains, resulting in a prolonged period (sometimes a decade or more) in which resident mice populations are displaced by uninhabitable aquatic areas (U.S. Fish and Wildlife Service 2010). Despite these temporary adverse effects, the draft recovery plan and Suisun Marsh Plan advocate strongly for restoration of tidal wetlands through the conversion of managed wetlands. These plans are based on the premise that managed wetlands are at high risk of loss of salt marsh harvest mouse habitat from a variety of factors, including flooding from levee failure and cessation of active management (which is often necessary to maintain habitat values in managed wetlands). Therefore, the temporary effects under BDCP would be consistent with those deemed acceptable in the draft recovery plan for salt marsh harvest mouse and the Suisun Marsh Plan.

- To ensure that temporal loss as a result of tidal natural communities restoration does not adversely affect the salt marsh harvest mouse population, restoration in Suisun Marsh would be carefully phased over time to offset adverse effects of restoration as it occurs, ensure that short-term population loss is relatively small and incremental, and maintain local source populations to recolonize newly restored areas. The tidal restoration projects in Suisun Marsh would be implemented in 150-acre or greater patches that provide viable habitat areas for the salt marsh harvest mouse habitat consistent with the draft tidal marsh recovery plan (U.S. Fish and Wildlife Service 2010).

- The salt marsh harvest mouse population would be monitored during the phasing process (see BDCP Chapter 3, Section 3.4.4.3.4,), and adaptive management would be applied to ensure maintenance of the population as described in the BDCP (BDCP Chapter 3, Section 3.4.4.4 and Section 3.6).
- The BDCP commits to manage reserve areas so that perennial pepperweed cover is no more than 10% in tidal brackish emergent wetlands (Objective TBEWNC2.1), which would benefit pickleweed production in the marsh. Salt marsh harvest mouse depends on pickleweed for forage and cover.

Because there would be no project level impacts on salt marsh harvest mouse resulting from CM1, the analysis of the effects and conservation actions does not include a comparison with standard ratios used for project level CEQA analyses.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan*, and *AMM26 Salt Marsh Harvest Mouse and Suisun Shrew*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be less than significant under CEQA.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 35,588 acres of salt marsh harvest mouse modeled habitat. Alternative 9 as a whole would result in effects to 6,968 acres of saltmarsh harvest mouse modeled habitat over the term of the Plan, which would include 5,376 acres of permanent losses and 1,592 acres of habitat conversions. The Plan includes a commitment to restore or create 6,000 acres of tidal brackish emergent wetland, 1,500 acres of which would target middle and high marsh habitat (primary habitat for salt marsh harvest mouse) (TBEWNC1.1, TBEWNC1.2, SMHM1.1, associate with CM4); the protection of 6,500 acres of managed wetlands, 1,500 acres of which would be specifically managed for salt marsh harvest mouse (SMHM1.2 and MWNC1.1, associated with CM3), and the protection and/or restoration of grassland adjacent to tidal restoration (areas within 200 feet of tidal restoration) to provide upland refugia for salt marsh harvest mouse (GNC1.4, associated with CM3 and CM8). Other factors relevant to effects on salt marsh harvest mouse include:

- Tidal restoration actions would not immediately displace salt marsh harvest mouse in managed wetlands as noted in the draft recovery plan for salt marsh harvest mouse because the conversion of managed wetland to tidal marsh would be gradual. Tidal marsh restoration is often accomplished by breaching levees and converting diked nontidal marsh currently occupied by salt marsh harvest mouse populations to tidal wetlands, their historic condition. Conversion of these subsided areas requires sedimentation and accretion over time to restore marsh plains, resulting in a prolonged period (sometimes a decade or more) in which resident mice populations are displaced by uninhabitable aquatic areas (U.S. Fish and Wildlife Service

2010). Despite these temporary adverse effects, the draft recovery plan and Suisun Marsh Plan advocate strongly for restoration of tidal wetlands through the conversion of managed wetlands. These plans are based on the premise that managed wetlands are at high risk of loss of salt marsh harvest mouse habitat from a variety of factors, including flooding from levee failure and cessation of active management (which is often necessary to maintain habitat values in managed wetlands). Therefore, the temporary effects under BDCP are consistent with those deemed acceptable in the draft recovery plan for salt marsh harvest mouse and the Suisun Marsh Plan.

- In order to ensure that temporal loss as a result of tidal natural communities restoration does not adversely affect the salt marsh harvest mouse population, restoration in Suisun Marsh would be carefully phased over time to offset adverse effects of restoration as it occurs, ensure that short-term population loss is relatively small and incremental, and maintain local source populations to recolonize newly restored areas. The tidal restoration projects in Suisun Marsh would be implemented in 150-acre or greater patches that provide viable habitat areas for the salt marsh harvest mouse habitat consistent with the draft tidal marsh recovery plan (U.S. Fish and Wildlife Service 2010).

- The salt marsh harvest mouse population would be monitored during the phasing process (see BDCP Chapter 3, Section 3.4.4.3.4,), and adaptive management would be applied to ensure maintenance of the population as described in the BDCP (BDCP Chapter 3, Section 3.4.4.4 and Section 3.6).

- The BDCP commits to manage reserve areas so that perennial pepperweed cover is no more than 10% in tidal brackish emergent wetlands (Objective TBEWNC2.1), which would benefit pickleweed production in the marsh. Salt marsh harvest mouse depends on pickleweed for forage and cover.

- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value, which is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 6,046 acres and the protection of 1,550 acres of modeled habitat for salt marsh harvest mouse.

Alternative 9 would result in substantial modifications to salt marsh harvest mouse habitat in the absence of other conservation actions. However, with habitat protection, restoration, management, and enhancement associated with CM3, CM4, CM8 and CM11, guided by species-specific goals and objectives and by AMM1–AMM5 and AMM26, which would be in place throughout the construction period, Alternative 9 over the term of the BDCP would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the alternative would have a less-than-significant impact on salt marsh harvest mouse.

Impact BIO-159: Indirect Effects of Plan Implementation on Salt Marsh Harvest Mouse

Construction/disturbance activities associated tidal restoration (CM4), grassland restoration (CM8), and management and enhancement activities (CM11) could result in temporary noise and visual disturbances to salt marsh harvest mouse occurring within 100 feet of these areas over the term of the BDCP. These potential effects would be minimized or avoided through AMM1–AMM5, and AMM26, which would be in effect throughout the term of the Plan.

The use of mechanical equipment during the implementation of the conservation measures could cause the accidental release of petroleum or other contaminants that could affect salt marsh harvest mouse and its habitat. The inadvertent discharge of sediment could also have a negative effect on the species and its habitat. AMM1–AMM5 would minimize the likelihood of such spills and would ensure measures are in place to prevent runoff from the construction area and potential effects of sediment on salt marsh harvest mouse.

Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury. In general, the highest methylation rates are associated with high tidal marshes that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). High tidal marsh is considered to be primary habitat for salt marsh harvest mouse and thus the species could be exposed to methyl mercury in tidal restoration areas. Salt marsh harvest mouse may be exposed to elemental mercury by feeding on pickleweed, which is found concentrated in the distal tips of pickleweed leaves (Yee et. al., 2008). Though elemental mercury is less bioavailable than methylmercury, studies have shown that mercury can become methylated in the anaerobic portions of the intestinal tract (Rudd et al. 1980, Rieder et al. 2013) and could thus become a pathway for salt marsh harvest exposure to methylmercury. A study of small mammals residing in pickleweed around the San Francisco Bay showed an absence of salt marsh harvest mouse where mercury concentrations measured in house mice (*Mus musculus*) livers were ≥0.19 µg/g (dry weight) (Clark et al. 1992). Clark et al (1992) also report that the lack of salt marsh harvest mouse at these locations are not the result of undetected habitat differences or are by chance. Clarke et al (1992) suggest that the absence of salt marsh harvest mouse at certain locations may be associated with higher amounts of mercury and polychlorinated biphenyls (PCBs); however, because their study didn’t analyze contaminants in salt marsh harvest mouse and because (at that time) there was no data in the literature on contaminants in harvest mice, they could not make conclusions on these associations. Currently, it is unknown what the exact exposure pathways are or what tissue concentrations are harmful to the salt marsh harvest mouse.

The Suisun Marsh Plan (Bureau of Reclamation et al. 2010) anticipates that tidal wetlands restored under the plan would generate less methylmercury than the existing managed wetlands. The potential for salt marsh harvest mouse exposure to methyl mercury in Suisun Marsh may decrease in the long term because the creation of tidal brackish emergent wetland would predominantly result from the conversion of managed wetlands. *CM12 Methylmercury Management* includes provisions for project-specific Mercury Management Plans. Along with avoidance and minimization measures and adaptive management and monitoring, CM12 could reduce the effects of methylmercury on salt marsh harvest mouse resulting from BDCP tidal restoration.

NEPA Effects: Implementation of the AMMs listed above as part of implementing Alternative 9 would avoid and minimize indirect effects on salt marsh harvest mouse. These AMMs would also avoid and minimize effects that could substantially reduce the number of salt marsh harvest mouse, or restrict the species’ range. Therefore, the indirect effects of Alternative 9 would not have an adverse effect on salt marsh harvest mouse.

CEQA Conclusion: Indirect effects from construction-related noise and visual disturbances could impact salt marsh harvest mouse within 100 feet of these disturbances. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could impact salt marsh harvest mouse and its habitat. The inadvertent discharge of sediment adjacent to salt marsh harvest mouse habitat could also impact the species. With implementation of AMM1–AMM5 and AMM26 as part of Alternative 9 construction, operation and maintenance, the BDCP would avoid the potential for substantial adverse effects on salt marsh harvest mouse, either indirectly or through habitat modifications, in that the BDCP would not result in a substantial reduction in numbers or a restriction in the range of salt marsh harvest mouse. The indirect effects of Alternative 9 would have a less-than-significant impact on salt marsh harvest mouse.

Salt marsh harvest mouse could experience indirect effects from increased exposure to methylmercury as a result of tidal habitat restoration (CM4). With implementation of CM12, the potential indirect effects of methlymercury would not result in a substantial reduction in numbers or a restriction in the range of salt marsh harvest mouse, and, therefore, would have a less-than-significant impact on the species.

Suisun Shrew

Primary Suisun shrew habitat consists of all *Salicornia*-dominated natural seasonal wetlands and certain *Scirpus* and *Typha* communities found within Suisun Marsh only. Low marsh dominated by *Schoenoplectus acutus* and *S. californicus* and upland transitional zones within 150 feet of the tidal wetland edge were classified separately as secondary habitat because they are used seasonally (Hays and Lidicker 2000). All managed wetlands were excluded from the habitat model. Construction and restoration associated with Alternative 9 conservation measures would result in effects to modeled Suisun shrew habitat, which would include permanent losses and habitat conversions (i.e., existing habitat converted to greater or lesser valued habitat for the species post-restoration) as indicated in Table 12-9-58. All of the effects on the species would take place over an extended period of time as tidal marsh is restored in the Plan Area. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit Suisun shrew (BDCP Chapter 3, *Conservation Strategy*).

- Restore or create 6,000 acres of tidal brackish emergent wetland in CZ 11 to be consistent with the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (TBEWNC1.1, associated with CM4)
- Within the 6,000 acres of tidal brackish emergent wetland restored or created, distribute 1,500 acres of middle and high marsh (primary Suisun shrew habitat) to contribute to total (existing and restored) acreage targets for each complex as specified in the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (TBEWNC1.2, associated with CM4).
- Limit perennial pepperweed to no more than 10% cover in the tidal brackish emergent wetland natural community within the reserve system (TBEWNC2.1).
- Protect or restore grasslands adjacent t restored tidal brackish emergent wetlands to provide at least 200 feet of adjacent grasslands beyond the sea level rise accommodation area, which provides refugia during high tides (GNC1.4, associated with CM3 and CM8).

As explained below, with the restoration or protection of these amounts of habitat, impacts on the Suisun shrew would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-58. Changes in Suisun Shrew Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-160: Loss or Conversion of Habitat for and Direct Mortality of Suisun shrew

BDCP tidal restoration (CM4) would be the only conservation measure resulting in loss of habitat to Suisun shrew. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. Each of these activities is described in detail below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM4 Tidal Natural Communities Restoration* would result in effects to 401 acres of Suisun shrew modeled habitat, which would include 377 acres of permanent losses and 24 acres of habitat conversions. Suisun shrew may be displaced temporarily from areas of converted habitat but would ultimately provide suitable habitat for the species. However, all 24 acres would be converted from secondary to primary habitat and therefore over would be a net benefit to the species. The hypothetical restoration footprints overlap with two CNDDB records for Suisun shrew (California Department of Fish and Wildlife 2013).

- *CM11 Natural Communities Enhancement and Management:* As described in the BDCP, the restoration of at least 6,000 acres of tidal brackish emergent wetland would be managed to provide habitat for covered species, including Suisun shrew. A variety of habitat management actions included in *CM11 Natural Communities Enhancement and Management* that are designed to enhance and manage these areas may result in localized ground disturbances that could temporarily remove small amounts of Suisun shrew habitat. The areas of grasslands that would be protected and/or restored within 200 feet of restored tidal marsh would also have enhancement and management actions that would include invasive species control, nonnative wildlife control, and vegetation management. Ground-disturbing activities, such as removal of

nonnative vegetation are expected to have minor effects on habitat and are expected to result in overall improvements to and maintenance of Suisun shrew habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.

- Injury and Direct Mortality: The use of heavy equipment and handtools may result in injury or mortality to Suisun shrew during restoration, enhancement, and management activities. However, preconstruction surveys, construction monitoring, and other measures would be implemented to avoid and minimize injury or mortality of this species during these activities, as required by the AMMs listed below.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

The near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of near-term covered activities would not be adverse under NEPA. Alternative 9 would affect 105 acres of Suisun shrew modeled habitat in the study area in the near-term. These effects include 90 acres of permanent loss and 15 acres of converted habitat, which is all secondary habitat being converted to primary habitat.

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal brackish emergent wetland and the protection and/or restoration of grasslands within 200 feet of restored tidal wetlands, of which approximately 150 feet of this area would benefit the species. These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of tidal restoration and the commitment to protection of adjacent uplands contained in the near-term Plan goals would keep pace with the loss of habitat and effects to Suisun shrew.

Other factors relevant to effects on Suisun shrew are listed below.

- Restoration would be sequenced and oriented in a manner that minimizes any temporary, initial loss of habitat and habitat fragmentation.
- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value and quantity, with is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.
- The amount of tidal habitat restored in the near term (2,000 acres) greatly exceeds the amount permanently lost (105 acres).

Because there would be no project level impacts on Suisun shrew from CM1, the analysis of the effects and conservation actions does not include a comparison to standard ratios used for project level NEPA analyses.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and*

Countermeasure Plan, and *AMM26 Salt Marsh Harvest Mouse and Suisun Shrew*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 7,515 acres of Suisun shrew modeled habitat. Alternative 9 as a whole would result in effects on 401 acres of Suisun shrew modeled habitat over the term of the Plan, which would include 377 acres of permanent losses and 24 acres of habitat conversions (roughly 5% of the habitat in the study area).

The Plan includes a commitment to restore or create 6,000 acres of tidal brackish emergent wetland, 1,500 acres of which would target middle and high marsh habitat (primary habitat for Suisun shrew) (Objectives TBEWNC1.1, TBEWNC1.2, SMHM1.1, associated with CM4) and the protection and/or restoration of grassland adjacent to tidal restoration (areas within 200 feet of tidal restoration, of which approximately 150 feet would likely benefit the species) to provide upland refugia for Suisun shrew (Objectives GNC1.4, associated with CM3 and CM8). Other factors relevant to effects on Suisun shrew are listed below.

- Restoration would be sequenced and oriented in a manner that minimizes any temporary, initial loss of habitat and habitat fragmentation.
- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value and quantity, with is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.

The amount of tidal habitat restored (6,000 acres) greatly exceeds the amount permanently lost and converted (401 acres). The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 6,006 acres and the protection of 232 acres of modeled habitat for Suisun shrew.

NEPA Effects: In the absence of other conservation actions, the effects on Suisun shrew habitat from Alternative 9 would represent an adverse effect as a result of habitat modification and potential for direct mortality of a special-status species. However, the BDCP has committed to habitat protection, restoration, management, and enhancement with CM3, CM4, CM8, and CM11. This habitat protection, restoration, management, and enhancement would be guided by biological goals and objectives and by AMM1–AMM5 and AMM26, which would be in place throughout the construction period. Considering these commitments, losses and conversions of Suisun shrew habitat and potential mortality of individuals in the near-term and late long-term under Alternative 9 would not be an adverse effect.

CEQA Conclusion:

Near-Term Timeframe

The near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of near-term covered activities would be less than significant under CEQA. Alternative 9 would affect 105 acres of Suisun shrew modeled habitat in the study area in the near-term. These effects include 90 acres of permanent loss and 15 acres of converted habitat, which is all secondary habitat being converted to primary habitat.

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal brackish emergent wetland and the protection and/or restoration of grasslands within 200 feet of restored tidal wetlands, of which approximately 150 feet of this area would benefit the species. These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of tidal restoration and the commitment to protection of adjacent uplands contained in the near-term Plan goals would keep pace with the loss of habitat and effects to Suisun shrew.

Other factors relevant to effects on Suisun shrew are listed below.

- Restoration would be sequenced and oriented in a manner that minimizes any temporary, initial loss of habitat and habitat fragmentation.
- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value and quantity, with is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.
- The amount of tidal habitat restored in the near term (2,000 acres) greatly exceeds the amount permanently lost (105 acres).

Because there are no project level impacts on Suisun shrew from CM1, the analysis of the effects and conservation actions does not include a comparison with standard ratios used for project level NEPA analyses.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, and AMM26 Salt Marsh Harvest Mouse and Suisun Shrew*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be less than significant under CEQA.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 7,515 acres of Suisun shrew modeled habitat. Alternative 9 as a whole would result in effects to 401 acres of Suisun shrew modeled habitat over the term of the Plan, which would include 377 acres of permanent losses and 24 acres of habitat conversions (roughly 5% of the habitat in the study area). The Plan includes a commitment to restore or create 6,000 acres of tidal brackish emergent wetland, 1,500 acres of which would target middle and high marsh habitat (primary habitat for Suisun shrew) (Objectives TBEWNC1.1, TBEWNC1.2, and SMHM1.1, associated with CM4), and the protection and/or restoration of grassland adjacent to tidal restoration (areas within 200 feet of tidal restoration, of which approximately 150 feet of this area would benefit the species) to provide upland refugia for

Suisun shrew (Objective GNC1.4, associated with CM3 and CM8). Other factors relevant to effects on Suisun shrew are listed below.

- Restoration would be sequenced and oriented in a manner that minimizes any temporary, initial loss of habitat and habitat fragmentation.
- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value and quantity, with is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.
- The amount of tidal habitat restored (6,000 acres) greatly exceeds the amount permanently lost and converted (401 acres).

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 6,006 acres and the protection of 232 acres of modeled habitat for Suisun shrew.

Alternative 9 would result in substantial modifications to Suisun shrew habitat in the absence of other conservation actions. However, with habitat protection, restoration, management, and enhancement associated with CM3, CM4, CM8, and CM11, guided by species-specific goals and objectives and by AMM1–AMM5, and AMM26, which would be in place throughout the construction period, Alternative 9 over the term of the BDCP would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the alternative would have a less-than-significant impact on Suisun shrew.

Impact BIO-161: Indirect Effects of Plan Implementation on Suisun Shrew

Construction/disturbance activities associated tidal restoration (CM4), grassland restoration (CM8), and management and enhancement activities (CM11) could result in temporary noise and visual disturbances to Suisun shrew occurring within 100 feet of these areas over the term of the BDCP. These potential effects would be minimized or avoided through AMM1–AMM5, and AMM26, which would be in effect throughout the term of the Plan.

The use of mechanical equipment during the implementation of the conservation measures could cause the accidental release of petroleum or other contaminants that could affect Suisun shrew and its habitat. The inadvertent discharge of sediment could also have a negative effect on the species and its habitat. AMM1–AMM5 would minimize the likelihood of such spills and would ensure measures are in place to prevent runoff from the construction area and potential effects of sediment on Suisun shrew.

Tidal marsh restoration has the potential to increase Suisun shrew's exposure to mercury. Mercury is transformed into the more bioavailable form of methylmercury under anaerobic conditions, which in the environment typically occurs in sediments subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury. In general, the highest methylation rates are associated with high tidal marshes that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). High and mid tidal marsh is considered to be primary habitat for Suisun shrew and thus the species could be exposed to methylmercury in tidal restoration areas. Suisun shrew could be exposed to methylmercury by feeding on marsh invertebrates that may bioaccumulate methylmercury from marsh sediments. Toxic concentrations of methylmercury have been found in the kidneys of shrews that inhabit contaminated sites and forage on earthworms and other prey that live within contaminated sediments (Talmage and Walton 1993; Hinton and Veiga 2002).

The Suisun Marsh Plan (Bureau of Reclamation et al. 2010) anticipates that tidal wetlands restored under the plan would generate less methylmercury than the existing managed wetlands. The potential for Suisun shrew exposure to methyl mercury in Suisun Marsh may decrease in the long term because the creation of tidal brackish emergent wetland would predominantly result from the conversion of managed wetlands. *CM12 Methylmercury Management* includes provisions for project-specific Mercury Management Plans. Along with avoidance and minimization measures and adaptive management and monitoring, CM12 could reduce the effects of methylmercury on Suisun shrew resulting from BDCP tidal restoration.

NEPA Effects: Implementation of the AMMs listed above as part of implementing Alternative 9 would avoid and minimize the potential for substantial adverse effects on Suisun shrew, either indirectly or through habitat modifications. These AMMs would also avoid and minimize effects that could substantially reduce the number of Suisun shrew, or restrict the species' range. Therefore, the indirect effects of Alternative 9 would not have an adverse effect on Suisun shrew.

CEQA Conclusion: Indirect effects from construction-related noise and visual disturbances could impact Suisun shrew within 100 feet of these disturbances. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could impact Suisun shrew and its habitat. The inadvertent discharge of sediment adjacent to Suisun shrew habitat could also impact the species. With implementation of AMM1–AMM5, and AMM26 as part of Alternative 9 construction, operation and maintenance, the BDCP would avoid the potential for substantial adverse effects on Suisun shrew, either indirectly or through habitat modifications, in that the BDCP would not result in a substantial reduction in numbers or a restriction in the range of Suisun shrew. The indirect effects of Alternative 9 would have a less-than-significant impact on Suisun shrew.

Suisun shrew could experience indirect effects from increased exposure to methylmercury as a result of tidal habitat restoration (CM4). With implementation of CM12, the potential indirect effects of methlymercury would not result in a substantial reduction in numbers or a restriction in the range of Suisun shrew, and, therefore, would have a less-than-significant impact on the species.

San Joaquin Kit Fox and American Badger

Within the study area, the modeled habitat for the San Joaquin kit fox and potential habitat for the American badger is restricted to 5,327 acres of grassland habitat west of Clifton Court Forebay along the study area's southwestern edge, in CZ 7–CZ 10. The study area represents the extreme northeastern corner of the San Joaquin kit fox's range in California, which extends westward and southward from the study area border. The northern range of the San Joaquin kit fox (including the study area) was most likely marginal habitat historically and has been further degraded due to development pressures, habitat loss, and fragmentation (Clark et al. 2007). CNDDB (California Department of Fish and Wildlife 2013) reports eight occurrences of San Joaquin kit foxes along the extreme western edge of the Plan Area within CZ 8, south of Brentwood (Figure 12-49). However, Clark et al. (2007) provide evidence that a number of CNDDB occurrences in the northern portion of the species' range may be coyote pups misidentified as San Joaquin kit foxes. Smith et al. (2006) suggest that the northern range may possibly be a population sink for the San Joaquin kit fox. There are five American badger records in the study area (California Department of Fish and Wildlife 2013). Two are from 1938 and no longer extant. The remaining three are all located in CZ 8, west of Clifton Court Forebay.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of San Joaquin kit and American badger habitat (Table 12-9-59). Grassland restoration, and protection and management of natural communities could affect modeled San Joaquin kit fox habitat and potential American badger habitat. Full implementation of Alternative 9 would also include biological objectives over the term of the BDCP to benefit the San Joaquin kit fox which would also benefit American badger which uses similar habitat (BDCP Chapter 3, *Conservation Strategy*). The conservation strategy for the San Joaquin kit fox involves protecting and enhancing habitat in the northern extent of the species' range to increase the likelihood that San Joaquin kit fox may reside and breed in the Plan Area; and providing connectivity to habitat outside the Plan Area. The conservation measures that would be implemented to achieve the biological goals and objectives are summarized below.

- Protect and improve habitat linkages that allow terrestrial covered and other native species to move between protected habitats within and adjacent to the Plan Area (Objective L3.1, associated with CM3-8, and CM11).
- Protect 150 acres of alkali seasonal wetland in CZ 1, CZ 8, and/or CZ 11 among a mosaic of protected grasslands and vernal pool complex (Objective ASWNC1.1, associated with CM3).
- Restore or create alkali seasonal wetlands in CZ 1, CZ 8, and/or CZ 11 (up to 72 acres of alkali seasonal wetland complex restoration) (Objective ASWNC1.2, associated with CM3 and CM9).
- Protect 600 acres of existing vernal pool complex in CZ 1, CZ 8, and/or CZ 11, primarily in core vernal pool recovery areas identified in the Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (U.S. Fish and Wildlife Service 2005) (Objective VPNC1.1, associated with CM3).
- Restore vernal pool complex in CZ 1, CZ 8, and/or CZ 11 to achieve no net loss of vernal pool acreage (up to 67 acres of vernal pool complex restoration) (Objective VPNC1.2, associated with CM3 and CM9).
- Protect 8,000 acres of grassland (Objective GNC1.1, associated with CM3).
- Restore 2,000 acres of grasslands to connect fragmented patches of protected grassland (Objective GNC1.2, associated with CM3 and CM8).
- Increase burrow availability for burrow-dependent species in grasslands surrounding alkali seasonal wetlands within restored and protected alkali seasonal wetland complex (Objective ASWNC2.3, associated with CM11).
- Increase prey, especially small mammals and insects, for grassland-foraging species in grasslands surrounding alkali seasonal wetlands within restored and protected alkali seasonal wetland complex (Objective ASWNC2.4, associated with CM11).
- Increase burrow availability for burrow-dependent species in grasslands surrounding vernal pools within restored and protected vernal pool complex (Objective VPNC2.4, associated with CM11).

- Increase prey, especially small mammals and insects, for grassland-foraging species in grasslands surrounding vernal pools within restored and protected vernal pool complex (Objective VPNC2.5, associated with CM11).
- Increase burrow availability for burrow-dependent species (Objective GNC2.3, associated with CM11).
- Increase prey abundance and accessibility, especially small mammals and insects, for grassland-foraging species (Objective GNC2.4, associated with CM11).

As explained below, with the restoration and protection of these amounts of habitat, in addition to implementation of AMMs to reduce potential effects, impacts on San Joaquin kit fox and American badger would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-59. Changes in San Joaquin Kit Fox Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]

Impact BIO-162: Loss or Conversion of Habitat for and Direct Mortality of San Joaquin Kit Fox and American Badger

Alternative 9 conservation measures would result in the permanent and temporary loss combined of 33 acres of modeled habitat for the San Joaquin kit fox (Table 12-9-59). Because American badger uses grasslands for denning and foraging and may occupy the same range as the San Joaquin kit fox in the project area, effects on are anticipated to be the same as those described for San Joaquin kit fox. There are no San Joaquin kit fox and no American badger occurrences that overlap with the Plan footprint. Construction of Alternative 9 water conveyance facilities (CM1) and recreation facilities (CM11) would remove habitat. Habitat enhancement and management activities (CM11) could result in local adverse effects on species. In addition, construction vehicle activity could cause injury or mortality of San Joaquin kit foxes and badgers. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of the conveyance facilities would result in the permanent loss of approximately 15 acres and the temporary loss of 10 acres of modeled San Joaquin kit fox habitat and American badger habitat. This habitat is located in areas of naturalized grassland in a highly disturbed or modified setting on lands immediately adjacent to Clifton Court Forebay, in CZ 8.

- *CM11 Natural Communities Enhancement and Managemen*t: The creation of recreational trails and recreational staging areas would result in the permanent removal of 8 acres of San Joaquin kit fox modeled habitat and American badger potential habitat. *AMM24 San Joaquin Kit Fox,* would be implemented to ensure that San Joaquin kit fox dens are avoided, as described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*. Mitigation Measure BIO-162*: Conduct Preconstruction Survey for American Badger* would be implemented to ensure that American badger dens are avoided.

  Passive recreation in the reserve system could result in disturbance of San Joaquin kit foxes and American badgers at their den site. Natal and pupping dens would be particularly vulnerable to human disturbance. Additionally, disease could be transmitted from domestic dogs that enter the reserve system with recreational users. However, *AMM37 Recreation* and Mitigation Measure BIO-162 would prohibit construction of new trails within 250 feet of active San Joaquin kit fox and American badger dens. Existing trails would be closed within 250 feet of active natal/pupping dens until young have vacated, and within 50 feet of other active dens. No dogs would be allowed on reserve units with active San Joaquin kit fox and American badger populations. Rodent control would be prohibited even on grazed or equestrian access areas with San Joaquin kit fox or American badger populations. AMM37 measures to protect San Joaquin kit fox would also benefit American badger if present. With these restrictions, recreation-related effects on San Joaquin kit fox and American badger are expected to be minimal.

  The BDCP would require the protection of grasslands in large patch sizes connected to existing large areas of grassland, habitat corridors and transition habitat areas to improve the ecological functions of the grasslands necessary to support the San Joaquin kit fox. American badger is expected to benefit in a similar fashion.

  The BDCP would require the enhancement and management of these protected existing grasslands and restored grasslands to improve their function as a natural community of plants and wildlife and for associated covered species, including San Joaquin kit fox and American badger. The BDCP also includes actions to improve rodent prey availability.

  However, management activities could result in injury or mortality of San Joaquin kit fox or American badger if individuals were present in work sites or if dens were located in the vicinity of habitat management work sites. A variety of habitat management actions included in *CM11* that are designed to enhance wildlife values on protected lands may result in localized ground disturbances that could temporarily remove small amounts of San Joaquin kit fox and American badger habitat near Clifton Court Forebay, in CZ 8. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, are expected to have minor effects on available habitat and are expected to result in overall improvements to and maintenance of San Joaquin kit fox and badger habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized through the AMMs and mitigation measures listed below. These AMMs and mitigation measures would remain in effect throughout the BDCP's construction phase.

- Operations and maintenance: Ongoing maintenance of BDCP facilities would be expected to have little if any adverse effect on San Joaquin kit fox or American badger. Postconstruction operations and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect either species' use of the surrounding habitat near Clifton Court Forebay, in CZ 8. Maintenance activities would include vegetation management, levee and structure repair, and regrading of roads and permanent work areas. These effects, however, would be minimized with implementation of AMM1–AMM6, AMM10, and AMM24 and with preconstruction surveys for the American badger, as required by Mitigation Measure BIO-162, *Conduct Preconstruction Survey for American Badger*.
- Injury and direct mortality: Construction vehicle activity may cause injury to or mortality of either species. If San Joaquin kit fox or American badger reside where activities take place (most likely in the vicinity of Clifton Court Forebay, in CZ 8), the operation of equipment for land clearing, construction, operations and maintenance, and restoration, enhancement, and management activities could result in injury to or mortality of either species. Measures would be implemented to avoid and minimize injury to or mortality of these species as described in AMM1–AMM6, AMM10, and AMM24 (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*) and Mitigation Measure BIO-162, *Conduct Preconstruction Survey for American Badger*.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

Near-Term Timeframe

Because water conveyance facilities construction is being evaluated at the project level, the near-term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction effects would not be adverse under NEPA.

Under Alternative 9 there would be a loss of 28 acres of San Joaquin kit fox modeled habitat and American badger habitat from CM1 (25 acres) and CM11 (3 acres).

Typical NEPA project-level mitigation ratio for the natural community that would be affected and that is identified in the biological goals and objectives for San Joaquin kit fox in Chapter 3 of the BDCP would be 2:1 for protection of grassland. Using this ratio would indicate that 56 acres of grassland should be protected for San Joaquin kit fox to mitigate near-term losses.

The BDCP has committed to near-term restoration of 58 acres of alkali seasonal wetland (Objective ASWNC1.2), 40 acres of vernal pool complex (Objective VPNC1.2), and 1,140 acres of grassland (Objective GNC1.2). In addition, there would be near-term protection of 120 acres of alkali seasonal wetland (Objective ASWNC1.1), 400 acres of vernal pool complex (Objective VPNC1.1), and 2,000 acres of grassland (Objective GNC1.1). The natural community restoration and protection activities are expected to be concluded during the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for NEPA purposes. These commitments are more than sufficient to support the conclusion that the near-term effects of

Alternative 9 would be not be adverse under NEPA, because the number of acres required to meet the typical ratios described above would be only 56 acres of grassland protected.

The effects on San Joaquin kit fox and American badger habitat from Alternative 9 as a whole would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of other conservation actions. However, the effects of Alternative 9 would be not be adverse with habitat protection, restoration, and management and enhancement in addition to implementation of *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM24 San Joaquin Kit Fox*, and *AMM37 Recreation*. These AMMs include elements that avoid or minimize the risk of construction activity affecting habitat and species adjacent to work areas and storage sites. Remaining effects would be addressed by implementation of Mitigation Measure BIO-162, *Conduct Preconstruction Survey for American Badger*. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Late Long-Term Timeframe

There are 5,327 acres of modeled San Joaquin kit fox habitat in the study area. Alternative 9 as a whole would result in the permanent loss of and temporary effects to 33 acres of modeled habitat for San Joaquin kit fox and potential habitat for American badger representing less than 1% of the modeled habitat.

With full implementation of the BDCP, at least 1,000 acres of grassland would be protected in CZ 8, where the San Joaquin kit fox and American badger is most likely to occur if present in the Plan Area. Additionally, a portion of the 2,000 acres of grassland restoration would likely occur in CZ 8. Assuming the restored grasslands would provide suitable San Joaquin kit fox habitat proportional to the amount of modeled habitat in this natural community in the Plan Area (6.8% of the grasslands in the Plan Area consist of modeled San Joaquin kit fox habitat), an estimated 132 acres of restored grasslands would be suitable for both species (6.6% of 2,000 acres).

Because San Joaquin kit fox home ranges are large (ranging from around 1 to 12 square miles; see BDCP Appendix 2.A, *Covered Species Accounts*), habitat connectivity is key to the conservation of the species. Grasslands would be acquired for protection in locations that provide connectivity to existing protected breeding habitats in CZ 8 (Objective L3.1)and to other adjoining San Joaquin kit fox habitat within and adjacent to the Plan Area. Connectivity to occupied habitat adjacent to the Plan Area would help ensure the movement of San Joaquin kit foxes and American badger, if present, to larger habitat patches outside of the Plan Area in Contra Costa County. Grassland protection would focus in particular on acquiring the largest remaining contiguous patches of unprotected grassland habitat, which are located south of SR 4 in CZ 8 (BDCP Appendix 2.A). This area connects to over 620 acres of existing habitat that was protected under the East Contra Costa County HCP/NCCP.

Grasslands in CZ 8 would also be managed and enhanced to increase prey availability and to increase mammal burrows, which could benefit the San Joaquin kit fox and American badger by increasing potential den sites, which are a limiting factor for the San Joaquin kit fox in the northern portion of its range (Objectives ASWNC2.3, ASWNC2.4, VPNC2.4, Objective VPNC2.5, Objective GNC2.3, Objective GNC2.4). These management and enhancement actions are expected to benefit the

San Joaquin kit fox as well as the American badger by increasing the habitat value of the protected and restoration grasslands.

CZ 8 supports 74% of the modeled San Joaquin kit fox grassland habitat in the study area, and the remainder of habitat consists of fragmented, isolated patches that are unlikely to support this species. The BDCP's commitment to protect the largest remaining contiguous habitat patches (including grasslands and the grassland component of alkali seasonal wetland and vernal pool complexes) in CZ 8 and to maintain connectivity with the remainder of the satellite population in Contra Costa County would sufficiently offset the impacts resulting from water conveyance facilities construction.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of grassland and vernal pool that could overlap with the species model, would result in the restoration of 131 acres of modeled habitat for San Joaquin kit fox. In addition, protection of grassland and vernal pool complex could overlap with the species model and would result in the protection of 1,011 acres of modeled habitat for San Joaquin kit fox. These restoration and protection actions would also benefit the American badger.

***NEPA Effects*:** In the absence of other conservation actions, the effects on San Joaquin kit fox and American badger habitat from Alternative 9 would represent an adverse effect as a result of habitat modification and potential direct mortality of special-status species. However, with habitat protection, restoration, management, and enhancement associated with CM3, CM8, and CM11, and guided by AMM1–AMM6, AMM10, AMM24, and AMM37, which would be in effect during the construction period, and with implementation of Mitigation Measure BIO-162, *Conduct Preconstruction Survey for American Badger*, the effects of Alternative 9 as a whole on San Joaquin kit fox and American badger would not be adverse under NEPA.

***CEQA Conclusion*:**

Near-Term Timeframe

Because water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction impacts would be less than significant under CEQA.

Under Alternative 9 there would be a loss of 28 acres of San Joaquin kit fox modeled habitat and American badger habitat from CM1 (25 acres) and CM11 (3 acres).

Typical CEQA project-level mitigation ratio for the natural community that would be affected and that is identified in the biological goals and objectives for San Joaquin kit fox in Chapter 3 of the BDCP would be 2:1 for protection of grassland. Using this ratio would indicate that 56 acres of grassland should be protected for San Joaquin kit fox and American badger to mitigate near-term losses.

The BDCP has committed to near-term restoration of 58 acres of alkali seasonal wetland (Objective ASWNC1.2), 40 acres of vernal pool complex (Objective VPNC1.2), and 1,140 acres of grassland (Objective GNC1.2). In addition, there would be near-term protection of 120 acres of alkali seasonal wetland (Objective ASWNC1.1), 400 acres of vernal pool complex (Objective VPNC1.1), and 2,000 acres of grassland (Objective GNC1.1). The natural community restoration and protection activities are expected to be concluded during the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for CEQA purposes. These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would not be significant under CEQA, because the number of acres required to meet the typical ratios described above would be only 56 acres of grassland protected.

The BDCP also contains commitments to implement AMM1–AMM6, AMM10, AMM24, and AMM37 which include elements that avoid or minimize the risk of construction activity impacting habitat and species adjacent to work areas and storage sites. Remaining effects would be addressed by implementation of Mitigation Measure BIO-162. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 on San Joaquin kit fox and American badger would be less than significant under CEQA, because the number of acres required to meet the typical ratios described above would be only 56 acres of grassland protected

Late Long-Term Timeframe

There are 5,327 acres of modeled San Joaquin kit fox habitat in the study area. Alternative 9 as a whole would result in the permanent loss of and temporary effects to 33 acres of modeled habitat for San Joaquin kit fox and potential habitat for American badger representing less than 1% of the modeled habitat.

With full implementation of the BDCP, at least 1,000 acres of grassland would be protected in CZ 8, where the San Joaquin kit fox and American badger are most likely to occur if present in the Plan Area. Additionally, a portion of the 2,000 acres of grassland restoration would likely occur in CZ 8. Assuming the restored grasslands would provide suitable San Joaquin kit fox habitat proportional to the amount of modeled habitat in this natural community in the Plan Area (6.8% of the grasslands in the Plan Area consist of modeled San Joaquin kit fox habitat), an estimated 132 acres of restored grasslands would be suitable for the species (6.6% of 2,000 acres).

Because San Joaquin kit fox home ranges are large (ranging from around 1 to 12 square miles; see BDCP Appendix 2.A, *Covered Species Accounts*), habitat connectivity is key to the conservation of the species. Grasslands would be acquired for protection in locations that provide connectivity to existing protected breeding habitats in CZ 8 (Objective L3.1)and to other adjoining San Joaquin kit fox and American badger habitat within and adjacent to the Plan Area. Connectivity to occupied habitat adjacent to the Plan Area would help ensure the movement of San Joaquin kit foxes and American badgers, if present, to larger habitat patches outside of the Plan Area in Contra Costa County. Grassland protection would focus in particular on acquiring the largest remaining contiguous patches of unprotected grassland habitat, which are located south of SR 4 in CZ 8 (BDCP Appendix 2.A). This area connects to over 620 acres of existing habitat that was protected under the East Contra Costa County HCP/NCCP.

Grasslands in CZ 8 would also be managed and enhanced to increase prey availability and to increase mammal burrows, which could benefit the San Joaquin kit fox and American badger by increasing potential den sites, which are a limiting factor for the San Joaquin kit fox in the northern portion of its range (Objectives ASWNC2.3, ASWNC2.4, VPNC2.4, Objective VPNC2.5, Objective GNC2.3, Objective GNC2.4). These management and enhancement actions are expected to benefit the

San Joaquin kit fox as well as the American badger by increasing the habitat value of the protected and restoration grasslands.

CZ 8 supports 74% of the modeled San Joaquin kit fox grassland habitat in the study area, and the remainder of habitat consists of fragmented, isolated patches that are unlikely to support this species. The BDCP's commitment to protect the largest remaining contiguous habitat patches (including grasslands and the grassland component of alkali seasonal wetland and vernal pool complexes) in CZ 8 and to maintain connectivity with the remainder of the satellite population in Contra Costa County would sufficiently offset the impacts resulting from water conveyance facilities construction.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of grassland and vernal pool that could overlap with the species model, would result in the restoration of 131 acres of modeled habitat for San Joaquin kit fox. In addition, protection of grassland and vernal pool complex could overlap with the species model and would result in the protection of 1,011 acres of modeled habitat for San Joaquin kit fox. These restoration and protection actions would also benefit the American badger.

In the absence of other conservation actions, the effects on San Joaquin kit fox and American badger habitat from Alternative 9 would represent a significant impact as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection, restoration, management, and enhancement associated with CM3, CM8, and CM11, and guided by AMM1–AMM6, AMM10, AMM24, and AMM37, which would be in place throughout the time period of construction, and with implementation of Mitigation Measure BIO-162, the impact of Alternative 9 as a whole on San Joaquin kit fox and American badger would be less than significant.

Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger

A qualified biologist provided by DWR will survey for American badger concurrent with the preconstruction survey for San Joaquin kit fox and burrowing owl. If badgers are detected, the biologist will passively relocate badgers out of the work area prior to construction if feasible. If an active den is detected within the work area, DWR will establish a suitable buffer distance and avoid the den until the qualified biologist determines the den is no longer active. Dens that are determined to be inactive by the qualified biologist will be collapsed by hand to prevent occupation of the den between the time of the survey and construction activities. In addition, ground disturbance within project-related conservation areas within 50 feet of active American badger dens would be prohibited. Existing trails would be closed within 250 feet of active natal/pupping dens until young have vacated, and within 50 feet of other active dens. No dogs would be allowed on conservation areas with active American badger populations. Rodent control would be prohibited on areas with American badger populations to ensure rodent prey availability. Mitigation Measure BIO-162 is applicable to all ground-disturbing activities related to construction, restoration, and operations and maintenance.

Impact BIO-163: Indirect Effects of Plan Implementation on San Joaquin Kit Fox and American Badger

Noise and visual disturbances outside the project footprint but within 250 feet of construction activities could temporarily affect modeled San Joaquin kit fox habitat and potential American badger. Water conveyance facilities operations and maintenance activities would include vegetation and weed control, rodent control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. Because operations and maintenance are covered activities rodent control would be prohibited in areas with San Joaquin kit fox or American badger populations to ensure rodent prey availability. While maintenance activities are not expected to remove San Joaquin kit fox and badger habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in injury or mortality of individual foxes and badgers, if present. Given the remote likelihood of active San Joaquin kit fox or badger dens in the vicinity of the conveyance facility, the potential for this effect is small and would further be minimized with the implementation of seasonal no-disturbance buffers around occupied dens, if any, and other measures as described in AMM24 and Mitigation Measure BIO-162.

***NEPA Effects*:** Implementation of the AMMs listed above and Mitigation Measure BIO-162, *Conduct Preconstruction Survey for American Badger,* would avoid the potential for substantial adverse effects on San Joaquin kit fox or American badger, either indirectly or through habitat modifications. These measures would also avoid and minimize effects that could substantially reduce the number of San Joaquin kit fox or American badger, or restrict either species' range. Therefore, the indirect effects of Alternative 9 would not have an adverse effect on San Joaquin kit fox or American badger.

CEQA Conclusion: Indirect effects from conservation measure operations and maintenance as well as construction-related noise and visual disturbances could impact San Joaquin kit fox and American badger. With implementation of AMM1–AMM6, AMM10, AMM24, and AMM37 as part of Alternative 9 construction, operation, and maintenance, the BDCP would avoid the potential for significant adverse effects on either species, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of either species. In addition, Mitigation Measure BIO-162, *Conduct Preconstruction Survey for American Badger,* would reduce the impact of indirect effects of Alternative 9 on American badger to a less-than-significant level.

Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger

Please see Mitigation Measure BIO-162 under Impact BIO-162.

San Joaquin Pocket Mouse

Habitat for this species consists of the grassland natural community throughout the Plan Area. The species requires friable soils for burrowing. Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of San Joaquin pocket mouse habitat as indicated in Table 12-9-60. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP that would likely benefit San Joaquin pocket mouse.

- Protect 8,000 acres of grasslands (GNC1.1, associated with CM3).
- Restore 2,000 acres of grasslands to connect fragmented patches of protected grasslands (GNC1.2, associated with CM8).
- Restore and sustain a mosaic of grassland vegetation alliances, reflecting localized water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical states (GNC2.1).

As explained below, with the restoration or protection of these amounts of habitat, impacts on San Joaquin pocket mouse would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-60. Changes in San Joaquin Pocket Mouse Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent NT	Permanent LLT[c]	Temporary NT	Temporary LLT[c]	Periodic[d] CM2	Periodic[d] CM5
CM1	Grassland	82	82	344	344	NA	NA
Total Impacts CM1		**82**	**82**	**344**	**344**		
CM2–CM18	Grassland	889	2,057	239	273	385–1,277	514
Total Impacts CM2–CM18		**889**	**2,057**	**239**	**273**	**385–1,277**	**514**
TOTAL IMPACTS		**971**	**2,139**	**583**	**617**	**385–1,277**	**514**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-164: Loss or Conversion of Habitat for and Direct Mortality of San Joaquin Pocket Mouse

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 2,756 acres of habitat for San Joaquin pocket mouse (of which 2,139 acres would be a permanent loss and 617 acres would be a temporary loss of habitat, Table 12-9-60). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration*, *CM7 Riparian Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM10 Nontidal Marsh Restoration*, *CM11 Natural Communities Enhancement and Management*, and *CM18 Conservation Hatcheries*. The majority of habitat loss would result from CM4. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate San Joaquin pocket mouse habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 426 acres of potential San

Joaquin pocket mouse habitat (82 acres of permanent loss, 344 acres of temporary loss) in CZ 5, CZ 6, and CZ 8. The majority of grassland that would be removed would on the existing levees along the conveyance route. These areas represent poor-value habitat for the species because most of these areas consists of narrow strips of grass that are often managed to remove burrowing species.

- *CM2 Yolo Bypass Fisheries Enhancement:* Construction of the Yolo bypass fisheries enhancement (CM2) would permanently remove 388 acres of potential San Joaquin pocket mouse habitat in the Yolo Bypass in CZ 2. In addition, 239 acres would be temporarily removed. Most of the grassland losses would occur at the north end of the bypass below Fremont Weir, along the Toe Drain/Tule Canal, and along the west side channels.
- *CM4 Tidal Natural Communities Restoration:* Tidal habitat restoration (CM4) site preparation and inundation would permanently remove an estimated 1,122acres of potential San Joaquin pocket mouse habitat. The majority of the losses would likely occur in the vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the upslope fringes of Suisun Marsh, and along narrow bands adjacent to waterways in the South Delta ROA. Tidal restoration would directly impact and fragment remaining grassland just north of Rio Vista in and around French and Prospect Islands, and in an area south of Rio Vista around Threemile Slough.
- *CM5 Seasonally Inundated Floodplain Restoration:* Construction of setback levees to restore seasonally inundated floodplain (CM5) would permanently and temporarily remove approximately 85 acres of San Joaquin pocket mouse habitat (51 permanent, 34 temporary). These losses would be expected to occur along the San Joaquin River and other major waterways in CZ 7.
- *CM7 Riparian Natural Community Restoration*: Riparian restoration would impact 410 acres of grasslands, primarily in CZ 7, as part of tidal natural communities restoration (11 acres) and seasonal floodplain restoration (399 acres).
- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:* Up to 10 acres of grassland would be permanently converted to vernal pool complex. The vernal pool and alkali seasonal wetland restoration would leave intact the grasslands surrounding the vernal pools. Temporary construction-related disturbance of grassland habitat would result from implementation of *CM9* in CZ 1, CZ 8, and CZ 11. However, all areas would be restored to their original or higher value habitat after the construction periods.
- *CM11 Natural Communities Enhancement and Management:* The creation of recreational trails and recreational staging areas would result in the permanent removal of 50 acres of grassland. The protection of 8,000 acres of grassland for covered species is also expected to benefit San Joaquin pocket mouse by protecting existing habitats from potential loss or degradation that otherwise could occur with future changes in existing land use. Habitat management and enhancement-related activities could cause disturbance to or direct mortality of San Joaquin pocket mouse if the species is present near work areas.

A variety of habitat management actions included in *CM11 Natural Communities Enhancement and Management* that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of San Joaquin pocket mouse habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. Noise and visual disturbance from management-related equipment operation could temporarily displace individuals or alter the behavior of the species if adjacent to work areas. With full implementation of the BDCP, enhancement and management actions designed for western burrowing owl would also be expected to benefit these species. San Joaquin pocket mouse would benefit particularly from protection of grassland habitat against potential loss or degradation that otherwise could occur with future changes in existing land use.

- *CM18 Conservation Hatcheries:* Implementation of CM18 would remove up to 35 acres of San Joaquin pocket mouse habitat.
- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect San Joaquin pocket mouse use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and conservation actions as described below.
- Injury and Direct Mortality: Construction could result in direct mortality of San Joaquin pocket mouse if present in construction areas.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 1,554 acres of San Joaquin pocket mouse habitat (971 permanent, 583 temporary) in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 426 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration*, *CM7 Riparian Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management*, and *CM18 Conservation Hatcheries*—1,128 acres).

Typical NEPA project-level mitigation ratios for those natural communities affected by CM1 would be 2:1 protection of grassland habitat. Using these typical ratios would indicate that 852 acres of grassland natural communities should be protected to mitigate the CM1 losses of 426 acres of San Joaquin pocket mouse habitat. The near-term effects of other conservation actions would remove 1,128 acres of modeled habitat, and therefore require 2,256 acres of protection of San Joaquin pocket mouse habitat using the same typical NEPA and CEQA ratios (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community in CZ 1, CZ 2, CZ 4, CZ 5, CZ 7, CZ 8, and CZ 11. The protection and restoration of grasslands, would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand habitat for San Joaquin pocket mouse and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities*

Enhancement and Management, San Joaquin pocket mouse would likely benefit from the management of the grasslands for general wildlife benefit.

These natural community biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions for the species. The acres of protection and restoration contained in the near-term Plan goals would satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and RTM storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Late Long-Term Timeframe

Based on the habitat model, the study area supports approximately 78,047 acres of potential habitat for San Joaquin pocket mouse. Alternative 9 as a whole would result in the permanent loss of and temporary effects to 2,756 acres of grasslands that could be suitable for San Joaquin pocket mouse (4% of the habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes a commitment to restore or create 2,000 acres of grassland in CZ 1, 8 and 11 (Objective GNC1.2) and to protect 8,000 acres of grassland (with at least 2,000 acres protected in CZ 1, at least 1,000 acres in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed throughout CZ 1, 2, 4, 5, 7, 8, and 11 in the study area) (Objective GNC1.1). The Plan's commitment to restore grasslands such that they connect fragmented patches of already protected grasslands (Objective GNC1.2) would improve habitat connectivity and dispersal abilities of San Joaquin pocket mouse within and outside of the plan area. All protected habitat would be managed under *CM11 Natural Communities Enhancement and Management*.

NEPA Effects: In the near-term, the loss of San Joaquin pocket mouse habitat and potential for direct mortality would not be adverse because the BDCP has committed to protecting and restoring an acreage that would meet the typical mitigation ratios described above. In the absence of other conservation actions, the effects on San Joaquin pocket mouse habitat and potential mortality of a special-status species resulting from Alternative 9 would represent an adverse effect in the late long-term. However, the BDCP has committed to habitat protection and restoration associated with CM3, CM8, and CM11. This habitat protection and restoration would be guided by biological goals and objectives and by AMM1–AMM6 and AMM10, which would be in place throughout the construction period. Considering these commitments, losses of San Joaquin pocket mouse habitat and potential mortality under Alternative 9 would not be an adverse effect.

***CEQA Conclusion*:**

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the impacts of construction would be less than significant. Alternative 9 would remove 1,554 acres of modeled (971 permanent, 583 temporary) habitat for San Joaquin pocket mouse in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 426 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration*, *CM7 Riparian Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management*, and *CM18 Conservation Hatcheries*—1,128 acres).

The typical CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 2:1 protection of grassland habitat. Using this ratio would indicate that 852 acres of grassland natural communities should be protected to mitigate the CM1 losses of 426 acres of San Joaquin pocket mouse habitat. The near-term effects of other conservation actions would remove 1,128 acres of modeled habitat, and therefore require 2,256 acres of protection of San Joaquin pocket mouse habitat using the same typical NEPA and CEQA ratio (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community in CZ 1, CZ 2, CZ 4, CZ 5, CZ 7, CZ 8, and CZ 11. The protection and restoration of grasslands, would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand habitat for San Joaquin pocket mouse and reduce the effects of current levels of habitat fragmentation. Under CM11 Natural Communities Enhancement and Management, San Joaquin pocket mouse would likely benefit from the management of the grasslands for general wildlife benefit.

These natural community biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions for the species. The acres of protection and restoration contained in the near-term Plan goals would satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, and AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and RTM storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be less than significant under CEQA.

Late Long-Term Timeframe

Based on the habitat model, the study area supports approximately 78,047 acres of potential habitat for San Joaquin pocket mouse. Alternative 9 as a whole would result in the permanent loss of and temporary impacts on 2,756 acres of grasslands that could be suitable for San Joaquin pocket mouse (4% of the habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes a commitment to restore or create 2,000 acres of grassland in CZ 1, 8 and 11 (Objective GNC1.2) and to protect 8,000 acres of grassland (with at least 2,000 acres protected in CZ 1, at least 1,000 acres in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed throughout CZ 1, 2, 4, 5, 7, 8, and 11 in the study area) (Objective GNC1.1). The Plan's commitment to restore grasslands such that they connect fragmented patches of already protected grasslands (Objective GNC1.2) would improve habitat connectivity and dispersal abilities of San Joaquin pocket mouse within and outside of the plan area. All protected habitat would be managed under *CM11 Natural Communities Enhancement and Management*.

Considering these protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with implementation of AMM1–AMM6 and AMM10, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of San Joaquin pocket mouse. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on San Joaquin pocket mouse.

Impact BIO-165: Indirect Effects of Plan Implementation on San Joaquin Pocket Mouse

Construction activities associated with water conveyance facilities, conservation components and ongoing habitat enhancement, as well as operations and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances and noise with localized effects on San Joaquin kit pocket mouse and its habitat over the term of the BDCP. These potential effects would be minimized and avoided through AMM1–AMM6, and AMM10, which would be in effect throughout the plan's construction phase.

Water conveyance facilities operations and maintenance activities would include vegetation and weed control, ground squirrel control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. While maintenance activities are not expected to remove pocket mouse habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in injury or mortality of individual pocket mice, if present.

***NEPA Effects*:** Implementation of the AMMs listed above would avoid the potential for substantial adverse effects on San Joaquin pocket mouse, either indirectly or through habitat modifications. These measures would also avoid and minimize effects that could substantially reduce the number of San Joaquin pocket mouse, or restrict the species' range. Therefore, the indirect effects of Alternative 9 would not have an adverse effect on San Joaquin pocket mouse.

***CEQA Conclusion*:** Indirect effects from conservation measure operations and maintenance as well as construction-related noise and visual disturbances could impact San Joaquin pocket mouse. With implementation of AMM1–AMM6 and AMM10, as part of Alternative 9 construction, operation, and maintenance, the BDCP would avoid the potential for significant adverse effects on either species, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of the species. Therefore, the indirect effects under this alternative would have a less-than-significant impact on San Joaquin pocket mouse.

Special-Status Bat Species

Special-status bat species with potential to occur in the study area employ varied roost strategies, from solitary roosting in foliage of trees to colonial roosting in trees and artificial structures, such as tunnels, buildings, and bridges. Various roost strategies could include night roosts, maternity roosts, migration stopover, or hibernation. The habitat types used to assess effects for special-status bats roosting habitat includes valley/foothill riparian natural community, developed lands and landscaped trees, including eucalyptus, palms and orchards. Potential foraging habitat includes all riparian habitat types, cultivated lands, developed lands, grasslands, and wetlands.

There is potential for at least thirteen different bat species to be present in the study area (Figure 12-51), including four California species of special concern and nine species ranked from low to moderate priority by the Western Bat Working Group (Table 12A-2 in Appendix 12A, *Special-Status Species with Potential to Occur in the Study Area*). In 2009, DHCCP conducted a large-scale effort that involved habitat assessments, bridge surveys, and passive acoustic monitoring surveys for bats (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report* for details on methods and results).

The majority of the parcels assessed during field surveys contained bat foraging and roosting features and were considered highly suitable habitat. At the time of the 2009 field surveys, DWR biologists initially identified 145 bridges in their survey area. Eleven of the 145 bridges were not accessible and thirteen were determined to not be suitable for bats. Evidence of bat presence was observed at six of the bridges and bat sign (guano, urine staining, odor, or vocalizations) was observed at 26 of the bridges. biologists observed Mexican free-tailed bats at four of the bridges and unidentified species at the remaining two bridges. One of these bridges, over the Yolo Causeway, was used by approximately 10,000 Mexican free-tailed bats, indicating a maternity roost. A second roost site of about 50 individuals was observed under a bridge in eastern Solano County.

The remaining 89 bridges contained structural features that were considered conducive to maternity, solitary, day and/or night roosting. Night roosts may have crevices and cracks but more often have box beams or other less protected roosting spots where bats rest temporarily while feeding. Day roosts are commonly found in bridges with expansion joints, crevices, or cracks where bats are protected from predators and weather. Seventeen bridges in the survey area had no potential for roosting because they lacked surface features from which bats could hang and offered no protection from weather or predators.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of foraging and roosting habitat for special-status bats as indicated in Table 12-4-61. Protection and restoration for special-status bat species focuses on habitats and does not include manmade structures such as bridges. The conservation measures that would be implemented to achieve the biological goals and objectives that would also benefit special-status bats are summarized below.

- Protect or restore 142,200 acres of high-value natural communities (Objective L1.1, associated with CM3). This objective includes protecting and restoring a variety of habitat types described below (BDCP Chapter 3, Table 3.3-4).
    - Protect 150 acres of alkali seasonal wetland in CZ 1, CZ 8, and/or CZ 11 among a mosaic of protected grasslands and vernal pool complex (Objective ASWNC1.1, associated with CM3).
    - Protect 600 acres of existing vernal pool complex (Objective VPNC1.1, associated with CM3).
    - Protect 8,000 acres of grassland (Objective GNC1.1, associated with CM3).
    - Protect 8,100 acres of managed wetland (Objective MWNC1.1, associated with CM3 and CM11).
    - Protect 48,625 acres of cultivated lands (Objective CLNC1.1, associated with CM3 and CM11).
    - Protect, restore, or create 2,740 acres of rice land or equivalent habitat type for the giant garter snake (Objective GGS3.1, associated with CM3, CM4, and CM10).
    - Restore 2,000 acres of grasslands to connect fragmented patches of protected (Objective GNC1.2, associated with CM3 and 8).
    - Restore 67 acres of vernal pool complex (Objective VPNC1.2, associated with CM3 and 9).
    - Restore and protect 65,000 acres of tidal natural communities (Objective L1.2, associated with CM2, 3, and 4).
    - Restore or create 5,000 acres of valley/foothill riparian natural community (Objective VFRNC1.1, associated with CM3 and CM7).
    - Protect 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).

As explained below, with the restoration and protection of these amounts of habitat, in addition to mitigation measures to reduce potential effects, impacts on special-status bats would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-61. Changes in Special-Status Bat Roosting and Foraging Habitat Associated with Alternative 9[a]

Conservation Measure[b]	Habitat Type[c]	Permanent		Temporary		Periodic[e]	
		NT	LLT[d]	NT	LLT[d]	CM2	CM5
CM1	Roosting	74	74	284	284	NA	NA
	Foraging	1,289	1,289	3,583	3,583	NA	NA
Total Impacts CM1		**1,363**	**1,363**	**3,867**	**3,867**	**NA**	**NA**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] Affected roosting habitat acreages include valley/foothill riparian habitat, developed lands, and orchards. An unknown number of buildings, bridges, tunnels, and individual trees could also be affected but were not included in this analysis. Foraging habitat includes all natural communities, cultivated lands, and developed lands in the study area. Foraging habitat effects for CM2-CM18 were not considered adverse as they reflect a conversion from one foraging habitat type (mostly cultivated lands) to another foraging habitat (wetlands).

[d] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[e] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as the maximum possible based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-166: Loss or Conversion of Habitat for and Direct Mortality of Special-Status Bats

Alternative 9 conservation measure CM1 would result in the permanent and temporary loss combined of up to 358 acres of roosting habitat and 4,872 acres of foraging habitat for special-status bats in the study area. DWR identified 12 bridges that could be affected by Alternative 9 construction in CM1. Conservation measures Fremont Weir/Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), and floodplain restoration (CM5) and would result in the permanent and temporary loss of 1,782 acres of roosting habitat and the conversion of approximately 65,525 acres of foraging habitat from mostly cultivated lands and managed wetlands to tidal and nontidal wetlands. Habitat enhancement and management activities (CM11) could result in local adverse effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could affect special-status bat habitat. A summary of combined impacts and NEPA effects and a CEQA conclusion follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of Alternative 9 conveyance facilities would result in the permanent loss of approximately 74 acres of roosting habitat and 1,289 acres of foraging habitat in the study area. Development of the water conveyance facilities would also result in the temporary removal of up to 284 acres of roosting habitat and up to 3,583 acres of foraging habitat for special-status bats in the study area (Table 12-9-61). DWR identified twelve bridges within the area of channel dredging, fish screen, and operable barrier that provide potential roosting habitat that could be affected by construction for CM1. Two of these bridges had positive sign for bats.

- *CM2 Yolo Bypass Fisheries Enhancement*: Improvements in the Yolo Bypass would result in the conversion of approximately 2,025 acres of foraging habitat into wetlands that could still be used by bats for foraging. CM2 would also result in the permanent removal of 89 acres and temporary removal of 167acres of roosting habitat for special-status bats. The maternity colony of Mexican free-tailed bats located at both ends of the Yolo Causeway bridge could also be affected during construction for CM2. Implementation of Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, would ensure that improvements in the Yolo Bypass avoid effects on roosting special-status bats.

- C*M4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would result in the conversion of approximately 56,810 acres of foraging habitat into wetlands that could still be used by bats for foraging. Approximately 1,425 acres of roosting habitat for special-status bats would permanently affected. This habitat is of low value, consisting of a small, isolated patch surrounded by cultivated lands, and the species has a relatively low likelihood of being present in these areas. The roosting habitat that would be removed consists of relatively small and isolated patches along canals and irrigation ditches surrounded by cultivated lands in the Union Island and Roberts Island areas, and several small patches along the San Joaquin River. Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, described below, requires that tidal natural communities restoration avoid effects on roosting special-status bats.

- *CM5 Seasonally Inundated Floodplain Restoration*: Levee construction associated with floodplain restoration would result in the conversion of an estimated 3,690 acres of foraging habitat into wetlands that could still be used by bats for foraging. CM5 would also result in the permanent removal of 57 acres and temporary removal of 45 acres of roosting habitat for special-status bats in the study area.

- *CM11 Natural Communities Enhancement and Management*: Implementation of Alternative 9 would result in an overall benefit to special-status bats within the study area through protection and restoration of their foraging and roosting habitats. The majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands. Restored foraging habitats primarily would replace agricultural lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats. Noise and visual disturbances during implementation of riparian habitat management actions could result in temporary disturbances that, if bat roost sites are present, could cause temporary abandonment of roosts. This effect would be minimized with implementation of Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*.

- Operations and maintenance: Ongoing facilities operation and maintenance is expected to have little if any adverse effect on special-status bats. Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect special-status bat use of the surrounding habitat in the Yolo Bypass, the Cache Slough area, and the north and south Delta (CZ 1, CZ 2, CZ 4, CZ 5, CZ 6, CZ 7, and CZ 8). Maintenance activities would include vegetation management, levee and structure repair, and regrading of roads and permanent work areas. These effects, however, would be minimized with implementation of the mitigation measures described below.

- Injury and direct mortality: In addition, to habitat loss and conversion, construction activities, such as grading, the movement of construction vehicles or heavy equipment, and the installation of water conveyance facilities components and new transmission lines, may result in the direct mortality, injury, or harassment of roosting special-status bats. Construction activities related to conservation components could have similar affects. Preconstruction surveys would be conducted and if roosting or maternity sites are detected, seasonal restrictions would be placed while bats are present, as described below in the mitigation measures.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA effects and CEQA conclusions are also included.

Near-Term Timeframe

Because water conveyance facilities construction is being evaluated at the project level, the near-term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction effects would not be adverse under NEPA. Because the majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands this analysis focuses only on losses to roosting habitat for CM1, CM2, and CM4 in the near-term.

Alternative 9 would permanently or temporarily affect 1,049 acres of roosting habitat for special-status bats in the near-term as a result of implementing CM1 (358 acres roosting habitat), CM2 (256acres roosting habitat), and CM4 (435 acres roosting habitat). Effects from CM5 would all occur in the late long-term. Only 784 acres of the 1,049 acres of roosting habitat losses would be in valley/foothill riparian habitat.

Typical NEPA project-level mitigation ratios for those natural communities that would be affected for roosting habitat would be 1:1 for restoration and protection of the valley/foothill riparian natural community. Using these ratios would indicate that 784 acres of riparian habitat should be restored and 784 acres of riparian habitat should be protected.

Implementation of BDCP actions in the near-term would result in an overall benefit to special-status bats within the study area through protection and restoration of their foraging and roosting habitats (Objective L1.1). BDCP actions in the near-term would restore 800 acres of riparian roosting and foraging habitat (Objective VFRNC1.1) and 21,288 acres of foraging habitat in natural communities and developed lands (Objective L1.1, Objective GNC1.2, Objective VPNC1.2, Objective L1.2, and Objective L2.11). In addition, the BDCP would protect 750 acres of riparian roosting and foraging habitat (Objective VFRNC1.2) and 41,445 acres of foraging habitat (Objective L1.1, Objective ASWNC1.1, Objective VPNC1.1, Objective MWNC1.1, Objective CLNC1.1, Objective GGS3.1, and Objective GNC1.1,). Restored foraging habitats would replace primarily cultivated lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats. Conservation components in the near-term would sufficiently offset the adverse effects resulting from near-term effects from Alternative 9.In addition, activities associated with natural communities enhancement and protection and with ongoing facilities operations and maintenance could affect special-status bat use of surrounding habitat and could result in harassment, injury or mortality of bats. Mitigation Measure BIO-166, described below, requires preconstruction surveys to reduce these effects.

The BDCP also contains commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities.* These AMMs include elements that avoid or minimize the risk of construction activity affecting habitat and species adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

Alternative 9 as a whole would affect 2,140 acres of roosting habitat (Table 12-9-61). Because the majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands this analysis focuses only on losses to roosting habitat for CM1, CM2, CM4, and CM5 in the late long-term.

Implementation of BDCP actions in the late long-term would result in an overall benefit to special-status bats within the study area through protection and restoration of approximately 142,200 acres of their foraging and roosting habitats (Objective L1.1). Achieving this objective is intended to protect the highest quality natural communities and covered species habitat in the Plan Area to optimize the ecological value of the reserve system for conserving covered species and native biodiversity. The target for total protected and restored acreage is based on the sum of all natural community acreage targets. Achieving this objective is intended to protect and restore natural communities, species-specific habitat elements, and species diversity on a landscape-scale., Achieving this objective is also intended to conserve representative natural and seminatural landscapes in order to maintain the ecological integrity of large habitat blocks, including desired ecosystem function, and biological diversity.

BDCP actions in the late long-term would restore and protect 5,750 acres of riparian roosting and foraging habitat (Objective VFRNC1.1 and Objective VFRNC1.2), and 136,450 acres of foraging habitat (Objective L1.1, Objective GNC1.2, Objective VPNC1.2, Objective L1.2, Objective L2.11, Objective L1.1, Objective ASWNC1.1, Objective VPNC1.1, Objective MWNC1.1, Objective CLNC1.1, Objective GGS3.1, and Objective GNC1.1,) in natural communities and developed lands. Restored foraging habitats would replace primarily cultivated lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats.

Should any of the special-status bat species be detected roosting in the study area, construction of water conveyance facilities and restoration activities would have an adverse effect on roosting special-status bats. Noise and visual disturbances and the potential for injury or mortality of individuals associated within implementation of the restoration activities on active roosts would be minimized with implementation of Mitigation BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*. Conservation components would sufficiently offset the adverse effects resulting from late long-term effects from CM1, CM2, CM4, and CM5.

NEPA Effects: In the near-term the losses of roosting habitat for special-status bats associated with implementing Alternative 9 are not expected to result in substantial adverse effects on special-status bats, either directly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of special-status bats because the BDCP has committed to protecting the acreage required to meet the typical mitigation ratios described above. In the late long-term, the losses of roosting habitat for special-status bats associated with Alternative 9, in the absence of other conservation actions, would represent an adverse effect as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection and restoration associated with the conservation components, guided by landscape-scale goals and objectives and by AMM1–AMM6 and AMM10, and with implementation of Mitigation Measure BIO-166, the effects of Alternative 9 as a whole on special-status bats would not be adverse

***CEQA Conclusion*:**

Near-Term Timeframe

Because water conveyance facilities construction is being evaluated at the project level, the near-term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction effects would be less than significant for CEQA purposes. Because the majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands this analysis focuses only on losses to roosting habitat for CM1, CM2, and CM4 in the near-term.

Alternative 9 would permanently or temporarily affect 1,049 acres of roosting habitat for special-status bats in the near-term as a result of implementing CM1 (358 acres roosting habitat), CM2 (256 acres roosting habitat), and CM4 (435 acres roosting habitat). Effects from CM5 would all occur in the late long-term. Only 784 acres of the 1,049 acres of roosting habitat losses would be in valley/foothill riparian habitat Typical CEQA project-level mitigation ratios for those natural communities that would be affected for roosting habitat would be 1:1 for restoration and protection of the valley/foothill riparian natural community. Using these ratios would indicate that 784 acres of riparian habitat should be restored and 784 acres of riparian habitat should be protected.

Implementation of BDCP actions in the near-term would result in an overall benefit to special-status bats within the study area through protection and restoration of their foraging and roosting habitats (Objective L1.1). BDCP actions in the near-term would restore 800 acres of riparian roosting and foraging habitat (Objective VFRNC1.1) and 21,288 acres of foraging habitat in natural communities and developed lands (Objective L1.1, Objective GNC1.2, Objective VPNC1.2, Objective L1.2, and Objective L2.11). In addition, the BDCP would protect 750 acres of riparian roosting and foraging habitat (Objective VFRNC1.2) and 41,445 acres of foraging habitat (Objective L1.1, Objective ASWNC1.1, Objective VPNC1.1, Objective MWNC1.1, Objective CLNC1.1, Objective GGS3.1, and Objective GNC1.1,). Restored foraging habitats would replace primarily cultivated lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats. Conservation components in the near-term would sufficiently offset the adverse effects resulting from near-term effects from Alternative 9.In addition, activities associated with natural communities enhancement and protection and with ongoing facilities operations and maintenance could affect special-status bat use of surrounding habitat and could result in harassment, injury or mortality of bats. Mitigation Measure BIO-166, described below, requires preconstruction surveys to reduce these impacts to a less-than-significant level.

The permanent loss of roosting habitat from Alternative 9 would be mitigated through implementation of Mitigation Measure BIO-166, which would ensure there is no significant impact under CEQA on roosting special-status bats, either directly or through habitat modifications and no substantial reduction in numbers or a restriction in the range of special-status bats. The BDCP also contains commitments to implement AMM1–AMM6 and AMM10. These AMMs include elements that avoid or minimize the risk of construction activity affecting habitat and species adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

Alternative 9 as a whole would affect 2,140 acres of roosting habitat (Table 12-9-61). Because the majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands this analysis focuses only on losses to roosting habitat for CM1, CM2, CM4, and CM5 in the late long-term.

Implementation of BDCP actions in the late long-term would result in an overall benefit to special-status bats within the study area through protection and restoration of approximately 142,200 acres of their foraging and roosting habitats (Objective L1.1). Achieving this objective is intended to protect the highest quality natural communities and covered species habitat in the Plan Area to optimize the ecological value of the reserve system for conserving covered species and native biodiversity. The target for total protected and restored acreage is based on the sum of all natural community acreage targets. Achieving this objective is intended to protect and restore natural communities, species-specific habitat elements, and species diversity on a landscape-scale., Achieving this objective is also intended to conserve representative natural and seminatural landscapes in order to maintain the ecological integrity of large habitat blocks, including desired ecosystem function, and biological diversity.

BDCP actions in the late long-term would restore and protect 5,750 acres of riparian roosting and foraging habitat (Objective VFRNC1.1 and Objective VFRNC1.2), and 136,450 acres of foraging habitat (Objective L1.1, Objective GNC1.2, Objective VPNC1.2, Objective L1.2, Objective L2.11, Objective L1.1, Objective ASWNC1.1, Objective VPNC1.1, Objective MWNC1.1, Objective CLNC1.1, Objective GGS3.1, and Objective GNC1.1,) in natural communities and developed lands. Restored foraging habitats would replace primarily cultivated lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats. Should any of the special-status bat species roost in the study area, construction of water conveyance facilities and restoration activities could have an adverse effect on roosting special-status bats. Noise and visual disturbances and the potential for injury or mortality of individuals associated within implementation of construction activities would be minimized with implementation of Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*. Conservation components would sufficiently offset the adverse effects resulting from late long-term effects from CM1, CM2, CM4, and CM5.

The permanent loss of roosting habitat from Alternative 9 would be mitigated through implementation of Mitigation Measure BIO-166, which would ensure that there would be no significant impact on roosting special-status bats, either directly or through habitat modifications, and that there would be no substantial reduction in numbers or a restriction in the range of special-status bats. Therefore, Alternative 9 would not result in a significant impact on special-status bats under CEQA.

Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures

The following measure was designed to avoid and minimize adverse direct and indirect effects on special-status bats. However, baseline data are not available or are limited on how bats use the study area, and on individual numbers of bats and how they vary seasonally. Therefore, it is difficult to determine if there would be a substantial reduction in species numbers. Bat species with potential to occur in the study area employ varied roost strategies, from solitary roosting in foliage of trees to colonial roosting in trees and artificial structures, such as buildings and bridges. Daily and seasonal variations in habitat use are common. To obtain the highest likelihood of detection, preconstruction bat surveys will be conducted by DWR and will include these components.

- Identification of potential roosting habitat within project footprint.
- Daytime search for bats and bat sign in and around identified habitat.
- Evening emergence surveys at potential day-roost sites, using night-vision goggles and/or active full-spectrum acoustic monitoring where species identification is sought.
- Passive full-spectrum acoustic monitoring and analysis to detect bat use of the area from dusk to dawn over multiple nights.
- Additional on-site night surveys as needed following passive acoustic detection of special status bats to determine nature of bat use of the structure in question (e.g., use of structure as night roost between foraging bouts).
- Qualified biologists will have knowledge of the natural history of the species that could occur in the study area and experience using full-spectrum acoustic equipment. During surveys, biologists will avoid unnecessary disturbance of occupied roosts.

Preconstruction Bridges and Other Structure Surveys

Before work begins on the bridge/structure, qualified biologists will conduct a daytime search for bat sign and evening emergence surveys to determine if the bridge/structure is being used as a roost. Biologists conducting daytime surveys would listen for audible bat calls and would use naked eye, binoculars, and a high-powered spotlight to inspect expansion joints, weep holes, and other bridge features that could house bats. Bridge surfaces and the ground around the bridge/structure would be surveyed for bat sign, such as guano, staining, and prey remains.

Evening emergence surveys will consist of at least one biologist stationed on each side of the bridge/structure watching for emerging bats from a half hour before sunset to 1–2 hours after sunset for a minimum of two nights within the season that construction would be taking place. Night-vision goggles and/or full-spectrum acoustic detectors shall be used during emergence surveys to assist in species identification. All emergence surveys would be conducted during favorable weather conditions (calm nights with temperatures conducive to bat activity and no precipitation predicted).

Additionally, passive monitoring with full-spectrum bat detectors will be used to assist in determining species present. A minimum of four nights of acoustic monitoring surveys will be conducted within the season that the construction would be taking place. If site security allows, detectors should be set to record bat calls for the duration of each night. To the extent possible, all monitoring will be conducted during favorable weather conditions (calm nights with temperatures conducive to bat activity and no precipitation predicted). The biologists will analyze the bat call data using appropriate software and prepare a report with the results of the surveys. If acoustic data suggest that bats may be using the bridge/structure as a night roost, biologists will conduct a night survey from 1–2 hours past sunset up to 6 hours past sunset to determine if the bridge is serving as a colonial night roost.

If suitable roost structures would be removed, additional surveys may be required to determine how the structure is used by bats, whether it is as a night roost, maternity roosts, migration stopover, or for hibernation.

Preconstruction Tree Surveys

If tree removal or trimming is necessary, qualified biologists will examine trees to be removed or trimmed for suitable bat roosting habitat. High-value habitat features (large tree cavities, basal hollows, loose or peeling bark, larger snags, palm trees with intact thatch, etc.) will be identified and the area around these features searched for bats and bat sign (guano, culled insect parts, staining, etc.). Riparian woodland, orchards, and stands of mature broadleaf trees should be considered potential habitat for solitary foliage roosting bat species.

If bat sign is detected, biologists will conduct evening visual emergence survey of the source habitat feature, from a half hour before sunset to 1–2 hours after sunset for a minimum of two nights within the season that construction would be taking place. Methodology should follow that described above for the bridge emergence survey.

Additionally, if suitable tree roosting habitat is present, acoustic monitoring with a bat detector will be used to assist in determining species present. These surveys would be conducted in coordination with the acoustic monitoring conducted for the bridge/structure.

Protective Measures for Bats using Bridges/Structures and Trees

Avoidance and minimization measures shall be necessary if it is determined that bats are using the bridge/structure or trees as roost sites and/or sensitive bats species are detected during acoustic monitoring. Appropriate measures will be determined by DWR in consultation with CDFW and shallinclude, as applicable, measures listed below.

- Ensure that bats are protected from noise, vibrations, and light that result from construction activities associated with water conveyance facilities, conservation components and ongoing habitat enhancement, as well as operations and maintenance of above-ground water conveyance facilities, including the transmission facilities. This would be accomplished by either directing noise barriers and lights inward from the disturbance or ensuring that the disturbances do not extend more than 300 feet from the point source.

- Disturbance of the bridge will be avoided between March 1 and October 31 (the maternity period) to avoid impacts on reproductively active females and dependent young.
- Installation of exclusion devices from March 1 through October31 to preclude bats from occupying the bridge during construction. Exclusionary devices will only be installed by or under the supervision of an experienced bat biologist.
- Tree removal will be avoided between April 15 and September 15 (the maternity period for bats that use trees) to avoid impacts on pregnant females and active maternity roosts (whether colonial or solitary).
- Tree removal will be conducted between September 15 and October 31 to the maximum extent feasible, which corresponds to a time period when bats would not likely have entered winter hibernation and would not be caring for flightless young. If weather conditions remain conducive to regular bat activity beyond October 31, later tree removal may be considered in consultation with CDFW.
- Trees will be removed in pieces, rather than felling the entire tree.
- If a maternity roost is located, whether solitary or colonial, that roost will remain undisturbed with a buffer as determined in consultation with CDFW until September 15 or until a qualified biologist has determined the roost is no longer active.
- If a non-maternity roost is found, that roost will be avoided to the maximum extent feasible and an appropriate buffer established in consultation with CDFW. Every effort would be made to avoid the roost to the maximum extent feasible, as methods to evict bats from trees are largely untested. However, if the roost cannot be avoided, eviction will be attempted and procedures designed in consultation with CDFW to reduce the likelihood of mortality of evicted bats. In all cases:
    - Eviction will not occur before September 15th and will match the timeframe for tree removal approved by CDFW.
    - Qualified biologists will carry out or oversee the eviction tasks and monitor the tree trimming/removal.
    - Eviction will take place late in the day or in the evening to reduce the likelihood of evicted bats falling prey to diurnal predators.
    - Eviction will take place during weather and temperature conditions conducive to bat activity.
    - Special-status bat roosts will not be disturbed.

  Eviction procedures shall include but are not limited to:

    - Pre-eviction surveys to obtain data to inform the eviction approach and subsequent mitigation requirements. Relevant data may include the species, sex, reproductive status and/or number of bats using the roost, and roost conditions themselves such as temperature and dimensions. Surveys may include visual emergence, night vision, acoustic, and/or capture.

- Structural changes may be made to the roost, performed without harming bats, such that the conditions in the roost are undesirable to roosting bats and the bats leave on their own (e.g., open additional portals so that temperature, wind, light and precipitation regime in the roost change).
- Non-injurious harassment at the roost site to encourage bats to leave on their own, such as ultrasound deterrents or other sensory irritants.

- Prior to removal/trimming, after other eviction efforts have been attempted, any confirmed roost tree would be shaken, repeatedly struck with a heavy implement such as an axe and several minutes should pass before felling trees or trimming limbs to allow bats time to arouse and leave the tree. The biologists should search downed vegetation for dead and injured bats. The presence of dead or injured bats will be reported to CDFW.

Compensatory mitigation for the loss of roosting habitat will also be determined through consultation with CDFW and may include the construction and installation of suitable replacement habitat onsite. Depending on the species and type of roost lost, various roost replacement habitats have met with some success (e.g., bat houses, "bat bark," planting cottonwood trees, leaving palm thatch in place rather than trimming). The creation of natural habitat onsite is generally preferable to artificial.

Artificial roosts are often unsuccessful, and care must be taken to determine as closely as possible the conditions in the natural roost to be replaced. Even with such care, artificial habitat may fail. Several artificial roosts have been highly successful in replacing bridge roost habitat when incorporated into new bridge designs. "Bat bark" has been successfully used by Arizona Department of Game and Fish to create artificial crevice-roosting bat habitat mounted on pine trees (Mering and Chambers 2012: 765). Bat houses have at best an inconsistent track record but information is mounting on how to create successful houses. There is no single protocol or recipe for bat-house success. Careful study of the roost requirements of the species in question; the particular conditions at the lost roost site including temperature, orientation of the openings, airflow, internal dimensions and structures (cavity vs. crevice, etc.) should increase the chances of designing a successful replacement.

Restoring riparian woodland with plantings shows signs of success in Colorado. Western red bat activity has been positively correlated with increased vegetation and tree growth, canopy complexity and restoration acreage at cottonwood-willow restoration sites along the Lower Colorado River (Broderick 2012: 39). These complex woodland areas would ultimately provide a wider range of bat species with preferred roost types, including both foliage-roosting and crevice-/cavity-roosting bats.

Impact BIO-167: Indirect Effects of Plan Implementation on Special-Status Bats

Construction activities associated with water conveyance facilities, conservation components and ongoing habitat enhancement, as well as operations and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic disturbances from light, vibrations, and noise with localized effects on special-status bats and their roosting habitat over the term of the BDCP.

Water conveyance facilities operations and maintenance activities would include vegetation and weed control, ground squirrel control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. While maintenance activities are not expected to remove special-status bat habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in disturbances to roosting bats, if present. Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, is available to address these adverse effects.

Increased exposure to methylmercury associated with tidal natural community's restoration would potentially indirectly affect special-status bat species. *CM12 Methylmercury Management* describes the process by which tidal natural communities restoration may increase methyl mercury levels in wetlands in the study area. Mercury has been found in high concentrations in some bat species, such as the Indiana bat. Many bat species forage heavily on aquatic insects, which might result in rapid bioaccumulation (Evers et al. 2012). Measures described in *CM12 Methylmercury Management* are expected to reduce the effects of methylmercury on special-status bat species resulting from BDCP tidal natural community's restoration.

NEPA Effects: Implementation of the Mitigation Measure BIO-166 for special-status bats would avoid the potential for substantial adverse effects on roosting special-status bats, either indirectly or through habitat modifications. This mitigation measure would also avoid and minimize effects that could substantially reduce the number of special-status bats, or restrict species' range. Therefore, the indirect effects of Alternative 9 would not have an adverse effect on special-status bats.

CEQA Conclusion: Indirect effects from conservation components operations and maintenance as well as construction-related noise and visual disturbances could have a significant impact on special-status bat species, either indirectly or through habitat modifications. Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, would reduce this impact to a less-than-significant level and ensure Alternative 9 would not result in a substantial reduction in numbers or a restriction in the range of species.

Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures

See Mitigation Measure BIO-166 under Impact BIO-166.

Impact BIO-168: Periodic Effects of Inundation of Special-Status Bat Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from *CM2 Yolo Bypass Fisheries Enhancement* would periodically affect 324 acres of roosting habitat and 21,265 acres of foraging habitat for special-status bats in the study area (Table 12-9-61).

CM5 Seasonally Inundated Floodplain Restoration would periodically inundate up to 411 acres of roosting habitat and 10,137 acres of foraging habitat for special-status bats (Table 12-9-61). Potential roosting trees are likely to be retained within seasonally flooded areas, although high velocity flooding could uproot some trees. Seasonal flooding would not adversely affect foraging habitat for the species. The overall effect of seasonal inundation in existing riparian natural communities may instead be beneficial. Historically, flooding was the main natural disturbance regulating ecological processes in riparian areas, and flooding promotes the germination and establishment of many native riparian plants. In the late long-term, seasonal inundation in areas currently occupied by riparian vegetation may contribute to the establishment of high-value habitat for special-status bats that use riparian habitats.

NEPA Effects: Periodic effects on roosting and foraging habitat for special-status bats associated with implementing Alternative 9 are not expected to result in substantial adverse effects on special-status bats, either directly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of special-status bats. Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, is available to address any effects of periodic inundation on special-status bats and roosting habitat. Therefore, Alternative 9 would not adversely affect the species.

CEQA Conclusion: Periodic inundation under CM2 and floodplain restoration under CM5 would periodically affect foraging and roosting habitat for special-status bats in the study area. Any impact of periodic inundation on special-status bats would be mitigated through implementation of Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, which would ensure there is no significant impact on roosting special-status bats, either directly or through habitat modifications and no substantial reduction in numbers or a restriction in the range of special-status bats.

Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures

See Mitigation Measure BIO-166 under Impact BIO-166.

Plant Species

The effects of constructing the water conveyance facilities under Alternative 9 would be substantially different than under any of the other alternatives. However, effects of implementing habitat restoration would be the same as under Alternative 1A.

Vernal Pool Plants

Five covered plant species and 12 noncovered special-status plant species occur in vernal pools in the study area (Tables 12-2, 12-3, summarized in Table 12-9-62). The vernal pool habitat model used for the impact analysis was based on vegetation types and associations from various data sets which were used to create maps showing the distribution of vernal pool habitat in the study area according to three habitat types in which the species are known to occur, including vernal pool complex and degraded vernal pool complex, and alkali seasonal wetland habitat. Vernal pool complex habitat consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Degraded vernal pool complex habitat consists of habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, discing, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. Because wetlands in the degraded vernal pool complex are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or small populations of species that are found in vernal pools and swales. However, they do not possess the full complement of ecosystem and community characteristics of natural vernal pools, swales and their associated uplands and they are generally ephemeral features that are eliminated during the course of normal agricultural practices. A small amount of alkali seasonal wetland habitat was included in the model because alkaline vernal pools are also present in some areas mapped as alkali seasonal wetland.

Because each of the vernal pool species addressed in this EIR/EIS have specific microhabitat affinities, and because vernal pool habitat within the study area is highly heterogeneous with respect to habitat parameters such as soil type and pool depth, the vernal pool habitat model greatly overestimates the extent of habitat in the study area occupied by each species. However, the vernal pool habitat model is likely to encompass all or most of the potential area within which special-status vernal pool plant species would occur. Therefore, it is not likely to underestimate the extent of occupied habitat or to underestimate the effects of Alternative 9.

Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP to benefit covered vernal pool plants (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect two currently unprotected occurrences of alkali milk-vetch in the Altamont Hills or Jepson Prairie core recovery areas (Objective VPP1.1, associated with CM3).
- Maintain no net loss of Heckard's peppergrass in Conservation Zones 1, 8, or 11 within restoration sites or within the area of affected tidal range of restoration projects (Objective VPP1.2, associated with CM3 and CM9).

The restoration activities covered under Alternative 9 could have impacts on special-status vernal pool plants. No modeled habitat and no known occurrences of the 17 vernal pool plants are within the proposed footprint for the Alternative 9 water conveyance facilities. Modeled vernal pool habitat would be affected by tidal habitat restoration, although no known occurrences of 17 vernal pool plants are within the hypothetical footprint for restoration activities. Table 12-9-62 summarizes the acreage of modeled vernal pool habitat in the study area, the number of occurrences of each special-status vernal pool plant in the study area, and the potential effects.

Table 12-9-62. Summary of Impacts on Vernal Pool Plants under Alternative 9

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Modeled Habitat					
Vernal pool complex	9,557	1			Habitat loss from tidal habitat restoration
Degraded vernal pool complex	2,576	370			Habitat loss from tidal habitat restoration
Alkali Seasonal Wetland	188	0			None
Total	**12,321**	**372**			
Covered Species					
Alkali milk-vetch			16	0	None
Dwarf downingia			12	0	None
Boggs Lake hedge-hyssop			1	0	None
Legenere			8	0	None
Heckard's peppergrass			4[a]	0	None
Noncovered Species					
Ferris' milk-vetch			6	0	None
Vernal pool smallscale			2	0	None
Hogwallow starfish			0	0	None
Ferris' goldfields			4	0	None
Contra Costa goldfields			7	0	None
Cotula-leaf navarretia			5	0	None
Baker's navarretia			3	0	None
Colusa grass			1	0	None
Bearded popcorn-flower			5	0	None
Delta woolly marbles			3	0	None
Saline clover			9	0	None
Solano grass			1	0	None

[a] One additional occurrence is in alkali seasonal wetlands.

Impact BIO-169: Effects on Habitat and Populations of Vernal Pool Plants

Alternative 9 could affect habitat for special-status vernal pool plants. The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: No modeled habitat and no known occurrences of the 17 vernal pool plants are within the proposed footprint for the Alternative 9 water conveyance facilities. Therefore, under Alternative 9, construction and operation of the water conveyance facilities would not affect the five covered vernal pool plant or the 12 noncovered special-status plants.

- *CM2 Yolo Bypass Fisheries Enhancement*: No modeled vernal pool habitat and no known occurrences of the 17 vernal pool plants are within the hypothetical footprint for construction or operation of the Yolo Bypass fisheries enhancements. Therefore, construction and operation of the Yolo Bypass fisheries enhancements would not affect the covered or noncovered vernal pool plants.
- *CM3 Natural Communities Protection and Restoration*: The BDCP proposes to benefit covered vernal pool plants by protecting 600 acres of vernal pool complex in CZs 1, 8, and 11 (Objective VPNC1.1). The protected vernal pool habitat would be managed and enhanced to sustain populations of native vernal pool species. These benefits also would accrue to any noncovered vernal pool plants occurring in the protected vernal pool complex.
- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration would result in the inundation of 372 acres of vernal pool complex and would, therefore, potentially affect special-status vernal pool plants. However, no known occurrences of covered and noncovered vernal pool plants would be affected. Most of this modeled habitat (370 acres) consists of degraded vernal pool habitat that is unlikely to contain special-status plants. In addition, 257.8 acres of critical habitat for Contra Costa goldfields could be affected.
- *CM5 Seasonally Inundated Floodplain Restoration*: No vernal pool habitat or occurrences of special-status vernal pool plants are present within areas proposed for floodplain restoration. Therefore, floodplain restoration and construction of new floodplain levees would have no impacts on covered and noncovered vernal pool plants.
- *CM6 Channel Margin Enhancement*: No vernal pool habitat or occurrences of special-status vernal pool plants are present within areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on covered and noncovered vernal pool plants.
- *CM7 Riparian Natural Community Restoration*: No vernal pool habitat or occurrences of special-status vernal pool plants are present within areas proposed for riparian habitat enhancement. Therefore, riparian habitat enhancement would have no impacts on covered and noncovered vernal pool plants.
- *CM8 Grassland Natural Community Restoration*: Although the vernal pool complex habitat includes grassland matrix within which the vernal pools occur, grassland restoration activities would take place in non-grasslands (ruderal habitat, cultivated land) or degraded grasslands that are not included within vernal pool complex habitat. Therefore, grassland communities restoration would have no impacts on covered and noncovered vernal pool plants.
- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: If, through unforeseen circumstances, BDCP activities result in the net loss of vernal pool habitat, CM9 would be implemented to compensate for that loss. Because vernal pool complex restoration would focus on habitat that had been cleared and leveled but maintained an intact duripan or claypan, the likelihood of affecting any special-status vernal pool plants would be low. However, vernal pool restoration could adversely affect remnant populations of special-status vernal pool plants or affect vernal pool habitat adjacent to the restoration areas.
- *CM10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid vernal pool habitat and would have no impacts on covered and noncovered vernal pool plants.

- *Avoidance and Minimization Measures*: Effects on covered vernal pool plants potentially resulting from implementation of CM4 would be avoided or minimized though *AMM11 Covered Plant Species, AMM2 Construction Best Management Practices and Monitoring, AMM12 Vernal Pool Crustaceans*, and *AMM37 Recreation*. AMM11 prohibits ground disturbance or hydrologic disturbance within 250 feet of existing vernal pools. In addition, AMM11 specifies that individual projects be designed to avoid critical habitat for listed plant and wildlife vernal pool species. AMM12 limits the direct removal of vernal pool crustacean habitat to no more than 10 wetted acres and the indirect effect to no more than 20 wetted acres through the life of the Plan. AMM12 also requires that that tidal natural communities restoration or other ground-disturbing covered activities in Conservation Zones 1 and 11 will not result in the adverse modification of primary constituent elements of critical habitat for vernal pool fairy shrimp, conservancy fairy shrimp, and vernal pool tadpole shrimp. These protections would also apply to critical habitat for Contra Costa goldfields, where it overlaps with critical habitat for these vernal pool crustaceans. AMM37 requires that new recreation trails avoid populations of covered vernal pool plants.

In addition, the BDCP includes species-specific goals to benefit covered vernal pool plants. This includes protecting two occurrences of alkali milk-vetch (Objective VPP1.1) and requiring no net loss of Heckard's peppergrass (Objective VPP1.2).

In summary, no adverse effects on covered special-status vernal pool plants would be expected from implementing Alternative 9. No known occurrences of 17 special-status vernal pool plants would be affected. Beneficial effects on special-status vernal pool plants could occur by protecting 600 acres of vernal pool complex in CZs 1, 8, and 11 and by protecting occurrences of alkali milk-vetch.

The GIS analysis estimated that up to 371 acres of vernal pool complex could be adversely affected by covered activities under Alternative 9. However, the actual effect on habitat for special-status vernal pool plants is expected to be much less than the estimated impact because the BDCP limits the total loss of wetted vernal pool habitat resulting from specific projects to 10 acres (approximately 67 acres of vernal pool complex) over the permit term (AMM12). At the proposed restoration ratios of 1:1 (prior to impact) and 1.5:1 (concurrent with impact), between 67 and 100.5 acres of vernal pool complex restoration would be required to compensate for the loss of modeled habitat for special-status vernal pool plants (Objective VPNC1.2, associated with CM9). This would be consistent with typical NEPA and CEQA project-level mitigation ratios for vernal pool impacts. The limitation on the loss of wetted vernal pool habitat will constrain the implementation of tidal restoration projects that are adjacent to vernal pool complex, which could affect the feasibility of restoring 65,000 acres of tidal habitat (Objective TPANC1.1, associated with CM4).

***NEPA Effects*:** Implementation of the BDCP under Alternative 9 would not have an adverse effect on threatened and endangered vernal pool plant species.

***CEQA Conclusion*:** Because loss of modeled habitat for vernal pool plant species would be offset through restoration, and because impacts on occurrences of special-status vernal pool plants would be avoided, implementation of Alternative 9 would not result in a reduction in the range or numbers of 17 covered and noncovered special-status vernal pool plants in the study area. Therefore, impacts on special-status vernal pool plants be less than significant. No mitigation is required.

Alkali Seasonal Wetland Plants

Five covered species and three noncovered plants occur in alkali seasonal wetlands in the study area (Tables 12-2, 12-3, summarized in Table 12-9-63). Alkali seasonal wetland habitat was modeled separately for four covered plant species occurring in seasonal alkali wetlands.

The San Joaquin spearscale habitat model approximated the distribution of suitable San Joaquin spearscale habitat in the study area according to the species' preferred habitat types, intersected with soil series and slope position. Historical and current records of San Joaquin spearscale in the study area indicate that its current distribution is limited to alkaline soil areas with shallow basin or swale microtopography along the western border. The vegetation cover of the alkaline soils is typically a combination of alkaline soil-adapted species and annual grasses, including annual ryegrass and Mediterranean barley. Habitat types used for the model included alkali seasonal wetlands, vernal pool complex, and grasslands. Soil series used in the model consisted of either clays or clay loams with alkaline horizons. San Joaquin spearscale typically occurs in swales or in level terrain but occasionally occurs on the lower slopes adjacent to streams or swales or where seeps are present. Because some of the soil series with which San Joaquin spearscale is associated can occur on hillsides, slope was used to limit the extent of the model to the toe of the slope where these soils occur by excluding areas with slope greater than 1%. Land uses that are incompatible with the species' habitat requirements, such as modeled habitat polygons falling on leveled or developed lands, were removed from the model.

Modeled habitat for brittlescale was mapped as hydrologic features such as stream corridors and playa pools located on alluvium associated with the Montezuma Block along the western boundary of the study area or on alluvium associated with tertiary formations located along the southwest boundary of the study area. Stream corridors (intermittent and perennial) that intersected these geologic units were selected and truncated at the point at which they encountered the upper elevation of intertidal marsh. The corridors were buffered 50 feet (15.2 meters) on either side of their centerlines to capture the estimated maximum extent of alluvium deposits in proximity to the streams. Mapped habitat that was occupied by urban or intensive agricultural uses was removed from the model.

The habitat model for heartscale was based on the species distribution in the study area (Solano and Yolo Counties) and on the soil types and plant communities within which it occurs. Potential habitat was determined by intersecting the GIS coverage for three parameters: 1) Yolo and Solano County boundaries; 2) Solano, Pescadero, and Willows soils; and 3) grassland, alkali seasonal wetland, and vernal pool complex natural communities. The model excluded areas that have been developed or cultivated, i.e., where the topography, soils, and hydrology have been substantially altered.

Delta button-celery habitat was modeled as alkali seasonal wetland complex, vernal pool complex, other natural seasonal wetland, and grassland occurring on Brentwood, Grangerville, Marcuse, Solano, and Vernalis soil map units within the San Joaquin Basin (i.e., south of the mainstem San Joaquin River). For this species, land cover north of the Discovery Bay area where intensive agriculture was classified as annual grassland were manually deleted from the area of predicted habitat. Additionally, other areas of potential habitat that have been developed were also manually deleted.

Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP to benefit covered alkali seasonal wetland plants (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Of the 150 acres of alkali seasonal wetland complex protected under Objective ASWNC1.1, 600 acres of vernal pool complex protected under Objective VPNC1.1, and 8,000 acres of grassland natural community protected under Objective GNC1.1, protect at least 75 acres of suitable brittlescale habitat and 75 acres of suitable heartscale habitat in Conservation Zones 1, 8, or 11 (Objective BRIT/HART/SJSC1.1, associated with CM3).
- Protect two currently unprotected occurrences of San Joaquin spearscale in Conservation Zones 1, 8, or 11 (Objective BRIT/HART/SJSC1.2, associated with CM3).

No adverse effects on Delta button celery, crownscale, palmate-bracted bird's-beak or recurved larkspur would be expected. Table 12-9-63 summarizes the acreage of modeled alkali seasonal wetland habitat in the study area and the number of occurrences of each special-status alkali seasonal wetland plant in the study area.

Table 12-9-63. Summary of Impacts on Seasonal Alkali Wetland Plants under Alternative 9

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
San Joaquin spearscale modeled habitat	14,933	680			Habitat loss from tidal habitat restoration, Yolo Bypass fisheries enhancements, and levee construction
Brittlescale modeled habitat	451	4			Habitat loss from tidal habitat restoration
Heartscale modeled habitat	6,528	306			Habitat loss from tidal habitat restoration and Yolo Bypass fisheries enhancements
Delta button celery modeled habitat	3,330[a]	0			None
Alkali seasonal wetlands	3,273	72			Habitat loss from tidal habitat restoration and Yolo Bypass fisheries enhancements
Covered Species					
San Joaquin spearscale			19	1	Population loss from tidal habitat restoration
Brittlescale			8	0	None
Heartscale			3	0	None
Delta button celery			1[b]	0	None
Heckard's peppergrass			1[c]	1	Population loss from tidal habitat restoration
Noncovered Species					
Crownscale			17	0	None
Palmate-bracted bird's-beak			1	0	None
Recurved larkspur			4	0	None

[a] A portion of this acreage consists of riparian habitat.
[b] A second occurrence in study area is in riparian habitat.
[c] Four additional occurrences of Heckard's peppergrass are associated with vernal pools.

Impact BIO-170: Effects on Habitat and Populations of Alkali Seasonal Wetland Plants

Alternative 9 would have adverse effects on modeled seasonal alkali wetland habitat for San Joaquin spearscale, brittlescale, and heartscale. It could also have adverse effects on occurrences of San Joaquin spearscale and Heckard's peppergrass.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: No alkali seasonal wetland habitat or occurrences of special-status alkali seasonal wetland plants are present within areas proposed for construction of the water facilities or channel dredging. Therefore, construction and operation of the water conveyance facilities would have no impacts on covered and noncovered alkali seasonal wetland plant species.
- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo Bypass fisheries improvements would permanently remove 56 acres of modeled habitat for San Joaquin spearscale. No known occurrences of San Joaquin spearscale would be affected. No modeled habitat and no known occurrences of the seven other alkali seasonal wetland plants are within the hypothetical footprint for construction or operation of the Yolo Bypass fisheries enhancements.
- *CM3 Natural Communities Protection and Restoration*: The BDCP proposes to benefit alkali seasonal wetland plants by protecting 150 acres of alkali seasonal wetland in Conservation Zones 1, 8, and/or 11. The protected alkali seasonal wetland habitat would be managed and enhanced to sustain populations of native plant species.
- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration is expected to convert alkali seasonal wetlands on the margins of tidal wetlands to freshwater or brackish tidal marsh. Tidal habitat restoration would convert 680 acres of modeled habitat for San Joaquin spearscale to tidal marsh. Tidal habitat restoration would permanently remove 4 acres of modeled habitat for brittlescale in CZ 1 near Lindsey Slough and in CZ 11 near Nurse Slough; however, the BDCP would allow up to 50 acres of modeled habitat to be converted to tidal wetlands. Tidal habitat restoration would remove 306 acres of modeled habitat for heartscale in CZ 1 in the vicinity of Jepson Prairie and in CZ 11 adjacent to Suisun Marsh. The extent to which the modeled habitat is actually occupied by these species is not known; modeled habitat is assumed to encompass all potential habitat for a species and may therefore overestimate the area actually occupied. Tidal habitat restoration could adversely affect an occurrence of Heckard's peppergrass at Hass Slough and an occurrence of San Joaquin spearscale at Main Prairie, both in CZ 1. These occurrences are based on historic records, and the whether or not the populations still exist is not known. In each case, the loss of modeled habitat and occurrences for covered species would be adverse effects. Delta button celery, crownscale, palmate-bracted bird's-beak, and recurved larkspur would not be affected by tidal habitat restoration.
- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration levee construction would result in the removal of 2 acres of modeled habitat for San Joaquin spearscale. No known occurrences of San Joaquin spearscale would be affected. No other alkali seasonal wetland habitat or occurrences of special-status alkali seasonal wetland plants are present within areas proposed for floodplain restoration. Therefore, floodplain restoration and construction of new

floodplain levees would have no impacts on covered and noncovered alkali seasonal wetland plants.

- *CM6 Channel Margin Enhancement*: No alkali seasonal wetland habitat or occurrences of special-status alkali seasonal wetland plants are present within areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on covered and noncovered alkali seasonal wetland plants.
- *CM7 Riparian Natural Community Restoration*: No alkali seasonal wetland habitat or occurrences of special-status alkali seasonal wetland plants are present within areas proposed for riparian habitat enhancement. Therefore, riparian habitat enhancement would have no impacts on covered and noncovered alkali seasonal wetland plants.
- *CM8 Grassland Natural Community Restoration*: Although the alkali seasonal wetland habitat includes the grassland matrix within which the wetlands occur, grassland restoration activities would take place in non-grasslands (ruderal habitat, cultivated land) or degraded grasslands that are not included within alkali seasonal wetland habitat. Therefore, grassland communities restoration would have no impacts on covered and noncovered alkali seasonal wetland plants.
- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: Although some vernal pools are alkaline, alkali seasonal wetlands in the study area consist of alkali grassland, alkali meadow, or iodine bush scrub. Therefore, vernal pool restoration would avoid alkali seasonal wetland habitat and would have no impacts on covered and noncovered alkali seasonal wetland plants. In addition, the BDCP would compensate for the loss of alkali seasonal wetlands from other CMs by restoring or creating 72 acres of alkali seasonal wetlands in Conservation Zones 1, 8, or 11 to achieve no net loss of this habitat.
- *CM10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid alkali seasonal wetland habitat and would have no impacts on covered and noncovered alkali seasonal wetland plants.
- *Avoidance and Minimization Measures*: Effects on special-status alkali seasonal wetland plants potentially resulting from implementation of CM4 would be avoided or minimized though *AMM11 Covered Plant Species*, *AMM2 Construction Best Management Practices and Monitoring*, and *AMM37 Recreation*. Under AMM11, surveys for covered plant species would be performed during the planning phase of projects, and any impacts on populations of covered species would be avoided through project design or subsequently minimized though AMM2. In addition, AMM11 prohibits ground disturbance or hydrologic disturbance within 250 feet of existing vernal pools, which would protect those species with modeled habitat that includes vernal pool complex. Occurrences of covered species in vernal pools near tidal wetlands would not be affected by tidal habitat restoration where critical habitat for vernal pool species is present and would be avoided under AMM11. AMM37 requires that new recreation trails avoid populations of covered alkali seasonal wetland plants.

In summary, one historic occurrence of Heckard's peppergrass and one historic occurrence of San Joaquin spearscale could be affected by tidal restoration activities, if those occurrences still exist. AMM11 would be implemented to avoid an adverse effect on the Heckard's peppergrass and San Joaquin spearscale occurrences.

The primary effect of Alternative 9 on special-status alkali seasonal wetland plants would be the loss of potential (i.e., modeled) habitat for San Joaquin spearscale, brittlescale, heartscale, and Delta button-celery. Approximately 72 acres of this habitat loss would be alkali seasonal wetlands. The actual effect on modeled habitat for alkali seasonal wetland plants is expected to be somewhat less than the estimated impact because some of this habitat is composed of vernal pool complex, and the BDCP limits the total loss of wetted vernal pool habitat to 10 acres (approximately 67 acres of vernal pool complex) over the permit term (AMM12). Loss of modeled habitat would be compensated for by restoring or creating vernal pool complex, alkali seasonal wetlands, and grasslands, in proportion to the amount of each habitat removed. At the proposed restoration ratios of 1:1 (prior to impact) and 1.5:1 (concurrent with impact), between 67 and 100.5 acres of vernal pool complex restoration would be required to compensate for the loss of modeled habitat composed of vernal pool complex (Objective VPNC1.2, associated with CM9). Approximately 72 acres of alkali seasonal wetlands would be restored (Objective ASWC1.2, associated with CM9). Loss of modeled habitat composed of grasslands would be compensated for by restoring grassland habitat on a 1:1 basis (Objective GNC1.1, associated with CM8). These compensation levels would be consistent with typical NEPA and CEQA project-level mitigation ratios for impacts on vernal pools, alkali seasonal wetlands, and grasslands.

Alternative 9 would have a small beneficial effect on special-status alkali seasonal wetland plants by protecting 150 acres of alkali seasonal wetland habitat. The BDCP also includes the species-specific goals that 75 acres of the protected alkali seasonal wetland habitat would be modeled habitat for brittlescale and heartscale (Objective BRIT/HART/SJSC1.1) and that 2 occurrences of San Joaquin spearscale would be protected (Objective BRIT/HART/SJSC1.2). The benefits of habitat protection and management also would accrue to any noncovered alkali seasonal wetland plants occurring in the protected habitat.

***NEPA Effects*:** Under Alternative 9, loss of modeled habitat for alkali seasonal wetland plant species would be offset through restoration of grassland, vernal pool, and alkali seasonal wetland habitat (CM8, CM9), and impacts on one occurrence of San Joaquin spearscale and one occurrence of Heckard's peppergrass would be avoided through AMM11. With avoidance and habitat restoration, these effects would not be adverse.

***CEQA Conclusion*:** Because loss of modeled habitat for alkali seasonal wetland plant species would be offset through restoration, and because impacts on occurrences of covered alkali seasonal wetland plants would be avoided, impacts on alkali seasonal wetlands as a result of implementing Alternative 9, would not result in substantially reducing the number or restricting the range of five covered and three noncovered plant species, and this impact would be less than significant. No mitigation is required.

Grassland Plants

One covered plant and 11 noncovered special-status plants occur in grasslands in the study area (Tables 12-2, 12-3, summarized in Table 12-9-64). The only covered plant species occurring in grassland is Carquinez goldenbush. Carquinez goldenbush modeled habitat included hydrological features such as stream corridors on alluvium derived from the Montezuma Formation. Stream corridors (intermittent and perennial) that intersected these geologic units were selected and truncated at the point at which they encountered the upper elevation of intertidal marsh. The corridors were buffered 50 feet (15 meters) on either side in an effort to capture the estimated maximum extend of alluvium deposits in close proximity to the actual rivers/streams.

Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP to benefit covered grassland plants (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect three unprotected occurrences of the Carquinez goldenbush in Conservation Zones 1 and/or 11 (Objective CGB1.1, associated with CM3).
- Maintain and enhance occupied Carquinez goldenbush habitat to slow erosion and reverse degradation from livestock grazing (Objective CGB1.2, associated with CM11).

Of 78,047 acres of grasslands in the study area, Alternative 9 would adversely affect 2,706 acres under Alternative 9, including 4 acres that are modeled habitat for Carquinez goldenbush. For 10 of the plants, no known occurrences would be affected. One of five Parry's rough tarplant occurrences in the study area could be affected by Alternative 9. Table 12-9-64 summarizes the acreage of grassland habitat in the study area and the number of occurrences of each special-status grassland plant in the study area.

Table 12-9-64. Summary of Impacts on Grassland Plants under Alternative 9

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Carquinez goldenbush modeled habitat	1,346	4			Habitat loss from tidal habitat restoration
Grassland	78,047	2,706			Habitat loss from construction of water conveyance facilities, tidal restoration, Yolo Bypass fisheries enhancements, floodplain restoration, and construction of conservation hatcheries facilities
Covered Species					
Carquinez goldenbush			10	1	Occurrence affected by tidal restoration
Noncovered Species					
Big tarplant			5	0	None
Round-leaved filaree			2	0	None
Pappose tarplant			7	0	None
Parry's rough tarplant			5	1	Periodic inundation of one occurrence as a result of Yolo Bypass operations
Small-flowered morning-glory			0	0	None
Diamond-petaled poppy			1	0	None
Stinkbells			1	0	None
Fragrant fritillary			4	0	None
Gairdner's yampah			0	0	None
Streamside daisy[a]			1	0	None
Caper-fruited tropidocarpum			8	0	None

[a] This species actually occurs in upland woodland, a habitat that has not been mapped or quantified in the BDCP.

Impact BIO-171: Effects on Habitat and Populations of Grassland Plant Species

Alternative 9 could have adverse effects on modeled habitat for Carquinez goldenbush. It could also affect one occurrence of Carquinez goldenbush and one occurrence of Parry's rough tarplant. Although Alternative 9 would have no expected effects on known occurrences of the other special-status plant species that occur in grasslands, the loss of 3,389 acres of grassland would have the potential to adversely affected undocumented populations of special-status grassland species.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: No modeled habitat for Carquinez goldenbush and no known occurrences of the 12 special-status grassland plants are within the proposed footprint for the Alternative 9 water conveyance facilities. About 427 acres of grassland habitat would be affected by construction of the water conveyance facilities. However, this grassland habitat consists of small patches of herbaceous ruderal vegetation along levees that do not provide habitat for special-status grassland species. Therefore, under Alternative 9, construction and operation of the water conveyance facilities would not affect the 12 special-status grassland plants.
- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo Bypass fisheries enhancements would remove 627 acres of grassland habitat. Yolo Bypass operations would result in more frequent and longer inundation of 1,597 acres of grasslands in the Yolo Causeway (CZ 2) that include habitat for one occurrence of Parry's rough tarplant. Parry's rough tarplant is a summer-blooming plant that occurs in areas subject to occasional inundation during the wet season, such as swales and seasonal wetlands. Increasing the frequency or duration of inundation may decrease the distribution in some areas by making some conditions too wet but would also expand the distribution into areas that may currently be too dry. Overall, changing the frequency and duration of inundation in the area of this occurrence should not result in a substantial change in the range of numbers of Parry's rough tarplant. Construction and operation of the Yolo Bypass fisheries enhancements would not affect modeled habitat for Carquinez goldenbush or known occurrences of other special-status grassland plants.
- *CM3 Natural Communities Protection and Restoration*: The BDCP proposes to preserve 8,000 acres of grassland habitat, some of which may contain modeled habitat for Carquinez goldenbush. Protection of grassland habitat may also protect undiscovered occurrences of special-status plant species.
- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration would permanently remove 1,122 acres of grassland habitat Four acres of modeled habitat for Carquinez goldenbush along the eastern side of Suisun Marsh could be loss as a result of habitat conversion, including part of one known occurrence. Tidal restoration would have not affect other known occurrences of special-status grassland plants.
- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of new floodplain levees would result in the loss of 85 acres of grassland habitat, and periodic inundation of the floodplain would affect 513 acres of grassland habitat,. However, no modeled habitat for Carquinez goldenbush or known occurrences of special-status grassland plants are present within areas proposed for floodplain restoration, and the affected grassland habitat consists of herbaceous ruderal vegetation that does not support special-status grassland plants. Therefore, floodplain restoration and construction of new floodplain levees would have no impacts on covered and noncovered grassland plants.
- *CM6 Channel Margin Enhancement*: No known occurrences of special-status grassland plants are present within areas proposed for channel margin habitat enhancement. Areas mapped as grassland along levees that would be affected by channel margin habitat enhancement are small patches of ruderal vegetation along levees that do not provide habitat for special-status grassland species and are not modeled habitat for Carquinez goldenbush. Therefore, channel

margin habitat enhancement would have no impacts on covered and noncovered grassland plants.

- *CM7 Riparian Natural Community Restoration*: No modeled habitat for Carquinez goldenbush or known occurrences of special-status grassland plants are present within areas proposed for riparian habitat enhancement. About 401 acres of grassland habitat would be converted to riparian habitat. The affected grassland habitat consists of herbaceous ruderal vegetation that does not support special-status grassland plants. Therefore, riparian habitat enhancement would have no impacts on covered and noncovered grassland plants.
- *CM8 Grassland Natural Community Restoration*: Grassland restoration would restore 2,000 acres of grassland habitat. Restoration activities would take place in non-grasslands (ruderal habitat, cultivated land) or degraded grasslands. These areas do not currently provide habitat for special-status grassland plants. Therefore, grassland community restoration would have no impacts on covered and noncovered grassland plants.
- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: Vernal pool complex includes vernal pools as well as the surrounding grassland matrix. Because the habitat to be restored would consist of areas of former vernal pool complex that have been leveled for cultivation, special-status grassland plants would not be present. Therefore, vernal pool complex restoration would not affect special-status grassland plants.
- *CM10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid grassland habitat and would have no impacts on covered and noncovered grassland plants.
- *CM18 Conservation Hatcheries*: Construction of the conservation hatcheries would remove 35 acres of grassland habitat. The removed habitat would consist of ruderal herbaceous vegetation that would not be likely to provide habitat for special-status grassland plants. Therefore, construction of the conservation hatcheries would not be expected to affect special-status grassland plants.
- *Avoidance and Minimization Measures*: Effects on Carquinez goldenbush potentially resulting from implementation of CM4 and potential effects on undiscovered populations of special-status grassland plants would be avoided or minimized though *AMM11 Covered Plant Species*, *AMM2 Construction Best Management Practices and Monitoring*, and *AMM37 Recreation*. Under AMM11, surveys for covered plant species would be performed during the planning phase of projects, and any impacts on populations of covered species would be avoided through project design or subsequently minimized though AMM2. AMM37 requires that new recreation trails avoid populations of Carquinez goldenbush.

The primary effect of Alternative 9 on special-status grassland plants is the loss of potential (i.e., modeled) habitat for Carquinez goldenbush, including part of one known occurrence. Adverse effects on the occurrence will be minimized through AMM11. Protecting three unprotected occurrences of Carquinez goldenbush (Objective CGB1.1, associated with CM3) and maintaining and enhancing occupied Carquinez goldenbush (Objective CGB1.2, associated with CM11) would compensate for any residual effects. One occurrence of Parry's rough tarplant would be affected by CM2, but the effect is not expected to be adverse. No known occurrences of the other special-status grassland plants would be affected.

Alternative 9 would have a potential beneficial effect on special-status grassland plants by protecting 8,000 acres of grassland habitat. To ensure that this habitat preservation would specifically benefit Carquinez goldenbush, the plan proposes to protect three Carquinez goldenbush occurrences in CZs 1 and 11 that are currently not protected and to maintain and enhance occupied Carquinez goldenbush habitat. The preservation of modeled or potential habitat, together with avoidance and minimization of impacts on species occurrences, would reduce any effects Alternative 9 on covered grassland plants to a level that is no longer adverse.

***NEPA Effects*:** The loss of modeled and occupied habitat for Carquinez goldenbush would be offset through CM3, CM8, and CM11. Therefore, implementation of Alternative 9 would result in no adverse effects on special-status grassland plants.

***CEQA Conclusion*:** Because adverse effects on special-status grassland plant species would be avoided or compensated for, Alternative 9 would not result in substantially reducing the numbers or restricting the range of one covered or 11 noncovered special-status grassland plants, and this impact would be less than significant. No mitigation is required.

Valley/Foothill Riparian Plants

Two covered plants and two noncovered special-status plants occur in valley/foothill riparian habitat in the study area (Tables 12-2, 12-3, summarized in Table 12-9-65). The valley/foothill riparian habitat model for Delta button-celery and slough thistle was mapped as all of the study area along the flood plain of the San Joaquin River between the levees from the Mossdale Bridge to Vernalis. Whether or not this modeled habitat is actually occupied by Delta button-celery and slough thistle is unknown; all known occurrences of these species within the area of modeled habitat are believed to be extirpated.

Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP to benefit covered valley/foothill riparian plants (BDCP Chapter 3 Section 3.3, *Biological Goals and Objectives*).

- Protect and enhance two occurrences of delta button celery. If occurrences are not found in the Plan Area, establish self-sustaining occurrences of delta button celery for a total of two occurrences within the restored floodplain habitat on the mainstem of the San Joaquin River in Conservation Zone 7 between Mossdale and Vernalis. (Objective DBC1.1, associated with CM3 and CM11)
- Protect and enhance two occurrences of slough thistle. If occurrences are not found in the Plan Area, establish self-sustaining occurrences of slough thistle for a total of two occurrences within the 10,000 acres of restored floodplain on the mainstem of the San Joaquin River in Conservation Zone 7 between Mossdale and Vernalis (Objective ST1.1: associated with CM3 and CM11).

Of 17,966 acres of valley/foothill riparian habitat in the study area, Alternative 9 would adversely affect 1,116 acres, including 15 acres that are modeled habitat for Delta button-celery and 11 acres that are modeled habitat for slough thistle. Table 12-9-65 summarizes the acreage of modeled habitat for Delta button-celery and slough thistle and the number of occurrences of each special-status grassland plant in the study area.

Table 12-9-65. Summary of Impacts on Valley/Foothill Riparian Plants under Alternative 9

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Delta button celery modeled habitat	3,361[a]	15			Habitat loss from floodplain restoration
Slough thistle modeled habitat	1,834	11			Habitat loss from floodplain restoration
Valley/foothill riparian habitat	17,966	1,116			Habitat loss from construction of water conveyance facilities, tidal restoration, Yolo Bypass fisheries enhancements, and floodplain restoration
Covered Species					
Delta button celery			1[b]	1	Occurrence potentially affected by floodplain restoration
Slough thistle			2	2	Occurrences potentially affected by floodplain restoration
Noncovered Species					
Northern California black walnut			1	0	None
Wright's trichocoronis			1	0	None

[a] A portion of this acreage consists of alkali seasonal wetland
[b] A second occurrence is in alkali seasonal wetland

Impact BIO-172: Effects on Habitat and Populations of Valley/Foothill Riparian Plants

No extant occurrences of Delta button-celery, slough thistle, Northern California black walnut, or Wright's trichocoronis are present in the study area. Therefore, no impacts on special-status valley/foothill riparian plants are expected. Modeled habitat for Delta button-celery and slough thistle, which may support undocumented occurrences of these species, would be affected by restoration of seasonally inundated floodplain.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of the water conveyance facilities would remove 310 acres of valley-foothill riparian habitat under Alternative 9. However, no modeled habitat and no known occurrences of the four special-status valley/foothill riparian plants are within the proposed footprint for the Alternative 9 water conveyance facilities. Therefore, under Alternative 9, construction and operation of the water conveyance facilities would not affect covered or noncovered special-status valley/foothill riparian plants.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction and operation of the Yolo Bypass fisheries enhancements would adversely affect 176 acres of valley/foothill riparian habitat. However, no modeled habitat and no known occurrences of the four special-status valley/foothill riparian plants are within the hypothetical footprint for construction or operation of the Yolo Bypass fisheries enhancements. Therefore, construction and operation of the Yolo Bypass fisheries enhancements would not affect the covered or noncovered valley/foothill riparian plants.
- *CM3 Natural Communities Protection and Restoration*: The BDCP proposes to protect 552 acres of existing valley/foothill riparian forest in CZ 7. This action would have no substantial effects on special-status valley/foothill plants because no extant occurrences of special-status valley/foothill plants are present in the study area.
- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration would inundate 552 acres of valley/foothill riparian habitat. However, no modeled habitat and no known occurrences of the four special-status valley/foothill riparian plants are within the hypothetical footprint for tidal restoration. Therefore, tidal restoration would not affect the covered or noncovered valley/foothill riparian plants.
- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration levee construction would remove about 78 acres of valley/foothill riparian habitat, including 15 acres of modeled habitat for Delta button-celery along the San Joaquin River in CZ 7. In addition, floodplain restoration would result in more frequent and longer inundation of 18 acres of modeled habitat for Delta button-celery in this area. The area affected contains one historic occurrence of Delta button celery. This occurrence is considered to be extirpated, because all habitat for Delta button-celery at his location has been converted to agriculture (California Department of Fish and Wildlife 2013). Therefore, Alternative 9 would not have an adverse effect on Delta button celery in CZ 7.

  The BDCP proposes to benefit Delta button-celery at this location by restoring 5,000 acres of valley/foothill riparian habitat and re-introducing two occurrences of Delta button-celery. Although Delta button celery occurs in riparian habitat, it is not associated with woodland or scrub habitats; rather, it occurs in alkali seasonal wetlands in floodplains, which may or may not also contain adjacent woody riparian habitat. Restoring habitat for Delta button-celery may not be compatible with restoring woody riparian habitat. In addition, establishing new populations of Delta button-celery is an untried, unproven procedure and may not be feasible. Therefore, any beneficial effects on Delta button-celery would be speculative.

  Floodplain restoration levee construction would remove 11 acres of modeled habitat for slough thistle and would result in more frequent and longer inundation of 6 acres of modeled habitat for slough thistle along the San Joaquin River in CZ 7. However, the BDCP would allow up to 50 acres of modeled habitat to be converted to riparian habitat. Whether the affected modeled habitat is actually occupied by slough thistle is not known; however, of two historic occurrences of slough thistle present in the study area, only one is considered to be extirpated (California Department of Fish and Wildlife 2013). The BDCP would protect and enhance two occurrences of slough thistle. If occurrences are not found in the study area, then two, self-sustaining occurrences of slough thistle would be established using locally-sourced genetic material for a total of two occurrences within the restored floodplain habitat on the main stem of the San Joaquin River in CZ 7 between Mossdale and Vernalis. Establishing new populations of slough thistle is an untried, unproven procedure and may not be feasible. Therefore, any beneficial effects on slough thistle would be speculative.

One historic occurrence of Wright's trichocoronis in the study area near Lathrop (CZ 7) could also be affected by floodplain restoration. The occurrence is presumed to be extant because the presence or absence of suitable habitat has not been verified by field surveys (California Department of Fish and Wildlife 2013). However, the species has not been observed at this location for nearly a century, and habitat for Wright's trichocoronis, which would have been similar to that for Delta button celery and slough thistle, no longer appears to be present in aerial photographs of the area. Therefore, Alternative 9 would not be expected to have an adverse effect on Wright's trichocoronis.

- *CM6 Channel Margin Habitat Enhancement*: No modeled habitat or occurrences of special-status valley/foothill riparian plants are present within areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on covered and noncovered valley/foothill riparian plants.
- *CM7 Riparian Natural Community Restoration*: No extant occurrences of special-status valley/foothill riparian plants are present within areas proposed for riparian habitat restoration. Therefore, riparian habitat restoration would have no impacts on covered and noncovered valley/foothill riparian plants.
- *CM8 Grassland Natural Community Restoration*: No occurrences of special-status valley/foothill riparian plants are present within areas proposed for grassland communities restoration. Therefore, grassland communities restoration would have no impacts on covered and noncovered valley/foothill riparian plants.
- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: No occurrences of special-status valley/foothill riparian plants are present within areas proposed for vernal pool and alkali seasonal wetland complex restoration. Therefore, vernal pool complex restoration would have no impacts on covered and noncovered valley/foothill riparian plants.
- *CM10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid valley/foothill riparian habitat and would have no impacts on covered and noncovered valley/foothill riparian plants.
- *Avoidance and Minimization Measures*: Effects on Delta button-celery and slough thistle potentially resulting from implementation of CM5 would be avoided or minimized though *AMM11 Covered Plant Species* and *AMM2 Construction Best Management Practices and Monitoring*. Under AMM11, surveys for covered plant species would be performed during the planning phase of projects, and any impacts on populations of covered species would be avoided through project design or subsequently minimized though AMM2.

Because no extant occurrences of special-status valley/foothill riparian plants are known to occur in the study area, Alternative 9 is not expected to adversely affect any special-status valley/foothill riparian plants. Modeled habitat for both Delta button-celery and slough thistle would be affected. Under AMM11, surveys for covered plants would be performed during the planning phase for floodplain restoration. If Delta button-celery or slough thistle were found to be present in the floodplain restoration area, then the project would be designed to avoid impacts on the populations. Therefore, Alternative 9 would not have an adverse effect on these species.

The BDCP proposes to benefit Delta button-celery and slough thistle by restoring 5,000 acres of valley/foothill riparian habitat and re-introducing two occurrences of both species. Establishing new populations of Delta-button-celery or slough thistle would be a beneficial effect. However, establishing new populations is an untried, unproven procedure and may not be feasible.

NEPA Effects: Implementation of the BDCP under Alternative 9 would not have an adverse effect on special-status valley/foothill riparian plant species.

CEQA Conclusion: Alternative 9 would not result in a reduction in the range and numbers of covered and noncovered valley/foothill riparian plants. This impact would be less than significant. No mitigation is required.

Tidal Wetland Plants

Seven covered plants and one noncovered special-status plant occur in tidal wetlands in the study area (Tables 12-2, 12-3, summarized in Table 12-9-66). Five tidal wetland habitat models were developed for the seven covered plant species occurring in tidal wetland habitat.

Modeled habitat for Mason's lilaeopsis and Delta mudwort was mapped as areas within 10 feet (3 meters) on either side of the landward boundary of tidal perennial aquatic land cover type, which was obtained from the BDCP GIS vegetation data layer.

The side-flowering skullcap model mapped the distribution of suitable habitat in the study area according to the species' habitat association with woody riparian habitat. The model selected Delta riparian vegetation types providing the habitat characteristics that side-flowering skullcap seems to require, namely, woody substrate in freshwater tidal areas. The model included vegetation subunits of the BDCP Valley Riparian natural community characterized by California dogwood, white alder, and arroyo willow.

The modeled habitat for soft bird's-beak consisted of pickleweed- and saltgrass-dominated vegetation units located west of the Antioch Bridge. Modeled habitat for these two plant species was mapped as areas within 10 feet (3 meters) on either side of the landward boundary of tidal perennial aquatic land cover types. The model used all Tidal Brackish Emergent Wetland polygons that were limited by specific vegetation units that are known to be closely associated with soft bird's-beak habitat.

Habitat for Delta tule pea and Suisun Marsh aster was modeled separately based on the salinity of the water. For the tidal freshwater emergent wetland BDCP land cover type, modeled habitat was mapped as the area within 10 feet (3 meters) of the landward side of the landward boundary, exclusively where this land cover type is adjacent to grassland, vernal pool complex, valley/foothill riparian, or cultivated land habitat cover types. For brackish water areas in and near Suisun Marsh, the model used all tidal brackish emergent wetland polygons within an elevation range of 7 to 10 feet (2 to 3 meters) to capture elevations 1 foot (30 centimeters) below intertidal to 2 feet (60 centimeters) above intertidal.

The modeled habitat for Suisun thistle in and near Suisun Marsh consists of all tidal brackish emergent wetland polygons with the appropriate vegetation. This included vegetation units dominated by saltscale, saltgrass, pickleweed, and broad-leaved peppergrass.

Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP to benefit covered tidal wetland plants (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- No net loss of Mason's lilaeopsis and delta mudwort occurrences within restoration sites, or within the area of affected tidal range of restoration projects (Objective DMW/ML1.1, associated with CM4 and CM11).
- No net loss of Delta tule pea and Suisun Marsh aster occurrences within restoration sites (Objective DTP/SMA1.1, associated with CM4 and CM11).
- Restore tidal inundation to wetlands in the Hill Slough Ecological Reserve and to the ponded area at Rush Ranch (Objective SBB/SuT1.1, associated with CM4).
- Complete seed banking of all existing Suisun Marsh populations and the representative genetic diversity using accepted seed banking protocols (Objective SBB/SuT1.2, associated with CM11).
- Establish a cultivated population of Suisun thistle from wild seed using accepted seed collection protocols (Objective SBB/SuT1.3, associated with CM11).
- Establish two occurrences of Suisun thistle in Conservation Zone 11 (Objective SBB/SuT1.4, associated with CM11).

Of 17,357 acres of tidal wetlands in the study area, Alternative 9 would affect 193 acres, including areas that are modeled habitat for Mason's lilaeopsis, Delta mudwort, side-flowering skullcap, Delta tule pea, Suisun Marsh aster, soft bird's-beak, and Suisun thistle. Known occurrences of all of these species would be affected. In addition, three occurrences of Bolander's water-hemlock, a noncovered special-status plant, could be affected by tidal habitat restoration. Table 12-9-66 summarizes the acreage of modeled habitat for covered tidal wetland species and the number of occurrences of each special-status tidal wetland plants in the study area.

Table 12-9-66. Summary of Impacts on Tidal Wetland Plants under Alternative 9

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Delta mudwort/ Mason's lilaeopsis modeled habitat	6,081	163			Habitat loss from construction of water conveyance facilities, tidal habitat restoration, Yolo Bypass fisheries enhancements, and floodplain restoration
Side-flowering skullcap modeled habitat	2,497	173			Habitat loss from construction of water conveyance facilities, conveyance facilities, tidal habitat restoration, Yolo Bypass fisheries enhancements, and floodplain restoration
Soft bird's-beak modeled habitat	1,228	73			Habitat loss from tidal habitat restoration
Delta tule pea/ Suisun Marsh aster modeled habitat	5,853	26			Habitat loss from construction of water conveyance facilities, tidal habitat restoration, Yolo Bypass fisheries enhancements, and floodplain restoration
Suisun thistle modeled habitat	1,281	73			Habitat loss from tidal habitat restoration

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Tidal brackish emergent wetland	8,501	0			None
Tidal freshwater emergent wetland	8,856	193			Habitat loss from construction of water conveyance facilities, tidal habitat restoration, Yolo Bypass fisheries enhancements, and floodplain restoration
Covered Species					
Delta mudwort			58	10	Occurrences affected by construction of water conveyance facilities and tidal habitat restoration
Delta tule pea			106	30	Occurrences affected by construction of water conveyance facilities and tidal habitat restoration
Mason's lilaeopsis			181	27	Occurrences affected by construction of water conveyance facilities and tidal habitat restoration
Side-flowering skullcap			12	1	Occurrences affected by construction of water conveyance facilities
Soft bird's-beak			13	7	Occurrences affected by tidal habitat restoration
Suisun Marsh aster			164	27	Occurrences affected by construction of water conveyance facilities and tidal habitat restoration
Suisun thistle			4	0	None
Noncovered Species					
Bolander's water hemlock			8	3	Occurrences affected by construction of water conveyance facilities and tidal habitat restoration

Impact BIO-173: Effects on Habitat and Populations of Tidal Wetland Plants

Alternative 9 would have adverse effects on tidal marsh special-status plants through implementation of CM1, CM2, CM4, and CM5. No adverse effects are expected from implementation of CM3, CM6, CM7, CM8, and CM9.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of the Alternative 9 water conveyance facilities would remove 163 acres of modeled habitat for delta mudwort and Mason's lilaeopsis, 173 acres of modeled habitat for side-flowering skullcap, and 26 acres of modeled habitat for Delta tule pea and Suisun Marsh aster. The extent to which modeled habitat is actually occupied by these species is not known; however, 12 occurrences of Mason's lilaeopsis, eight occurrences of Delta mudwort, one occurrence of Suisun Marsh aster, two occurrences of side-flowering skullcap, and one occurrence of Bolander's water-hemlock in the study area could be affected by construction impacts. No known occurrences of soft bird's-beak or Suisun thistle would be affected by construction of the water conveyance facilities.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo Bypass fisheries enhancements would remove 5 acres of modeled habitat for Mason's lilaeopsis and delta mudwort. The extent to which modeled habitat is actually occupied by these species is not known; however, no known occurrences in the study area would be affected. Yolo Bypass operations would result in more frequent and longer inundation of 8 acres of modeled habitat Delta tule peas and Suisun Marsh aster. Two occurrences of Suisun Marsh aster would be affected by Yolo Bypass operations. Habitat for these species is normally periodically inundated or saturated; therefore, a small increase in the frequency and duration of periodic inundation of the habitat would not be expected to have a substantial effect.
- *CM3 Natural Communities Protection and Restoration*: The BDCP proposes restoring or creating 20 linear miles of transitional tidal areas within other natural communities that would be created or restored, including 6,000 acres of tidal brackish emergent wetland and 24,000 acres of tidal freshwater emergent wetland. In addition, the habitat and ecosystem functions of these areas would be maintained and enhanced. The BDCP does not specifically propose to protect any occurrences of tidal wetland plants nor does it propose active restoration of affected habitat or occurrences. Instead, the BDCP assumes that the 20 linear miles of restored transitional tidal areas will be passively colonized by the covered tidal wetland plants.
- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration would permanently remove 6 acres of modeled habitat for Mason's lilaeopsis and Delta mudwort. Habitat loss would occur through conversion of the species habitat (at and immediately above the tidal zone in marshes and along rivers and streams) to inundated tidal habitat. The extent to which modeled habitat is actually occupied by the species is not known; however, 14 of 176 known occurrences of Mason's lilaeopsis and three of 57 known occurrences of delta mudwort in the study area could be affected by tidal habitat restoration.

  Tidal habitat restoration would remove 4 acres of modeled habitat for side-flowering skullcap. Whether the affected modeled habitat is actually occupied by side-flowering skullcap is not known; however, none of the 12 known occurrences in the study area would be affected.

  Tidal habitat restoration would remove 2 acres of modeled habitat for Delta tule pea and Suisun Marsh aster. However, the BDCP would allow up to 50 acres of modeled habitat to be removed. Habitat loss would result from conversion of the species habitat (at and immediately above the tidal zone in marshes and along rivers and streams) to inundated tidal habitat. The extent to which modeled habitat is actually occupied by the species is not known; however, 26 of 112 known occurrences of Delta tule pea and 24 of 145 occurrences of Suisun Marsh aster in the study area would be affected.

  Tidal habitat restoration could affect 73 acres of modeled habitat for soft bird's-beak and Suisun thistle, including 1.3 acres of critical habitat. The extent to which modeled habitat is actually occupied by the species is not known; however, seven of 12 known occurrences of soft bird's-beak in the study area could be affected. None of the four known occurrences of Suisun thistle in the study area would be affected.

Tidal habitat restoration could affect three of eight known occurrences of Bolander's water-hemlock, a noncovered special-status species in the study area. Because Bolander's water-hemlock occurs in tidal marsh, it may benefit from tidal marsh restoration. However, site preparation, earthwork, and other site activities could adversely affect Bolander's water-hemlock through direct habitat removal.

- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration levee construction would remove 3 acres of modeled habitat for Mason's lilaeopsis and delta mudwort and 2 acres of modeled habitat for side-flowering skullcap. No known occurrences of these species in the study area would be affected by floodplain restoration.

  Floodplain restoration would result in more frequent and longer inundation of 2 acres of modeled habitat for Mason's lilaeopsis and delta mudwort, 18 acres of modeled habitat for side-flowering skullcap, and 1 acre of modeled habitat for Delta tule peas and Suisun Marsh aster. No known occurrences of these species in the study area would be affected by periodic inundation of restored floodplain habitat. Habitat for these species is normally periodically inundated or saturated; therefore, a small increase in the frequency and duration of periodic inundation of the habitat would not be expected to have a substantial effect.

- *CM6 Channel Margin Enhancement*: Effects of channel margin enhancement were not analyzed separately from the effects of tidal habitat restoration. Channel margin enhancement would have adverse effects on tidal wetland plants through direct removal and habitat modification. However, it would have beneficial effects on these species by improving the habitat functions for these species as a result of riprap removal and creation of floodplain benches. Side-flowering skullcap would benefit from installation of large woody material, which it appears to colonize.

- *CM7 Riparian Natural Community Restoration*: Riparian habitat restoration is not expected to adversely affect special-status tidal wetland plants. Preparatory work that involves habitat disturbance would occur during implementation of CM4 and CM5. Riparian plantings carried out for CM7 would be placed in floodplain areas, not in tidal wetlands.

- *CM8 Grassland Natural Community Restoration*: No tidal wetlands or occurrences of special-status tidal wetland plants are present within areas proposed for grassland communities restoration. Therefore, grassland communities restoration would have no impacts on covered and noncovered tidal wetland plants.

- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: No tidal wetlands or occurrences of special-status tidal wetland plants are present within areas proposed for vernal pool complex restoration. Therefore, vernal pool complex restoration would have no impacts on covered and noncovered tidal wetland plants.

- *CM10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid tidal wetland habitat and would have no impacts on covered and noncovered tidal wetland plants.

- *Avoidance and Minimization Measures*: Effects on covered tidal wetland plants potentially resulting from implementation of CM1, CM2, CM4, and CM5 would be avoided or minimized though *AMM11 Covered Plant Species, AMM2 Construction Best Management Practices and Monitoring, AMM12 Vernal Pool Crustaceans, AMM30 Transmission Line Design and Alignment Guidelines,* and *AMM37 Recreation*. Under AMM11, surveys for covered plant species would be performed during the planning phase of projects, and any impacts on populations of covered species would be avoided through project design or subsequently minimized though AMM2. In addition, AMM11 contains specific guidance to avoid adverse modification of any of the primary constituent elements for Suisun thistle or soft bird's-beak critical habitat. AMM30, which specifies that the alignment of proposed transmission lines will be designed to avoid sensitive terrestrial and aquatic habitats when siting poles and towers, to the maximum extent feasible, would avoid some impacts on Mason's lilaeopsis. AMM37 requires that new recreation trails avoid populations of covered tidal wetland plants.

In summary, the GIS analysis indicates that Alternative 9 would result in the loss of modeled habitat for all of the covered species and result in adverse effects on known occurrences of most of the special-status plants occurring in tidal wetlands. However, the BDCP predicts that habitat restoration activities would greatly expand the amount of habitat available to each of these species, offsetting any potential loss of habitat or occurrences resulting from covered activities.

Delta mudwort could lose 163 acres of modeled habitat (2.7%), including all or part of ten occurrences. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by Delta mudwort, which could offset this habitat loss. Channel margin enhancement (CM6) and riparian natural community restoration (CM7) will also consider the potential for creating habitat for Delta mudwort; creation of suitable habitat under these measures could also help offset this habitat loss. Although active restoration of this species is not proposed, the BDCP predicts that natural expansion of populations into the restored habitat would take place and result in no net loss of occurrences (Objective DMW/ML1.1, associated with CM11). Post-implementation monitoring of affected occurrences and occurrences in reserve lands would be done to confirm that no net loss of occurrences has been achieved (Monitoring Action CM11–CM21, associated with CM11).

Mason's lilaeopsis could lose 163 acres of modeled habitat (2.7%), including all or part of 27 occurrences. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by Mason's lilaeopsis, which could offset this habitat loss. Channel margin enhancement (CM6) and riparian natural community restoration (CM7) will also consider the potential for creating habitat for Mason's lilaeopsis; creation of suitable habitat under these measures could also help offset this habitat loss. Although active restoration of this species is not proposed, the BDCP predicts that natural expansion of populations into the restored habitat would take place and result in no net loss of occurrences (Objective DMW/ML1.1, associated with CM11). Post-implementation monitoring of affected occurrences and occurrences in reserve lands would be done to confirm that no net loss of occurrences has been achieved (Monitoring Action CM11–CM21, associated with CM11).

Delta tule pea could lose 26 acre of modeled habitat (0.4%), including all or part of 30 occurrences. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by Delta tule pea, which could offset this habitat loss. Channel margin enhancement (CM6) and riparian natural community restoration (CM7) will also consider the potential for creating habitat for Delta tule pea; creation of suitable habitat under these measures could also help offset this habitat loss. Although active restoration of this species is not proposed, the BDCP predicts that natural expansion of populations into the restored habitat would take place and result in no net loss of occurrences (Objective DTP/SMA1.1, associated with CM11). Post-implementation monitoring of affected occurrences and occurrences in reserve lands would be done to confirm that no net loss of occurrences has been achieved (Monitoring Action CM11–CM22, associated with CM11).

Suisun Marsh aster could lose 26 acre of modeled habitat (0.4%), including all or part of 27 occurrences. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by Suisun Marsh aster, which could offset this habitat loss. Channel margin enhancement (CM6) and riparian natural community restoration (CM7) will also consider the potential for creating habitat for Suisun marsh aster; creation of suitable habitat under these measures could also help offset this habitat loss. Although active restoration of this species is not proposed, the BDCP predicts that natural expansion of populations into the restored habitat would occur and result in no net loss of occurrences (Objective DTP/SMA1.1, associated with CM11). Post-implementation monitoring of affected occurrences and occurrences in reserve lands would be done to confirm that no net loss of occurrences has been achieved (Monitoring Action CM11–CM22, associated with CM11).

All four of these species (Delta mudwort, Mason's lilaeopsis, Delta tule pea, and Suisun Marsh aster) are widespread in the study area with many occurrences. Habitat modification and loss are the primary stressors that are responsible for their decline and that currently limit their distribution and abundance. Therefore, restoring large areas of habitat and improving habitat functions for these species would provide a reasonable expectation that the distribution and abundance of these species would also improve. Because a relatively small amount of modeled habitat would be adversely affected (less than 1% of the total), it is likely that the initial adverse effects of covered activities on these species would be offset and that the overall effect of Alternative 9 on these species would not be adverse.

Side-flowering skullcap could lose 173 acres of modeled habitat (7%), including all or part of one occurrence. Under AMM11, this occurrence would be surveyed for, and because this is a tidal freshwater wetland species, avoidance of the habitat during project construction would be highly likely. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by side-flowering skullcap, which could offset this habitat loss. Channel margin enhancement (CM6) and riparian natural community restoration (CM7) will also consider the potential for creating habitat for side-flowering skullcap; creation of suitable habitat under these measures could also help offset this habitat loss. No active restoration of this species is proposed, and no post-implementation monitoring of affected occurrences and occurrences in reserve lands would be done. Because impacts on occurrences of side-flowering skullcap would be avoided, and because loss of modeled habitat for the species would be offset through restoration, the overall effect of Alternative on this species would not be adverse.

Soft bird's-beak could lose 73 acres of modeled habitat (6%), including all or part of seven occurrences. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by soft bird's-beak, which could offset this habitat loss. Tidal restoration in the Hill Slough Ecological Reserve would be done to increase potential habitat there for soft bird's-beak (Objective SBB/SuT1.1, associated with CM4). In addition, activities to control invasive plants and manage livestock in tidal marsh habitat under CM11 could enhance habitat for soft bird's-beak. Although no active restoration of this species is proposed, post-implementation monitoring of soft bird's-beak occurrences in proximity to tidal restoration sites would be done to confirm that occurrences are stable or increasing (Monitoring Action CM11–CM22, associated with CM11). Soft bird's-beak has a restricted distribution in the study area with highly localized occurrences, and habitat modification is the primary factor responsible for the species' decline and limiting the species' distribution and abundance. Improving habitat functions for this species would provide a reasonable expectation that the distribution and abundance of soft bird's-beak would also improve. Although a substantial amount of modeled habitat could be affected, the primary habitat for soft bird's-beak is high tidal brackish marsh, and the affected habitat is low tidal brackish marsh. Therefore, it is likely that the overall effect of Alternative 9 on this species would not be adverse.

Suisun thistle could lose 73 acres of modeled habitat (6%), although no occurrences would be affected. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by Suisun thistle, which could offset this habitat loss. Tidal restoration in the Hill Slough Ecological Reserve and at Rush Ranch would be done to increase potential habitat there for Suisun thistle (Objective SBB/SuT1.1, associated with CM4). In addition, activities to control invasive plants and manage livestock in tidal marsh habitat under CM11 could enhance habitat for Suisun thistle. In addition, two new occurrences of Suisun thistle would be established in CZ 11 (Objective SBB/SuT1.4, associated with CM11). Post-implementation monitoring of Suisun thistle occurrences in proximity to tidal restoration sites would be done to confirm that occurrences are stable or increasing (Monitoring Action CM11–CM22, associated with CM11). Habitat restoration, enhancement of habitat functions, and establishment of new occurrences would offset any potential loss of modeled habitat for Suisun Marsh thistle.

Three occurrences of Bolander's water-hemlock could be affected. Although the extent of potential habitat affected was not determined, it would be comparable to that for Delta tule pea and Suisun Marsh aster (5 acres). Tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) could increase the extent of habitat available for colonization by Bolander's water-hemlock, which could offset this habitat loss. Because only a few scattered occurrences of Bolander's water-hemlock are present in the study area, there is no reasonable expectation that habitat restoration without active species-specific restoration activities would result in the establishment of new occurrences to offset the losses. Also, because Bolander's water-hemlock is a noncovered species, the species protections and occurrence monitoring afforded to covered species under the BDCP would not apply to this species. Therefore, the effects of Alternative 9 on Bolander's water hemlock could be adverse.

NEPA Effects: The loss of modeled and occupied habitat for special-status tidal wetland plants would be offset through tidal habitat restoration (CM4). Therefore, implementation of Alternative 9 would result in no adverse effects on seven of eight special-status grassland plants in the study area. Alternative 9 would result in a reduction in the range and numbers of Bolander's water-hemlock, which would be an adverse effect. Adverse effects on Bolander's water-hemlock could be avoided or offset through implementation of Mitigation Measure BIO-170.

CEQA Conclusion: Because loss of occurrences and modeled habitat for covered tidal habitat plant species would be offset through habitat restoration, impacts on covered tidal wetland plants as a result of implementing Under Alternative 9 would not be significant. However, the loss of Bolander's water-hemlock populations in CZ 11 would result in a reduction in the range and numbers of this species and would be a significant impact. Implementation of Mitigation Measure BIO-170 would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant Species

DWR will evaluate all projects for their impacts on special-status plants, avoid or minimize impacts on species that occur on project sites, and compensate for impacts on species. All impacts on diamond-petaled California poppy and caper-fruited tropidocarpum shall be avoided. Impacts on other special-status plant species shall be avoided to the extent feasible, and any unavoidable impacts shall be compensated for.

- DWR shall conduct surveys for the special-status plant species within and adjacent to all project sites. Special-status plant surveys required for project-specific permit compliance will be conducted during the planning phase to allow design of the individual restoration projects to avoid adverse modification of habitat for specified covered plants if feasible. The purpose of these surveys will be to verify that the locations of special-status plants identified in previous record searches or surveys are extant, identify any new special-status plant occurrences, and cover any portions of the project area not previously surveyed. The extent of mitigation of direct loss of or indirect effects on special-status plants will be based on these survey results.
- All surveys shall be conducted by qualified biologists using the using *Guidelines for Conducting and Reporting Botanical Inventories for Federally Listed, Proposed and Candidate Plants* (U.S. Fish and Wildlife Service 1996) and *Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Natural Communities* (California Department of Fish and Game 2009) during the season that special-status plant species would be evident and identifiable, i.e., during their blooming season. Locations of special-status plants in proposed construction areas will be recorded using a GPS unit and flagged.
- The construction monitoring plan for the protection of covered fish, wildlife, and plant species, prepared by DWR before implementing an approved project, will provide for construction activity monitoring in areas identified during the planning stages and species/habitat surveys as having noncovered special-status plant species.
- Where surveys determine that a special-status plant species is present in or adjacent to a project site, direct and indirect impacts of the project on the species shall be avoided if feasible through the establishment of 250-foot activity exclusion zones surrounding the periphery of occurrences, within which no ground-disturbing activities shall take place, including construction of new facilities, construction staging, or other temporary work areas. Activity exclusion zones for special-status plant species shall be established according to a 250-foot buffer surrounding the periphery of each plant species occurrence, the boundaries of which shall be clearly marked with standard orange plastic construction exclusion fencing or its equivalent. The establishment of activity exclusion zones shall not be required if no construction-related disturbances will occur within 250 feet of the occurrence periphery. The size of activity exclusion zones may be reduced through consultation with a qualified biologist and with concurrence from USFWS or CDFW based on project site-specific conditions.
- Where avoidance of impacts on a special-status plant species is infeasible, DWR will compensate for loss of individuals or occupied habitat of a special-status plant species through the acquisition, protection, and subsequent management in perpetuity of other existing occurrences at a 2:1 ratio (preservation: impact). DWR will provide detailed information to USFWS and CDFW on the location of the preserved occurrences, quality of

the preserved habitat, feasibility of protecting and managing the areas in-perpetuity, responsible parties, and other pertinent information. If suitable occurrences of a special-status plant species are not available for preservation, then the project shall be redesigned to remove features that would result in impacts on that species.

Inland Dune Plants

Impact BIO-174: Effects on Habitat and Populations of Inland Dune Plants

Alternative 9 would have no adverse effects on inland dune plants (Table 12-9-67). No construction activities or habitat restoration would take place where the species occur. No specific actions to benefit inland dune species are proposed.

Table 12-9-67. Summary of Impacts on Inland Dune Plants under Alternative 9

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Modeled Habitat					
Inland Dunes	19	0			None
Noncovered Species					
Hoover's cryptantha			1	0	None
Antioch Dunes buckwheat			1	0	None
Mt. Diablo buckwheat			1	0	None
Contra Costa wallflower			3	0	None
Antioch Dunes evening-primrose			9	0	None

NEPA Effects: Implementation of the BDCP under Alternative 9 would not affect special-status inland dune plant species.

CEQA Conclusion: Implementation of Alternative 9 would have no impacts on inland dune species. No mitigation is required.

Nontidal Wetland Plants

No covered plant species occur in nontidal wetlands in the study area; however, six noncovered special-status plant species occur in nontidal wetlands in the study area. Table 12-9-68 summarizes the acreage of nontidal wetland habitat in the study area and the number of occurrences of each special-status nontidal wetland plant in the study area.

Table 12-9-68. Summary of Impacts on Nontidal Wetland Plants under Alternative 9

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Nontidal freshwater aquatic	5,567	269			Loss of habitat from construction of Yolo Bypass fisheries enhancements, tidal habitat restoration, and floodplain restoration
Nontidal freshwater perennial emergent wetland	1,509	151			Loss of habitat from construction of water conveyance facilities, tidal habitat restoration, Yolo Bypass fisheries enhancements, and floodplain restoration
Noncovered Species					
Watershield			3	0	None
Bristly sedge			18	1	Loss of habitat from construction of water conveyance facilities
Woolly rose-mallow[a]			121	14	Loss of habitat from construction of water conveyance facilities, tidal habitat restoration
Eel-grass pondweed			1	1	Loss of habitat from construction of water conveyance facilities
Sanford's arrowhead			23	2	Loss of habitat from construction of water conveyance facilities, tidal habitat restoration
Marsh skullcap[a]			5	1	Loss of habitat from construction of water conveyance facilities

[a] Also occurs in valley/foothill riparian habitat.

Impact BIO-175: Effects on Habitat and Populations of Nontidal Wetland Plants

Under Alternative 9, known occurrences eel-grass pondweed, bristly sedge, woolly rose-mallow, Sanford's arrowhead, and marsh skullcap would be within the proposed footprint for the water conveyance facilities or within the hypothetical footprint for restoration activities and would be adversely affected. Alternative 9 would have no adverse effects on watershield.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Under Alternative 9, the primary effect on noncovered plants would be the loss of occupied habitat as a result of in-stream island dredging and construction of operable barriers. One occurrence of bristly sedge in CZ 5 would be adversely affected by construction of a temporary access road. One occurrence of Sanford's arrowhead in CZ 5 would be adversely affected by installation of an operable barrier and associated transmission lines. Thirteen occurrences of woolly rose-mallow would be affected by channel dredging, construction of operable barriers, and other construction activities: five in CZ 6, one in

CZ 5, one in CZ 4, and six in CZ 8. One occurrence of eel-grass pondweed at the Webb Tract and one occurrence of marsh skullcap on the Middle River are present within areas in CZ 6 that would be affected by construction of water conveyance facilities. The locations of these two occurrences are not known with certainty (i.e., nonspecific occurrences), so the likelihood or extent of the impact cannot be determined.

- *CM2 Yolo Bypass Fisheries Enhancement*: No known occurrences of special-status nontidal wetland plants are present in the hypothetical footprint for construction or operation of the Yolo Bypass fisheries enhancements. Therefore, construction and operation of the Yolo Bypass Fisheries enhancements would not affect special-status nontidal marsh plants.
- *CM3 Natural Communities Protection and Restoration*: No specific natural communities protection is proposed for nontidal wetlands under the BDCP. Therefore, no occurrences of special-status nontidal plants are proposed for protection.
- *CM4 Tidal Natural Communities Restoration*: One known occurrence of Sanford's arrowhead is present within areas that could be affected by tidal habitat restoration in CZ 2. One known occurrence of woolly rose-mallow is present within areas that could be affected by tidal habitat restoration in CZ 7. No other known occurrences of special-status nontidal wetland plants are present within areas proposed for tidal habitat restoration. Therefore, tidal habitat restoration could have adverse effects on three special-status nontidal wetland plants.
- *CM5 Seasonally Inundated Floodplain Restoration*: No known occurrences of special-status nontidal wetland plants are present within areas proposed for floodplain restoration.
- *CM6 Channel Margin Enhancement*: No known occurrences of special-status nontidal wetland plants are present within areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on special-status nontidal wetland plants.
- *CM7 Riparian Natural Community Restoration*: No known occurrences of special-status nontidal wetland plants are present within areas proposed for riparian habitat restoration. Therefore, riparian habitat restoration would have no impacts on special-status nontidal wetland plants.
- *CM8 Grassland Natural Community Restoration*: No known occurrences of special-status nontidal wetland plants are present within areas proposed for grassland communities restoration. Therefore, grassland communities restoration would have no impacts on special-status nontidal wetland plants.
- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: No known occurrences of special-status nontidal wetland plants are present within areas proposed for vernal pool complex restoration. Therefore, vernal pool complex restoration would have no impacts on special-status nontidal wetland plants.
- *CM10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid existing nontidal marsh and would have no adverse effects on special-status nontidal wetland plants. The BDCP may benefit nontidal wetland species by creating 400 acres of nontidal freshwater marsh, including components of nontidal perennial aquatic and nontidal freshwater perennial emergent wetland communities, and by maintaining and enhancing the habitat functions of protected and created nontidal wetland habitats for covered and other native species. However, no specific actions to benefit noncovered species are proposed.

Under Alternative 9, 1,500 acres of nontidal marsh would be restored (Objective NFEW/NPANC1.1, addressed under CM10). However, these wetlands would be restored primarily as habitat for giant garter snake. These habitat restoration activities would be unlikely to expand the amount of habitat available to bristly sedge, woolly rose-mallow, eel-grass pondweed, marsh skullcap, and Sanford's arrowhead, potential loss of habitat or occurrences resulting from covered activities would not be compensated for. Moreover, because special-status nontidal wetland plant species are not covered under the BDCP, the species protections afforded to covered species under the AMMs do not apply to these species, and the effects of Alternative 9 on these species would be adverse.

NEPA Effects: Implementation of the BDCP under Alternative 9 could result in a reduction in the range and numbers of bristly sedge, woolly rose-mallow, eel-grass pondweed, marsh skullcap, and Sanford's arrowhead, five noncovered nontidal wetland species, which would be an adverse effect. Adverse effects on these species could be avoided or offset through implementation of Mitigation Measure BIO-170.

CEQA Conclusion: Under Alternative 9, construction of the water conveyance facilities and tidal habitat restoration would result in a reduction in the range and numbers of bristly sedge, woolly rose-mallow, eel-grass pondweed, marsh skullcap, and Sanford's arrowhead. These impacts would be significant. Implementation of Mitigation Measure BIO-170, *Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant Species*, would reduce these impacts to a less-than-significant level.

Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant Species

Please see Mitigation Measure BIO-170 under Impact BIO-173.

General Terrestrial Biology Effects

Wetlands and Other Waters of the United States

Alternative 9 actions would both permanently and temporarily remove or convert wetlands and open water that are regulated by USACE under Section 404 of the CWA. The Section 404 regulations and relevant information regarding mitigation of impacts on wetlands and waters of the United States are described in Section 12.2.1.1. The following two impacts address the project-level effects of CM1 on these potential wetlands and waters, and the programmatic-level effects of other relevant conservation actions (CM2–CM10). CM11–CM21 would not directly result in loss or conversion of wetlands or other waters of the United States. The methods used to conduct these analyses are described in Section 12.3.2.4, *Methods Used to Assess Wetlands and Other Waters of the United States*. The waters of the United States data used for this analysis is based on a verified wetland delineation from USACE that was completed in early 2015. These waters of the United States were mapped at finer scale than that which was done for the natural community mapping for the BDCP; therefore, the acreages of these two datasets differ. The waters of the United States mapping identified numerous agricultural ditches and seasonal wetlands occurring within and associated with cultivated lands, which explains the majority of the difference.

Impact BIO-176: Effects of Constructing Water Conveyance Facilities (CM1) on Wetlands and Other Waters of the United States

Alternative 9 proposes the construction, maintenance, and operation of water conveyance facilities within, or requiring the unavoidable fill of, waters of the United States. The estimated fill of jurisdictional waters associated with this alternative is described in Table 12-9-69. Based on the methodology used to conduct this analysis, these effects would occur at channel dredging sites, canal construction sites, operable barrier construction sites and channel widening sites throughout the study area, and at multiple temporary work areas associated with the construction activity. The permanent and temporary wetland effects would occur primarily in open tidally-influenced channels of the central and south Delta, including Middle River, Victoria Canal and Old River from channel dredging and canal construction. Construction of various operable barriers in major rivers, canals and sloughs throughout the central and south Delta would also contribute to the large acreage affected by water conveyance construction. Most of the construction and dredging activities would not permanently remove the waterways, but would permanently modify the channel bottoms and eliminate any associated aquatic vegetation. An additional effect on waters of the United States is the dredging of 517 acres of tidal flow in Middle River and Victoria and North Canals.

Table 12-9-69. Estimated Fill of Waters of the United States Associated with the Construction of Water Conveyance Facilities under Alternative 9 (acres)

Wetland/Water Type	Permanent Impact	Temporary Impacts Treated as Permanent[a]	Temporary Impact[b]	Total Impact
Agricultural Ditch	36.4	8.0	1.0	45.3
Alkaline Wetland	0	0	0	0
Clifton Court Forebay	13.2	0	0	13.2
Conveyance Channel	0.4	0	0	0.4
Depression	4.9	0.1	0	4.9
Emergent Wetland	54.1	9.0	165.0	64.0
Forest	23.5	14.0	60.0	38.0
Lake	0	0	0	0
Scrub-Shrub	5.2	4.0	42.0	9.0
Seasonal Wetland	91.6	28.6		120.2
Tidal Channel	687.0	24.0	401.0	712.0
Vernal Pool	0	0	0	0
Total	**916**	**88**	**669**	**1,674**

[a] Temporary impacts treated as permanent are temporary impacts expected to last over one year. These impact sites will eventually be restored to pre-project conditions; however, due to the duration of effect, compensatory mitigation will be included for these areas.

[b] Temporary impacts are due to dredging Delta channels.

The majority of the impacts on wetlands and waters of U.S. are on tidal channels, emergent wetlands, and on wetlands and waters found within cultivated lands (agricultural ditches and seasonal wetlands). These impacts mostly result from dredging work, spoils areas, and canal construction. The impacted seasonal wetlands mapped within the Conveyance Planning Area, as described in Section 12.3.2.4, *Methods Used to Assess Wetlands and Other Waters of the United States*, all occur in the central Delta within plowed agricultural fields.

Unavoidable impacts on waters of the United States would be offset such that the loss of acreage and functions due to construction activities are fully compensated. Wetland functions are defined as a process or series of processes that take place within a wetland. These include the storage of water, transformation of nutrients, growth of living matter, and diversity of wetland plants, and they have value for the wetland itself, for surrounding ecosystems, and for people. Functions can be grouped broadly as habitat, hydrologic/hydraulic, or water quality. Not all wetlands perform all functions nor do they perform all functions equally well. The location and size of a wetland may determine what functions it will perform. For example, the geographic location may determine its habitat functions, and the location of a wetland within a watershed may determine its hydrologic/hydraulic or water-quality functions. Many factors determine how well a wetland will perform these functions: climatic conditions, quantity and quality of water entering the wetland, and disturbances or alteration within the wetland or the surrounding ecosystem. Wetland disturbances may be the result of natural conditions, such as an extended drought, or human activities, such as land clearing, dredging, or the introduction of nonnative species. Wetlands are among the most productive habitats in the world, providing food, water, and shelter for fish, shellfish, birds, and mammals, and serving as a breeding ground and nursery for numerous species. Many endangered plant and animal species are dependent on wetland habitats for their survival. Hydrologic and hydraulic functions are those related to the quantity of water that enters, is stored in, or leaves a wetland. These functions include such factors as the reduction of flow velocity, the role of wetlands as ground-water recharge or discharge areas, and the influence of wetlands on atmospheric processes. Water-quality functions include the trapping of sediment, pollution control, and the biochemical processes that take place as water enters, is stored in, or leaves a wetland.

The functions of the waters of the United States that wwould be temporarily or permanently impacted by this alternative vary greatly depending primarily on existing land uses and historical levels of disturbance. Generally, agricultural ditches and conveyance channels, which are regularly maintained and often devoid of vegetation, support only minimal hydraulic function (water conveyance), with virtually no water quality or habitat function. With respect to Clifton Court Forebay, the facility is regularly maintained, but supports some hydrologic, hydraulic, and water quality functions (e.g., reduction of velocity, groundwater recharge, and trapping of sediment). Tidal channels affected by this alternative support functions in all three categories, but the level at which these functions perform vary depending on setting, size, and level of disturbance. The alkaline wetlands and vernal pools exist in non-native grasslands and have been subjected to some disturbance due to past land uses. Although these features likely support habitat, water quality, and hydrologic/hydraulic functions, the capacity of these features to perform such functions vary depending on the overall ecological setting and level of disturbance. Functions associated with emergent wetland, forest, and scrub-shrub, depend primarily on the location of these habitat types. Where they exist as in-stream (in-channel islands) or as the thick band of habitat adjacent to a waterway, these features are expected to function at a high level. However, where these habitats exist as thin bands, or where they are situated in agricultural fields, their habitat functions will be considerably lower. All of the wetlands classified as seasonal wetlands occur in agricultural fields. As such, their habitat functions have been greatly compromised, but they retain some water quality and hydrologic/hydraulic function. Like seasonal wetlands, most depressions occur within agricultural areas; however the depressions may support wetland vegetation at their edges. The areas mapped as lake are the dredged borrow ponds created during the construction of Interstate 5. Although relatively small, each lake is likely performing functions from all three categories.

A functional assessment of wetlands proposed for fill will be conducted during the development of the Conceptual Mitigation Plan as part of the CWA permitting process. The results of this assessment will be compared with the expected functions at the proposed mitigation site(s) such that it can be confirmed that the compensatory mitigation will in fact accomplish full functional replacement of impacted wetlands. All impacted wetlands would be replaced with fully functional compensatory wetland habitat demonstrating high levels of habitat, water quality, and hydrologic/hydraulic function. Because many impacted wetlands are significantly less than high function, the compensatory mitigation would result in a net increase in wetland function.

Alternative 9 was designed to avoid waters of the United States to the maximum extent practicable. Each of the conveyance components has been located in upland areas where it was feasible to do so. Once construction begins, specific measures will be implemented, as described in the AMMs set out in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to further avoid and minimize effects on waters of the United States as well as on special-status species. The AMMs would be implemented at all phases of a project, from siting through design, construction, and on to operations and maintenance. The AMMs that pertain specifically to waters of the U.S. are *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils*, *AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM12 Vernal Pool Crustaceans*, *AMM30 Transmission Line Design and Alignment Guidelines*, *AMM34 Construction Site Security*, and *AMM36 Notification of Activities in Waterways*.

The implementation of measures to avoid and minimize impacts on habitat for aquatic species and species which utilize aquatic habitats, such as California tiger salamander, giant garter snake, California red legged frog, western pond turtle, riparian woodrat, and riparian brush rabbit, will also result in further avoidance and minimization of effects to waters of the United States.

Aside from wetland habitats that would be created as a result of implementing CM4–CM10, some of which could serve the dual purpose of offsetting effects to species and mitigating impacts on waters of the United States, more specific mitigation is required to ensure that there is no net loss of wetland functions and values as a result of implementing Alternative 9 pursuant to USACE's and EPA's Mitigation Rule (see Section 12.2.1.1). Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the United States,* would be available to address adverse impacts on waters of the United States.

NEPA Effects: The permanent and temporary loss of these jurisdictional wetlands and waters as a result of constructing Alternative 9 water conveyance facilities would be a substantial effect if not compensated by wetland protection and/or restoration. This loss would represent a removal of federally protected wetlands as defined by Section 404 of the CWA. A. Project proponents would implement AMM1–AMM7, AMM10, AMM12, AMM30, AMM34, and AMM36, which would avoid and minimize fill of wetlands and waters and any indirect effects to wetlands and waters. However, specific mitigation would be required to ensure that Alternative 9 does not result in a loss of functions and values of waters of the United States and thus that the affect is not adverse. Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the United States*, would be available to reduce these effects such that they are not adverse.

CEQA Conclusion: The permanent and temporary loss of these jurisdictional wetlands and waters of the United States as a result of constructing Alternative 9 water conveyance facilities would be a significant impact. Specific mitigation would be required to ensure that Alternative 9 does not result in a loss of functions and values of waters of the United States. Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the United States*, would be available to reduce the impact to a less-than-significant level. Additionally, Alternative 9 does propose to restore up to 76,721 acres of wetland natural communities under the Plan, which would include 65,000 acres of tidal marsh restoration (CM4), 10,000 acres of seasonally inundated floodplain restoration (CM5), 21 acres of vernal pool/alkali seasonal wetlands (CM9; 67 acres of vernal pool complex and 72 acres of alkali seasonal wetland complex assuming a wetland density of 15%), and 1,700 acres of nontidal marsh restoration (CM10). In addition, Alternative 9 would restore 5,000 acres of riparian habitat (CM7), some portion of which may also qualify as forested or scrub-shrub wetland. In addition, 20 miles of levees will have channel margin enhancement conducted on them (CM6), which would include improving channel geometry and restoring riparian, marsh, and mudflat habitats on the water side of levees. Impacts on wetlands from CM1 construction would occur in the first 10 years after BDCP approval. Approximately 20,065 acres of this wetland restoration would occur during this time period.

The success in implementing these conservation measures would be assured through effectiveness monitoring, which includes success criteria, and adaptive management as outlined in the *Adaptive Management and Monitoring* sections of the BDCP for tidal marsh restoration (BDCP Chapter 3, Section 3.4.4.4), seasonal floodplain restoration (BDCP Section 3.4.5.4), channel margin enhancement (BDCP Section 3.4.6.4), valley/foothill riparian restoration (BDCP Section 3.4.7.4), vernal pool and alkali seasonal wetland complex restoration (BDCP Section 3.4.9.4), and nontidal marsh restoration (BDCP Section 3.4.10.3). All restored areas will be secured in fee-title or through conservation easements.

Alternative 9 would also result in the protection and management of the following natural communities that contain wetlands: 750 acres of valley/foothill riparian, 600 acres of vernal pool complex, 150 acres of alkali seasonal wetland complex, 8,100 acres of managed wetlands, and 50 acres of nontidal marsh. In addition, 8,000 acres of grasslands and 51,625 acres of cultivated lands will be protected and managed, which would likely include areas of seasonal wetlands, ponds, and agricultural ditches.

Project proponents under Alternative 9 would also implement AMM1–AMM7, AMM10, AMM12, AMM30, AMM34, and AMM36, which would avoid and minimize fill of waters of the United States and any indirect effects on wetlands and waters. As stated above, specific mitigation would be required to ensure that Alternative 9 does not result in a loss of functions and values of waters of the United States. Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the United States*, would be available to reduce the impact to a less-than-significant level.

Mitigation Measure BIO-176: Compensatory Mitigation for Fill of Waters of the United States

All mitigation proposed as compensatory mitigation would be subject to specific success criteria, success monitoring, long-term preservation, and long-term maintenance and monitoring pursuant to the requirements of the Mitigation Rule. All compensatory mitigation shall fully replace lost function through the mechanisms discussed below which will result in restoration and/or creation of habitat with at least as much function and value as those of the impacted habitat. In some cases, the mitigation habitat will afford significantly higher function and value than that of impacted habitat.

Compensation ratios are driven by type, condition, and location of replacement habitat as compared to type, condition and location of impacted habitat. Compensatory mitigation usually includes restoration, creation, or rehabilitation of aquatic habitat. The USACE does not typically accept preservation as the only form of mitigation; use of preservation as mitigation typically requires a very high ratio of replacement to impact. It is anticipated that ratios will be a minimum of 1:1, depending on the factors listed above.

Compensatory mitigation will consist of restoration, creation, and/or rehabilitation of aquatic habitat. Typically, impacted habitat will be replaced in-kind, although impacts on some habitat types such as agricultural ditches, conveyance channels, and Clifton Court Forebay, will be mitigated out-of-kind with higher functioning habitat types such as riparian wetland, marsh, and/or seasonal wetland. Compensatory mitigation shall be accomplished by one, or a combination of the following methods:

- Purchase credits for restored/created/rehabilitated habitat at an approved wetland mitigation bank;
- On-site (adjacent to the project footprint) restoration or rehabilitation of wetlands converted to uplands due to past land use activities (such as agriculture) or functionally degraded by such activities;
- On-site (adjacent to the project footprint) creation of aquatic habitat;
- Off-site (within the Delta) restoration or rehabilitation of wetlands converted to uplands due to past land use activities (such as agriculture) or functionally degraded by such activities;
- Off-site (within the Delta) creation of aquatic habitat; and/or
- Payment into the Corps' Fee-in-Lieu program.

Purchase of Credits or Payment into Fee-in-Lieu Program

It is envisioned that purchase of bank credits and/or payment into a fee-in-lieu program will be utilized for habitat types that would be difficult to restore or create within the Delta. Examples are vernal pool habitat, which requires an intact hardpan or other impervious layer and very specific soil types, and alkali seasonal wetland, which requires a specific set of chemical soil parameters. It is anticipated that only a small amount of compensatory mitigation will fall into these categories.

On-Site Restoration, Rehabilitation and/or Creation

Much of the Delta consists of degraded or converted habitat that is more or less functioning as upland. Opportunities will be sought where on-site restoration, rehabilitation, and/or creation could occur immediately adjacent to the project footprint. It is anticipated that some of the compensatory mitigation will fall into this category.

Off-Site Restoration, Rehabilitation and/or Creation

There exists, within the immediate vicinity of the project area, Delta land which has been subject to agricultural practices or other land uses which have degraded or even converted wetlands that existed historically. Sites within the Delta will be evaluated for their restoration, rehabilitation, and/or creation potential. It is anticipated that most of the compensatory mitigation will fall into this category.

Compensatory mitigation will result in no net loss of acreage of waters of the United States and will accomplish full functional replacement of impacted wetlands. All impacted wetlands will be replaced with fully functioning wetland habitat demonstrating high levels of habitat, water quality, and hydrologic/hydraulic function. Since many impacted wetlands are likely to function at significantly less than high levels, the compensatory mitigation will result in a significant net increase in wetland function.

Impact BIO-177: Effects of Implementing Other Conservation Measures (CM2–CM10) on Wetlands and Other Waters of the United States

The habitat protection and restoration activities associated with Alternative 9's other conservation measures (CM2–CM10) would alter the acreages and functions and values of wetlands and Waters of the United States in the study area during the course of BDCP conservation action implementation. Because these conservation measures have not been defined to the level of site-specific footprints, it is not possible to delineate and quantify these effects in detail. Several of the conservation measures (CM2, CM4, and CM5) have been described with theoretical footprints for purposes of the effects analysis contained in BDCP Chapter 5, *Effects Analysis*.

Because the wetland delineation was only conducted within the Conveyance Planning Area and not the remainder of the Plan Area, the effects on potential wetlands and waters of the United States from CM2–CM10 were analyzed by looking at effects on wetland natural communities mapped within the theoretical footprints for CM2, CM4, and CM5 by assuming that 100% of the predominantly wetland natural communities listed in Appendix 12E, *Detailed Accounting of Direct Effects of Alternatives on Natural Communities*, and that 10% of all of the non-wetland natural communities listed in that table would qualify as wetlands or other waters of the United States under the CWA. Based on this approach approximately 19,850 acres of potentially jurisdictional wetlands and waters could be affected by CM2–CM10. The majority of these impacts are attributable to the conversion of 13,746 acres of managed wetland to tidal marsh under CM4, which would likely result in an improvement of wetland function in the Plan Area.

NEPA Effects: The conversion of existing wetland natural communities to other types of wetland natural communities through implementation of CM2–CM10 for Alternative 9 would be approximately 19,850 acres. Most of these wetlands would be converted to tidal wetlands and open water through implementation of CM4. Although the increase in wetland acreage and wetland functions from these restoration actions could in part offset the effects on waters of the United States in these areas, implementation of Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the United States*, would be required to ensure that these effects are not adverse.

CEQA Conclusion: The conversion of existing wetland natural communities to other types of wetland natural communities through implementation of CM2–CM10 for Alternative 9 would be approximately 19,850 acres. Most of these wetlands would be converted to tidal wetlands and open water through implementation of CM4. In total, up to 76,721 acres of wetland natural communities would be restored under Alternative 9. Although the increase in wetland acreage and wetland functions from these restoration could in part offset the effects on waters of the United States occurring in these areas, implementation of Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the United States*, would be required to ensure that the impacts are reduced to a less-than-significant level.

Shorebirds and Waterfowl

Managed wetlands, tidal natural communities, and cultivated lands (including grain and hay crops, pasture, field crops, rice, and idle lands) provide freshwater nesting, feeding, and resting habitat for a large number of Pacific flyway waterfowl and shorebirds. The primary effects of concern for shorebirds and waterfowl are related to the conversion of managed wetland and cultivated lands to tidal marsh associated with habitat restoration. Ducks Unlimited (2013) conducted an analysis to determine the effects of BDCP conservation measures on waterfowl, as well as to determine whether BDCP actions would impede attainment of the goals established by the Central Valley Joint Venture (CVJV) Implementation Plan for the Delta, Yolo, and Suisun Marsh drainage basins. The CVJV efforts are guided by its 2006 Implementation Plan, which is founded on the principles of strategic habitat conservation (Central Valley Joint Venture 2006). Those principles emphasize the establishment of population abundance objectives and the use of species-habitat models to link population objectives to habitat needs. The CVJV has used species-habitat models to translate bird abundance objectives into habitat objectives, while explicitly identifying the biological assumptions that underpin these models and the data used to populate them. As a result, the CVJV's biological planning provides a framework for evaluating the effects of the BDCP on waterfowl.

The Ducks Unlimited waterfowl analysis focused primarily on dabbling ducks. Less than 5% of all geese in the Central Valley occur in the Yolo, Delta, and Suisun Marsh drainage basins. Moreover, geese in the Central Valley rely mostly on agricultural habitats to meet their food energy needs. The BDCP's effect on agricultural habitats is limited to the Delta Basin where about 2500 acres of corn now available to geese would be converted to other habitats (Ducks Unlimited 2013: Table 5). Food supplies for geese would still be well in excess of demand even with the loss of these agricultural habitats (Central Valley Joint Venture 2006, Ducks Unlimited 2013). The duck population objectives used in the analysis were taken directly from the CVJV Plan. Dabbling duck species make up 92% of this objective, while diving duck species make up the remaining 8%. Thus, the results were mostly driven by dabbling duck needs and largely interpreted in the context of dabbling duck foraging ecology. The 55,000 acres of Tidal Natural Communities Restoration (CM4) would be expected to benefit diving ducks by providing deep water foraging habitat. Refer to the Ducks Unlimited Report (Ducks Unlimited 2013) for details of the analysis and methods with respect to the TRUMET model used to quantify effects on food biomass and food quality.

An analysis was conducted to determine the effects of the BDCP covered activities on wintering and breeding shorebird habitat (ICF International 2013). This analysis evaluated the relative increase and decrease in natural communities known to provide important foraging, roosting, and breeding habitat. Similar to the waterfowl analysis, the results were broken up into the three Central Valley Joint Venture Basins that overlap with the BDCP study area: Yolo, Delta, and Suisun. Natural community losses and gains were then translated into species-specific outcomes, comparing the relative habitat value of each BDCP natural community for each Central Valley shorebird species (Table 1, ICF International 2013). The shorebird species ranking system displayed in Table 1 (ICF International 2013) was modified from a table in Stralberg et. al (2011). The table was created using survey data and experts' species-specific habitat rankings. The survey data included fall, winter, and spring density data. This resulted in an overall, cross-season representation of habitat requirements.

Impact BIO-178: Loss or Conversion of Habitat for Waterfowl and Shorebirds as a Result of Water Conveyance Facilities Construction

Development of the water conveyance facilities (CM1) would result in the permanent removal of approximately 3 acres of managed wetland, 6 acres of tidal wetlands, 13 acres of nontidal wetlands, and 2,541 acres of suitable cultivated lands (including grain and hay crops, pasture, field crops, rice, and idle lands). In addition, 83 acres of managed wetland, 6 acres of tidal wetlands, 10 acres of nontidal wetlands, and 899 acres of cultivated lands would be temporarily impacted.

These losses of habitat would occur within the first 10 years of Alternative 9 implementation in the Delta Basin. The BDCP has committed to the near-term protection of 15,400 acres of non-rice cultivated lands, 200 acres of rice, and 700 acres of rice or "rice equivalent" natural communities including nontidal wetlands in the near-term. In addition, 4,100 acres of managed wetlands would be created, protected, and enhanced, 8850 acres of freshwater tidal wetlands would be restored, and 2,000 acres of tidal brackish emergent wetland would be restored (Table 3-4, Chapter 3, *Description of Alternatives*).

Construction activities could have an adverse effect on nesting shorebirds or waterfowl if they were present in or adjacent to work areas and could result in destruction of nests or disturbance of nesting and foraging behaviors. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on nesting birds.

***NEPA Effects*:** Habitat loss from construction of the Alternative 9 water conveyance facilities would not result in an adverse effect on shorebirds and waterfowl because of the acres of natural communities and cultivated lands that would be restored and protected in the near-term timeframe. If waterfowl were present in or adjacent to work areas, construction activities could result in destruction of nests or disturbance of nesting and foraging behaviors, which would be an adverse affect on nesting shorebirds and waterfowl. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on nesting birds.

***CEQA Conclusion*:** Habitat loss from construction of the Alternative 9 water conveyance facilities would have a less-than-significant impact on shorebirds and waterfowl because of the acres of natural communities and cultivated lands that would be restored and protected in the near-term timeframe. If waterfowl were present in or adjacent to work areas, construction activities could result in destruction of nests or disturbance of nesting and foraging behaviors, which would be a significant impact. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact on nesting birds to a less-than-significant level.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-179: Loss or Conversion of Habitat for Wintering Waterfowl as a Result of Implementation of Conservation Components

Suisun Marsh: Managed seasonal wetlands in Suisun Marsh would be reduced by an estimated 8,818 acres as a result of Alternative 9 implementation. This would represent a 25% decrease in managed seasonal wetlands compared with long-term conditions without Alternative 9 (Ducks Unlimited 2013, Table 5). There is considerable uncertainty about the biomass and nutritional quality of waterfowl foods produced in Suisun Marsh's managed wetlands, which makes it difficult to identify the amount of mitigation needed. To address this uncertainty, three levels of food biomass and three levels of nutritional quality were modeled for these existing habitats (Ducks Unlimited 2013, Table 7). Three mitigation scenarios based on these energetic assumptions of biomass and food quality were then run to determine a minimum acreage of managed seasonal wetlands to be protected and enhanced to compensate for the loss of productivity resulting from habitat conversion to tidal wetlands.

- Scenario 1) Assume that existing managed seasonal wetlands provide low food biomass and low food quality. Under this assumption, the managed seasonal wetlands in Suisun Marsh produce 50% of the seed biomass of seasonal wetlands elsewhere in the Central Valley, and these seeds have 60% of the metabolizable energy of seeds produced outside of Suisun Marsh. Given the assumption that managed seasonal wetlands in Suisun could be enhanced to provide high food biomass and high food quality (equal to wetlands in the Central Valley), 5,000 acres of managed wetlands protected and managed for high biomass and high food quality would mitigate the conversion of 8,857 acres of managed seasonal wetland to tidal marsh.
- Scenario 2) Assume that the managed seasonal wetlands lost provide medium food biomass and medium food quality. Under this assumption, the managed seasonal wetlands in Suisun Marsh produce 75% of the seed biomass of seasonal wetlands elsewhere in the Central Valley, and these seeds have 80% of the metabolizable energy of seeds produced outside of Suisun Marsh. Given the assumption that managed seasonal wetlands in Suisun Marsh could be enhanced to provide high food biomass and high food quality (equal to wetlands in the Central Valley), 13,300 acres of managed wetlands protected and managed for high biomass and high food quality would mitigate the conversion of 8,857 acres of managed seasonal wetland to tidal marsh.
- Scenario 3) Assume that existing managed seasonal wetlands provide low food biomass and low food quality. Given the assumption that managed seasonal wetlands in Suisun Marsh could only be enhanced to provide medium food biomass and medium food quality (produce 75% of the seed biomass of seasonal wetlands elsewhere in the Central Valley, with these seeds having 80% of the metabolizable energy of seeds produced outside of Suisun Marsh), 8,800 acres of managed wetlands protected and managed for medium biomass and medium food quality would mitigate the conversion of 8,857 acres of managed seasonal wetland to tidal marsh.

The BDCP has committed to protecting and enhancing a minimum of 5,000 acres of managed seasonal wetlands in Suisun Marsh to compensate for the loss of productivity from habitat conversion to tidal marsh. This minimum commitment of 5,000 acres would mitigate the reduced productivity resulting from conversion of managed seasonal wetlands under the assumptions that 1) existing managed seasonal wetlands on average in Suisun Marsh provide low biomass and low-quality food to wintering waterfowl and 2) protected seasonal wetlands can be managed to produce high biomass and high food quality. However, the food biomass and productivity in Suisun Marsh would need to be quantified in order to determine if the 5,000 acres was sufficient to avoid an adverse effect on wintering waterfowl in the Suisun Marsh, or if additional mitigation would be needed. Mitigation Measure BIO-179a, *Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh*, would be available to address this adverse effect.

Yolo and Delta Basins: The replacement of 1,400 acres of managed seasonal wetland with 19,000 acres of palustrine tidal wetlands in the Delta watershed, and the replacement of 600 acres of managed seasonal wetlands with 2,000 acres of palustrine tidal wetlands in the Yolo watershed would not be expected to have an adverse effect on food productivity, under the assumption that these wetlands would provide adequate food sources. However, a monitoring component and a food study in these tidal habitats would be necessary in order to demonstrate that there would be a less than significant loss of food value in these habitats for wintering waterfowl. If it is determined from monitoring that there in fact would be a significant loss in food productivity resulting from habitat conversion to tidal wetlands, the protection and enhancement of managed wetlands in these watersheds would require mitigation for the change in food biomass and quality. Mitigation Measure *BIO-179b, Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins*, would be available to address this uncertainty.

***NEPA Effects*:** There is considerable uncertainty about the biomass and nutritional quality of waterfowl foods produced in Suisun Marsh's managed wetlands, which makes it difficult to identify the level of effect that Alternative 9 habitat loss or conversion would have. The BDCP has committed to protecting and enhancing a minimum of 6,600 acres of managed seasonal wetlands in Suisun Marsh to compensate for the loss of productivity resulting from habitat conversion to tidal marsh. Of this 6,600 acres, at least 5,000 acres would be managed to benefit wintering waterfowl. This minimum commitment of 5,000 acres for wintering waterfowl would mitigate the reduced productivity from conversion of managed seasonal wetlands under the assumptions that 1) existing managed seasonal wetlands on average in Suisun Marsh provide low biomass and low-quality food to wintering waterfowl and 2) protected seasonal wetlands can be managed to produce high biomass and high-quality food. However, the food biomass and productivity in Suisun Marsh would need to be quantified to determine if the 5,000 acres would be sufficient for Alternative 9 to avoid an adverse effect on wintering waterfowl in the Suisun Marsh. Mitigation Measure BIO-179a, *Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh*, would be available to address this adverse effect.

The replacement of 1,400 acres of managed seasonal wetlands with 19,000 acres of palustrine tidal wetlands in the Delta watershed, and the replacement of 600 acres of managed seasonal wetlands with 2,000 acres of palustrine tidal wetlands in the Yolo watershed would not be expected to alter food productivity for wintering waterfowl. However, the conclusion that these new wetlands would provide adequate food sources is entirely dependent on assumptions about food production in palustrine tidal habitats. Mitigation Measure BIO-179b, *Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins*, would be available to address this uncertainty and avoid an adverse effect on wintering waterfowl.

***CEQA Conclusion*:** There is considerable uncertainty about the biomass and nutritional quality of waterfowl foods produced in Suisun Marsh's managed wetlands, which makes it difficult to identify the level of impact that Alternative 9 habitat loss or conversion would have. The BDCP has committed to protecting and enhancing a minimum of 6,600 acres of managed seasonal wetlands in Suisun Marsh to compensate for the loss of productivity resulting from habitat conversion to tidal marsh. Of this 6,600 acres, at least 5,000 acres would be managed to benefit wintering waterfowl. This minimum commitment of 5,000 acres for wintering waterfowl would mitigate the reduced productivity resulting from conversion of managed seasonal wetlands under the assumptions that 1) existing managed seasonal wetlands on average in Suisun Marsh provide low biomass and low-quality food for wintering waterfowl and 2) protected seasonal wetlands can be managed to produce high biomass and high-quality food. However, the food biomass and productivity in Suisun Marsh would need to be quantified to determine if the 5,000 acres would be sufficient for Alternative 9 to avoid having a significant impact on wintering waterfowl in the Suisun Marsh, or if additional mitigation would be needed. Implementation of Mitigation Measure BIO-179a, *Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh*, would address this potential significant impact.

The replacement of 1,400 acres of managed seasonal wetlands with 19,000 acres of palustrine tidal wetlands in the Delta watershed, and the replacement of 600 acres of managed seasonal wetlands with 2,000 acres of palustrine tidal wetlands in the Yolo watershed would not be expected to alter food productivity. However, the conclusion that these tidal wetlands would provide adequate food sources for wintering waterfowl is entirely dependent on assumptions about food production in palustrine tidal habitats. Studies of food biomass and food quality in palustrine tidal habitats are needed to confirm that no mitigation for wintering waterfowl would be required in the Yolo and Delta Basins. Implementation of Mitigation Measure BIO-179b, *Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins*, would address this uncertainty and would reduce this impact on wintering waterfowl to a less-than-significant level.

Mitigation Measure BIO-179a: Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh

Poorly managed wetlands (considered low biomass and food quality) will be identified and managed by BDCP proponents to improve food quality and biomass. Studies will be required to quantify 1) food production of existing managed wetlands in Suisun Marsh and 2) energetic productivity of brackish and tidal marsh habitats. Protected wetlands will be monitored to measure changes in the energetic productivity of these sites. Based on the food studies and monitoring results, BDCP proponents will determine if the minimum commitment of 5,000 acres is sufficient to meet the goal of 1:1 compensation for loss of wintering waterfowl habitat with the protection and management of managed wetlands in perpetuity. If monitoring demonstrates that additional acreage is needed to meet this goal, additional acreage of protection or creation of managed wetlands and management will be required.

Mitigation Measure BIO-179b: Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins

In order to address the uncertainty of the impact of loss of managed wetlands in the Yolo and Delta Basins on wintering waterfowl, BDCP proponents will conduct food studies and monitoring to demonstrate the food quality of palustrine tidal habitats in these basins. If studies show that the assumption of no effect was inaccurate, and the food quality goal of 1:1 compensation for wintering waterfowl food value is not met, additional acreage of protection or creation of managed wetland and management will be required.

Impact BIO-180: Loss or Conversion of Habitat for Breeding Waterfowl from Implementation of Conservation Components

Alternative 9 would reduce managed wetlands in the Yolo and Delta basins by 437 acres and 1,155 acres respectively. Under the assumption that 15% of these wetlands are managed as semi-permanent wetlands, Alternative 9 would reduce semipermanent wetlands in the Yolo and Delta drainage basins by 77 acres and 203 acres, respectively. While a reduction in these semipermanent habitats would represent a habitat loss for breeding waterfowl, with the restoration of 24,000 acres of palustrine tidal wetlands (Table 3-4, Chapter 3, *Description of Alternatives*) in the Yolo and Delta basins there would be a less than adverse effect on breeding waterfowl. These palustrine habitats would presumably contain water during the breeding period (i.e., March through July), and would be expected to compensate for the loss of 280 acres of managed semi-permanent wetlands in the Yolo and Delta watersheds attributed to the BDCP.

Suisun Marsh: Total managed wetlands in Suisun Marsh would decline from 41,012 acres to 30,640 acres from the conversion of managed seasonal and semi-permanent wetlands to tidal habitats. Some of the remaining seasonal wetlands could be managed as semi-permanent wetlands to offset the loss of breeding habitat, but this could further reduce food supplies available to wintering waterfowl under the assumption that semi-permanent wetlands provide few food resources compared to seasonally managed habitats (Central Valley Joint Venture 2006).

The BDCP includes a commitment to protect and enhance 1,600 acres of permanently flooded managed wetlands in Suisun Marsh to provide habitat for breeding waterfowl. In addition, 5,000 acres of semipermanent wetlands that would be protected and enhanced for wintering and migratory waterfowl (Table 3-4, Chapter 3; BDCP Chapter 3, *Conservation Strategy*, Objective MWNC1.1,).

Food studies and monitoring would be necessary to determine how increases in tidal marsh and salinity levels would affect the overall reproductive capacity of the marsh. These studies would be needed in order to quantify impacts on breeding waterfowl in Suisun Marsh and to determine not only the number of acres that would compensate for loss of breeding habitat at a ratio of 1:1 for habitat value, but how those acres should be managed. Mitigation Measure BIO-180, *Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh*, would be available to address the uncertainty of this effect.

In addition to providing semipermanent wetlands to breeding waterfowl, the Suisun Marsh contains several key upland areas that have significant nesting value. The largest block of upland habitat in the region is the core area on the Grizzly Island Wildlife Area. This area does not overlap with the hypothetical footprint for *CM4 Tidal Natural Communities Restoration*. However, this core area includes over 2,000 acres of upland grasslands that have some of the highest duck nesting densities in California (Central Valley Joint Venture 2006). A few small wetland areas are scattered within this core grassland mosaic that provide necessary freshwater brooding habitat. If restoration footprints were changed during the implementation process of BDCP to overlap with this area, the effects on breeding waterfowl would likely be greatly increased.

NEPA Effects: Alternative 9 would reduce managed wetlands in the Yolo and Delta basins by 437 acres and 1,155 acres, respectively. Under the assumption that 15% of these wetlands are managed as semi-permanent wetlands, Alternative 9 would reduce semi-permanent wetlands in the Yolo and Delta drainage basins by 77 acres and 203 acres, respectively. The reduction in these semi-permanent habitats would represent a habitat loss for breeding waterfowl. However, with the restoration of 24,000 acres of palustrine tidal wetlands in the Yolo and Delta basins, Alternative 9 would not have an adverse effect on breeding waterfowl. These palustrine habitats would presumably contain water during the breeding period (March through July), and would be expected to compensate for the loss of 280 acres of managed semi-permanent wetlands in the Yolo and Delta watersheds attributed to Alternative 9 implementation. Total managed wetlands in Suisun Marsh would decline from 41,012 acres to 30,640 acres with the conversion of managed seasonal and semi-permanent wetlands to tidal habitats. Some of the remaining seasonal wetlands could be managed as semi-permanent wetlands to offset the loss of breeding habitat, but such management could further reduce food supplies available to wintering waterfowl under the assumption that semi-permanent wetlands provide few food resources compared with seasonally managed habitats. The protection and enhancement of 1,600 acres of permanently flooded managed wetlands would provide habitat for breeding waterfowl. However, food studies and monitoring would be necessary to determine how increases in tidal marsh and salinity levels would affect the overall reproductive capacity of the marsh. Therefore, the loss of breeding waterfowl habitat resulting from implementation of Alternative 9 could have an adverse effect. Mitigation Measure BIO-180, *Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh*, would be available to address the uncertainty of model assumptions and the potential adverse effect of habitat conversion on breeding waterfowl in Suisun Marsh.

CEQA Conclusion: Alternative 9 would reduce managed wetlands in the Yolo and Delta basins by 437 acres and 1,155 acres, respectively. Under the assumption that 15% of these wetlands are managed as semi-permanent wetlands, Alternative 9 would reduce semi-permanent wetlands in the Yolo and Delta drainage basins by 77 acres and 203, acres respectively. The reduction in these semi-permanent habitats would represent a habitat loss for breeding waterfowl. However, with the restoration of 24,000 acres of palustrine tidal wetlands in the Yolo and Delta basins, Alternative 9 would have a less-than-significant impact on breeding waterfowl. These palustrine habitats would presumably contain water during the breeding period (March through July), and would be expected to compensate for the loss of 280 acres of managed semi-permanent wetlands in the Yolo and Delta watersheds attributed to Alternative 9.

Total managed wetlands in Suisun Marsh would decline from 41,012 acres to 30,640 acres with the conversion of managed seasonal and semi-permanent wetlands to tidal habitats. Some of the remaining seasonal wetlands could be managed as semi-permanent wetlands to offset the loss of breeding habitat, but this management could further reduce food supplies available to wintering waterfowl under the assumption that semi-permanent wetlands provide few food resources compared with seasonally managed habitats. The protection and enhancement of 1,600 acres of permanently flooded managed wetlands would provide habitat for breeding waterfowl. However, food studies and monitoring would be necessary to determine how increases in tidal marsh and salinity levels would affect the overall reproductive capacity of the marsh. Therefore, the loss or conversion of habitat from implementation of Alternative 9 could have a significant impact on breeding waterfowl in Suisun Marsh. Implementation of Mitigation Measure BIO-180, *Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh*, would address the uncertainty of model assumptions and reduce the impact to a less-than-significant level.

Mitigation Measure BIO-180: Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh

To address the uncertainty of the impact of loss of managed wetlands in Suisun Marsh on breeding waterfowl, BDCP proponents will conduct food studies and monitoring to determine how increases in tidal marsh and salinity levels will affect the overall reproductive capacity of the marsh.

The required studies will examine how increases in tidal marsh and salinity levels will affect the overall reproductive capacity of the Marsh. Reproductive studies will address but will not be limited to the following questions:

- How does the distribution of breeding waterfowl in Suisun Marsh differ in tidal versus managed habitats and across salinity gradients?
- How does waterfowl nest success and nest density vary with respect to tidal versus managed habitats and across salinity gradients?
- What are the patterns of habitat selection and movements by waterfowl broods in relation to tidal vs. managed habitats, and are there impacts on duckling survival?
- What is the current relationship between waterfowl reproductive success and interactions with alternate prey and predators, and how is tidal restoration likely to alter these relationships?

Impact BIO-181: Loss or Conversion of Habitat for Shorebirds from Implementation of Conservation Components

Shorebird use of the study area varies by species and fluctuates both geographically and by habitat type throughout the year. Shallow flooded agricultural fields and wetlands support large numbers of wintering and migrating shorebirds (Shuford et al. 1998), particularly least and western sandpipers, dunlin, greater yellowlegs and long-billed dowitcher. Rice lands of the Sacramento Valley provide important breeding habitat for shorebirds such as American avocet and black-necked stilt (Shuford et al. 2004) and have been designated as a Western Hemisphere Shorebird Reserve Network Site of International Importance (Hickey et al. 2003). Managed wetlands provide suitable foraging and roosting habitat for shorebirds; black-necked stilts, avocets, and yellowlegs use this habitat type almost exclusively. Water depth in all of these habitat types is an important habitat variable as the majority of shorebird species require water depths of approximately 10–20cm for foraging (Isola et al. 2000, Hickey et al. 2003).

Managed Wetlands

Yolo Basin: Primarily as a result of *CM4 Tidal Natural Communities Restoration* within the Yolo Basin, 1,185 acres of managed wetland habitat would be permanently converted; 1,066 acres of which are protected. In addition, 42 acres of managed wetland habitat would be temporarily lost by construction-related activities associated with tidal restoration (CM4) and Fisheries Enhancement activities (CM2) (Table 2, ICF International 2013). Increased inundation frequency, depth and duration associated with the ongoing operation of a modified Fremont Weir (CM2) could periodically affect managed wetlands ranging from an estimated 643 acres during a notch flow of 1,000 cfs to an estimated 2,055 acres during a notch flow of 4,000 cfs Table 5.4-2, in BDCP Chapter 5, *Effects Analysis*) in the Yolo Basin.

Delta Basin: Within the Delta Basin, 90 acres of managed wetland habitat would be permanently converted, as a result of tidal restoration (CM4). Thirteen of the 90 acres are protected (Table 3, ICF International 2013). Periodic flooding would not affect this natural community type in Delta Basin.

Suisun Basin: Within the Suisun Basin, 11,532 acres of managed wetland habitat would be permanently converted as a result of tidal restoration (CM4); 10,354 of which are protected. (Table 4, ICF International 2013). Periodic flooding would not affect this natural community type in Suisun Basin.

According to Stralberg et al. 2011, the following species of shorebirds had a rank 1 designation for managed wetland habitat suitability (Table 1, ICF International 2013): black-necked stilt (*Himantopus mexicanus*), greater yellowlegs (*Tringa melanoleuca*), and long-billed dowitcher (*Limnodromus scolopaceus*). Dunlin (*Calidris alpine*), least sandpiper (*Calidris minutilla*), semipalmated plover (Charadrius semipalmatus), and western sandpiper (*Calidris mauri*), had a rank 2 for managed wetland habitat suitability. Black-bellied plover (*Pluvialis squatarola*) and whimbrel (*Numenius phaeopus*) both had rank 3 for managed wetland habitat suitability.

Managed wetlands would decrease in overall extent by 20% (Table 5, ICF International 2013). Most of this loss would occur in Suisun with some additional acreage loss in the Yolo Basin. The loss of managed wetland habitat for covered species and waterfowl would be compensated for with 8,200 acres remaining managed wetland protection in Suisun Marsh. Of these 8,200 acres, the 5,000 acres of seasonal wetland protected, enhanced, and managed to provide overwintering waterfowl foraging habitat would be the habitat type most likely to benefit overwintering shorebirds. However, the 1,600 acres of semi-permanent and permanent managed wetlands for breeding waterfowl and 1,500 acres of managed wetlands for salt marsh harvest mouse would also be expected to have some benefit to wintering and breeding shorebirds.

Cultivated Lands

Yolo Basin: Primarily as a result of tidal restoration (CM4) and Fisheries Enhancement activities (CM2) within the Yolo Basin, 8,309 acres of cultivated lands would be permanently converted; 1,272 acres of which are protected. Also within the Yolo Basin, increased inundation frequency, depth and duration associated with the ongoing operation of a modified Fremont Weir (CM2) could affect an estimated 3,219 acres of cultivated lands during a notch flow of 1,000 cfs to an estimated 5,512 acres during a notch flow of 6,000 cfs (Table 5.4-2, in BDCP Chapter 5, *Effects Analysis*)

Delta Basin: Within the Delta Basin, as a result of tidal restoration (CM4) and floodplain restoration (CM5), 25,633 acres of cultivated lands would be permanently converted. There would also be an additional 112 acres lost temporarily due to CM5 activities. Of the total permanently converted lands, 3,925 acres are protected (Table 3, ICF International 2013). Seasonal flooding (CM5) on the restored floodplain would periodically affect 738 acres of cultivated lands in Delta.

According to Stralberg et al. 2011, the following species of shorebirds had a rank 1 designation for cultivated lands habitat suitability (Table 1, ICF International 2013): killdeer (*Charadrius vociferous*), long-billed curlew, and whimbrel within pasture habitat. Long-billed dowitcher and killdeer both had a rank 2 for idle crop habitat suitability and black-bellied plover was ranked 2 for pasture habitat. Red-necked phalarope (*Phalaropus lobatus*) and Wilson's phalarope (*Phalaropus tricolor*) were both ranked 2 for grain and hay crops. Long-billed dowitcher, dunlin, least sandpiper, and long-billed curlew were all ranked 3 for rice habitat suitability and killdeer was ranked 3 for field crop habitat suitability.

Cultivated land loss would occur in all three basins, but the majority of acreage loss would occur in the Delta basin. Pasture crop types would decrease in overall extent by 15% over baseline (Table 5, ICF International 2013), but would increase in protection by 135%. More than half of all cultivated lands within the 48,000-acre BDCP cultivated lands reserve would be in pasture production (primarily alfalfa) and enhanced and managed to benefit Swainson's hawk. Idle crop types are not identified as a specific conservation target in the BDCP, are expected to occur within the reserve and are recognized in the BDCP as having "moderate" foraging habitat value for Swainson's hawk, white-tailed kite, and greater sandhill crane.

Grain and hay crop would be expected to decrease by 13% (Table 5, ICF International 2013) while protection, enhancement and management would be expected to increase by 28% (Table 6, ICF International 2013). These crop types would be managed for a tricolored blackbirds, Swainson's hawk, white-tailed kite, greater sandhill crane, and burrowing owls.

Rice would decrease in overall extent by 2% (Table 5, ICF International 2013) but increase in total protection by 57%. Rice lands would be protected, enhanced, and managed for the benefit for giant garter snake.

Tidal Wetlands

Yolo Basin: As a result of tidal restoration (CM4) and Fisheries Enhancement activities (CM2) within the Yolo Basin, 194 acres of tidal wetland habitat would be permanently converted; 180 acres of which are protected. In addition, 12 acres of tidal wetland habitat would be temporarily lost by construction-related activities associated with Fisheries Enhancement activities (CM2) (Table 2, ICF International 2013). Periodic flooding in Yolo Bypass would affect 3,957 acres of tidal wetlands in Yolo Basin.

Delta Basin: Within the Delta Basin, 54 acres of tidal wetlands would be permanently converted as a result of tidal restoration (CM4) (Table 3, ICF International 2013). Of the total permanently converted lands, 26 acres are protected. Periodic flooding in Yolo Bypass would affect 26 acres of tidal wetlands in Delta Basin.

Suisun Basin: Within the Suisun Basin, 219 acres of tidal wetland habitat would be permanently converted as a result of tidal restoration (CM4); 215 of which are protected. (Table 4, ICF International 2013). Periodic flooding would not affect this natural community type in Suisun Basin.

According to Stralberg et al. 2011, the following species of shorebirds had a rank 1 designation for tidal mudflat habitat suitability (Table 6, ICF International 2013): black-bellied plover, dunlin, least sandpiper, marbled godwit (*Limosa fedoa*), semipalmated plover, short-billed dowitcher (*Limnodromus griseus*), western sandpiper, and willet (*Tringa semipalmata*). Long-billed curlew (*Numenius americanus*) and whimbrel both had a rank 2 for tidal mudflat habitat suitability. American avocet (*Recurvirostra americana*) was ranked 3 for tidal mudflat habitat suitability. For tidal brackish emergent wetland/tidal freshwater emergent wetland, willet was ranked 2 and long-billed curlew and whimbrel were both ranked 3 for habitat suitability.

Tidal mudflat habitat would be estimated to increase in extent by 1,780 acres. This extremely large increase in tidal mudflat habitat would occur almost exclusively in Suisun Marsh as the result of tidal restoration and the conversion of existing mid- and high-marsh types to low marsh and tidal mudflats in response to sea level rise. BDCP Appendix 3.B, *BDCP Tidal Habitat Evolution Assessment*, details the methods and assumptions modeled to come about this result. Tidal mudflat habitats would be expected to require management, however, sediment augmentation has been discussed as an experimental method that could be employed in places like Suisun to combat the loss of intertidal marshes in the face of sea level rise and reduced sediment supplies.

Tidal emergent wetland habitat would increase in extent by 152% (Table 5, ICF International 2013). Of the 30,000 acres of emergent wetland restoration, 6,000 acres would be in the Suisun Basin and the rest would be distributed between the Yolo and Delta Basins. Enhancement and management on these lands would be likely to be focused on nonnative, invasive species management. Any additional actions in Suisun would be focused on salt marsh harvest mouse, Suisun shrew, California clapper rail, black rail, Suisun thistle, and soft bird's-beak. In freshwater marshes, enhancement and management would be likely to focus on black rail, western pond turtle, and, in some cases, giant garter snake.

Nontidal Wetlands

Yolo Basin: As a result of tidal restoration (CM4) and Fisheries Enhancement activities (CM2) within the Yolo Basin, 313 acres of nontidal wetland habitat would be permanently converted; 119 acres of which are protected. In addition, 11 acres of nontidal wetland habitat would be temporarily lost by construction-related activities associated with Fisheries Enhancement activities (CM2) (Table 2, ICF International 2013). Periodic flooding in Yolo Bypass associated with ongoing Fremont Weir operation (CM2) would affect 305 acres of nontidal wetlands in Yolo Basin, specifically nontidal perennial aquatic habitat.

Delta Basin: Within the Delta Basin, 99 acres of nontidal wetlands would be permanently converted as a result of tidal restoration (CM4) and floodplain restoration (CM5) (Table 3, ICF International 2013). There would also be 8 acres of nontidal perennial aquatic habitat temporarily lost from CM5 activities. Of the total permanently converted lands, 29 acres are protected. Periodic flooding from CM5 would affect 4 acres of nontidal perennial aquatic habitat in Delta Basin.

Suisun Basin: Within the Suisun Basin, 1 acre of nontidal wetland habitat, specifically vernal pool complex, would be permanently converted as a result of tidal restoration (CM4); and is not protected. (Table 4, ICF International 2013). Periodic flooding would not affect this natural community type in Suisun Basin.

According to Stralberg et al. 2011, the following species of shorebirds had a rank 1 designation for nontidal wetland habitat suitability (Table 6, ICF International 2013): red-necked phalarope and Wilson's phalarope for nontidal freshwater perennial emergent wetland and American avocet for alkali seasonal wetland complex. Greater yellowlegs had a rank 2 for vernal pool complex habitat suitability. Red-necked phalarope and western sandpiper were both ranked 3 for alkali seasonal wetland habitat suitability and greater yellowlegs was ranked 3 for nontidal freshwater perennial emergent wetland habitat suitability.

Nontidal freshwater emergent wetland would increase in extent by 88% as a result of BDCP implementation (Table 5, ICF International 2013). These lands would be managed to benefit giant garter snake and located within the Delta Basin (likely in the vicinity of White Slough) and the Yolo Basin (in the Cache Slough area).

Impacts on wetted acres of vernal pool complex and alkali seasonal wetland complex would be avoided and thus loss of this community is not expected. However, up to 10 acres of wetted acre loss could be permitted under the Plan. Protection of vernal pool complex natural community would increase by 13% and by 6% for alkali seasonal wetlands (Table 6, ICF International 2013). Protection of these two community types would enhance and manage habitat for vernal pool crustaceans and alkali-related plant species.

The protection and restoration of natural communities would also include management and enhancement actions under *CM11 Natural Communities Enhancement and Management.* The following management activities to benefit shorebirds would be considered for implementation under CM11 in areas where they would not conflict with covered species management.

- Managed Wetlands
  - Managed wetlands can be potentially manipulated to provide the optimum water depths for foraging shorebirds and islands for nesting (Hickey et al. 2003).
  - During fall and spring, stagger the timing and location of draining and flooding to optimize the extent of shallow-water habitat; varying depths within the wetland unit helps to create temporal variation in foraging opportunities. During warm, dry springs when wetland units dry quickly, wetland units can be re-supplied with water to extend habitat availability for shorebirds.
  - Provide open, shallow water habitat adjacent to minimally vegetated, shallowly sloped edges for nesting shorebirds between April and July.
  - Provide islands with little to no vegetation to increase the likelihood of shorebird roosting and nesting.
  - Create low slopes on islands and levees; gradual angles (10–12:1) are better than steep angles.
  - Limit levee maintenance during the nesting season (April through July). However, mowing the center of levees is fine.
  - Potentially add material to levees or to islands to encourage nesting for some species.
- Cultivated Lands
  - Maintaining a mosaic of dry and flooded crop types, and varying water depths will promote a diverse community of waterbirds, including shorebirds, during fall migration and winter (Shuford et al. 2013).
  - To provide wintering habitat for multiple waterbird guilds, including shorebirds, use a combination of flooding practices that include one-time water application and maintenance flooding while also providing unflooded habitat (Strum et al. *in review*).
  - The post-harvest flooding of winter wheat and potato fields in early fall (July–September) can provide substantial benefits to shorebirds at a time of very limited shallow-water habitat on the landscape (Shuford et al. 2013).
  - Stagger the drawdown of flooded rice and other winter-flooded agricultural fields to prolong the availability of flooded habitat (Iglecia et al. 2012). Be aware of soil type because this practice may not be as effective on soils that drain quickly.
  - Remove as much stubble as possible in rice and other agricultural fields after harvest to increase the potential shorebird habitat on intentionally flooded or unflooded fields that may passively gather rain water (Iglecia et al. 2012).
  - Shallowly flood available agricultural fields during July, August, and September to provide early fall migration habitat for shorebirds. Fields should be free of vegetation prior to flooding, have minimal micro-topography (e.g., no large clods), and should remain flooded

for up to three week periods (after three weeks, vegetation encroachment reduces habitat value for shorebirds) (ICF International 2013).

- Manage levee habitats to have minimal vegetation but do not spray herbicide directly or drive on levees during the nesting season (April–July, Iglecia et al. 2012).
- Maintain a minimum top-width of 30 inches for levees, based on increased avocet use of wider levees (Iglecia et al. 2012).
- When possible, flood fields with nesting habitat (modified levees and islands) in late April to provide nesting habitat for American avocets (Iglecia et al. 2012).
- Finer grained substrate (clods smaller than a fist) in rice and other agricultural fields may be more appealing for nesting shorebirds (Iglecia et al. 2012).
- Maintain gently sloping levees and island sides (10–12:1; Iglecia et al. 2012).
- Islands should be disked along with the rest of the field after harvest to help inhibit vegetation growth (Iglecia et al. 2012).

NEPA Effects**:** Alternative 9 implementation would result in the conversion of managed wetland and cultivated lands to tidal natural communities, including tidal mudflat. The result would be substantial loss of the primary habitat of black-necked stilt, American avocet, greater yellowlegs, and long-billed dowitcher and a gain in the primary habitat of black-bellied plover, dunlin, least sandpiper, marbled godwit, semipalmated plover, short-billed dowitcher, western sandpiper, and willet. While substantial losses of cultivated lands would be incurred, protection, enhancement, and management of the remaining acres would likely have substantial benefits for select species of wintering and breeding shorebirds. This is because impacts on crop types would be distributed across all crop types, while protection would focus primarily on pasture lands, grain and hay, corn, and rice types. While the protection, enhancement, and management of these crop types are being driven by covered species, these management actions would also benefit shorebirds. The protection, enhancement, and management of remaining managed wetlands in Suisun Marsh, in compensation for the loss of substantial acreage, would have some incremental benefits for shorebirds, but would be unlikely to compensate for the overall loss. However, with the protection and restoration of acres in the Delta and Yolo watersheds, in addition to the implementation of the management actions outlined in *CM11 Natural Communities Enhancement and Management*, habitat conversion would not be expected to result in an adverse effect on shorebird populations in the study area.

CEQA Conclusion**:** Alternative 9 implementation would result in the conversion of managed wetland and cultivated lands to tidal natural communities, including tidal mudflat. The result would be significant loss of the primary habitat of black-necked stilt, American avocet, greater yellowlegs, and long-billed dowitcher and a gain in the primary habitat of black-bellied plover, dunlin, least sandpiper, marbled godwit, semipalmated plover, short-billed dowitcher, western sandpiper, and willet. While significant losses of cultivated lands would be incurred, protection, enhancement, and management of the remaining acres would likely have substantial benefits for select species of wintering and breeding shorebirds. This is because impacts on crop types would be distributed across all crop types, while protection would focus primarily on pasture lands, grain and hay, corn, and rice types. While the protection, enhancement, and management of these types are being driven by covered species, these management actions would also benefit shorebirds. The protection, enhancement, and management of remaining managed wetlands in Suisun Marsh, in compensation for substantial acreage loss, would have some incremental benefits for shorebirds, but would be unlikely to compensate for the overall loss. However, with the protection and restoration of acres in the Delta and Yolo watersheds, in addition to the implementation of the management actions outlined in *CM11 Natural Communities Enhancement and Management*, habitat conversion would be expected to have a less-than-significant impact on shorebird populations in the study area.

Impact BIO-182: Effects on Shorebirds and Waterfowl Associated with Electrical Transmission Facilities

New transmission lines installed in the study area would increase the risk for bird-power line strikes, which could result in injury or mortality of shorebirds and waterfowl. The existing network of power lines in the study currently poses a risk for shorebirds and waterfowl in the Delta. New transmission lines would increase this risk and have an adverse effect on shorebird and waterfowl species in the absence of other conservation actions. However, transmission lines constructed under Alternative 9 would be temporary and would be removed after the completion of CM1 construction activities (within the first 10 years of Plan implementation). In addition, implementation of *AMM20 Greater Sandhill Crane* would reduce potential effects through the installation of flight diverters on new transmission lines, and selected existing transmission lines in the study area.

***NEPA Effects*:** New transmission lines would increase the risk for shorebird and waterfowl power line strikes. With the implementation of *AMM20 Greater Sandhill Crane*, the potential effect of the construction of new transmission lines on shorebird and waterfowl would not be adverse.

***CEQA Conclusion*:** New transmission lines would increase the risk for shorebird and waterfowl power line strikes. The implementation of *AMM20 Greater Sandhill Crane* would reduce the potential impact of the construction of new transmission lines on shorebirds and waterfowl to a less-than-significant level.

Impact BIO-183: Indirect Effects of Plan Implementation on Shorebirds and Waterfowl

Indirect Construction- and Operation-Related Effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect shorebird and waterfowl use of modeled habitat. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect shorebirds and waterfowl or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to shorebirds and waterfowl in the study area could also have a negative effect on these species. AMM1–AMM7 would ensure that measures were in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including shorebird and waterfowl species. Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008).

Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect shorebirds and waterfowl, via uptake in lower trophic levels (as described in BDCP Appendix 5.D, *Contaminants*).

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. *CM12 Methylmercury Management* includes provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on shorebirds and waterfowl.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including shorebird and waterfowl species. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4–CM5) would lead to adverse effects on shorebirds and waterfowl species.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on shorebirds and waterfowl from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Noise and visual disturbances from the construction of Alternative 9 water conveyance facilities could reduce shorebird and waterfowl use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect shorebird and waterfowl use of the surrounding habitat. AMM1–AMM7 would minimize these effects, and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting individuals. Tidal habitat restoration could result in increased exposure of shorebirds and waterfowl to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Therefore, the indirect effects associated with noise and visual disturbances, and increased exposure to selenium from Alternative 9 implementation would not have an adverse effect on shorebirds and waterfowl. Tidal habitat restoration is unlikely to have an adverse effect on shorebirds and waterfowl through increased exposure to methylmercury, as these species currently nest and forage in tidal marshes with elevated methylmercury levels. However, it is unknown what concentrations of methylmercury are harmful to species of waterfowl and shorebirds, and the potential for increased exposure would vary substantially within the study area. Site-specific restoration plans in addition to monitoring and adaptive management, described in *CM12 Methylmercury Management*, would address the uncertainty of methylmercury levels in restored tidal marsh. Once site-specific sampling and other information is developed, the site-specific planning phase of marsh restoration would be the appropriate place to assess the potential risk of shorebird and waterfowl exposure to methylmercury.

CEQA Conclusion: Noise, potential hazardous spills, and increased dust and sedimentation as a result of Alternative 9 water conveyance facilities construction and operation and maintenance would have a significant impact on shorebirds and waterfowl. AMM1–AMM7 would minimize these impacts, and implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce the impacts to a less-than-significant level. Tidal habitat restoration is unlikely to have a significant impact on shorebirds and waterfowl species through increased exposure to methylmercury, as these species currently nest and forage in tidal marshes with elevated methylmercury levels. However, it is unknown what concentrations of methylmercury are harmful to species of waterfowl and shorebirds. Site-specific restoration plans that address the creation and mobilization of mercury, as well as the monitoring and adaptive management described in CM12, would be the appropriate place to assess the potential risk of shorebird and waterfowl exposure to methylmercury in the study area. Tidal habitat restoration could result in increased exposure of shorebirds and waterfowl to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Therefore, the indirect effects of Alternative 9 implementation would have a less-than-significant impact on shorebirds and waterfowl.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Common Wildlife and Plants

Common wildlife and plants are widespread, often abundant, species that are not covered under laws or regulations that address conservation or protection of individual species. Examples of common wildlife and plants occurring in the study area are provided within the discussion for each natural community type in Section 12.1.2.2, *Special-Status and Other Natural Communities*. Impacts on common wildlife and plants would occur through the same mechanisms discussed for natural communities and special-status wildlife and plants for each alternative.

Impact BIO-184: Effects on Habitat and Populations of Common Wildlife and Plants

Effects on habitat of common wildlife and plants, including habitat removal and conversion, are discussed in the analysis of Alternative 9 effects on natural communities. In general, effects on habitat of common wildlife and plants would not be adverse. Through the course of implementing the Plan over a 50-year time period, several natural communities and land cover types would be reduced in size, primarily from restoration of other natural communities. Grassland, managed wetland and cultivated lands would be reduced in acreage, so the common species that occupy these habitats would be affected. However, the losses in acreage and value of these habitats would be offset by protection, restoration, enhancement and management actions contained in the BDCP, including *CM3 Natural Communities Protection and Restoration*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration*, *CM6 Channel Margin Enhancement*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM10 Nontidal Marsh Restoration*, and *CM11 Natural Communities Enhancement and Management*. In addition, the AMMs contained in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, would be in place to reduce or eliminate the potential to adversely affect both special-status and common wildlife and plants.

Direct effects on common wildlife and plants from constructing water conveyance facilities and implementing Alternative 9 conservation measures would include construction or inundation-related disturbances that result in injury or mortality of wildlife or plants and the immediate displacement of wildlife. Indirect effects include project-related disturbances to nearby wildlife and plants during construction (e.g., disruption of breeding and foraging behaviors from noise and human activity, habitat degradation from fugitive dust and runoff) and effects occurring later in time (e.g., collisions of birds with transmission lines, habitat fragmentation, vegetation management). Indirect effects could result both from construction and from operations and maintenance (e.g., ground disturbances could result in the spread and establishment of invasive plants).

NEPA Effects: The direct and indirect effects associated with implementing the conservation measures of Alternative 9 would not be adverse because the conservation measures and AMMs also expand and protect natural communities, avoid or minimize effects on special-status species, prevent the introduction and spread of invasive species, and enhance natural communities. These actions would result in avoiding and minimizing effects on common wildlife and plants as well.

CEQA Conclusion**:** Construction and operation of the water conveyance facilities and habitat restoration activities would have impacts on common wildlife and plants in the study area through habitat loss and through direct or indirect loss or injury of individuals. The loss of habitat would not be substantial, because habitat restoration would increase the amount and extent of habitat available for use by most common wildlife and plant species. Conservation measures to avoid or minimize effects on special-status species, to prevent the introduction and spread of invasive species, and to enhance natural communities also would result in avoiding and minimizing effects on common wildlife and plants. Consequently, implementation of the BDCP is not expected to cause any populations of common wildlife or plants to drop below self-sustaining levels, and this impact would be less than significant. No mitigation would be required.

Wildlife Corridors

ECAs are lands likely to be important to wildlife movement between large, mostly natural areas at the state wide level. The ECAs form a functional network of wildlands that are considered important to the continued support of California's diverse natural communities. Four general areas were identified within the Plan Area that contain ECAs (Figure 12-2). The BDCP also identified important landscape linkages in the Plan Area to guide reserve design, which can also be seen on Figure 12-2.

Impact BIO-185: Effect of BDCP Conservation Measures on Wildlife Corridors

Alternative 9 would have conveyance facility construction occurring within the Mandeville Island-Staten Island ECA. The conveyance facility construction would also occur along two linkages identified in the BDCP, the *Middle River* linkage (#6 in Figure 12-2) and the *White Slough to Stone Lakes* linkage (#11 in Figure 12-2).

The construction of an operable barrier and associated transmission lines would occur on the northwestern tip of Mandeville Island. These facilities would not create a substantial barrier to wildlife movement within and outside of this ECA. The construction of transmission lines may result in localized impacts on sandhill cranes and other avian species during periods of low visibility, but these transmission lines are relatively short and would not substantially affect flight patterns.

The Alternative 9 dredge spoils areas and an operable barrier identified along Middle River (linkage #6) would greatly conflict with the BDCP's plan for riparian conservation and establishing riparian connectivity along this stretch of Middle River. The dredge disposal areas could make a substantial section of Middle River unsuitable for BDCP riparian conservation actions.

The construction of a transmission line across BDCP the *White Slough to Stone Lakes* linkage would not substantially conflict with the BDCP's plans for giant garter snake conservation along this corridor.

Restoration activities would be implemented in the ECAs within Yolo Bypass (*CM2 Yolo Bypass Fisheries Enhancement*) and within the Grizzly Island-Lake Marie ECA (*CM4 Tidal Natural Communities Restoration*). These activities would generally improve the movement of wildlife within and outside of the study area. In addition, the preservation of restored lands (CM3) and the enhancement and management of these areas (CM11) would improve and maintain wildlife corridors within the study area.

NEPA Effects**:** Alternative 9 would conflict with the BDCP's planned riparian conservation along Middle River; however, compared to No Action this alternative would not result in adverse effects on wildlife corridors.

CEQA Conclusion**:**

The construction of an operable barrier and associated transmission lines would occur on the northwestern tip of Mandeville Island. These facilities would not create a substantial barrier to wildlife movement within and outside of the Mandevill Island-Staten Island ECA. The construction of transmission lines may result in localized impacts on sandhill cranes and other avian species during periods of low visibility, but these transmission lines are relatively short and would not substantially affect flight patterns.

The Alternative 9 dredge spoils areas and an operable barrier identified along Middle River (linkage #6) would greatly conflict with the BDCP's plan for riparian conservation and establishing riparian connectivity along this stretch of Middle River. The dredge disposal areas could make a substantial section of Middle River unsuitable for BDCP riparian conservation actions.

The construction of a transmission line across BDCP the *White Slough to Stone Lakes* linkage would not substantially conflict with the BDCP's plans for giant garter snake conservation along this corridor.

Restoration activities would be implemented in the ECAs within Yolo Bypass (*CM2 Yolo Bypass Fisheries Enhancement*) and within the Grizzly Island-Lake Marie ECA (*CM4 Tidal Natural Communities Restoration*). These activities would generally improve the movement of wildlife within and outside of the study area. In addition, the preservation of restored lands (CM3) and the enhancement and management of these areas (CM11) would improve and maintain wildlife corridors within the study area.

Alternative 9 would conflict with the BDCP's planned riparian conservation along Middle River; however, under the Existing Conditions, this alternative would overall result in less-than-significant impacts on wildlife corridors.

Invasive Plant Species

The invasive plant species that primarily affect each natural community in the study area, which include water hyacinth, perennial pepperweed, giant reed, and Brazilian waterweed, are discussed in Section 12.1.4. Invasive species compete with native species for resources and can alter natural communities by altering fire regimes, hydrology (e.g., sedimentation and erosion), light availability, nutrient cycling, and soil chemistry but also have the potential to harm human health and the economy by adversely affecting natural ecosystems, water delivery, flood protection systems, recreation, agricultural lands, and developed areas (Randall and Hoshovsky 2000). The construction and restoration activities covered under the BDCP could result in the introduction or spread of invasive plant species by creating temporary ground disturbance that provides opportunities for colonization by invasive plants in the study area.

The primary mechanisms for the introduction of invasive plants as the result of implementation of Alternative 9 are listed here.

- Grading, excavation, grubbing, and placement of fill material.
- Breaching, modification, or removal of existing levees and construction of new levees.

- Modification, demolition, and removal of existing infrastructure (e.g., buildings, roads, fences, electric transmission and gas lines, irrigation infrastructure).
- Maintenance of infrastructure.
- Removal of existing vegetation and planting/seeding of vegetation.
- Maintaining vegetation and vegetation structure (e.g., grazing, mowing, burning, trimming).
- Dredging waterways.

Clearing operations and the movement of vehicles, equipment, and construction materials in the study area would facilitate the introduction and spread of invasive plants by bringing in or moving seeds and other propagules. These effects would result from four activities.

- Spreading chipped vegetative material from clearing operations over topsoil after earthwork operations are complete.
- Importing, distributing, storing, or disposing of fill, reusable tunnel material, borrow, spoil, or dredge material.
- Traffic from construction vehicles (e.g., water and cement trucks) and personal vehicles of construction staff.
- Transport of construction materials and equipment within the study area and to/from the study area.

Table 12-9-70 lists the acreages of temporary disturbance in each natural community in the study area that would result from implementation of Alternative 9 of the BDCP.

Table 12-9-70. Summary of Temporary Disturbance in Natural Communities under Alternative 9

Natural Community	Temporary Impacts (acres)
Tidal perennial aquatic	360
Tidal brackish emergent wetland	0
Tidal freshwater emergent wetland	123
Valley foothill riparian	367
Grassland	590
Inland dune scrub	0
Alkali seasonal wetland complex	0
Vernal pool complex	0
Other natural seasonal wetland	0
Nontidal freshwater perennial emergent wetland	25
Nontidal perennial aquatic	27
Managed wetlands	65
Agricultural lands	1,959
Total	**3,516**

Impact BIO-186: Adverse Effects on Natural Communities Resulting from the Introduction and Spread of Invasive Plant Species

Under Alternative 9, the BDCP would have adverse effects on natural communities from the introduction and spread of invasive plant species through implementation of CM1–CM10 and AMM6. No adverse effects are expected from implementation of CM11–CM21.

- *CM1 Water Facilities and Operation*: Construction of the Alternative 9 water conveyance facilities would result in the temporary disturbance of 3,507 acres that would provide opportunities for colonization by invasive plant species.
- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo Bypass fisheries enhancements would result in the temporary disturbance of 758 acres that would provide opportunities for colonization by invasive plant species. Vegetation maintenance activities for the Fremont Weir and Yolo Bypass improvements may include the removal of giant reed; however, the clearing of linear areas to facilitate water flow may also result increased opportunities for invasion. Sediment removal, transportation, and application as a source material for restoration or levee projects as part of Fremont Weir and Yolo Bypass maintenance activities could also result in the spread of invasives if the sediment contains viable invasive plant propagules.
- *CM3 Natural Communities Protection and Restoration*: The restoration activities in the natural communities located in the eleven CZs would result in the temporary disturbance of restoration areas that would provide opportunities for colonization by invasive plant species.
- *CM4 Tidal Natural Communities Restoration*: The activities associated with the restoration of tidal perennial aquatic, tidal mudflat, tidal freshwater emergent wetland, and tidal brackish emergent wetland in ROAs would result in the temporary disturbance of tidal areas that would provide opportunities for colonization by invasive plant species. These adverse effects would be reduced by designing restoration projects to minimize the establishment of nonnative submerged aquatic vegetation, and early restoration projects would be monitored to assess the response of nonnative species to restoration designs and local environmental conditions. If indicated by monitoring results, the BDCP Implementation Office would implement invasive plant control measures in restored natural communities to help ensure the establishment of native marsh plain plant species. Additionally, the BDCP Implementation Office would actively remove submerged and floating aquatic vegetation in subtidal portions of tidal natural community restoration sites.
- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration levee construction would result in the temporary disturbance of 1,285 acres along channels in the north, east, and south Delta (San Joaquin, Old, and Middle Rivers) that would provide opportunities for colonization by invasive plant species.
- *CM6 Channel Margin Enhancement*: The temporary effects of channel margin enhancement were not estimated because specific locations for this activity and their areal extent have not been developed. Channel margin enhancement (Sacramento River between Freeport and Walnut Grove, San Joaquin River between Vernalis and Mossdale, Steamboat and Sutter Sloughs, and salmonid migration channels in the interior Delta) would result in the temporary disturbance of channel areas that would provide opportunities for colonization by invasive plant species.

- *CM7 Riparian Natural Community Restoration*: The restoration of valley/foothill riparian habitat would result in the temporary disturbance of riparian areas that would provide opportunities for colonization by invasive plant species.
- *CM8 Grassland Natural Community Restoration*: The restoration of grassland habitat in CZs 1, 8 and/or 11 would result in the temporary disturbance of degraded grassland or cultivated land that would provide opportunities for colonization by invasive plant species.
- *CM9 Vernal Pool and Alkali Season Wetland Complex Restoration*: The restoration of vernal pool and alkali seasonal wetland complexes in CZs 1, 8, or 11 would result in the temporary disturbance of grassland areas that would provide opportunities for colonization by invasive plant species.
- *CM10 Nontidal Marsh Restoration*: Nontidal marsh restoration, which would take place through conversion of agricultural lands in CZs 2 and 4, would result in the temporary disturbance of fallow agricultural areas that would provide opportunities for colonization by invasive plant species. These adverse effects would be reduced by monitoring the development of marsh vegetation to determine if nonnative vegetation needs to be controlled to facilitate the establishment of native marsh vegetation or if restoration success could be improved with supplemental plantings of native species. If indicated by monitoring, nonnative vegetation control measures and supplemental plantings would be implemented.
- *Avoidance and Minimization Measures*: *AMM6 Disposal and Reuse of Spoils* would have adverse effects if spoils, RTM, dredged material, or chipped vegetative materials containing viable invasive plant propagules are used as topsoil in uninfested areas.

The adverse effects that would result from the introduction and spread of invasive plants through colonization of temporarily disturbed areas would be minimized by implementation of CM11, AMM4 AMM10 and AMM11.

CM11 Natural Communities Enhancement and Management would reduce these adverse effects by implementing invasive plant control within the BDCP reserve system to reduce competition on native species, thereby improving conditions for covered species, ecosystem function, and native biodiversity. The invasive plant control efforts would target new infestations that are relatively easy to control or the most ecologically damaging nonnative plants for which effective suppression techniques are available. In aquatic and emergent wetland communities, Brazilian waterweed, perennial pepperweed, barbgrass, and rabbitsfoot grass would be controlled (and tidal mudflats would be maintained). In riparian areas, invasive plant control would focus on reducing or eliminating species such as Himalayan blackberry, giant reed, and perennial pepperweed. In grassland areas, techniques such as grazing and prescribed burning may be used to decrease the cover of invasive plant species.

Implementation of AMM4, AMM10, and AMM11 would also reduce the adverse effects that could result from construction activities. The AMMs provide methods to minimize ground disturbance, guidance for developing restoration and monitoring plans for temporary construction effects, and measures to minimize the introduction and spread of invasive plants. AMM4 would include the preparation and implementation of an erosion and sediment control plan that would control erosion and sedimentation and restore soils and vegetation in affected areas. The restoration and monitoring plans for implementation of AMM10 would involve methods for stockpiling, storing, and restoring topsoil, revegetating disturbed areas, monitoring and maintenance schedules, adaptive management strategies, reporting requirements, and success criteria. AMM10 would also include planting native species appropriate for the natural community being restored, with the exception of some borrow sites in cultivated lands that would be restored as grasslands.

AMM11 specifies that the BDCP Implementation Office would retain a qualified botanist or weed scientist prior to clearing operations to determine if affected areas contain invasive plants. If areas to be cleared do contain invasive plants, then chipped vegetation material from those areas would not be used for erosion control but would be disposed of to minimize the spread of invasive plant propagules (e.g., burning, composting). During construction of the water conveyance facilities and construction activities associated with the other conservation measures, construction vehicles and construction machinery would be cleaned prior to entering construction sites that are in or adjacent natural communities other than cultivated lands and prior to entering any BDCP restoration sites or conservation lands other than cultivated lands. Vehicles working in or travelling off paved roads through areas with infestations of invasive plant species would be cleaned before travelling to other parts of the study area. Cleaning stations would be established at the perimeter of BDCP covered activities along construction routes as well as at the entrance to reserve system lands. Biological monitoring would include locating and mapping locations of invasive plant species within the construction areas during the construction phase and the restoration phase. Infestations of invasive plant species would be targeted for control or eradication as part of the restoration and revegetation of temporarily disturbed construction areas.

***NEPA Effects*:** The implementation of AMM4, AMM10, AMM11, and CM11 would reduce the potential for the introduction and spread of invasive plants and avoid or minimize the potential effects on natural communities and special-status species; therefore, these effects would not be adverse.

***CEQA Conclusion*:** Under Alternative 9, impacts on natural communities from the introduction or spread of invasive plants as a result of implementing the BDCP would not result in the long-term degradation of a sensitive natural community due to substantial alteration of site conditions and would, therefore, be less than significant. No mitigation would be required.

Compatibility with Plans and Policies

Impact BIO-187: Compatibility of the Proposed Water Conveyance Facilities and Other Conservation Measures with Federal, State, or Local Laws, Plans, Policies, or Executive Orders Addressing Terrestrial Biological Resources in the Study Area

Constructing the water conveyance facilities (CM1) and implementing CM2–CM21 for Alternative 9 have the potential for being incompatible with plans and policies related to managing and protecting terrestrial biological resources of the study area. A number of laws, plans, policies, programs, and executive orders that are relevant to actions in the study area provide guidance for terrestrial biological resource issues as overviewed in Section 12.2, *Regulatory Setting*. This overview of plan and policy compatibility evaluates whether Alternative 9 would be compatible or incompatible with such enactments, rather than whether impacts would be adverse or not adverse, or significant or less than significant. If the incompatibility relates to an applicable plan, policy, or executive order adopted to avoid or mitigate terrestrial biological resource effects, then an incompatibility might be indicative of a related significant or adverse effect under CEQA and NEPA, respectively. Such physical effects of Alternative 9 on terrestrial biological resources are addressed in the impacts on natural communities and species. The following is a summary of compatibility evaluations related to terrestrial biological resources for laws, plans, policies, and executive orders relevant to the BDCP. Federal and State Legislation

- The federal *Clean Water Act*, *Endangered Species Act*, *Fish and Wildlife Coordination Act*, *Migratory Bird Treaty Act*, *Rivers and Harbors Act* and *Marine Mammal Protection Act* all contain legal guidance that either directly or indirectly promotes or stipulates the protection and conservation of terrestrial biological resources in the process of undertaking activities that involve federal decision making. The biological goals and objectives contained in the BDCP that provide the major guidance for implementing the various conservation elements of Alternative 9 are all designed to promote the long-term viability of the natural communities, special-status species, and common species that inhabit the study area. While some of the conservation measures of the alternative involve permanent and temporary loss of natural communities and associated habitats during facilities construction and expansion of certain natural communities, the long-term guidance in the Plan would provide for the long-term viability and expansion of the habitats and special-status species populations in the study area. Alternative 9 conservation actions would be compatible with the policies and directives for terrestrial biological resources contained in these federal laws.

- The *California Endangered Species Act*, *California Native Plant Protection Act*, *Porter-Cologne Water Quality Control Act*, and *Natural Communities Conservation Planning Act* are state laws that have relevance to the management and protection of terrestrial biological resources in the study area. Each of these laws promotes consideration of wildlife and native vegetation either through comprehensive planning or through regulation of activities that may have an adverse effect on the terrestrial and aquatic natural resources of the state. The BDCP, which is the basis for Alternative 9, contains biological goals and objectives that have been developed to promote the species protection and natural resource conservation that are directed by these state laws. Alternative 9 conservation actions would be compatible with the policies and directives contained in these laws.

- The *Johnston-Baker-Andal-Boatwright Delta Protection Act of 1992* (*Delta Protection Act*) and the *Sacramento-San Joaquin Delta Reform Act*, which updated the Delta Protection Act, promote the maintenance and protection of natural resources and the protection of agricultural land uses in the Delta's primary zone through the goals and policies contained in the 2009 updated Land Use and Resources Management Plan (LURMP). While nothing in the LURMP is binding on state agencies that are BDCP proponents, the LURMP does promote restoration and enhancement of habitats for the terrestrial and aquatic species of the Delta on public land. The BDCP biological goals and objectives would be compatible with these LURMP goals (Delta Protection Commission 2010).

- The *Suisun Marsh Preservation Act* of 1974 was designed to protect the Suisun Marsh for long-term use as wildlife habitat, with a goal of preserving and enhancing the quality and diversity of the Marsh's aquatic and wildlife habitats. The BDCP and its plans for protection and restoration of tidal marsh habitats in Suisun Marsh would be compatible with the intent of the Suisun Marsh Preservation Act.

Plans, Programs, and Policies

- *The Delta Plan*, which was developed by the Delta Stewardship Council in compliance with the 2009 Sacramento-San Joaquin Delta Reform Act, is mandated to achieve two co-equal goals: provide for a more reliable water supply for California and protect, restore, and enhance the

Delta ecosystem. The co-equal goals are to be achieved in a manner that protects and enhances the unique cultural, recreational, natural resource, and agricultural values of the Delta as an evolving place. The BDCP is intended to become a component of the Delta Plan. The Delta Stewardship Council would determine whether the BDCP is compatible with the goals and objectives of the Delta Plan prior to its incorporation into the Plan. The compatibility of the BDCP with the Delta Plan is considered in detail in Section 13.2.2.2 of Chapter 13, *Land Use*.

- *California Wetlands Conservation Policy*, which was adopted by Executive Order in 1993, promotes a long-term gain in the quantity, quality and permanence of wetlands acreages and values in California. Alternative 9 conservation measures that provide for a significant expansion of wetland acreage and quality in the Delta and Suisun Marsh are compatible with the intent of the California Wetlands Conservation Policy.

- *The North American Waterfowl Management Plan* (*NAWMP*) and *Central Valley Joint Venture* (*CVJV*) strive to maintain and expand wetlands and uplands for waterfowl and shorebirds in the major basins of California's Central Valley. The NAWMP is a management plan jointly approved by the United States and Canada in 1986. It contains general guidance from the principal wildlife management agencies of the two countries for sustaining abundant waterfowl populations by conserving landscapes through self-directed partnerships (joint ventures) that are guided by sound science. The CVJV is the joint venture established for overseeing NAWMP implementation in the Central Valley. The CVJV is made up of 21 conservation organizations, state and federal government agencies, and one corporation that have formed a partnership to improve the habitat conditions for breeding and nonbreeding waterfowl, breeding and nonbreeding shorebirds, waterbirds, and riparian-dependent songbirds in the Central Valley. The CVJV's 2006 Implementation Plan (Central Valley Joint Venture 2006) establishes conservation objectives and priorities for these bird groups within the basins of the Central Valley. The BDCP Plan Area includes all or portions of three Implementation Plan basins—the Delta, Yolo and Suisun basins. The 2006 Implementation Plan contains basin-specific objectives for wetland restoration, protection of existing wetland habitats, wetland enhancement, adequate power and water supplies for wetland management, agricultural land enhancement, farmland easements that maintain waterfowl food resources on agricultural land, and farmland easements that buffer existing wetlands from urban and residential growth.

  Implementation of the Alternative 9 conservation measures would result in significant reductions in cultivated land and managed wetland acreage in the Delta, Yolo and Suisun basins; however, significant increases in tidal and nontidal wetlands in these basins would be another result. Because of the large conversion of managed wetland in the Suisun basin, the BDCP has included a large managed wetland conservation and enhancement goal for this area. For the Suisun basin conversions to be compatible with the 2006 Implementation Plan goals, this EIR/EIS has added mitigation that would require food production studies and adaptive management to ensure that the Suisun basin would continue to provide the waterfowl and shorebird habitat envisioned in the Implementation Plan.

- *Stone Lakes National Wildlife Refuge Comprehensive Conservation Plan*, *Cosumnes River Preserve Management Plan*, *Brannan Island and Franks Tract State Recreation Areas General Plan*, *Yolo Bypass Wildlife Area Land Management Plan*, *Grizzly Island Wildlife Area Management Plan*, and the *Lower Sherman Island Wildlife Area Land Management Plan* are primarily designed to preserve and enhance the natural resource and recreation qualities of these areas. Implementing Alternative 9, especially construction of CM1 and CM2 facilities, and land modification associated with CM4 restoration activities, could create temporary disruptions to the terrestrial biological resource management activities in these management areas. The ultimate goals of aquatic and terrestrial habitat enhancement and restoration contained in the BDCP would be compatible with the long-term management goals of these areas. Proposed restoration areas in the Yolo Bypass, on Sherman Island, and in Suisun Marsh would be designed to be compatible with and to complement the current management direction for these areas and would be required to adapt restoration proposals to meet current policy established for managing these areas.

- *Suisun Marsh Preservation Agreement* and *Suisun Marsh Plan* are the most recent efforts by the state and federal agencies responsible for Suisun Marsh (the Marsh) to maintain its long-term viability as managed wetlands and wildlife habitat, consistent with the Suisun Marsh Preservation Act. The SMPA was signed in 1987 and modified in 2005 by DWR, CDFW, Reclamation and the Suisun Resource Conservation District to establish the mitigation approach in the Marsh for effects of operating the SWP and CVP. The primary concerns were the effects of CVP and SWP Delta diversions on salinity in the Marsh. The SMPA focused on ways to ensure adequate water quality and quantity for the managed wetlands and wildlife habitats in the Marsh to assure equal waterfowl values in the Marsh. The Suisun Marsh Plan, for which a Final EIS/EIR was released in 2010 by these agencies, provides for restoration of tidal marsh habitat and enhancement of managed wetland in the Marsh, maintenance of waterfowl hunting and recreational opportunities in the Marsh, maintenance and improvement of the Marsh levee system, and protection and enhancement of water quality for beneficial uses of the Marsh. An integral component of the Suisun Marsh Plan is balancing continued managed wetland operation with new tidal wetland restoration to provide improved and greater habitat for fish and wildlife species. The Suisun Marsh Plan is a programmatic, long-term plan and does not include specific projects, project proponents, or funding mechanisms. However, the Suisun Marsh Plan relies on tidal restoration to allow for managed wetland operations to continue. The BDCP would provide a funding mechanism and increased management potential relative to existing and restored habitats, assisting the Suisun Marsh Plan in meeting its broader ecological goals, consistent with long-term operation of the SWP and CVP water conveyance facilities. The conservation actions contained in the BDCP, which are designed to ensure the long-term protection and recovery of special-status fish and wildlife species dependent on the Marsh, would be compatible with the water quality and habitat restoration goals of the SMPA and Suisun Marsh Plan.

- *California Aquatic Invasive Species Management Plan* does not address terrestrial invasive species. Implementation of the Plan's long-term control and management objectives affect terrestrial species that utilize study area aquatic habitats. These effects are positive in that Plan objectives are to control and remove invasive aquatic species that are detrimental to native aquatic and terrestrial species. Implementation of BDCP's conservation actions would be undertaken with the goal of avoiding any further spread of aquatic invasive species. Alternative 9 would, therefore, be compatible with the objectives of the California Aquatic Invasive Species Management Plan.

- *Habitat Conservation Plans* and *Natural Community Conservation Plans* are the subject of a detailed analysis at the end of this chapter. The analysis considers the compatibility of the BDCP with all HCPs and NCCPs that share planning area with the BDCP Plan Area.

Executive Orders

- *Executive Order 11990: Protection of Wetlands* requires all federal agencies to consider wetland protection in their policies and actions. The BDCP proposes to protect, enhance and expand the wetlands of the Plan Area, and, therefore, would be compatible with Executive Order 11990.
- *Executive Order 13112: Invasive Species* directs federal agencies to prevent and control the introduction and spread of invasive species in a cost-effective and environmentally sound manner. Alternative 9 construction and restoration actions have the potential to both introduce and spread invasive species in the study area. Implementation of mitigation measures described in this chapter would be capable of making Alternative 9 implementation compatible with Executive Order 13112.
- *Executive Order 113443: Facilitation of Hunting Heritage and Wildlife Conservation* directs federal agencies whose activities affect public land management, outdoor recreation, and wildlife management to facilitate the expansion and enhancement of hunting opportunities, and the management of game species and their habitat. Alternative 9 conservation measures that involve conversion of cultivated land and managed wetland to tidal and nontidal wetlands and other natural communities would conflict with the hunting expansion and enhancement aspects of this executive order. Refer to Chapter 15, *Recreation*, for a detailed analysis of the effects of alternatives on hunting opportunities. The habitat protection and expansion conservation measures of Alternative 9 would be compatible with the executive order's goal of facilitating the management of habitats for some game species.

CEQA Conclusion: The potential plan and policy incompatibilities of implementing Alternative 9 identified in the analysis above indicate the potential for a physical consequence to the environment. The primary physical consequence of concern is the conversion of large acreages of cultivated land and managed wetland to natural wetland and riparian habitat in the Plan Area. The physical effects are discussed in the Shorebirds and Waterfowl analysis above and no additional CEQA conclusion is required related to the compatibility of the alternative with relevant plans and polices. The reader is referred to Section 13.2.3 of Chapter 13, *Land Use*, for a further discussion of the responsibilities of state and federal agencies to comply with local regulations and the relationship between plan and policy consistency and physical consequences to the environment.

12.3.4 Effects and Mitigation Approaches—Alternatives 4A, 2D, and 5A

12.3.4.1 No Action Alternative Early Long-Term

Effects of the No Action Alternative (ELT) as considered for the purposes of Alternative 4A, 2D, and 5A would be similar to the effects described for the No Action Alternative (LLT), except that the shorter timeframe would reduce the effects of many projects and programs listed in Table 12-7 in Section 12.3.3.1. The reduced timeframe would also lessen the potential effects of sea level rise and would reduce, but not eliminate, the risks to biological resources from flood- or seismic-related failure of Delta levees.

Implementation of the ongoing habitat expansion projects is likely to show significant progress in the ELT time period as efforts are made to counteract the terrestrial habitat losses associated with land conversion (primarily agricultural) and urban and infrastructure development in a timely fashion. These habitat expansions would be expected to counteract any transportation- or water-related infrastructure development or urban development in the study area because of the tight controls on these developments in the Delta. Management of the state and federal wildlife areas and the private wetlands would continue to emphasize a balance of protection for sensitive plant and wildlife species and the need for recreation opportunities and long-term agricultural viability. The number of habitat enhancement projects and the acreage of natural habitats restored and protected would likely be lower than what would be expected over a 50-year timeframe. Ongoing water management activities under the No Action Alternative (ELT) would not be likely to substantially modify the natural communities of the study area during the ELT time period. Most water management strategies being developed by state and federal water management agencies are designed to improve the conditions for special-status fish, wildlife, and plants in the study area.

The potential for adverse effects on biological resources from gradual sea level rise and from levee system failures due to major flooding episodes or seismic activity would be significantly reduced under No Action Alternative (ELT), compared with the 50-year timeframe under No Action Alternative (LLT). The extent of marsh habitat conversion would be lessened on the periphery of Suisun Marsh and the Yolo Basin, and along the Delta waterways, with a lower rise in sea level. The risk of habitat destruction from levee failure and subsequent flooding of riparian and cropland areas on Delta islands due to major flood events or seismic shaking would be reduced in the ELT. However, over the long-term, the risk would remain that major areas of cropland and adjacent natural habitats could be lost due to the poor condition of many Delta levees.

NEPA Effects: Even though the No Action Alternative (ELT) time period is significantly reduced from the No Action Alternative (LLT) time period, the overall direction of existing and ongoing programs and policies that influence land conversion and land management in the study area would continue to be toward maintaining the mix of agricultural, recreational, water management, and wildlife uses in the Delta, Yolo Bypass, and Suisun Marsh. Some actions under the No Action Alternative (ELT) will expand natural and manmade terrestrial and wetland habitats that will either benefit or have no effect on the special-status and common plants and wildlife in the study area. These activities may also result in impacts on some species but the overall benefit of these activities would not be adverse for many species by the ELT time period (see Table ES-8 in the *Executive Summary*). The potential will remain, however, for long-term trends in levee deterioration, global climate change, and seismic activity that could damage levees and result in significant changes in natural communities and cultivated lands.

CEQA Conclusion: Under the No Action Alternative (ELT) existing plans, programs and policies would affect terrestrial biological resources in the study area in a mostly positive way. Risks associated with natural processes that could damage or destroy Delta levees that protect both natural habitats and agricultural lands will continue, only over a shorter time period than under the No Action Alternative (LLT). The risks include flood-related levee deterioration, potential for seismically induced levee collapse, and, to a lesser extent, sea level rise associated with climate change. These risks, even over the shorter time period, if unchecked, could result in a net reduction in sensitive natural communities and special-status species. Many plans and programs call for expanded development and management of wetland and riparian habitats and increased management of cultivated lands for joint benefit to the farmer and wildlife. The implementation of these plans and programs would also likely impact some terrestrial biological resources, although on balance these impacts would be offset by habitat improvements and would result in less-than-significant impacts under CEQA by the ELT time period (see Table ES-8 in the *Executive Summary*). For some species, especially those that occur in the study area at higher elevations, there may be no impact from these plans and programs.

12.3.4.2 Alternative 4A—Dual Conveyance with Modified Pipeline/Tunnel and Intakes 2, 3, and 5 (9,000 cfs; Operational Scenario H)

Natural Communities

Tidal Perennial Aquatic

Construction, operation, maintenance, and management associated with the implementation of Alternative 4A would have no long-term adverse effects on the habitats associated with the tidal perennial aquatic natural community. Initial development and construction of water conveyance facilities would result in both permanent and temporary removal or modification of this community (see Table 12-4A-1). A small amount of this community could also be lost to channel margin habitat enhancement (Environmental Commitment 6).

Table 12-4A-1. Changes in Tidal Perennial Aquatic Natural Community Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Water Conveyance Facilities	280	2,019[b]
Environmental Commitment 4[a]	0	0
Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	**280**	**2,019**

[a] See discussion below for a description of applicable Environmental Commitments.
[b] The large acreage of tidal perennial aquatic habitat affected by Alternative 4A is related primarily to dredging of Clifton Court Forebay; the habitat would not be permanently removed, it would be expanded.

Impact BIO-1: Changes in Tidal Perennial Aquatic Natural Community as a Result of Implementing Alternative 4A

Construction and land grading activities that would accompany the implementation of water conveyance facilities for Alternative 4A would permanently affect an estimated 280 acres and temporarily remove 2,019 acres of tidal perennial aquatic natural community in the study area. The large temporary loss of this natural community would be primarily related to dredging of Clifton Court Forebay (1,931 acres). These modifications represent less than 3% of the 86,263 acres of the community that is mapped in the study area. The permanent and temporary effects would occur during the construction period for Alternative 4A as water conveyance facilities are developed. An undetermined amount of this natural community could also be affected by channel margin habitat enhancement along the major Delta waterways. The 450-acre expansion of Clifton Court Forebay during the water conveyance facility construction would offset the permanent losses.

The effects of water conveyance facilities and Environmental Commitment 6 are addressed below. A summary statement of impacts and NEPA and CEQA conclusions follows the individual environmental commitment discussion.

- *Water Facilities and Operation:* Construction of the Alternative 4A water conveyance facilities would permanently remove 280 acres and temporarily disturb 2,019 acres of tidal perennial aquatic community. Most of the permanent loss would occur where new facilities are constructed at Clifton Court Forebay and where Intakes 2, 3, and 5 encroach on the Sacramento River's east bank between Clarksburg and Courtland (see the Terrestrial Biology Mapbook for a detailed view of proposed facilities overlain on natural community mapping). The footings and the screens at the intake sites would be placed into the river margin and would displace moderately deep to shallow, flowing open water with a mud substrate and very little aquatic vegetation. Permanent losses would also occur where new control structures would be built into the California Aqueduct and the Delta Mendota Canal adjacent to Clifton Court Forebay, where Clifton Court Forebay levees are modified.
- The temporary effects on tidal perennial aquatic habitats would occur at numerous locations, with the largest effect occurring at Clifton Court Forebay, where the entire forebay would be dredged to provide additional storage capacity. Other temporary effects would occur in the Sacramento River at Intakes 2, 3, and 5, and at temporary barge unloading facilities established at four locations along the tunnel route. The barge unloading construction would temporarily affect Snodgrass Slough just south of Hood, Potato Slough at the south end of Boldin Island, Venice Reach of the San Joaquin River at the south end of Venice Island, Connection Slough at the north end of Bacon Island, and Old River just south of its junction with North Victoria Canal. In addition, temporary transmission lines have been identified as resulting in temporary impacts; however, these areas will likely ultimately be avoided by spanning these areas of open water. The details of these locations can be seen in the Terrestrial Biology Mapbook. These losses would take place during the 14-year construction time period.
- *Environmental Commitment 6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in filling of small amounts of tidal perennial aquatic habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would be implemented on tidal perennial aquatic habitat margins, including levees and channel banks. The improvements could be implemented on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.

The following paragraphs summarize the effects discussed above and describe other project actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

During the first 14 years of Alternative 4A implementation, the project would affect the tidal perennial aquatic community through water conveyance facilities construction losses (280 acres permanent and 2,019 acres temporary). These losses would occur primarily at Clifton Court Forebay due to dredging, and along the Sacramento River at intake sites.

NEPA Conclusion: The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and restoration actions associated with Alternative 4A environmental commitments. Loss of tidal perennial aquatic natural community would be considered both a loss in acreage of a sensitive natural community and a loss of waters of the United States as defined by Section 404 of the CWA. The largest loss would occur at Clifton Court Forebay, and would be temporary. This tidal perennial habitat is of relatively low value to special-status terrestrial species in the study area. The permanent expansion of the Clifton Court Forebay aquatic habitat (approximately 450 acres) during the first 14 years of Alternative 4A implementation would offset the permanent loss; the restoration of Clifton Court

Forebay aquatic habitat following construction-related dredging would offset the temporary project effects. These actions would avoid any adverse effect. Typical project-level mitigation ratios (1:1 for restoration) would indicate 2,299 acres of restoration would be needed to offset (i.e., mitigate) the 2,299 acres of effect (the total permanent and temporary effects listed in Table 12-4A-1) associated with water conveyance facilities construction; however, as noted above, 1,931 acres of the temporary impacts are associated with the dredging within the existing Clifton Court Forebay. The forebay is an enclosed system that would prevent suspended sediments from spreading outside of the area of disturbance, and the forebay would essentially revert back to pre-project conditions once dredging is complete.

The alternative also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS. Therefore, changes in tidal perennial aquatic natural community as a result of implementing Alternative 4A would not be adverse.

***CEQA Conclusion*:** Alternative 4A would result in the loss, conversion, and temporary disturbance of approximately 2,299 acres of tidal perennial aquatic natural community due to construction of the water conveyance facilities. The construction losses would occur primarily at Clifton Court Forebay, along the Sacramento River at intake sites, and along various Delta waterways at barge offloading sites. The losses,conversions, and disturbance would be spread across the 14-year water conveyance facilities construction period. These effects would be offset by planned restoration and expansion of Clifton Court Forebay (a combined acreage of approximately 2,595) following project-related dredging scheduled for the first 14 years of Alternative 4A implementation. AMM1, AMM2, AMM6, AMM7, and AMM10 would also be implemented to minimize impacts. Because of these offsetting restoration activities and AMMs, there would be no permanent loss of this sensitive natural community and impacts would be less than significant. Typical project-level mitigation ratios (1:1 for restoration) would indicate that 2,299 acres of restoration would be needed to offset (i.e., mitigate) the 2,299 acres of loss, conversion, and disturbance. Impacts associated with changes in tidal perennial aquatic natural community as a result of implementing Alternative 4A would be less than significant. No mitigation is required.

Impact BIO-2: Increased Frequency, Magnitude and Duration of Periodic Inundation of Tidal Perennial Aquatic Natural Community

Alternative 4A would not result in periodic effects on the tidal perennial aquatic natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-3: Modification of Tidal Perennial Aquatic Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the water conveyance facilities and conservation lands that could affect tidal perennial aquatic natural community in the study area. The ongoing actions include diverting Sacramento River flows in the north Delta, and reduced diversion from south Delta channels. These actions are associated with water conveyance facilities. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities, levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with project mitigation requirements. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversion from south Delta channels (associated with Operational Scenario H) would not result in the permanent reduction in acreage of a sensitive natural community in the study area. Flow levels in the upstream rivers would not change such that the acreage of tidal perennial aquatic community would be reduced on a permanent basis. Some increases and some decreases would be expected to occur during some seasons and in some water-year types, but there would be no permanent loss. Similarly, increased diversions of Sacramento River flows in the north Delta would not result in a permanent reduction in tidal perennial aquatic community downstream of these diversions. Tidal influence on water levels in the Sacramento River and Delta waterways would continue to be dominant. Reduced diversions from the south Delta channels would not create a reduction in this natural community.

  The periodic changes in flows in the Sacramento River, Feather River, and American River associated with Alternative 4A operations would affect salinity, water temperature, dissolved oxygen levels, turbidity, contaminant levels, and dilution capacity in these rivers and Delta waterways. These changes are discussed in detail in Chapter 8, *Water Quality*. Potentially substantial increases in electrical conductivity (salinity) are predicted for the Delta and Suisun Marsh as a result of increased export of Sacramento River water. These salinity changes are not expected to result in a permanent reduction in the acreage or value of tidal perennial aquatic natural community for terrestrial species in the study area.

- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with Alternative 4A actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in tidal perennial aquatic habitats. This activity could lead to increased soil erosion, turbidity and runoff entering tidal perennial aquatic habitats. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within aquatic habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and conservation sites. Use of herbicides to control nuisance vegetation could pose a long-term hazard to tidal perennial aquatic natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to tidal perennial aquatic areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the project to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with conservation activities.

- *Channel dredging.* Long-term operation of the Alternative 4A intakes on the Sacramento River and at Clifton Court Forebay would include periodic dredging of sediments that might accumulate in front of intake screens. The dredging would occur in tidal perennial aquatic natural community and would result in short-term increases in turbidity and disturbance of the substrate. These conditions would not eliminate the community, but would diminish its value for special-status and common species that rely on it for movement corridor or foraging area. The individual species effects are discussed in the *Wildlife Species* section.
- *Habitat enhancement.* Alternative 4A includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For tidal perennial aquatic natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for species. Actions would include control of invasive nonnative plant and animal species, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of tidal perennial aquatic natural community in the study area through changes in flow patterns and changes in water quality. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the alternative, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small reductions in acreage, these reductions would be greatly offset by restoration activities planned as part of *Environmental Commitment 4 Tidal Natural Communities Restoration*, and the restoration and expansion of this community at Clifton Court Forebay. The management actions associated with levee repair, periodic dredging and control of invasive plant species would also result in a long-term benefit to the species associated with tidal perennial aquatic habitats by improving water movement.

NEPA Effects: Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be no adverse effect on the tidal perennial aquatic natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 4A would have the potential to create minor losses in total acreage of tidal perennial aquatic natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, and AMM5 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including improved water movement in these habitats. Long-term restoration activities associated with *Environmental Commitment 4 Tidal Natural Communities Restoration* and enlargement of Clifton Court Forebay would greatly expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in the acreage or value of this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact on the tidal perennial aquatic natural community.

Tidal Brackish Emergent Wetland

Construction associated with Alternative 4A water conveyance facilities and the alternative's Environmental Commitments would not affect the tidal brackish emergent wetland natural community. Operation, maintenance, and management activities associated with the alternative could result in minor changes in total acreage of tidal brackish emergent wetland natural community in the study area, and could create temporary increases in turbidity and sedimentation.

As explained below, with the restoration and enhancement of tidal marsh as part of Alternative 4A, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Impact BIO-4: Changes in Tidal Brackish Emergent Wetland Natural Community as a Result of Implementing Alternative 4A

No tidal brackish emergent wetland would be lost or converted under Alternative 4A.

***NEPA Effects*:** No effect.

CEQA Conclusion: No impact.

Impact BIO-5: Modification of Tidal Brackish Emergent Wetland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with water conveyance facilities and Environmental Commitment 4 of Alternative 4A are constructed and the water management practices associated with changed reservoir operations, diversions from the north Delta, and marsh restoration are in effect, there would be new ongoing and periodic actions that could affect tidal brackish emergent wetland natural community in the study area. The ongoing actions include water releases and diversions, access road and levee repair, and replacement of levee armoring, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversion from south Delta channels (associated with Operational Scenario H) would not result in the permanent reduction in acreage of tidal brackish emergent wetland natural community in the study area. Flow levels in the upstream rivers would not directly affect this natural community because it does not exist upstream of the Delta. Increased diversions of Sacramento River flows in the north Delta would not result in a permanent reduction in tidal brackish emergent wetland downstream of these diversions. Salinity levels in Suisun Marsh would be similar or less relative to the No Action Alternative (ELT). There would be no increase in the long-term average electrical conductivity at modeled Suisun Marsh locations, and for some locations long-term average electrical conductivity would decrease (see Chapter 8, *Water Quality*); therefore, there would not be a change the acreage of brackish marsh. This natural community persists in an environment that experiences natural fluctuations in salinity due to tidal ebb and flow. Reduced diversions from the south Delta channels would not create a reduction in this natural community.

- The increased diversion of Sacramento River flows in the north Delta would result in reductions in sediment load (annual mass) flowing into the central and west Delta, and Suisun Marsh. The reduction is estimated to be approximately 9% of the river's current sediment load for Alternative 4A, which would have a north Delta diversion capacity of 9,000 cfs under Operational Scenario H (see Appendix 5.C, Attachment 5C.D, Section 5C.D.3.3, *Summary of Changes to Sediment Supply in the Plan Area Due to BDCP Shift in Export Location and Volume*, in the BDCP for a detailed analysis of this issue). This would contribute to a decline in sediment reaching the Delta and Suisun Marsh that has been occurring over the past 50-plus years due to a gradual depletion of sediment from the upstream rivers. The depletion has been caused by a variety of factors, including depletion of hydraulic mining sediment in upstream areas, armoring of river channels and a cutoff of sediment due to dam construction on the Sacramento River and its major tributaries (Wright and Schoellhamer 2004; Barnard et al. 2013).

- Reduced sediment load flowing into the Delta and Suisun Marsh could have an adverse effect on tidal marsh, including tidal brackish emergent wetland. Sediment trapped by the marsh vegetation allows the emergent plants to maintain an appropriate water depth as water levels gradually rise from the effects of global warming (see Chapter 29, *Climate Change*). The project proponents have incorporated an environmental commitment (see Appendix 3B, Section 3B.2.18, *Disposal and Reuse of Spoil, Reusable Tunnel Material and Dredged Material*) into the project that would lessen this potential effect. The Sacramento River water diverted at north Delta intakes would pass through sedimentation basins before being discharged to water conveyance structures. The commitment states that sediment collected in these basins would be periodically removed and reused, to the greatest extent feasible, in the study area for a number of purposes, including marsh restoration, levee maintenance, subsidence reversal, flood response, and borrow area fill. The portion of the sediment re-introduced to the Delta and estuary for marsh restoration would remain available for marsh accretion. With this commitment to reuse in the study area, the removal of sediment at the north Delta intakes would not result in a net reduction in the acreage and value of this special-status marsh community. The effect would not be adverse (NEPA) and would be less than significant (CEQA).

- *Access road and levee repair.* Periodic repair of access roads and levees associated with Alternative 4A actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in tidal brackish emergent wetland habitats. This activity could lead to increased soil erosion, turbidity and runoff entering these habitats. The activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan*. Any vegetation removal or earthwork adjacent to or within aquatic habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment (Environmental Commitment 11), would be a periodic activity associated with the long-term maintenance of restoration sites. Use of herbicides to control nuisance vegetation could pose a long-term hazard to tidal brackish emergent wetland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to wetland areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of Alternative 4A to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic environments would also reduce the risk of affecting natural communities adjacent to levees associated with tidal wetland restoration activities.

- *Habitat enhancement.* Alternative 4A includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For tidal brackish emergent wetland natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for special-status species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage and value of tidal brackish emergent wetland natural community in the study area through water operations, levee and road maintenance, and vegetation management in or adjacent to this community. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the alternative, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be greatly offset by restoration activities planned as part of *Environmental Commitment 4 Tidal Natural Communities Restoration*. The management actions associated with levee repair and control of invasive plant species would also result in a long-term benefit to the species associated with tidal brackish emergent wetland habitats by improving water movement.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 4A would not result in a net permanent reduction in the tidal brackish emergent wetland natural community within the study area. There would be no adverse effect on the tidal brackish emergent wetland natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of tidal brackish emergent wetland natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, and AMM5 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including improved water movement in these habitats. Restoration activities associated with *Environmental Commitment 4 Tidal Natural Communities Restoration* would expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact.

Tidal Freshwater Emergent Wetland

Construction, operation, maintenance and management associated with the Environmental Commitments of Alternative 4A would have no long-term adverse effects on the habitats associated with the tidal freshwater emergent wetland natural community. Initial development and construction of water conveyance facilities would result in both permanent and temporary removal of small acreages of this community (see Table 12-4A-2). Small areas of this community could also be lost to the development of channel margin habitat associated with Environmental Commitment 6.

As explained below, with the restoration and enhancement of tidal habitat, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-2. Changes in Tidal Freshwater Emergent Wetland Natural Community Associated with Alternative 4A (acres)[a]

Project Component	Permanent	Temporary
Water Conveyance Facilities	1	10
Environmental Commitment 4[a]	0	0
Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	**1**	**10**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-6: Changes in Tidal Freshwater Emergent Wetland Natural Community as a Result of Implementing Alternative 4A

Construction and land grading activities that would accompany the implementation of water conveyance facilities for Alternative 4A would permanently eliminate an estimated 1 acre and temporarily remove 10 acres of tidal freshwater emergent wetland natural community in the study area. These modifications represent less than 1% of the 8,856 acres of the community that is mapped in the study area. The majority of the permanent and temporary losses would happen during the first 14 years of Alternative 4A implementation, as water conveyance facilities are constructed. Smaller areas of this natural community could be affected by levee breaching, grading, and contouring associated with Environmental Commitment 4 and Environmental Commitment 6 restoration activities. Natural communities restoration would add at least 295 acres of tidal wetland during the course of project restoration activities, which would expand the area of that habitat and offset the losses.

The individual effects of water conveyance facilities, Environmental Commitment 4, and Environmental Commitment 6 are addressed below. A summary statement of the impacts and NEPA and CEQA conclusions follows the Environmental Commitment discussion.

- *Water Facilities and Operation:* Construction of the Alternative 4A water conveyance facilities would permanently remove 1 acre and temporarily remove 10 acres of tidal freshwater emergent wetland community. Most of the loss would occur along rivers and canals in the central Delta from barge unloading facility construction (Old River on the east side of Victoria Island and Connection Slough at the north end of Bacon Island), and from transmission line construction (San Joaquin River and Potato Slough at the south and north ends of Venice Island, Connection Slough at the north end of Bacon Island, and Railroad Slough at the north end of Woodward Island; see Terrestrial Biology Mapbook). These losses would take place during the water conveyance facilities construction period.
- There is the potential for increased nitrogen deposition associated with construction vehicles during the construction phase of water conveyance facilities. Appendix 5.J, Attachment 5J.A, *Construction-Related Nitrogen Deposition on BDCP Natural Communities,* of the BDCP addresses this issue in detail. It has been concluded that this potential deposition would pose a low risk of changing tidal freshwater emergent wetland natural community because the construction would occur primarily downwind of the natural community and the construction would contribute a negligible amount of nitrogen to regional projected emissions. No adverse effect is expected.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: The restoration activities associated with Environmental Commitment 4 would result in other effects that could alter the habitat value of tidal freshwater emergent wetland. Disturbances associated with levee breaching and grading or contouring would increase opportunities for the introduction or spread of invasive species. Implementation of Environmental Commitment 11 would limit this risk through invasive species control and wetland management and enhancement activities to support native species. Flooding of dry areas for tidal marsh creation could also increase the bioavailability of methylmercury, especially in the Cache Slough and Cosumnes/Mokelumne ROAs. Site-specific conditions would dictate the significance of this hazard to marsh vegetation and associated wildlife. A detailed review of the methylmercury issues associated with implementation of Alternative 4A is contained in Appendix 11F, *Substantive BDCP Revisions*. Site-specific restoration plans that address the creation and mobilization of mercury, and monitoring and adaptive management as described in *Environmental Commitment 12 Methylmercury Management*, would be available to address the uncertainty of methylmercury levels in restored tidal marsh. Water temperature fluctuations in newly created marsh is also an issue of concern that is difficult to quantify at the current stage of restoration design. None of these effects is expected to limit the extent or value of tidal freshwater emergent wetland in the study area.
- *Environmental Commitment 6 Channel Margin Enhancement:* Channel margin habitat enhancement could result in filling of small amounts of tidal freshwater emergent wetland habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this

time, but the majority of the enhancement activity would occur on narrow strips of habitat, including levees and channel banks. The improvements could occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.

The following paragraphs summarize the combined effects discussed above and describe other Alternative 4A environmental commitments that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

During the construction phase of Alternative 4A, the project would affect the tidal freshwater emergent wetland natural community through water conveyance facilities construction losses (1 acre permanent and 10 acres temporary). These losses would occur in the central Delta from construction of barge unloading facilities and transmission lines on the fringes of Venice, Bacon and Woodward Islands, and in various locations within the Yolo Bypass and the tidal restoration ROAs. An undetermined acreage would also be affected through channel margin habitat creation (Environmental Commitment 6) along the major Delta waterways.

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and restoration actions associated with Alternative 4A Environmental Commitments. Loss of tidal freshwater emergent wetland natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. However, the creation of 295 acres of tidal wetland as part of Environmental Commitment 4 during the construction phase of Alternative 4A would more than offset this loss, avoiding any adverse effect. Typical project-level mitigation ratios (1:1 for restoration) would indicate that 11 acres of restoration would be needed to offset (i.e., mitigate) the 11 acres of loss (the total permanent and temporary effects listed in Table 12-4A-2).

Alternative 4A also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The creation of 295 acres of tidal wetland as part of Environmental Commitment 4 during the construction phase of Alternative 4A would more than offset the construction and restoration effects of implementing water conveyance facilities and Environmental Commitment 6, avoiding any adverse effect. Because of the 295 acres of tidal wetland restoration that would occur as part of Alternative 4A, the project would not result in a net long-term reduction in the acreage of a sensitive natural community; the effect would not be adverse.

CEQA Conclusion: Alternative 4A would result in the loss of approximately 11 acres of tidal freshwater emergent wetland natural community (permanent and temporary) due to construction of the water conveyance facilities. The construction losses would occur in primarily in the central Delta on the fringes of Venice, Bacon and Victoria Islands, and in the Yolo Bypass and various tidal restoration ROAs. An unknown amount of tidal freshwater emergent wetland could also be lost to channel margin habitat creation (Environmental Commitment 6).The losses would be spread across the Alternative 4A construction timeframe and would be offset by planned restoration of 295 acres of tidal wetland scheduled for the first 14 years of Alternative 4A implementation (Environmental Commitment 4). AMM1, AMM2, AMM6, AMM7, and AMM10 would also be implemented to minimize impacts. Because of these offsetting restoration activities and AMMs, impacts would be less than significant. Typical project-level mitigation ratios (1:1 for restoration) would indicate that 11 acres of restoration would be needed to offset (i.e., mitigate) the 11 acres of loss. The restoration would be initiated at the beginning of Alternative 4A implementation to minimize any time lag in the availability of this habitat to special-status species, and would result in a net gain in acreage of this sensitive natural community. The impact would be less than significant. No mitigation is required.

Impact BIO-7: Increased Frequency, Magnitude and Duration of Periodic Inundation of Tidal Freshwater Emergent Wetland Natural Community

Alternative 4A would not result in periodic effects on the tidal freshwater emergent wetland natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-8: Modification of Tidal Freshwater Emergent Wetland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the Alternative 4A facilities and conservation lands that could affect tidal freshwater emergent wetland natural community in the study area. The ongoing actions would include modified operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels. These actions are associated with water conveyance facilities. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Reduced diversions from the south Delta channels would not create a reduction in tidal freshwater emergent wetland in the study area. However, the periodic changes in flows in the Sacramento River, Feather River, and American River associated with modified reservoir operations, and the increased diversion of Sacramento River flows at north Delta intakes associated with Alternative 4A (Operational Scenario H) would affect salinity, water temperature, dissolved oxygen levels, turbidity, contaminant levels and dilution capacity in these rivers and Delta waterways. These changes are discussed in detail in Chapter 8, *Water Quality*. Potentially substantial increases in electrical conductivity (salinity) are predicted for the west Delta and Suisun Marsh as a result of these changed water operations. These salinity changes may alter the plant composition of tidal freshwater emergent wetland along the lower Sacramento and San Joaquin Rivers and west Delta islands. The severity and extent of these salinity changes would be complicated by anticipated sea level rise and the effects of downstream tidal restoration over the life of the project. There is the potential that some tidal freshwater marsh may become brackish. These potential changes are not expected to result in a significant reduction in the acreage and value of tidal freshwater emergent wetland natural community in the study area.

- The increased diversion of Sacramento River flows in the north Delta would result in reductions in sediment load (annual mass) flowing into the central and west Delta, and Suisun Marsh. The reduction is estimated to be approximately 9% of the river's current sediment load for Alternative 4A, which would have a north Delta diversion capacity of 9,000 cfs under Operational Scenario H (see Appendix 5.C, Attachment 5C.D, Section 5C.D.3.3, *Summary of Changes to Sediment Supply in the Plan Area Due to BDCP Shift in Export Location and Volume*, in the BDCP for a detailed analysis of this issue). This would contribute to a decline in sediment reaching the Delta and Suisun Marsh that has been occurring over the past 50-plus years due to a gradual depletion of sediment from the upstream rivers. The depletion has been caused by a variety of factors, including depletion of hydraulic mining sediment in upstream areas, armoring of river channels and a cutoff of sediment due to dam construction on the Sacramento River and its major tributaries (Wright and Schoellhamer 2004; Barnard et al. 2013).

- Reduced sediment load flowing into the Delta and Suisun Marsh could have an adverse effect on tidal marsh, including tidal freshwater emergent wetland. Sediment trapped by the marsh vegetation allows the emergent plants to maintain an appropriate water depth as water levels gradually rise from the effects of global warming (see Chapter 29, *Climate Change*). The project proponents have incorporated an environmental commitment (see Appendix 3B, Section 3B.2.18, *Disposal and Reuse of Spoil, Reusable Tunnel Material and Dredged Material*) into the project that would lessen this potential effect. The Sacramento River water diverted at north Delta intakes would pass through sedimentation basins before being discharged to water conveyance structures. The commitment states that sediment collected in these basins would be periodically removed and reused, to the greatest extent feasible, in the study area for a number of purposes, including marsh restoration, levee maintenance, subsidence reversal, flood response, and borrow area fill. The portion of the sediment re-introduced to the Delta and estuary for marsh restoration would remain available for marsh accretion. With this commitment to reuse in the study area, the removal of sediment at the north Delta intakes would not result in a net reduction in the acreage and value of this special-status marsh community. The effect would not be adverse (NEPA) and would be less than significant (CEQA).

- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with Alternative 4A actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in or adjacent to tidal freshwater emergent wetland habitats. This activity could lead to increased soil erosion, turbidity and runoff entering tidal aquatic habitats. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within emergent wetland habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (Environmental Commitment 11). Use of herbicides to control nuisance vegetation could pose a long-term hazard to tidal freshwater emergent wetland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to tidal aquatic areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the project to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Channel dredging.* Long-term operation of the Alternative 4A intakes on the Sacramento River would include periodic dredging of sediments that might accumulate in front of intake screens. The dredging would occur in waterways adjacent to tidal freshwater emergent wetlands and would result in short-term increases in turbidity and disturbance of the substrate. These conditions would not eliminate the community, but would diminish its value for special-status and common species that rely on it for cover or foraging area. The individual species effects are discussed in the *Wildlife Species* section.
- *Habitat enhancement.* The project includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For tidal freshwater emergent wetland community, a management plan would be prepared that specifies actions to improve the value of the habitats for special-status species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of tidal freshwater emergent wetland natural community in the study area through changes in flow patterns and resultant changes in water quality. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with Alternative 4A, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be offset by restoration activities planned as part of *Environmental Commitment 4 Tidal Natural Communities Restoration*. The management actions associated with levee repair, periodic dredging and control of invasive plant species would also result in a long-term benefit to the species associated with tidal freshwater emergent wetland habitats by improving water movement.

NEPA Effects: Ongoing operation, maintenance, and management activities would not result in a net permanent reduction in the tidal freshwater emergent wetland natural community within the study area. Therefore, there would be no adverse effect on this natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 4A, including changed water operations in the upstream reservoirs, would have the potential to create minor changes in total acreage of tidal freshwater emergent wetland natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, and AMM5 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including improved water movement in these habitats. Restoration activities associated with *Environmental Commitment 4 Tidal Natural Communities Restoration* would expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact on the tidal freshwater emergent wetland natural community.

Valley/Foothill Riparian

Construction, operation, maintenance and management associated with Alternative 4A would have no long-term adverse effects on the habitats associated with the valley/foothill riparian natural community. Initial development and construction of water conveyance facilities, Environmental Commitment 4, and Environmental Commitment 6 would result in both permanent and temporary removal of this community (see Table 12-4A-3). Implementation of Alternative 4A would also include the following Environmental Commitments and Resource Restoration and Performance Principles over the term of the project to benefit the valley/foothill riparian natural community.

- Restore or create up to 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect up to 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).
- Maintain a single contiguous patch of mature riparian forest in either CZ4 or CZ7 (Resource Restoration and Performance Principle VFR2).
- The mature riparian forest intermixed with a portion of the early- to mid-successional riparian vegetation will be a minimum patch size of 50 acres and minimum width of 330 feet where practicable (Resource Restoration and Performance Principle VFR3).

As explained below, with the restoration and enhancement of these amounts of habitat, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-3. Changes in Valley/Foothill Riparian Natural Community Associated with Alternative 4A (acres)[a]

Project Component	Permanent	Temporary
Water Conveyance Facilities	37	24
Environmental Commitment 4[a]	11	0
Environmental Commitment 6	UNK	UNK
Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	**48**	**24**

UNK = Unknown quantity but impact possible

Impact BIO-9: Changes in Valley/Foothill Riparian Natural Community as a Result of Implementing Alternative 4A

Construction, land grading and habitat restoration activities that would accompany the implementation of water conveyance facilities and Environmental Commitment 4, would permanently eliminate an estimated 48 acres and temporarily remove 24 acres of valley/foothill riparian natural community in the study area. Also, a relatively small but unknown amount of habitat could be affected by *Environmental Commitment 6 Channel Margin Enhancement.* These modifications represent approximately 0.5% of the 17,966 acres of the community that is mapped in the study area. The majority of the permanent and temporary losses would happen during the construction of Alternative 4A and as habitat restoration is initiated. Valley/foothill riparian protection (103 acres) and restoration (251 acres) would be initiated during the same period, which would offset the losses.

The individual effects of each relevant Environmental Commitment are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation:* Construction of the Alternative 4A water conveyance facilities would permanently remove 37 acres and temporarily remove 24 acres of valley/foothill riparian natural community. The permanent losses would occur where Intakes 2, 3, and 5 encroach on the Sacramento River's east bank between Freeport and Courtland. The riparian areas here are very small patches, some dominated by valley oak and others by nonnative trees (acacia) and scrub vegetation (see Terrestrial Biology Mapbook). Cottonwood, willow and mixed brambles would be permanently lost at manmade ponds located north and south of Twin Cities Road just west of Interstate 5, as these sites would be used to deposit reusable tunnel material. Some cottonwood and valley oak riparian would be lost due to construction of a permanent access road from the new forebay west to an RTM disposal area. Blackberry brambles would also be lost to deposit of reusable tunnel material at the east end of Bouldin Island. Smaller areas dominated by blackberry would be eliminated at the forebay site adjacent to Clifton Court Forebay and patches of willow and blackberry would be lost along the transmission line corridors where they cross waterways in the central and south Delta. Permanent losses would occur along Lambert Road where temporary transmission lines would be installed. Temporary losses would also occur adjacent to temporary intake work areas. The riparian habitat in these areas is also composed of very small patches or stringers bordering waterways, which are composed of valley oak, cottonwood, willow and scrub vegetation. These losses would take place during the Alternative 4A construction period.

- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Environmental Commitment 4 would permanently inundate or remove an estimated11 acres of valley/foothill riparian community. The losses would occur in one or more of the ROAs established for tidal restoration (see Figure 12-1). No losses would occur in the Suisun Marsh ROA. These ROAs support a mix of riparian vegetation types, including valley oak stands, extensive willow and cottonwood stringers along waterways, and areas of scrub vegetation dominated by blackberry. These areas are considered of low to moderate habitat value (see BDCP Chapter 5, Section 5.4.5.1.1, *Permanent Loss and Fragmentation*). The actual loss of riparian habitat to marsh restoration would be expected to be smaller than predicted. As marsh restoration projects were identified and planned, sites could be selected that avoid riparian areas as much as possible.
- *Environmental Commitment 6 Channel Margin Enhancement:* Channel margin habitat enhancement could result in removal of small amounts of valley/foothill riparian habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur along waterway margins where riparian habitat stringers exist, including levees and channel banks. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.
- *Environmental Commitment 7 Riparian Natural Community Restoration:* The valley/foothill riparian natural community would be restored primarily in association with the tidal (Environmental Commitment 4) and channel margin (Environmental Commitment 6) enhancements. A total of 251 acres of this community would be restored and 103 acres would be protected during the construction period (14 years) of the project. A variety of successional stages would be sought to benefit the variety of sensitive plant and animal species that rely on this natural community in the study area.

The following paragraphs summarize the combined effects discussed above and describe other Alternative 4Aenviornmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Alternative 4A would affect the valley/foothill riparian natural community through water conveyance facilities construction losses (37 acres permanent and 24 acres temporary) and the Environmental Commitment 4 restoration actions (11 acres permanent). The water conveyance facilities losses would occur along the eastern bank of the Sacramento River at intake sites; along transmission lines in the central and south Delta and along Lambert Road; and at RTM storage sites near Twin Cities Road, Clifton Court Forebay, and on Bouldin Island. The 11 acres of Environmental Commitment 4 losses would occur in one or more of the ROAs mapped in Figure 12-1.

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and protection/restoration actions associated with Alternative 4A environmental commitments described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*. Loss of valley/foothill riparian natural community would be considered a loss in acreage of a sensitive natural community, and could be considered a loss of wetlands as defined in Section 404 of the CWA. As indicated above, most of the losses would be in small patches or narrow strips along waterways, with limited structural complexity. However, the restoration of up to 251 acres and protection (including significant enhancement) of 103 acres of valley/foothill riparian natural community as part of Environmental Commitment 7 and Environmental Commitment 3 during the Alternative 4A construction period would minimize this loss, avoiding any adverse effect. The restoration areas would be large areas providing connectivity with existing riparian habitats and would include a variety of trees and shrubs to produce structural complexity. Typical project-level mitigation ratios (1:1 for restoration and 1:1 for protection) would indicate that 72 acres of protection and 72 acres of restoration would be needed to offset (i.e., mitigate) the 72 acres of loss (the combination of permanent and temporary losses listed in Table 12-4A-3). The combination of the two approaches (protection and restoration) are designed to avoid a temporal lag in the value of riparian habitat available to sensitive species.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM6 Disposal and Reuse of Spoils, AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM18 Swainson's Hawk*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Implementation of Alternative 4A would result in the loss of approximately 0.5% of valley/foothill riparian natural community in the study area. These losses (48 acres of permanent and 24 acres of temporary) would be largely associated with construction of the water conveyance facilities and inundation during tidal marsh restoration (Environmental Commitment 4). Inundation losses would occur through the course of the project's tidal marsh restoration program at various tidal restoration sites throughout the study area. By the end of the project's construction period, a total of 251 acres of this natural community would be restored and 103 acres would be protected (Environmental Commitment 7 and Environmental Commitment 3, respectively), primarily in CZ 4 and CZ 7 in the Cosumnes/Mokelumne and South Delta ROAs (see Figure 12-1).

NEPA Effects: The restoration of up to 251 acres and protection (including significant enhancement) of 103 acres of valley/foothill riparian natural community as part of Environmental Commitment 7 and Environmental Commitment 3 together with Resource restoration and performance principles VFR1-VFR3 during the construction period for Alternative 4A would minimize the loss of this community, avoiding any adverse effect. Because of the project's commitment to restoration of up to 251 acres and protection of up to 103 acres of valley/foothill riparian natural community during the course of the project, Alternative 4A would not result in a net long-term reduction in the acreage of a sensitive natural community; the effect would not be adverse.

CEQA Conclusion: Alternative 4A would result in the loss of approximately 72 acres of valley/foothill riparian natural community due to construction of the water conveyance facilities and inundation during tidal marsh restoration (Environmental Commitment 4). The construction losses would occur primarily along the Sacramento River at intake sites; along transmission corridors in the central and south Delta and along Lambert Road; and at reusable tunnel material storage sites on Bouldin Island, Clifton Court Forebay and near Twin Cities Road, while inundation losses would occur at various tidal restoration sites throughout the study area. The construction losses would be spread across the 14-year construction time frame of the project. These losses would be minimized by planned restoration of up to 251 acres (Environmental Commitment 7) and protection (including significant enhancement) of 103 acres (Environmental Commitment 3) of valley/foothill riparian natural community scheduled for the construction period of Alternative 4A, which would be guided by Resource Restoration and Performance Principles VFR1-VFR3. AMM1, AMM2, AMM6, AMM7, AMM10, and AMM18 would also be implemented to minimize impacts.

Because of these restoration and protection activities and AMMs, impacts would be less than significant. Typical project-level mitigation ratios (1:1 for protection and 1:1 for restoration) would indicate that 72 acres of protection and 72 acres of restoration would be needed to offset (i.e., mitigate) the 72 acres of loss. The combination of the two approaches (protection and restoration) is designed to avoid a temporal lag in the value of riparian habitat available to sensitive species. The restoration would be initiated at the beginning of Alternative 4A implementation to minimize any time lag in the availability of this habitat to special-status species, and would result in a net gain in acreage of this sensitive natural community. Therefore, the impact would be less than significant.

Impact BIO-10: Increased Frequency, Magnitude and Duration of Periodic Inundation of Valley/Foothill Riparian Natural Community

Alternative 4A would not result in periodic effects on the valley/foothill riparian natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-11: Modification of Valley/Foothill Riparian Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the Alternative 4A facilities and conservation lands that could affect valley/foothill riparian natural community in the study area. The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels. These actions are associated with water conveyance facilities and Environmental Commitment 11. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified releases and water levels in upstream reservoirs.* Modified releases and water levels at Shasta Lake, Lake Oroville, Whiskeytown Lake, Lewiston Lake, and Folsom Lake would not affect valley/foothill riparian natural community. The anticipated water levels over time with Alternative 4A, as compared to no action, would be slightly lower in the October to May timeframe. The small changes in frequency of higher water levels in these lakes would not substantially reduce the small patches of riparian vegetation that occupy the upper fringes of the reservoir pools. Changes in releases that would influence downstream river flows are discussed below.
- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area and their resultant changes in flows in the Sacramento, American and Feather Rivers (associated with Operational Scenario H) would not be expected to result in the permanent reduction in acreage of valley/foothill riparian natural community along these waterways. There is no evidence that flow levels in the upstream rivers would change such that the acreage of this community would

be reduced on a permanent basis. Riparian habitats along the rivers of the Sacramento Valley have historically been exposed to significant variations in river stage. Based on modeling conducted for Alternative 4A (see Appendix 11C, *CALSIM II Model Results Utilized in the Fish Analysis*), flow levels in these upstream rivers could be reduced by as much as 33% (Feather River at confluence with Sacramento River) in the July to November time frame when compared to No Action, while flow levels in the February to May time frame could increase as much as 31% (Feather River at confluence with Sacramento River) with implementation of Alternative 4A. Similarly, increased diversions of Sacramento River flows in the north Delta would not be expected to result in a permanent reduction in valley/foothill riparian community downstream of these diversions, even though river flows are modeled to be reduced by 4–32% compared with No Action, depending on month and water-year type (see Appendix 11C, Section 11C.11, *Alternative 4A*). Reduced diversions from the south Delta channels would not create a reduction in this natural community.

- The periodic changes in flows in the Sacramento River, Feather River, and American River associated with modified reservoir operations, and the increased diversion of Sacramento River flows at north Delta intakes associated with Alternative 4A would affect salinity, water temperature, dissolved oxygen levels, turbidity, contaminant levels and dilution capacity in these rivers and Delta waterways. These changes are discussed in detail in Chapter 8, *Water Quality*. Potentially substantial increases in electrical conductivity (salinity) are predicted for the west Delta and Suisun Marsh as a result of these changed water operations. These salinity changes may alter the plant composition of riparian habitats along the lower Sacramento and San Joaquin Rivers and west Delta islands. The severity and extent of these salinity changes would be complicated by anticipated sea level rise and the effects of downstream tidal restoration over the life of the project. There is the potential that some valley/foothill riparian natural community may be degraded immediately adjacent to river channels. The riparian communities in the west Delta are dominated by willows, cottonwood and mixed brambles. These potential changes are not expected to result in a significant reduction in the acreage and value of valley/foothill riparian natural community in the study area.

- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with Alternative 4A actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in valley/foothill riparian habitats. This activity could lead to increased soil erosion, turbidity and runoff entering these habitats. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within riparian habitats would require use of sediment barriers, soil stabilization and revegetation of disturbed surfaces (*AMM10 Restoration of Temporarily Affected Natural Communities*). Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*Environmental Commitment 11 Natural Communities Enhancement and Management*). Use of herbicides to control nuisance vegetation could pose a long-term hazard to valley/foothill riparian natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to riparian areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the project to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in terrestrial environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Channel dredging.* Operation of the Alternative 4A intakes on the Sacramento River would include periodic dredging of sediments that might accumulate in front of intake screens. The dredging could occur adjacent to valley/foothill riparian natural community. This activity should not adversely affect riparian plants as long as dredging equipment is kept out of riparian areas and dredge spoil is disposed of outside of riparian corridors.
- *Habitat enhancement.* The project includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For the valley/foothill riparian natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of valley/foothill riparian natural community in the study area through changes in flow patterns and resultant changes in water quality. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the project, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be greatly offset by restoration and protection activities planned as part of *Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration*, or minimized by implementation of AMM2, AMM4, AMM5, AMM10, and AMM18. The management actions associated with levee repair, periodic dredging and control of invasive plant species would also result in a long-term benefit to the species associated with riparian habitats by improving water movement in adjacent waterways and by eliminating competitive, invasive species of plants.

***NEPA Effects*:** Ongoing operation, maintenance and management activities associated with implementation of Alternative 4A would not result in a net permanent reduction in the valley/foothill riparian natural community within the study area. Therefore, there would be no adverse effect on this natural community.

***CEQA Conclusion*:** The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of valley/foothill riparian natural community in the study area, and could create temporary increases in turbidity and sedimentation.

The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, AMM5, AMM10, and AMM18 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including reduced competition from invasive, nonnative plants in these habitats. Restoration and protection activities associated with *Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration* would expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact on the valley/foothill riparian natural community.

Nontidal Perennial Aquatic

Construction, operation, maintenance and management and Environmental Commitment 4 associated with Alternative 4A would have no long-term adverse effects on the habitats associated with the nontidal perennial aquatic natural community. Initial development and construction of water conveyance facilities would result in both permanent and temporary removal of this community (see Table 12-4A-4). Tidal restoration (Environmental Commitment 4) and channel margin habitat enhancement (Environmental Commitment 6) could also remove small areas of this natural community.

As explained below, with the restoration and enhancement of nontidal wetland habitat, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-4. Changes in Nontidal Perennial Aquatic Natural Community Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Water Conveyance Facilities	58	6
Environmental Commitment 4[a]	2	0
Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	**60**	**6**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-12: Changes in Nontidal Perennial Aquatic Natural Community as a Result of Implementing Alternative 4A

Construction and land grading activities that would accompany the implementation of water conveyance facilities and tidal restoration (Environmental Commitment 4) would permanently eliminate an estimated 60 acres and temporarily remove 6 acres of nontidal perennial aquatic natural community in the study area. These modifications represent approximately 1.2% of the 5,567 acres of the community that is mapped in the study area. Natural communities restoration would add 832 acres (Environmental Commitment 10) and protect up to 119 acres (Environmental

Commitment 3) of nontidal marsh during the same period which would expand the area of that habitat and offset the losses. The nontidal marsh restoration would include a mosaic of nontidal perennial aquatic and nontidal freshwater perennial emergent wetland natural communities. The nontidal marsh would be restored in the vicinity of giant garter snake subpopulations identified in the recovery plan for this species (U.S. Fish and Wildlife Service 1998).

The individual effects of each relevant Environmental Commitment are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation*: Construction of the Alternative 4A water conveyance facilities would permanently remove 58 acres and temporarily remove 6 acres of nontidal perennial aquatic community. Most of the permanent loss would occur at the linear manmade ponds located north and south of Twin Cities Road just west of I-5 and an RTM storage site on Bouldin Island (see Terrestrial Biology Mapbook). Most of the temporary loss would occur where transmission line construction would cross Mandeville Island. These wetlands are linear ponds or small, isolated areas surrounded by agricultural land. These losses would take place during the Alternative 4A construction period.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Environmental Commitment 4 would convert an estimated 2 acres of nontidal perennial aquatic habitat. The losses would occur in one or more of the ROAs established for tidal restoration (see Figure 12-1).
- *Environmental Commitment 6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in filling of small amounts of nontidal perennial aquatic habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur on the edges of tidal perennial aquatic habitat, including levees and channel banks. Nontidal marsh adjacent to these tidal areas could be affected. The improvements would be undertaken within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Environmental Commitment 10 would entail restoration of up to 832 acres of nontidal marsh in CZs 2, 4, and/or 5. The restoration would create a mosaic of nontidal perennial aquatic and nontidal freshwater perennial emergent natural communities. This marsh restoration would occur in 25-acre or larger patches in or near giant garter snake occupied habitat and would be accompanied by adjacent grassland restoration or protection.

The following paragraphs summarize the combined effects discussed above and describe other Alternative 4A environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

During the Alternative 4A construction period, activities would affect the nontidal perennial aquatic community through water conveyance facilities construction and tidal restoration (60 acres permanent and6 acres temporary). Additional small losses could also occur during this time frame as channel margin habitat enhancement is implemented.

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and restoration actions associated with Alternative 4A. Loss of nontidal perennial aquatic natural community would be considered both a loss in acreage of a sensitive natural community and a loss of waters of the United States as defined by Section 404 of the CWA. However, creating 832 acres of nontidal marsh as part of Environmental Commitment 10 during the Alternative 4A construction period would offset this loss, avoiding any adverse effect. Typical project-level mitigation ratios (1:1 for restoration and 1:1 for protection) would indicate 66 acres of restoration and 66 acres of protection would be needed to offset (i.e., mitigate) the 66 acres of loss. The project also includes protection of up to 119 acres of nontidal marsh habitat (Environmental Commitment 3). The protection acreage exceeds the typical 1:1 protection requirement and fully compensates for the construction losses.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan, and AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Implementation of Alternative 4A would result in relatively minor (1.2%) losses of nontidal perennial aquatic community in the study area. These losses (60 acres of permanent and 6 acres of temporary loss) would be largely associated with construction of the water conveyance facilities. By the end of project construction, a total of 832 acres of nontidal marsh would be restored. The restoration would potentially occur over a wide region of the study area, including within the Cosumnes/Mokelumne, Yolo Bypass, South Delta and East Delta ROAs (see Figure 12-1).

NEPA Effects: During the Alternative 4A construction period, creating 832 acres of nontidal marsh as part of Environmental Commitment 10 would offset the construction-related losses of 66 acres of nontidal perennial aquatic natural community. The effect would not be adverse.

CEQA Conclusion: Alternative 4A would result in the loss of approximately 66 acres of nontidal perennial aquatic natural community due to construction of the water conveyance facilities and tidal restoration. The construction losses would occur primarily at reusable tunnel material storage sites near Twin Cities Road and on Bouldin Island, and along the transmission corridor where it crosses Mandeville Island. In addition, an estimated 2 acres would be lost due to tidal natural communities restoration in one or more of the ROAs (see Figure 12-1). The losses would be spread across the Alternative 4A construction period (14 years). These losses would be offset by planned restoration of up to 832 acres and protection of up to 119 acres of nontidal marsh during the same time period (Environmental Commitment 10 and Environmental Commitment 3). Also, AMM1, AMM2, AMM6, AMM7, and AMM10 would be implemented to minimize impacts. Because of these offsetting restoration activities and AMMs, impacts would be less than significant. Typical project-level mitigation ratios (1:1 for restoration and 1:1 for protection) would indicate that 66 acres of restoration and 66 acres of protection would be needed to offset (i.e., mitigate) the 66 acres of loss. The project includes tidal marsh restoration (832 acres) and protection (119 acres) which is well in excess of the typical 1:1 restoration and protection acreages, and therefore compensates for all project-related losses. The restoration would be initiated at the beginning of Alternative 4A implementation to minimize any time lag in the availability of this habitat to special-status species, and would result in a net gain in acreage of this sensitive natural community. Therefore, the impact would be less than significant. No mitigation is required.

Impact BIO-13: Increased Frequency, Magnitude and Duration of Periodic Inundation of Nontidal Perennial Aquatic Natural Community

Alternative 4A would not result in periodic effects on the nontidal perennial aquatic natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-14: Modification of Nontidal Perennial Aquatic Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the Alternative 4A facilities and conservation lands that could affect nontidal perennial aquatic natural community in the study area. The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels. These actions would be associated with water conveyance facilities. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified releases and water levels in upstream reservoirs.* Modified releases and water levels at Shasta Lake, Lake Oroville, Whiskeytown Lake, Lewiston Lake, and Folsom Lake would affect nontidal perennial aquatic natural community, in the form of the reservoir pools. The Alternative 4A operations scheme would alter the surface elevations of these reservoir pools as described in Chapter 6, *Surface Water*. These fluctuations would occur within historic ranges and would not adversely affect the natural community. Changes in releases that would influence downstream river flows are discussed below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversion from south Delta channels (associated with Operational Scenario H) would not result in the permanent reduction in acreage of the nontidal perennial aquatic natural community in the study area. Flow levels in the upstream rivers would not change such that the acreage of nontidal perennial aquatic community would be reduced on a permanent basis. Some minor increases and some decreases would be expected to occur along the major rivers during some seasons and in some water-year types, but there would be no permanent loss. Similarly, increased diversions of Sacramento River flows in the north Delta would not result in a permanent reduction in nontidal perennial aquatic community downstream of these diversions. Nontidal wetlands below the diversions are not directly connected to the rivers, as this reach of the river is tidally influenced. Reduced diversions from south Delta channels would not create a reduction in this natural community.

- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with the Alternative 4A actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in nontidal perennial aquatic habitats. This activity could lead to increased soil erosion, turbidity and runoff entering nontidal perennial aquatic habitats. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within aquatic habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*Environmental Commitment 11 Natural Communities Enhancement and Management)*. Vegetation management is also the principal activity associated with *Environmental Commitment 13 Invasive Aquatic Vegetation Control.* Use of herbicides to control nuisance vegetation could pose a long-term hazard to nontidal perennial aquatic natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to nontidal perennial aquatic areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the project to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Habitat enhancement.* The project includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For nontidal perennial aquatic natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of nontidal perennial aquatic natural community in the study area through changes in flow patterns and changes in periodic inundation of this community. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the project, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be offset by restoration activities planned as part of *Environmental Commitment 10 Nontidal Marsh Restoration* and protection actions associated with *Environmental Commitment 3 Natural Communities*

Protection and Restoration. The management actions associated with levee repair and control of invasive plant species would also result in a long-term benefit to the species associated with nontidal perennial aquatic habitats by improving water movement.

***NEPA Effects*:** Ongoing operation, maintenance and management activities would not result in a net permanent reduction in the nontidal perennial aquatic natural community within the study area. Therefore, there would be no adverse effect on this natural community.

***CEQA Conclusion*:** The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of nontidal perennial aquatic natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, and AMM5 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including improved water movement in these habitats. Long-term restoration activities associated with *Environmental Commitment 10 Nontidal Marsh Restoration* and protection actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* would expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact on the nontidal perennial aquatic natural community.

Nontidal Freshwater Perennial Emergent Wetland

Construction, operation, maintenance and management associated with Alternative 4A would have no long-term adverse effects on the habitats associated with the nontidal freshwater perennial emergent wetland natural community. Initial development and construction of water conveyance facilities would result in both permanent and temporary removal of this community (see Table 12-4A-5). Small losses of this community could also occur with tidal restoration (Environmental Commitment 4) and planned channel margin enhancement activities (Environmental Commitment 6).

As explained below, with the restoration and enhancement of nontidal marsh habitat, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-5. Changes in Nontidal Freshwater Perennial Emergent Wetland Natural Community Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Water Conveyance Facilities	2	4
Environmental Commitment 4[a]	1	0
Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	**3**	**4**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-15: Changes in Nontidal Freshwater Perennial Emergent Wetland Natural Community as a Result of Implementing Alternative 4A

Construction and land grading activities that would accompany the implementation of water conveyance facilities and tidal restoration would permanently eliminate an estimated 3 acres and temporarily remove 4 acres of nontidal freshwater perennial emergent wetland natural community in the study area. These modifications represent approximately 0.5% of the 1,509 acres of the community that is mapped in the study area. Nontidal marsh restoration (Environmental Commitment 10) would add 832 acres of nontidal marsh and natural communities protection (Environmental Commitment 3) would protect up to 119 acres of nontidal marsh. These actions would be taken over the course of Alternative 4A marsh restoration activities, which would expand the area of that habitat and offset the losses. The nontidal marsh restoration would include a mosaic of nontidal perennial aquatic and nontidal freshwater perennial emergent wetland natural communities. The nontidal marsh protection would be designed to support tricolored blackbird and western pond turtle populations in the study area. The restoration would occur in blocks that are contiguous with or near giant garter snake subpopulations identified in the recovery plan for this species (U.S. Fish and Wildlife Service 1998), and in areas suitable for greater sandhill crane permanent roosting and foraging.

The individual effects of each relevant Environmental Commitment are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation:* Construction of the Alternative 4A water conveyance facilities would permanently remove 2 acres and temporarily remove 4 acres of tidal freshwater perennial emergent wetland community. The permanent losses would occur at the Clifton Court Forebay construction site and the RTM site on Bouldin Island (see Terrestrial Biology Mapbook). The temporary loss would occur in a temporary work area and where temporary powerlines would be constructed across Mandeville Island. These wetlands are extremely small and remote water bodies, surrounded by agricultural operations. These losses would take place during the project's construction period.
- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Environmental Commitment 4 would permanently inundate or remove an estimated 1 acre of tidal freshwater perennial emergent wetland. The losses would occur in one or more of the ROAs established for tidal restoration (see Figure 12-1).
- *Environmental Commitment 6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in filling of small amounts of nontidal freshwater perennial emergent wetland habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur on the edges of tidal perennial aquatic habitat, including levees and channel banks. Nontidal marsh adjacent to these tidal areas could be affected. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Environmental Commitment 10 would entail restoration of up to 832 acres of nontidal marsh in CZs 2, 4, and/or 5. The restoration would create a mosaic of nontidal perennial aquatic and nontidal freshwater perennial emergent natural communities. Some of this marsh restoration would occur in 25-

acre or larger patches in or near giant garter snake occupied habitat and would be accompanied by adjacent grassland restoration or protection.

The following paragraphs summarize the combined effects discussed above and describe other Alternative 4A environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

During the project's construction time frame, Alternative 4A would affect the nontidal freshwater perennial emergent wetland community through water conveyance facilities construction and tidal restoration (Environmental Commitment 6) (3 acres permanent and 4 acres temporary). Small additional losses could result where channel margin habitat enhancement occurs along major Delta waterways (Environmental Commitment 6).

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and restoration actions associated with the project. Loss of nontidal freshwater perennial emergent wetland natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. However, the combination of creating 832 acres and protecting 119 acres of nontidal perennial marsh as part of Environmental Commitment 3 and Environmental Commitment 10 during the construction of Alternative 4A would offset this loss, avoiding any adverse effect. Typical project-level mitigation ratios (1:1 for restoration and 1:1 for protection) would indicate 7 acres of restoration and7 acres of protection would be needed to offset (i.e., mitigate) the 7 acres of loss. The project includes well in excess of the typical 1:1 restoration and protection acreages for this natural community.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan and AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Implementation of Alternative 4A would result in small (0.5%) losses of nontidal freshwater perennial emergent wetland community in the study area. These losses (3 acres of permanent and 4 acres of temporary loss) would be associated with construction of the water conveyance facilities. By the end of water conveyance facilities construction, a total of 832 acres of nontidal marsh would be restored and 119 acres would be protected. The restoration would occur near giant garter snake occupied habitat and greater sandhill crane roosting and foraging areas in the eastern Delta. Approximately half of the 119 acres of protection would occur in CZ 1, 2, 8, or 11 to provide nesting habitat for tri-colored blackbird (see Figure 12-1).

NEPA Effects: The combination of creating 832 acres and protecting 119 acres of nontidal perennial marsh as part of Environmental Commitment 3 and Environmental Commitment 10 would offset the losses associated with construction of water conveyance facilities and tidal restoration, avoiding any adverse effect. With 832 acres of nontidal marsh restoration and 119 acres of protection, Alternative 4A would not result in a net long-term reduction in the acreage of a sensitive natural community; the effect would not be adverse.

CEQA Conclusion: Alternative 4A would result in the loss of approximately 7 acres of nontidal freshwater perennial emergent wetland natural community due to construction of the water conveyance facilities and tidal restoration. The construction losses would occur near Clifton Court Forebay and along transmission line construction areas on Mandeville Island, and tidal restoration would occur in one or more of the ROAs established for tidal restoration (see Figure 12-1). The losses would occur during the project construction timeframe. These losses would be offset by planned restoration of up to 832 acres and protection of up to 119 acres of nontidal marsh (Environmental Commitment 10 and Environmental Commitment 3). AMM1, AMM2, AMM6, AMM7, and AMM10 would also be implemented to minimize impacts. Typical project-level mitigation ratios (1:1 for restoration and 1:1 for protection) would indicate that 7 acres of restoration and 7 acres of protection would be needed to offset (i.e., mitigate) the 7 acres of loss. The project includes well in excess of the typical 1:1 restoration and protection acreages and therefore compensates for the construction-related losses. The restoration and protection would be initiated at the beginning of Alternative 4A implementation to minimize any time lag in the availability of this habitat to special-status species, and would result in a net gain in acreage of this sensitive natural community. Because of these offsetting restoration and protection activities and AMMs, impacts would be less than significant.

Impact BIO-16: Increased Frequency, Magnitude and Duration of Periodic Inundation of Nontidal Freshwater Perennial Emergent Wetland Natural Community

Alternative 4A would not result in periodic effects on the nontidal freshwater perennial emergent wetland natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-17: Modification of Nontidal Freshwater Perennial Emergent Wetland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the Alternative 4A facilities and conservation lands that could affect nontidal freshwater perennial emergent wetland natural community in the study area. The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels. These actions are associated with water conveyance facilities. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified releases and water levels in upstream reservoirs.* Modified releases and water levels at Shasta Lake, Lake Oroville, Whiskeytown Lake, Lewiston Lake, and Folsom Lake would not affect the nontidal freshwater perennial emergent wetland natural community. These reservoirs do not support significant stands of freshwater emergent wetlands. Changes in releases that would influence downstream river flows are discussed below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels (associated with Operational Scenario H) would not result in the permanent reduction in acreage of the nontidal freshwater perennial emergent wetland natural community in the study area. The majority of this wetland type exists outside of the levees of the larger rivers and would not be affected by flow changes in river or Delta channels. Similarly, increased diversions of Sacramento River flows in the north Delta would not result in a permanent reduction in nontidal freshwater perennial emergent wetland community downstream of these diversions. Nontidal wetlands below the diversions are not directly connected to the rivers, as this reach of the river is tidally influenced. Reduced diversions from south Delta channels would not create a reduction in this natural community.

- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with the project's actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in nontidal freshwater perennial emergent wetland habitats. This activity could lead to increased soil erosion, turbidity and runoff entering nontidal freshwater perennial habitats. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within aquatic habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*Environmental Commitment 11 Natural Communities Enhancement and Management).* Use of herbicides to control nuisance vegetation could pose a long-term hazard to nontidal freshwater perennial emergent wetland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to nontidal perennial wetland areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of Alternative 4A to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Habitat enhancement.* The project includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For nontidal freshwater perennial emergent wetland natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of nontidal freshwater perennial emergent wetland natural community in the study area through changes in flow patterns and facilities maintenance activities. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the project, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be greatly offset by restoration activities planned as part of *Environmental Commitment 10 Nontidal Marsh Restoration* and protection actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration*. The management actions associated with levee repair and control of invasive plant species would also result in a long-term benefit to the species associated with nontidal freshwater perennial emergent wetland habitats by improving water movement.

***NEPA Effects*:** Ongoing operation, maintenance and management activities associated with Alternative 4A would not result in a net permanent reduction in the nontidal freshwater perennial emergent wetland natural community within the study area. Therefore, there would be no adverse effect on this natural community.

***CEQA Conclusion*:** The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of nontidal freshwater perennial emergent wetland natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, and AMM5 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including improved water movement in and adjacent to these habitats. Long-term restoration activities associated with *Environmental Commitment 10 Nontidal Marsh Restoration* and protection actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* would expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact on the nontidal freshwater perennial emergent wetland natural community.

Alkali Seasonal Wetland Complex

Construction, operation, maintenance and management associated with Alternative 4A would have no long-term adverse effects on the habitats associated with the alkali seasonal wetland complex natural community. Initial development and construction of water conveyance facilities would result in a small permanent removal of this community (see Table 12-4A-6). Also, tidal restoration (Environmental Commitment 4) would remove a small estimated amount of alkali seasonal wetland complex. Implementation of Alternative 4A would also include the following Resource Restoration and Performance Principles over the term of the project to benefit the alkali seasonal wetland natural community.

- Restore vernal pool and alkali seasonal wetland complex to achieve no net loss of wetted acreage (Resource Restoration and Performance Principle VP/AW2).
- Increase the size and connectivity of protected vernal pool and alkali seasonal wetland complex in the greater Byron Hill area (Resource Restoration and Performance Principle VP/AW3).
- Provide appropriate seasonal flooding characteristics for supporting and sustaining vernal pool and alkali seasonal wetland complex species (Resource Restoration and Performance Principle VP/AW4).

As explained below, with the protection, restoration, and enhancement of the amounts of habitat proposed for Alternative 4A, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-6. Changes in Alkali Seasonal Wetland Complex Natural Community Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Water Conveyance Facilities	1	0
Environmental Commitment 4[a]	1	0
Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	**2**	**0**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-18: Changes in Alkali Seasonal Wetland Complex Natural Community as a Result of Implementing Alternative 4A

Construction and land grading activities that would accompany the implementation of water conveyance facilities under Alternative 4A would permanently eliminate an estimated 1 acre of alkali seasonal wetland complex natural community in the study area, a portion of which includes iodine bush scrub, a sensitive plant community. In addition, an estimated 1 acre of alkali seasonal wetland would be impacted through grading and/or inundation from tidal restoration activities. There would be no temporary impacts to alkali seasonal wetlands. These modifications represent approximately 0.05% of the 3,723 acres of the community that is mapped in the study area. The combined vernal pool/alkali seasonal wetland complex protection (188 acres) and restoration (48 acres) would be initiated during project construction; these actions would offset the losses.

The effects associated with construction of water conveyance facilities are addressed below. A summary statement of the impacts and NEPA and CEQA conclusions follows the individual Environmental Commitment discussion.

- *Water Facilities and Operation*: Construction of the Alternative 4A transmission lines immediately west of Clifton Court Forebay would permanently affect 1 acre of alkali seasonal wetland complex natural community (see the Terrestrial Biology Mapbook). The alkali seasonal wetland complex at this location is scattered and significantly degraded by past agricultural and water development-related activities. It is surrounded by or adjacent to vernal pool complex natural community.

The construction activity associated with water conveyance facilities also has the potential to lead to increased nitrogen deposition in alkali seasonal wetland habitats in the vicinity of Clifton Court Forebay. A significant number of cars, trucks, and land grading equipment involved in construction would emit small amounts of atmospheric nitrogen from fuel combustion; this material could be deposited in sensitive alkali seasonal wetland areas that are located west of the major construction areas at Clifton Court Forebay. Nitrogen deposition can pose a risk of adding a fertilizer to nitrogen-limited soils and their associated plants. Nonnative invasive species can be encouraged by the added nitrogen available. Appendix 5.J, Attachment 5J.A, *Construction-Related Nitrogen Deposition on BDCP Natural Communities*, in the BDCP addresses this issue in detail. It has been concluded that this potential deposition would pose a low risk of changing the alkali seasonal wetland complex in the construction area because the construction would occur primarily downwind of the natural community and the construction would contribute a negligible amount of nitrogen to regional projected emissions. No adverse effect is expected.

- *Environmental Commitment 3 Natural Communities Protection and Restoration:* Environmental Commitment 3 proposes to protect up to 188 acres of vernal pool/alkali seasonal wetland complex in the study area. The protection would occur in areas containing a mosaic of grassland and vernal pool complex in unfragmented natural landscapes supporting a diversity of native plant and wildlife species. These areas would be both protected and enhanced to increase the cover of alkali seasonal wetland plants relative to nonnative species.
- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Environmental Commitment 4 would permanently inundate or remove an estimated 1 acre of alkali seasonal wetland complex. The losses would occur in one or more of the ROAs established for tidal restoration (see Figure 12-1).
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:* Environmental Commitment 9 includes both vernal pool complex and alkali seasonal wetland complex restoration goals. The intent of the Environmental Commitment is to match the acreage of restoration with the actual acreage lost to other project measures (primarily water conveyance facilities). The current estimate for vernal pool/alkali seasonal wetland complex restoration is 48 acres. The goal is for no net loss of this natural community, consistent with the project's Resource Restoration and Performance Principles.

The following paragraphs summarize the combined effects discussed above and describe other project environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

During project construction, Alternative 4A would affect the alkali seasonal wetland complex natural community through water conveyance facilities construction and tidal restoration (Environmental Commitment 4) (2 acres permanent).

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and restoration actions associated with the project's Environmental Commitments. Loss of alkali seasonal wetland complex natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. However, the protection of up to 188 acres of combined vernal pool/alkali seasonal wetland complex as part of Environmental Commitment 3, the restoration of up to 48 acres of these communities as part of Environmental Commitment 9, and the implementation of *AMM30 Transmission Line Design and Alignment Guidelines* would offset this loss, avoiding any adverse effect. AMM30 would require that transmission line construction avoid any losses of alkali seasonal wetland complex natural community to the maximum extent feasible (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*, for a full description of AMM30). Because it is not possible to create iodine bush scrub, mitigation for impacts on this plant community must be through avoidance and/or protection of compensating mitigation areas. Protection of iodine bush scrub within the grassland/vernal pool complex/alkali seasonal wetland habitats adjacent to Clifton Court Forebay provides the only opportunity in the Plan Area to protect this habitat. Typical project-level mitigation ratios (2:1 for protection and 1:1 for restoration) would indicate 4 acres of protection and 2 acres of restoration would be needed to offset (i.e., mitigate) the 2 acres of loss.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Implementation of Alternative 4A would result in very minor (0.05%) losses of alkali seasonal wetland natural community in the study area. These losses (2 acres) would be associated with construction of the project's water conveyance facility and tidal restoration.

NEPA Effects: During the 14-year construction period for Alternative 4A, 188 acres of vernal pool/alkali seasonal wetland complex would be protected as part of Environmental Commitment 3 and 48 acres of these communities would be restored as part of Environmental Commitment 9, which would be guided by Resource Restoration and Performance Principles VP/AW2-VP/AW4. These Environmental Commitments would offset the loss of this community associated with water conveyance facilities and tidal restoration, avoiding any adverse effect. The protection and restoration would occur primarily in the Clifton Court Forebay area. Therefore, Alternative 4A would not have an adverse effect on the alkali seasonal wetland complex natural community.

CEQA Conclusion: Alternative 4A would result in the permanent loss of approximately 2 acres of alkali seasonal wetland complex natural community due to water conveyance facility construction and tidal restoration. The construction losses would occur primarily in the area adjacent to Clifton Court Forebay. The losses would occur during project construction. Tidal restoration losses would occur in one or more of the ROAs established for tidal restoration (see Figure 12-1).

The construction losses of this special-status natural community would represent a significant impact if they were not offset by avoidance and minimization measures and other actions associated with the project's environmental commitments. Loss of alkali seasonal wetland complex natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. However, the protection of up to 188 acres of combined vernal pool/alkali seasonal wetland complex as part of Environmental Commitment 3, the restoration of up to 48 acres of these communities as part of Environmental Commitment 9, Resource Restoration and Performance Principles VP/AW2-VP/AW4, and the implementation of *AMM30 Transmission Line Design and Alignment Guidelines* during construction of Alternative 4A would offset this loss, avoiding any significant impact. Typical project-level mitigation ratios (2:1 for protection and 1:1 for restoration) would indicate 4 acres of protection and 2 acres or restoration would be needed to offset (i.e., mitigate) the 2 acres of loss. AMM1, AMM2, AMM3, AMM4, and AMM10 would also be implemented to minimize impacts. Because of the offsetting protection and restoration activities and AMMs, impacts would be less than significant.

Impact BIO-19: Increased Frequency, Magnitude and Duration of Periodic Inundation of Alkali Seasonal Wetland Natural Community

Alternative 4A would not result in periodic effects on the alkali seasonal wetland natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-20: Modification of Alkali Seasonal Wetland Complex Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A were constructed and the stream flow regime associated with changed water management was in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the Alternative 4A facilities and conservation lands that could affect alkali seasonal wetland complex natural community in the study area. The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels. These actions are associated with water conveyance facilities and Environmental Commitment 11. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels (associated with Operational Scenario H) would not affect alkali seasonal wetland natural community. This natural community does not exist within or adjacent to the active Sacramento River system channels and Delta waterways that would be affected by modified flow levels.
- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with Alternative 4A actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in or adjacent to alkali seasonal wetland complex habitats. This activity could lead to increased soil erosion and runoff entering these habitats. These activities would be subject to normal erosion and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within alkali seasonal wetland complex habitats would require use of sediment barriers, soil stabilization and revegetation of disturbed surfaces

as required by *AMM10 Restoration of Temporarily Affected Natural Communities*. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*Environmental Commitment 11 Natural Communities Enhancement and Management).* Use of herbicides to control nuisance vegetation could pose a long-term hazard to alkali seasonal wetland complex natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to alkali seasonal wetland complex areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the project to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in terrestrial environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Habitat enhancement.* Alternative 4A includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For the alkali seasonal wetland complex natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of alkali seasonal wetland complex natural community in the study area. Activities could introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the project, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be offset by protection and restoration activities planned as part of *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, or minimized by implementation of AMM2, AMM4, AMM5, and AMM10. The management actions associated with control of invasive plant species would also result in a long-term benefit to the species associated with alkali seasonal wetland complex habitats by eliminating competitive, invasive species of plants.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 4A would not result in a net permanent reduction in this natural community within the study area. Therefore, there would be no adverse effect on the alkali seasonal wetland complex natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of alkali seasonal wetland complex natural community in the study area, and could create temporary increases sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, AMM5, and AMM10 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including reduced competition from invasive, nonnative plants in these habitats. Long-term restoration activities associated with *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* and protection actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* would ensure that the acreage of this natural community would not decrease in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this natural community within the study area. Therefore, there would be a less-than-significant impact on the alkali seasonal wetland complex natural community.

Vernal Pool Complex

Construction, operation, maintenance and management associated with the Environmental Commitments of Alternative 4A would have no long-term adverse effects on the habitats associated with the vernal pool complex natural community. Initial development and construction of water conveyance facilities would result in permanent removal of 19 acres of this community and tidal restoration would result in the conversion of an estimated 25 acres of vernal pool complex (see Table 12-4A-7). Implementation of Alternative 4A would also include the following Resource Restoration and Performance Principles over the term of the project to benefit the vernal pool complex natural community.

- Protect existing vernal pool complex in the greater Byron Hills area primarily in core vernal pool recovery areas identified in the *Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon* (U.S. Fish and Wildlife Service 2005) (Resource Restoration and Performance Principle VP/AW1).
- Restore vernal pool and alkali seasonal wetland complex to achieve no net loss of wetted acreage (Resource Restoration and Performance Principle VP/AW2).
- Increase the size and connectivity of protected vernal pool and alkali seasonal wetland complex in the greater Byron Hill area (Resource Restoration and Performance Principle VP/AW3).
- Provide appropriate seasonal flooding characteristics for supporting and sustaining vernal pool and alkali seasonal wetland complex species (Resource Restoration and Performance Principle VP/AW4).

As explained below, with the protection, restoration and enhancement of the amounts of habitat proposed for Alternative 4A, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-7. Changes in Vernal Pool Complex Natural Community Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Water Conveyance Facilities	19	3
Environmental Commitment 4[a]	25	0
Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	**44**	**3**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-21: Changes in Vernal Pool Complex Natural Community as a Result of Implementing Alternative 4A

Construction and land grading activities that would accompany the implementation of water conveyance facilities and tidal restoration would permanently eliminate an estimated 44 acres and temporarily remove 3 acres of vernal pool complex natural community in the study area. These acreages are based on the proposed location of the water conveyance facilities construction footprint and the estimated effects from tidal restoration (Environmental Commitment 4). The loss of this combined 47 acres would represent approximately 0.4% of the 12,133 acres of the community that is mapped in the study area. Vernal pool/alkali seasonal wetland complex protection (188 acres) and restoration (48 acres) would be initiated during the Alternative 4A construction period to counteract the loss of habitat. Because of the high sensitivity of this natural community and its shrinking presence in the study area, avoidance and minimization measures have been built into the project to eliminate the majority of this potential loss.

The individual effects of water conveyance facilities are addressed below. A summary statement of the impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation:* Construction of the Alternative 4A water conveyance facilities would directly affect 22 acres of vernal pool complex natural community, including 19 acres permanently affected and 3 acres temporarily affected. A portion of this habitat adjacent to Clifton Court Forebay includes iodine bush scrub, a sensitive plant community. The permanent loss would occur along the southern edge of Clifton Court Forebay, where the forebay would be expanded to provide greater storage capacity and from the construction of permanent transmission lines. The temporary losses would occur in a temporary work area immediately adjacent to Clifton Court Forebay (see Figure 12-1 and the Terrestrial Biology Mapbook).
- Because of the close proximity of construction activity to adjacent vernal pool complex near Clifton Court Forebay, there is also the potential for indirect loss or damage to vernal pools from changes in pool hydrology or deposition of construction-related sediment. These potential indirect effects are discussed in detail in the vernal pool crustaceans impact analysis in the *Wildlife Species* section.
- The construction activity associated with water conveyance facilities also has the potential to lead to increased nitrogen deposition in vernal pool complex habitats in the vicinity of Clifton Court Forebay and Stone Lakes NWR. A significant number of cars, trucks, and land grading equipment involved in construction would emit small amounts of atmospheric nitrogen from fuel combustion; this material could be deposited in sensitive vernal pool areas that are located

west of the major construction areas at Clifton Court Forebay and east of the construction areas adjacent to Stone Lakes NWR. Nitrogen deposition can pose a risk of adding a fertilizer to nitrogen-limited soils and their associated plants. Nonnative invasive species can be encouraged by the added nitrogen available. Appendix 5.J, Attachment 5J.A, *Construction-Related Nitrogen Deposition on BDCP Natural Communities*, of the BDCP addresses this issue in detail. It has been concluded that this potential deposition would pose a low risk of changing the vernal pool complex in the construction areas because the construction would contribute a negligible amount of nitrogen to regional projected emissions. Also, the construction at Clifton Court Forebay would occur primarily downwind of the natural community. At Stone Lakes NWR, USFWS refuge management undertakes active invasive species control, including use of grazing. No adverse effect is expected.

- *Environmental Commitment 3 Natural Communities Protection and Restoration:* Environmental Commitment 3 proposes to protect up to 188 acres of vernal pool complex/alkali seasonal wetland complex, primarily in the Clifton Court Forebay area. The protection would occur in areas containing a mosaic of grassland and vernal pool complex in unfragmented natural landscapes supporting a diversity of native plant and wildlife species. These areas would be both protected and enhanced to increase the cover of vernal pool complex plants relative to nonnative species.
- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Environmental Commitment 4 would permanently inundate or remove an estimated 25 acres of vernal pool complex. The losses would occur in one or more of the ROAs established for tidal restoration (see Figure 12-1).
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:* Environmental Commitment 9 includes both vernal pool complex and alkali seasonal wetland complex restoration goals. The current estimate for vernal pool/alkali seasonal wetland complex restoration is 48 acres. This restoration Environmental Commitment includes a “no net loss” policy normally applied to this natural community.

The following paragraphs summarize the combined effects discussed above and describe other project environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

During the project construction period (14 years), Alternative 4A could directly affect 47acres of vernal pool complex natural community through construction-related losses in habitat from water conveyance facilities and tidal restoration.

The construction loss of this special-status natural community would represent an adverse effect if it were not offset by avoidance and minimization measures and restoration actions associated with the project’s Environmental Commitments. Loss of vernal pool complex natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. The protection of up to 188 acres of vernal pool/alkali seasonal wetland complex as part of Environmental Commitment 3 and the restoration of up to 48 acres of these communities (including a commitment to have restoration keep pace with losses) as part of Environmental Commitment 9 during construction of Alternative 4A facilities would offset this loss. The project focuses this protection in the core vernal pool areas identified in the USFWS vernal pool recovery plan (U.S. Fish and Wildlife Service 2005). The core areas exist in CZ 1, CZ 8, and CZ 11 (see Figure 12-1). Typical project-level mitigation ratios (2:1 for protection and 1:1 for restoration) would indicate 94 acres of protection and 47 acres of restoration would be needed to offset (i.e., mitigate) the 47 acres of loss. In addition, because it is not possible to create iodine bush scrub, mitigation for impacts on this plant community must be through avoidance and/or protection of compensating mitigation areas. Protection of iodine bush scrub within the grassland/vernal pool complex/alkali seasonal wetland habitats adjacent to Clifton Court Forebay provides the only opportunity in the Plan Area to protect this habitat.

To further avoid adverse effect, the project includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM12 Vernal Pool Crustaceans,* and *AMM30 Transmission Line Design and Alignment Guidelines.* All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS. With these AMMs in place, Alternative 4A would not adversely affect vernal pool complex natural community.

NEPA Effects: The Environmental Commitments associated with Alternative 4A include protection of up to 188 acres (Environmental Commitment 3) and restoration of an estimated 48 acres (Environmental Commitment 9) of vernal pool/alkali seasonal wetland complex, which would be guided by Resource Restoration and Performance Principles VP/AW1-VP/AW4. The project focuses the protection in the core vernal pool areas identified in the USFWS vernal pool recovery plan (U.S. Fish and Wildlife Service 2005). A core area exists in CZ 1 (see Figure 12-1). With these Environmental Commitments and AMMs in effect through the entire project period, Alternative 4A would not have an adverse effect on the vernal pool complex natural community.

CEQA Conclusion: During the 14-year construction period, Alternative 4A could result in the direct loss of approximately 47 acres of vernal pool complex natural community due to construction of the water conveyance facility and tidal restoration.

The construction-related loss of this special-status natural community would represent a significant impact if it were not offset by avoidance and minimization measures and other actions associated with Alternative 4A Environmental Commitments. Loss of vernal pool complex natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. The protection of up to 188 acres of vernal pool/alkali seasonal wetland complex as part of Environmental Commitment 3 and the restoration of an estimated 48 acres of this community (including a commitment to have restoration keep pace with losses) as part of Environmental Commitment 9 during the construction of Alternative 4A facilities would offset this loss, Resource Restoration and Performance Principles VP/AW1-VP/AW4. Typical project-level mitigation ratios (2:1 for protection and 1:1 for restoration) would indicate 94 acres of protection and 47 acres of restoration would be needed to offset (i.e., mitigate) the 47 acres of loss. Alternative 4A also includes AMM1, AMM2, AMM3, AMM4, AMM10, AMM12, and AMM30 to minimize impacts. Because of the offsetting protection and restoration activities and implementation of AMMs, impacts would be less than significant.

Impact BIO-22: Increased Frequency, Magnitude and Duration of Periodic Inundation of Vernal Pool Complex Natural Community

Alternative 4A would not result in periodic effects on the vernal pool complex natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-23: Modification of Vernal Pool Complex Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the project facilities and conservation lands that could affect vernal pool complex natural community in the study area. The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels. These actions are associated with water conveyance facilities and Environmental Commitment 11. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels (associated with Operational Scenario H) would not affect vernal pool complex natural community. This natural community does not exist within or adjacent to the major Sacramento River system and Delta waterways.

- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with the Alternative 4A actions have the potential to require removal of adjacent vegetation and could entail earth and rock work adjacent to vernal pool complex habitats. This activity could lead to increased soil erosion and runoff entering these habitats. These activities would be subject to normal erosion and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to vernal pool complex habitats would require use of sediment barriers, soil stabilization and revegetation of disturbed surfaces as part of *AMM10 Restoration of Temporarily Affected Natural Communities*. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*Environmental Commitment 11 Natural Communities Enhancement and Management).* Use of herbicides to control nuisance vegetation could pose a long-term hazard to vernal pool complex natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to vernal pool complex areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the project to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in terrestrial or aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Habitat enhancement.* The project includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For the vernal pool complex natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of vernal pool complex natural community in the study area. Activities could introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the project, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be greatly offset by restoration activities planned as part of *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, or minimized by implementation of AMM2, AMM4, AMM5, AMM10, AMM12, and AMM30. The management actions associated with control of invasive plant species would also result in a long-term benefit to the species associated with vernal pool complex habitats by eliminating competitive, invasive species of plants.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 4A would not result in a net permanent reduction in the vernal pool complex natural community within the study area. Therefore, there would be no adverse effect on this natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of vernal pool complex natural community in the study area. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, AMM5, AMM10, AMM12,and AMM30 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including reduced competition from invasive, nonnative plants in these habitats. Long-term restoration activities associated with *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* and protection actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* would ensure that the acreage of this natural community would not decrease in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this natural community within the study area. Therefore, there would be a less-than-significant impact on the vernal pool complex natural community.

Managed Wetland

The construction of water conveyance facilities for Alternative 4A would reduce the acreage of managed wetland currently found in the study area. Initial development and construction of water conveyance facilities would result in both permanent and temporary removal of this community (see Table 12-4A-8). Also, tidal restoration (Environmental Commitment 4) would result in the removal or conversion of managed wetland (see Table 12-4A-8).

Creation of similar habitat values by restoring nontidal marsh as part of Environmental Commitment 10 would offset the losses of managed wetland. The net effect would be a decrease in the amount of managed wetland, but an increase in similar habitat value for special-status and common species as cultivated land is converted to nontidal marsh. Impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes. Refer to Impacts BIO-178 through BIO-183 in the *Shorebirds and Waterfowl* discussion for further consideration of the effects of removing managed wetland natural community.

Table 12-4A-8. Changes in Managed Wetland Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Water Conveyance Facilities	16	25
Environmental Commitment 4[a]	20	0
Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	**36**	**25**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-24: Changes in Managed Wetland Natural Community as a Result of Implementing Alternative 4A

Construction and land grading activities that would accompany the implementation of water conveyance facilities and tidal restoration (Environmental Commitment 4) would permanently eliminate an estimated 36 acres and temporarily affect 25 acres of managed wetland in the study area. These modifications represent approximately 0.09% of the 70,798 acres of managed wetland that is mapped in the study area. This loss would occur over the course of Alternative 4A construction (14 year period). Alternative 4A does not include protection or restoration actions directed specifically at managed wetland, but protection and restoration of nontidal wetland (119 acres and 832 acres, respectively) would replace the habitat values lost for special-status wildlife and plant species.

The individual effects of the relevant Environmental Commitment are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation*: Construction of the Alternative 4A water conveyance facilities would permanently remove 16 acres and temporarily remove 25 acres of managed wetland community. The permanent losses would occur near the northeast corner of Clifton Court

Forebay for the construction of a permanent shaft location, a permanent transmission line west of Clifton Court Forebay, and a permanent access road on Bouldin Island. Temporary impacts would occur in association with temporary work areas on Mandeville Island, a concrete batch plant on Bouldin Island, and a tunnel muck conveyor facility near Clifton Court Forebay (see the Terrestrial Biology Mapbook). Smaller losses would occur from construction of the temporary transmission lines that parallel the tunnel alignment northwest of the intermediate forebay and across the length of Mandeville Island.

- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Environmental Commitment 4 would permanently inundate or remove an estimated 20 acres of managed wetlands. The losses would occur in one or more of the ROAs established for tidal restoration (see Figure 12-1).
- *Environmental Commitment 6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in filling of small amounts of managed wetland habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur on the edges of tidal perennial aquatic habitat, including levees and channel banks. Managed wetland adjacent to these tidal areas could be affected. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.

The following paragraphs summarize the combined effects discussed above and describe other project environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

During construction of the water conveyance facility and implementation of tidal restoration, Alternative 4A would permanently remove 36 acres and temporarily remove 25 acres of managed wetland.

The construction loss of this special-status natural community would represent an adverse effect if it were not offset by the Environmental Commitments described in Chapter 3, Section 3.5.18.2, *Environmental Commitments*. Loss of managed wetland natural community would be considered both a loss in acreage of a sensitive natural community and potentially a loss of wetland as defined by Section 404 of the CWA. Many managed wetland areas are interspersed with small natural wetlands that would be regulated under Section 404. The restoration of up to 832 acres of nontidal wetland (Environmental Commitment 10) and protection and enhancement of 119 acres (Environmental Commitment 3) of nontidal wetland during the Alternative 4A construction period would offset the loss of the habitat values associated with managed wetland associated with water conveyance facilities managed wetland loss. Typical project-level mitigation ratios (1:1 for protection) would indicate 61 acres of protection would be needed to offset the 61 acres of loss associated with water conveyance facilities. The protection and restoration of nontidal marsh associated with Alternative 4A would fully compensate for the loss in habitat value associated with the managed wetland loss.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

In spite of the managed wetland protection, restoration and avoidance measures contained in Alternative 4A, there would be a net reduction in the acreage of this special-status natural community. This would be an adverse effect when judged by the significance criteria used for analysis of terrestrial biological resources (see Section 12.3.1.2, *Significance Criteria for Terrestrial Biological Resources*). However, the creation of nontidal marsh habitats (832 acres) that support similar ecological functions would offset this adverse effect. Also, there are other Environmental Commitments contained in the project (Environmental Commitment 3 and Environmental Commitment 11) that would improve management and enhance existing habitat values, further offsetting the effects of managed wetland loss on special-status terrestrial species and on common species that rely on this natural community for some life phase. As a result, there would be no adverse effect.

NEPA Effects: Alternative 4A would result in a loss of 61 acres of managed wetland within the study area; however, it would also protect and enhance up to 119 acres and restore up to 832 acres of habitat (nontidal wetland) with similar wildlife values. Therefore, there would be no adverse effect on managed wetland natural community.

CEQA Conclusion: During the project's construction time frame (14 years), Alternative 4A would permanently remove 36 acres and temporarily remove 25 acres of managed wetland through construction-related losses in habitat from water conveyance facilities activities and tidal restoration.

The construction loss of this special-status natural community would represent a significant impact if it were not offset by other the Environmental Commitments described in Chapter 3, Section 3.5.18.2. Loss of managed wetland natural community would be considered both a loss in acreage of a sensitive natural community and potentially a loss of wetland as defined by Section 404 of the CWA. The restoration of up to 832 acres and protection and enhancement of 119 acres of nontidal marsh as part of Environmental Commitment 3 and Environmental Commitment 10 during construction of Alternative 4A would fully offset the losses in habitat value associated with water conveyance facilities. Typical project-level mitigation ratios (1:1 for protection) would indicate 61 acres of protection would be needed to offset the 61 acres of loss associated with water conveyance facilities. The combined protection and restoration proposed for nontidal marsh would offset the loss of wildlife habitat value. This acreage would significantly exceed the number of acres of managed wetland lost.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

In spite of the nontidal marsh protection and restoration contained in Alternative 4A, there would be a net reduction in the acreage of managed wetland special-status natural community. This would be a significant impact when judged by the significance criteria listed in Section 12.3.1.2, *Significance Criteria for Terrestrial Biological Resources*. However, there are other Environmental Commitments contained in the project (Environmental Commitment 3, Environmental Commitment 10 and Environmental Commitment 11) that would improve management and enhance existing habitat values and expand habitat with similar values, further offsetting the impacts of managed wetland loss on special-status terrestrial species and on common species that rely on this natural community for some life phase. As a result, there would be a less-than-significant impact.

Impact BIO-25: Increased Frequency, Magnitude and Duration of Periodic Inundation of Managed Wetland Natural Community

Alternative 4A would not result in periodic effects on the managed wetland natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-26: Modification of Managed Wetland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the project facilities and conservation lands that could affect managed wetland natural community in the study area. The ongoing actions include changes in operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels. These actions are associated with water conveyance facilities and Environmental Commitment 11. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels (associated with Operational Scenario H) would not result in the reduction in acreage of the managed wetland natural community in the study area. Flow levels in the upstream rivers would not change to the degree that water levels in adjacent managed wetlands would be altered. Similarly, increased diversions of Sacramento River flows in the north Delta would not result in a permanent reduction in the managed wetland community downstream of these diversions. The majority of the managed wetlands below the diversions is not directly connected to the rivers. Reduced diversions from the south Delta channels would not create a reduction in this natural community.

- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with Alternative 4A actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in managed wetland habitats. This activity could lead to increased soil erosion, turbidity and runoff entering managed wetlands. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within managed wetland habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*Environmental Commitment 11 Natural Communities Enhancement and Management*). Use of herbicides to control nuisance vegetation could pose a long-term hazard to managed wetland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the community, or direct discharge of herbicides to managed wetland areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the project to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic and terrestrial environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Habitat enhancement.* The project includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For the managed wetland natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of managed wetland natural community in the study area through facilities maintenance and vegetation management. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the project, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be offset by restoration activities planned as part of *Environmental Commitment 10 Nontidal Marsh Restoration* and protection and restoration actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration*. The management actions associated with levee repair and control of invasive plant species would also result in a long-term benefit to the species associated with managed wetland habitats by improving water movement.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 4A would not result in a net permanent reduction in acreage of managed wetland natural community within the study area. Therefore, there would be no adverse effect on this natural community.

CEQA Conclusion**:** The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of managed wetland natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Hunting could intermittently reduce the availability of this community to special-status and common wildlife species. Implementation of environmental commitments and AMM2, AMM4, and AMM5 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including improved water movement in and adjacent to these habitats. Long-term restoration activities associated with *Environmental Commitment 10 Nontidal Marsh Restoration* and protection and restoration actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* would greatly expand the ecological functions of this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact on the managed wetland natural community.

Other Natural Seasonal Wetland

The other natural seasonal wetlands natural community encompasses all the remaining natural (not managed) seasonal wetland communities other than vernal pools and alkali seasonal wetlands. These areas mapped by CDFW (Hickson and Keeler-Wolf 2007) and ICF biologists (the western area of additional analysis; see Figure 12-1) consist of seasonally ponded, flooded, or saturated soils dominated by grasses, sedges, or rushes. The largest segments of this community in the study area are located along the Cosumnes River northeast of Thornton, and in the western extension of the study area northwest of Rio Vista. Most of the smaller mapped areas are located in the Suisun Marsh ROA on the western edge of the Montezuma Hills and in the interior of the Potrero Hills. There are also other natural seasonal wetlands mapped along Old River and Middle River in CZ 7. The only project conservation activity that would potentially affect this natural community is the channel margin enhancement measure (Environmental Commitment 6) (see Table 12-4A-9).

Table 12-4A-9. Changes in Other Natural Seasonal Wetland Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Water Conveyance Facilities	0	0

Environmental Commitment 7[a]	UNK	UNK
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	**0**	**0**

UNK = unknown

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-27: Modification of Other Natural Seasonal Wetland Natural Community as a Result of Implementing Alternative 4A

Because specific locations for implementing Alternative 4A's *Environmental Commitment 6 Channel Margin Enhancement* have not been identified, it is not known whether the creation of channel margin habitats along study area streams would remove other natural seasonal wetland community habitats. Several small patches of other natural seasonal wetland natural community are mapped along study area waterways. Because the areas of this community are small, and because their habitat values are also provided by other seasonal wetlands in the study area, the small potential that other natural seasonal wetland would be removed by channel margin enhancement is not expected to create an adverse effect on the special-status species that use this habitat.

NEPA Effects: Alternative 4A Environmental Commitments would not adversely affect other natural seasonal wetland natural community because of the small potential for this community to be displaced.

CEQA Conclusion: This community would not be significantly impacted because of the small potential for channel margin enhancement to displace other natural seasonal wetland acreage. There would be no substantial impact on the community. The impact would be less than significant.

Impact BIO-28: Modification of Other Natural Seasonal Wetland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the project facilities and conservation lands that could affect other natural seasonal wetland natural community in the study area. The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels. These actions are associated with water conveyance facilities. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels (associated with Operational Scenario H) would not affect other natural seasonal wetland natural community. The small areas mapped in the study area are not in or adjacent to streams that would experience changes in water levels as a result of these operations.
- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with the project actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in other natural seasonal wetland habitats. This activity could lead to increased soil erosion and runoff entering these habitats. These activities would be subject to normal erosion and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within other natural seasonal wetland habitats would require use of

sediment barriers, soil stabilization and revegetation of disturbed surfaces as required by *AMM10 Restoration of Temporarily Affected Natural Communities*. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*Environmental Commitment 11 Natural Communities Enhancement and Management*). Use of herbicides to control nuisance vegetation could pose a long-term hazard to the other natural seasonal wetland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to wetland areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the project to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in terrestrial or aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.
- *Habitat enhancement.* The project includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For the other natural seasonal wetland natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of other natural seasonal wetland natural community in the study area. Activities could introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the project, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be minor when compared to the restoration activities planned as part of *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, or minimized by implementation of AMM2, AMM4, AMM5, and AMM10. The vernal pool/alkali seasonal wetland complex Environmental Commitment (Environmental Commitment 9) includes restoration of up to 48 acres of seasonal wetlands with similar ecological values as the other natural seasonal wetland community. The management actions associated with control of invasive plant species would also result in a long-term benefit to the species associated with other natural seasonal wetland habitats by eliminating competitive, invasive species of plants.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 4A would not result in a net permanent reduction in this natural community within the study area. Therefore, there would be no adverse effect on the other natural seasonal wetland natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of other natural seasonal wetland natural community in the study area, and could create temporary increases in sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, AMM5, and AMM10 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including reduced competition from invasive, nonnative plants in these habitats. Long-term restoration activities associated with *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* and protection actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* would ensure that the ecological values provided by this small natural community would not decrease in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this natural community within the study area. Therefore, there would be a less-than-significant impact on the other natural seasonal wetland natural community.

Grassland

Construction, operation, maintenance and management associated with Alternative 4A would have no long-term adverse effects on the habitats associated with the grassland natural community. Initial development and construction of water conveyance facilities, tidal restoration (Environmental Commitment 4), and riparian restoration (Environmental Commitment 7) would result in both permanent and temporary removal of this community (see Table 12-4A-10). Implementation of Alternative 4A would also include the following Resource Restoration and Performance Principles over the term of the project to benefit the grassland natural community.

- Restore grasslands to connect fragmented patches of protected grassland and to provide upland habitat (Resource Restoration and Performance Principle G1).
- Restore and sustain a mosaic of grassland vegetation alliances, reflecting localized water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical sites (Resource Restoration and Performance Principle G3).
- Increase the extent, distribution, and density of native perennial grasses intermingled with other native species, including annual grasses, geophytes, and other forbs (Resource Restoration and Performance Principle G4).
- Maintain and enhance aquatic features in grasslands to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding for amphibian and aquatic reptile species (Resource Restoration and Performance Principle G7).
- Protect grassland on the landward side of levees adjacent to restored floodplain to provide flood refugia and foraging habitat for riparian brush rabbit (Resource Restoration and Performance Principle G8).

- Create or protect high-value upland giant garter snake habitat adjacent to the nontidal perennial aquatic habitat being restored and created (Resource Restoration and Performance Principle G9).
- Protect up to 647 acres of grassland in the Byron Hills area where practicable and/or in other appropriate locations (Resource Restoration and Performance Principle G10).

As explained below, with the protection, restoration and enhancement of the amounts of habitat included in the project, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-10. Changes in Grassland Natural Community Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Water Conveyance Facilities	467	158
Environmental Commitment 4[a]	40	0
Environmental Commitment 7[a]	1	0
Environmental Commitment 10[a]	0	0
Environmental Commitment 11[a]	20	0
TOTAL IMPACTS	**528**	**158**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-29: Changes in Grassland Natural Community as a Result of Implementing Alternative 4A

Construction and land grading activities that would accompany the implementation of water conveyance facilities, tidal restoration (Environmental Commitment 4), and riparian restoration (Environmental Commitment 7) would permanently eliminate an estimated 528 acres and temporarily remove 158 acres of grassland natural community in the study area. These modifications represent approximately 0.9% of the 78,047 acres of the community that is mapped in the study area.

The individual effects of each relevant Environmental Commitment are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation*: Construction of the Alternative 4A water conveyance facilities would permanently remove 467 acres and temporarily remove 158 acres of grassland natural community. The permanent losses would occur where Intakes 2, 3, and 5 encroach on the Sacramento River's east bank between Clarksburg and Courtland;; a reusable tunnel material storage site on Bouldin Island; at a permanent pipeline shaft access road on the east side of Bacon Island; and at various permanent facility sites around Clifton Court Forebay, including a reusable tunnel material storage site, new canal connections from Clifton Court Forebay to the two aqueducts, and in the forebay expansion area on the south side of the existing forebay. Most of the permanent losses would be of ruderal and herbaceous grassland areas that exist in very narrow bands adjacent to waterways, levees and roads (see the Terrestrial Biology Mapbook). Some of the grassland lost at the sites of new canals south of Clifton Court Forebay is composed of larger stands of ruderal and herbaceous vegetation and California annual grassland. A portion of the grassland habitat adjacent to Clifton Court Forebay includes iodine bush scrub, a sensitive plant community. The temporary losses would be associated with construction of the temporary access roads along the Sacramento River; temporary transmission lines; at work areas and barge offloading facility construction sites at the south end of Bouldin Island, at the north end of Bacon Island, and the south end of Venice Island and at the northwest corner of Victoria Island; at temporary access road sites on the northern and southern ends of Bacon Island and the northwest corner of Victoria Island; at temporary work areas on Mandeville and Bacon Islands; at the operable barrier construction site at the head of Old River, and various locations around Clifton Court Forebay. These losses would take place during the Alternative 4A construction period.

- The construction activity associated with water conveyance facilities also has the potential to lead to increased nitrogen deposition in grassland habitats in the vicinity of Clifton Court Forebay. A significant number of cars, trucks, and land grading equipment involved in construction in and around the forebay would emit small amounts of atmospheric nitrogen from fuel combustion; this material could be deposited in sensitive grassland areas that are located west of the major construction areas at Clifton Court Forebay. Nitrogen deposition can pose a risk of adding a fertilizer to nitrogen-limited soils and their associated plants. Nonnative invasive species can be encouraged by the added nitrogen available. Appendix 5.J, Attachment 5J.A, *Construction-Related Nitrogen Deposition on BDCP Natural Communities*, of the BDCP addresses this issue in detail. It has been concluded that this potential deposition would pose a low risk of changing the grassland in and adjacent to the construction areas because the construction would contribute a negligible amount of nitrogen to regional projected emissions and the existing grassland is dominated by nonnative invasive species of plants. Also, the construction at Clifton Court Forebay would occur primarily downwind of the natural community. No adverse effect is expected.
- *Environmental Commitment 3 Natural Community Protection and Restoration*: Approximately 1,060 acres of grassland natural community would be protected to restore and enhance aquatic and upland habitat for a number of amphibian, reptile and mammal special-status species.
- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Environmental Commitment 4 would permanently inundate or remove an estimated 40 acres of grassland. The losses would occur in one or more of the ROAs established for tidal restoration (see Figure 12-1).
- *Environmental Commitment 6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in removal of small amounts of grassland natural community along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur along waterway margins where grassland habitat stringers exist, including along levees and channel banks. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.
- *Environmental Commitment 7 Riparian Natural Community Restoration:* Environmental Commitment 7 would permanently remove an estimated 1 acre of grassland.
- *Environmental Commitment 8 Grassland Natural Community Restoration:* Up to 1,070 acres of grassland natural community would be restored primarily on the fringes of the Delta, where upland areas merge with Delta wetland and agricultural lands. Restoration would focus on CZ 1, CZ 8, and CZ 11, as proposed by the BDCP.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Natural communities enhancement and management would include a wide range of activities designed to improve habitat conditions in restored and protected lands associated with the project. This measure also promotes sound use of pesticides, vector control activities, invasive species control and fire management in preserve areas.

The following paragraphs summarize the combined effects discussed above and describe other project Environmental Commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

During the project's construction timeframe, Alternative 4A would affect the grassland natural community through water conveyance facilities construction, tidal restoration (Environmental Commitment 4), and riparian restoration (Environmental Commitment 7) (528 acres permanent and 158 acres temporary).

The construction losses of this natural community would not represent an adverse effect based on the significance criteria used for this section because grassland is not considered a special-status or sensitive natural community. Most Central Valley grasslands are dominated by nonnative annual grasses and herbs. However, the importance of grassland as a habitat that supports life stages of numerous special-status plants and wildlife is well documented (see Chapter 3, *Conservation Strategy*, of the BDCP). The significance of losses in grassland habitat is, therefore, discussed in more detail in species analyses in the *Wildlife Species* section. In addition, the loss of iodine bush scrub located in grassland adjacent to Clifton Court Forebay would be an adverse effect. The combination of restoring 1,070 acres grassland (Environmental Commitment 8), protecting and enhancing 1,060 acres (Environmental Commitment 3) of grassland natural community during the construction phase of the project (14 years), and the commitment to restore temporarily affected grassland (158 acres) to its pre-project condition within one year of completing construction as required by *AMM10 Restoration of Temporarily Affected Natural Communities*, would offset this construction loss, avoiding any loss in the value of this habitat for special-status species. The protected and restored habitat would be managed and enhanced to benefit special-status and common wildlife species (Environmental Commitment 3 and Environmental Commitment 11). Typical project-level mitigation ratios (2:1 for protection) would indicate that 1,372 acres of protection would be needed to offset (i.e., mitigate) the 686 acres of combined permanent and temporary loss. In addition, because it is not possible to create iodine bush scrub, mitigation for impacts on this plant community must be through avoidance and/or protection of compensating mitigation areas. Protection of iodine bush scrub within the grassland/vernal pool complex/alkali seasonal wetland habitats adjacent to Clifton Court Forebay provides the only opportunity in the Plan Area to protect this habitat. The combination of protection, along with the enhancement and management associated with Environmental Commitment 3 and Environmental Commitment 11 contained in the project, is designed to avoid a temporal lag in the value of grassland habitat available to sensitive species.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: By the end of the project's construction time frame, a total of 1,060 acres of grassland would be protected (Environmental Commitment 3) and 1,070 acres of grassland would be restored (Environmental Commitment 8), which would be guided by Resource Restoration and Performance Principles G1, G3, G4, and G7-G10. The protection would occur primarily in the west Delta and Clifton Court Forebay areas. Temporarily affected grassland would also be restored following construction activity as described in AMM10. There would be a permanent and temporary loss of 686 acres of grassland in the study area. However, the combination of restoration, protection and enhancement of grassland associated with Alternative 4A would replace the habitat lost and improve the habitat value of this community in the study area; there would not be an adverse effect on the grassland natural community.

CEQA Conclusion: Alternative 4A would result in the permanent and temporary loss of approximately 686 acres of grassland natural community due to construction of the water conveyance facilities.

The construction losses of this natural community would not represent a significant impact based on the significance criteria used for this section because grassland is not considered a special-status or sensitive natural community. Nonetheless, these losses would be offset by planned restoration of 158 acres of temporarily affected grassland, the restoration of up to 1,070 acres of grassland, and protection of up to 1,060 acres of grassland natural community scheduled for the 14-year construction period of Alternative 4A, which would be guided by Resource Restoration and Performance Principles G1, G3, G4, and G7-G10. Also, AMM1, AMM2, AMM6, and AMM7 would be implemented to minimize impacts. Because of these offsetting restoration and protection activities and AMMs, impacts would be less than significant. Typical project-level mitigation ratios (2:1 for protection) would indicate that 1,372 acres of protection would be needed to offset (i.e., mitigate) the 686 acres of loss. The combined protection (1,060 acres) and restoration (1,070 acres) of 2,130 acres of grassland would more than offset the losses from the project. The combination of two approaches (protection and restoration) contained in the project Environmental Commitments and avoidance and minimization measures is designed to avoid a temporal lag in the value of grassland habitat available to special-status species. The protection and restoration would be initiated at the beginning of Alternative 4A implementation to minimize any time lag in the availability of this habitat to special-status species. Therefore, there would be a less-than-significant impact on the grassland natural community.

Impact BIO-30: Increased Frequency, Magnitude and Duration of Periodic Inundation of Grassland Natural Community

Alternative 4A would not result in periodic effects on grassland natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-31: Modification of Grassland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the Alternative 4A facilities and conservation lands that could affect grassland natural community in the study area.

The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels. These actions are associated with water conveyance facilities. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels (associated with Operational Scenario H) would not result in the permanent reduction in acreage of grassland natural community in the study area. Flow levels in the upstream rivers would not change such that the acreage of this community would be reduced on a permanent basis. The grassland along rivers upstream of planned north Delta diversions is primarily ruderal vegetation on levee banks and is dependent on winter and spring rains for germination and growth rather on than river levels. Similarly, increased diversions of Sacramento River flows in the north Delta would not result in a permanent reduction in grassland natural community downstream of these diversions. The reductions in flows below the intakes would occur primarily in the wet months when the existing nonnative annual grasslands along river levees are dormant, and like upstream grassland, this community is dependent on winter and spring rains for germination and growth in the winter and spring months, not on river stage. Anticipated small changes in river salinity in the west Delta and Suisun Marsh would not create a substantial change in grassland acreage in these areas. Reduced diversions from south Delta channels would not create a reduction in this natural community.

- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with project actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in grassland habitats. This activity could lead to increased soil erosion and runoff entering these habitats. These activities would be subject to normal erosion and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within grassland habitats would require use of sediment barriers, soil stabilization and revegetation of disturbed surfaces (*AMM10 Restoration of Temporarily Affected Natural Communities*). Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*Environmental Commitment 11 Natural Community Enhancement and Management*). Use of herbicides to control nuisance vegetation could pose a long-term hazard to grassland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to grassland areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of Alternative 4A to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in terrestrial environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Channel dredging.* Long-term operation of the Alternative 4A intakes on the Sacramento River would include periodic dredging of sediments that might accumulate in front of intake screens. The dredging could occur adjacent to grassland natural community. This activity should not permanently reduce the acreage of grassland natural community because it is periodic in nature; the grassland in the vicinity of the proposed intakes is ruderal grasses and herbs with low habitat value.

- *Habitat enhancement.* Alternative 4A includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For the grassland natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of grassland natural community in the study area through changes in flow patterns and changes in periodic inundation of this community. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the Plan, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be offset by protection and enhancement activities planned as part of *Environmental Commitment 3 Natural Communities Protection and Restoration*, or minimized by implementation of AMM2, AMM4, AMM5, and AMM10. The management actions associated with levee repair, periodic dredging and control of invasive plant species would also result in a long-term benefit to the species associated with grassland habitats by improving water movement in adjacent waterways and by eliminating competitive, invasive species of plants.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 4A would not result in a net permanent reduction in grassland natural community within the study area. Therefore, there would be no adverse effect on this natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of grassland natural community in the study area, and could create temporary increases sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, AMM5, and AMM10 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including reduced competition from invasive, nonnative plants in these habitats. Protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* would increase the value of this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this natural community within the study area. Therefore, there would be a less-than-significant impact on the grassland natural community.

Inland Dune Scrub

The inland dune scrub natural community is composed of vegetated, stabilized sand dunes associated with river and estuarine systems. In the study area, the inland dune scrub community consists of remnants of low-lying ancient stabilized dunes related to the Antioch Dunes formation located near the town of Antioch (CZ 10; see Figure 12-1). While inland dune scrub is within the study area, none of the Alternative 4A actions is expected to affect this community.

Cultivated Lands

Cultivated lands is the major land cover type in the study area (487,106 acres, see Table 12-1 in Section 12.1.2, *Land Cover Types*). The Delta, the Yolo Bypass and the Cache Slough drainage are dominated by various types of agricultural activities, with crop production the dominant element (see Figure 12-1). Major crops and cover types in agricultural production include grain and hay crops (wheat, oats and barley), field crops (corn, beans and safflower), truck crops (tomatoes, asparagus and melons), pasture (alfalfa, native and nonnative pasture), rice, orchards, and vineyards. Tables 12-2 and 12-3 in Section 12.1.3, *Special-Status Species*, list special-status wildlife species supported by cultivated lands.

The effects of Alternative 4A on cultivated lands are discussed from various perspectives in this document. Chapter 14, *Agricultural Resources*, includes a detailed analysis of cropland conversion as it relates to agricultural productivity. Many of the discussions of individual terrestrial plant and wildlife species in this section also focus on the relevance of cultivated land loss. Because cultivated lands is not a natural community and because the effects of its loss are captured in the individual species analyses, there is no separate analysis of this land cover type presented here. For Alternative 4A, the total loss (permanent and temporary) is estimated to be 7,043 acres. The majority of the permanent loss would be associated with tidal marsh restoration (Environmental Commitment 4; 192 acres), riparian natural community restoration (Environmental Commitment 7; 250 acres), grassland restoration (Environmental Commitment 8; 1,070 acres), nontidal marsh restoration (Environmental Commitment 10; 832 acres), and construction of the modified tunnel and associated water conveyance facilities (permanent removal of 3,544 acres and temporary removal 1,155 acres of cultivated lands). Of the 7,043 acres, 6,844 would be made up of croplands and the other 199 acres would be non-cropland agricultural areas.

Developed Lands

Additional lands in the study area that were not designated with a natural community type have been characterized as developed lands (90,660 acres). Developed lands include lands with residential, industrial, and urban land uses, as well as landscaped areas, riprap, road surfaces and other transportation facilities (see Figure 12-1 and the Terrestrial Biology Mapbook). Developed lands support some common plant and wildlife species, whose abundance and species richness vary with the intensity of development. One special-status species, the giant garter snake, is closely associated with a small element of developed lands; specifically, embankments and levees near water that are covered with riprap provide giant garter snake habitat.

As with cultivated lands, no effort has been made to analyze the effects of Alternative 4A activities on this land cover type because it is not a natural community. The effects of its conversion are discussed in Chapter 13, *Land Use*. Where the loss of developed lands may affect individual special-status species or common species, the impact analysis is contained in that species discussion.

Wildlife Species

Vernal Pool Crustaceans

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of the Environmental Commitments, on vernal pool crustaceans (California linderiella, Conservancy fairy shrimp, longhorn fairy shrimp, midvalley fairy shrimp, vernal pool fairy shrimp, and vernal pool tadpole shrimp). The habitat model used to assess effects for the vernal pool crustaceans consists of: vernal pool complex, which consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly affected by agricultural or development practices; alkali seasonal wetlands in CZ 8; and degraded vernal pool complex, which consists of low-value ephemeral habitat ranging from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. For the purpose of the effects analysis, vernal pool complex is categorized as high-value for vernal pool crustaceans and degraded vernal pool complex is categorized as low-value for these species. Alkali seasonal wetlands in CZ 8 were included in the model as high-value habitat for vernal pool crustaceans. Also included as low-value habitat for vernal pool crustaceans are areas along the eastern boundary of CZ 11 that are mapped as vernal pool complex because they flood seasonally and support typical vernal pool plants, but which do not include topographic depressions that are characteristic of vernal pool crustacean habitat.

Alternative 4A would result in permanent losses (see Table 12-4A-11) and indirect conversions of vernal pool crustacean modeled habitat. Alternative 4A would also include the following Environmental Commitments and associated Resource Restoration and Performance Principles to benefit vernal pool crustaceans.

- Restore vernal pool complex and alkali seasonal wetland suitable for vernal pool crustaceans to achieve no net loss of wetted acreage (Environmental Commitment 9, Resource Restoration and Performance Principle VP/AW2).
- Increase size and connectivity of protected vernal pool complexes and alkali seasonal wetlands in the greater Byron Hill area (Resource Restoration and Performance Principle VP/AW3).
- Protect up to 188 acres of existing vernal pool/alkali seasonal wetland complex (Environmental Commitment 3) in the greater Byron Hills area, primarily in core vernal pool recovery areas identified in the *Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon* (U.S. Fish and Wildlife Service 2005) (Resource Restoration and Performance Principle VP/AW1).
- Provide appropriate seasonal flooding characteristics for supporting and sustaining vernal pool and alkali seasonal wetland complex species (Resource Restoration and Performance Principle VP/AW4).

As explained below, with the restoration and protection of these amounts of habitat, in addition to implementation of AMMs, impacts on vernal pool crustaceans would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-11. Changes in Vernal Pool Crustacean Modeled Habitat Associated with Alternative 4A (acres)[a]

Project Component	Habitat Type	Permanent	Temporary	Indirect
Water Conveyance Facilities	High-value	13	1	42
	Low-value	7	2	0
Total Impacts Water Conveyance Facilities		**20**	**3**	**42**
Environmental Commitments 4, 6–7, 9–11[a]	High-value	17	0	3
	Low-value	8	0	1
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**25**	**0**	**4**
TOTAL IMPACTS		**45**	**3**	**46**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-32: Loss or Conversion of Habitat for and Direct Mortality of Vernal Pool Crustaceans

Alternative 4A would result in the direct permanent and temporary loss combined of 48 acres of modeled vernal pool crustacean habitat from conveyance facilities construction and tidal restoration. In addition, water conveyance facilities construction and tidal restoration that causes hydrologic changes could result in the indirect conversion of an additional 45 acres of high-value and 1 acre of low-value vernal pool crustacean habitat. Construction of the water conveyance facilities and tidal restoration projects may result in the modification of hardpan and changes to the perched water table, which could lead to alterations in the rate, extent, and duration of inundation of nearby vernal pool crustacean habitat. USFWS typically considers construction within 250 feet of vernal pool crustacean habitat to constitute a possible conversion of crustacean habitat unless more detailed information is provided to further refine the limits of any such effects. For the purposes of this analysis, the 250-foot buffer was applied to the water conveyance facilities work areas where surface and subsurface disturbance activities would take place. Habitat enhancement and management activities (Environmental Commitment 11), which include disturbance or removal of nonnative vegetation, could result in local adverse habitat effects.

Alternative 4A would also result in impacts on critical habitat for vernal pool fairy shrimp (185 acres). These impacts would be from water conveyance facilities construction west of Clifton Court Forebay. Of the 185 acres of vernal pool fairy shrimp critical habitat, only 5 acres consist of modeled habitat for vernal pool crustaceans, with the remainder consisting of cultivated lands.

As specified in *AMM12 Vernal Pool Crustaceans* and *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, restoration projects are designed such that no more than a total of 10 wetted acres of vernal pool crustacean habitat are permanently lost. AMM12 would also ensure that no more than 20 wetted acres of vernal pool crustacean habitat are indirectly affected by alterations to hydrology resulting from adjacent habitat restoration activities, in particular tidal restoration. *AMM30 Transmission Line Design and Alignment Guidelines* would ensure that transmission lines avoid removal of wetted acres of vernal pools and alkali seasonal wetlands wetted acres of aquatic habitats to the maximum extent feasible. The term wetted acres refers to an area that would be defined by the three parameter wetland delineation method used by the U.S. Army Corps of Engineers to determine the limits of a wetland, which involve an evaluation of wetland soil, vegetation, and hydrology characteristics. This acreage differs from vernal pool complex acreages in that a vernal pool complex is composed of individual wetlands (vernal pools) and those upland areas that are in between and surrounding them, which provide the supporting hydrology (surface runoff and groundwater input), organic and nutrient inputs, and refuge for the terrestrial phase of some vernal pool species.

A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation*: Construction of Alternative 4A conveyance facilities would result in the permanent and temporary combined loss of approximately 23 acres of vernal pool crustacean habitat, composed of 14 acres of high-value and 9 acres of low-value habitat (Table 12-4A-11). The construction of the conveyance facilities would result in the permanent loss of habitat associated with a vernal pool fairy shrimp CNDDB occurrence as a result of the expansion of Clifton Court Forebay. In addition, conveyance facility construction could result in the indirect conversion of 42 acres of high-value vernal pool crustacean habitat in the vicinity of Clifton Court Forebay. The indirect effects would result from the construction of permanent transmission lines, from the storage of RTM, and permanent access roads. There are records of vernal pool fairy shrimp and midvalley fairy shrimp in the vicinity of these areas (California Department of Fish and Game 2013). Alternative 4A would also result in the permanent loss of 185 acres of critical habitat for vernal pool fairy shrimp. The permanent impacts on critical habitat are associated with the RTM disposal areas and an associated access road west of Clifton Court Forebay (177 acres), a new transmission line (5 acres), and upgrades to a permanent access road just south of this area (3 acres). However, as discussed above, only 5 acres of this critical habitat consists of modeled habitat for vernal pool crustaceans and the remaining critical habitat consist of cultivated lands that are not suitable for the species. *AMM30 Transmission Line Design and Alignment Guidelines* would ensure that transmission lines are designed to avoid removal of aquatic habitats to the maximum extent feasible.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal natural communities restoration would result in the conversion of an estimated 25 acres of modeled vernal pool crustacean habitat (17 acres high value and 8 acres low value habitat). Tidal restoration would also result in the indirect conversion of an estimated 4 acres of modeled vernal pool crustacean habitat. The effects would take place in one or more of the ROAs established for tidal restoration (see Figure 12-1).
- *Environmental Commitment 11 Natural Communities Enhancement and Management:* The project's restoration/creation of vernal pools to achieve no net loss and the protection of up to 188 acres of vernal pool/alkali seasonal wetland complex would benefit vernal pool crustaceans. A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in protected habitats may result in localized ground disturbances that could temporarily affect vernal pool crustacean habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on vernal pool crustacean habitat and are expected to result in overall improvements to and maintenance of vernal pool crustacean habitat values. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.

The proposed conservation efforts have been evaluated to determine whether they would provide sufficient habitat protection and restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA and would be less than significant under CEQA. Table 12-4A-11 lists the impacts on modeled vernal pool crustacean habitat that is based on the natural community mapping done within the study area. Table 12-4A-12 was prepared to further analyze the project's effects on vernal pool crustaceans using wetted acres of habitat in order to compare the effects of this alternative with the effect limits established in *AMM12 Vernal Pool Crustaceans*, which are measured in wetted acres of habitat. Wetted acres were estimated by using the BDCP's assumption that restored vernal pool complexes would have a 15% density of vernal pools (i.e., of 100 acres of vernal pool complex 15 acres would constitute vernal pools and the remaining 85 acres supporting uplands). Based on an informal evaluation of aerial photographs of the project area it is likely that the actual densities within the project area are approximately 10%, but the 15% density value was chosen as a conservative estimate for determining effects.

Table 12-4A-12. Estimated Effects on Wetted Vernal Pool Crustacean Habitat under Alternative 4A (acres)

	Direct Loss	Indirect Conversion
AMM 12 Impact Limit	10	20
Water Conveyance Facilities[a]	3.45	6.30
Environmental Commitments 4, 6-7, 9-11	3.75	0.60
Total	**7.2**	**6.9**

[a] These acreages were generated by assuming that the modeled habitat identified in Table 12-4A-11 has densities of wetted habitat at 15%. The direct effects numbers include permanent and temporary impacts.

Typical NEPA and CEQA project-level mitigation ratios for loss of vernal pools affected by Alternative 4A would be 1:1 for restoration and 2:1 for protection. Typically, indirect conversion impacts are mitigated by protecting vernal pools at a 2:1 ratio. Using these typical ratios would indicate that 7.2 wetted acres of vernal pool crustacean habitat (or 48 acres of vernal pool/alkali seasonal wetland complex) should be restored and 28.2 wetted acres (or 188 acres of vernal pool/alkali seasonal wetland complex) protected to mitigate Alternative 4A's direct and indirect effects on vernal pool crustacean habitat. With the implementation of AMM30, the effects on aquatic habitat would be avoided to the maximum extent feasible during the designing of the transmission line west of Clifton Court Forebay.

Project proponents would commit to protecting up to 188 acres of vernal pool/alkali seasonal wetland complex by protecting at least 2 wetted acres of vernal pools for each wetted acre directly or indirectly affected. Alternative 4A has also committed to restoring/creating vernal pools and alkali seasonal wetlands such that there is no net loss of vernal pool acreage. The final amount of restoration would be determined during implementation based on the following criteria.

- If restoration is completed (i.e., restored natural community meets all success criteria) prior to impacts, then 1.0 wetted acre of vernal pools and/or alkali seasonal wetlands suitable for the species would be restored for each wetted acre directly affected (1:1 ratio).
- If restoration takes place concurrent with impacts (i.e., restoration construction is completed, but restored habitat has not met all success criteria, prior to impacts occurring), then 1.5 wetted

acres of vernal pools and/or alkali seasonal wetlands suitable for the species would be restored for each wetted acre directly affected (1.5:1 ratio).

The protection and restoration efforts would include the following the Resource Restoration and Performance Principles.

- Protect existing vernal pool complex in the greater Byron Hills area primarily in core vernal pool recovery areas identified in the *Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon* (U.S. Fish and Wildlife Service 2005) (Resource Restoration and Performance Principle VP/AW1).
- Increase size and connectivity of protected vernal pool complexes and alkali seasonal wetlands in the greater Byron Hill area (Resource Restoration and Performance Principle VP/AW2).
- Provide appropriate seasonal flooding characteristics for supporting and sustaining vernal pool and alkali seasonal wetland complex species.

Alternative 4A also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM12 Vernal Pool Crustaceans,* and *AMM30 Transmission Line Design and Alignment Guidelines*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of vernal pool crustacean habitat under Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that meets the typical mitigation ratios described above. This habitat protection, restoration, management and enhancement would be guided by Resource Restoration and Performance Principles VP/AW1-VP/AW4, and by AMM1–AMM6, AMM10, AMM12, and AMM30, which would be in place throughout the period of construction and operations. Considering these commitments, losses and conversion of vernal pool crustacean habitat under Alternative 4A would not be an adverse effect.

CEQA Conclusion: Alternative 4A would have significant impact on vernal pool crustacean habitat as a result of habitat modification of a special-status species and potential for direct mortality in the absence of the protection and restoration of habitat. However, the project proponents have committed to habitat protection, restoration, management and enhancement associated with Environmental Commitment 3, Environmental Commitment 9, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principles VP/AW1-VP/AW4 and effects would be avoided and minimized by AMM1–AMM6, AMM10, AMM12, and AMM30, which would be in place throughout the period of construction and operations. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of vernal pool crustaceans. Therefore, Alternative 4A would have a less-than-significant impact on vernal pool crustaceans under CEQA.

Impact BIO-33: Indirect Effects of Alternative 4A on Vernal Pool Crustaceans

Construction and maintenance activities associated with water conveyance facilities, and restoration actions could indirectly affect vernal pool crustaceans and their habitat in the vicinity of construction and restoration areas, and maintenance activities. Ground-disturbing activities, stockpiling of soils, and maintenance and refueling of heavy equipment could result in the inadvertent release of sediment and hazardous substances into this habitat. Vernal pool crustaceans and their habitat could be periodically indirectly affected by maintenance activities at water conveyance facilities. Embankment maintenance activities around Clifton Court Forebay could result in the inadvertent discharge of sediments and hazardous materials into vernal pool crustacean habitat that occurs along the southern and western boundaries of the forebays.

NEPA Effects: Water conveyance facilities construction and restoration activities could indirectly affect vernal pool crustaceans and their habitat in the vicinity of construction areas. These potential effects would be avoided and minimized through AMM1–AMM6, AMM10, and AMM12, which would be in effect throughout the period of construction and operations. The indirect effects of Alternative 4A on vernal pool crustaceans and their habitat would not be adverse under NEPA.

CEQA Conclusion: Construction and maintenance activities associated with water conveyance facilities, and restoration actions could indirectly impact vernal pool crustaceans and their habitat in the vicinity of these work areas. These potential impacts would be minimized or avoided through AMM1–AMM6, AMM10, and AMM12, which would be in effect throughout the period of construction and operations. The indirect impacts of Alternative 4A on vernal pool crustaceans would be less than significant under CEQA.

Impact BIO-34: Periodic Effects of Inundation of Vernal Pool Crustacean Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on vernal pool crustacean habitat.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Valley Elderberry Longhorn Beetle

The habitat model used to assess the effects for valley elderberry longhorn beetle is based on riparian habitat and nonriparian habitat (vernal pool complexes and grasslands within 200 feet of channels). Alternative 4A would result in both temporary and permanent losses of valley elderberry longhorn beetle modeled habitat as indicated in Table 12-4A-13. The majority of the losses would take place over an extended period of time as the restoration Environmental Commitments are being implemented. In addition, an estimated 14 elderberry shrubs that were previously mapped by DWR in the DHCCP Conveyance Planning Area could be impacted by the Alternative 4A water conveyance alignment. Full implementation of Alternative 4A would also include the following Environmental Commitments and associated Resource Restoration and Performance Principles to benefit valley elderberry longhorn beetle.

- Mitigate impacts on elderberry shrubs consistent with USFWS conservation guidelines (U.S. Fish and Wildlife Service 1999a) for the species and planting shrubs in high-density cluster (Resource Restoration and Performance Principle VELB1).

- Site elderberry longhorn beetle habitat restoration with drainage immediately adjacent to or in the vicinity of occupied habitat (Resource Restoration and Performance Principle VELB2).
- Restore up to 251 acres of valley/foothill riparian (Environmental Commitment 7).
- Protect up to 103 acres of valley/foothill riparian (Environmental Commitment 3).

As explained below, with the restoration and protection of these amounts of habitat, impacts on valley elderberry longhorn beetle would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-13. Changes in Valley Elderberry Longhorn Beetle Modeled Habitat Associated with Alternative 4A (acres)[a]

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Riparian	37	24
	Nonriparian	201	87
Total Impacts Water Conveyance Facilities		**238**	**111**
Environmental Commitments 4, 6–7, 9–11[a]	Riparian	11	0
	Nonriparian	12	0
Total Impacts Environmental Commitments 4, 6–7, 9–11a		**23**	**0**
TOTAL IMPACTS		**261**	**111**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-35: Loss of Valley Elderberry Longhorn Beetle Habitat

Alternative 4A would result in the permanent and temporary loss combined of up to 372 acres of modeled valley elderberry longhorn beetle habitat (72 acres of riparian habitat and 300 acres of nonriparian habitat), and an estimated 14 elderberry shrubs from water conveyance facilities, which represent potential habitat for the species (Table 12-4A-13). Due to the limitation of the habitat suitability model, the effects on modeled habitat are assumed to be a large overestimate of the true effect on potential valley elderberry longhorn beetle habitat. These losses would be a result of water conveyance facilities and transmission line construction, and establishment and use of RTM areas, and tidal habitat restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other project physical facilities could degrade or eliminate valley elderberry longhorn beetle habitat. Implementation of the habitat protection and restoration contained in Alternative 4A and implementation of AMMs committed to would result in no adverse effects under NEPA and less-than-significant impacts under CEQA. Each of these activities is described below.

- *Water Facilities and Operation*: Construction of Alternative 4A conveyance facilities would result in the permanent and temporary combined loss of approximately 349 acres of modeled valley elderberry longhorn beetle habitat, composed of 61 acres of riparian habitat and 288 acres of nonriparian habitat (Table 12-4A-13). In addition, an estimated 14 shrubs could be removed as a result of conveyance facilities construction. As noted in Section 12.3.2.3, *Methods Used to Assess Species Effects*, elderberry shrubs were mapped in the DHCCP Conveyance Planning Area where accessible and thus the entire footprint of water conveyance facilities was not surveyed. In many cases, the data collected did not always specify the number of shrubs observed but rather the size class and a range of stem numbers. The exact number of shrubs to be impacted would be determined during pre-construction surveys of the footprints of the conveyance facility and associated work areas as part of the implementation of *AMM15 Valley Elderberry Longhorn Beetle*. Most of these impacts are associated with the intake and forebay construction in the north delta. There are no records of valley elderberry longhorn beetle within these impact areas. The portion of the above impacts that result from temporary habitat loss includes 111 acres of modeled valley elderberry longhorn beetle habitat (24 acres riparian and 87 acres nonriparian habitat). Elderberry shrubs could be affected from ground-disturbing activities associated with conveyance construction footprints, reusable tunnel material storage areas, geotechnical boring areas, temporary access roads, and staging areas.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal natural communities restoration would result in the permanent loss of approximately 23 acres of modeled habitat (11 acres of riparian and 12 acres of nonriparian habitat). Elderberry shrubs could be affected from ground-disturbing activities associated with the re-contouring of surface topography, excavation or modification of channels, type conversion from riparian and grasslands to tidal habitat, levee removal and modification, and removal of riprap and other protections from channel banks.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Activities associated with natural communities enhancement and management, such as grazing practices and ground disturbance or herbicide use in the control of nonnative vegetation, intended to maintain and improve habitat functions of protected habitats for species could result in loss of elderberry shrubs and the potential for injury or mortality to beetles. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.

- Operations and maintenance: Post-construction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect valley elderberry beetle. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas could affect elderberry shrubs occupied by the species. These effects, however, would be reduced by AMMs listed below.

The following paragraphs summarize the combined effects discussed above and describe the environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

The study area supports approximately 34,456 acres of modeled habitat (17,786 acres of riparian and 16,670 acres of nonriparian) for valley elderberry longhorn beetle. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 372 acres of modeled valley elderberry longhorn beetle habitat (72 acres of riparian habitat and 300 acres of nonriparian habitat) (1% of the modeled habitat in the study area). These losses would not fragment any known populations of valley elderberry longhorn beetle.

Typical NEPA and CEQA project-level mitigation ratios for riparian habitat affected by the project would be 1:1 for restoration and 1:1 for protection of riparian habitat. Using these typical ratios would indicate that 72 acres of the riparian habitat should be restored/created and 72 acres of existing riparian should be protected to mitigate project losses of valley elderberry longhorn beetle habitat.

Alternative 4A includes a commitment to restore/create up to 251 acres of riparian habitat and protect up to 103 acres of riparian habitat and in the project area. The Resource Restoration and Performance Principles identified under Alternative 4A for valley elderberry longhorn beetle conservation include implementing the USFWS conservation guidelines for the species (transplanting elderberry shrubs and planting elderberry seedlings and associated natives) (Resource Restoration and Performance Principle VELB1) and siting elderberry restoration within drainages immediately adjacent to or in the vicinity of sites confirmed to be occupied by valley elderberry longhorn beetle (Resource Restoration and Performance Principle VELB2). These Resource Restoration and Performance Principles would be met through the implementation of *Environmental Commitment 7 Riparian Natural Community Restoration*. *Environmental Commitment 7 Riparian Natural Community Restoration* specifically calls for the planting of elderberry shrubs in large, contiguous clusters with a mosaic of associated natives as part of riparian restoration consistent with USFWS conservation guidelines (U.S. Fish and Wildlife Service 1999a). The acres of riparian protection and restoration proposed would satisfy the typical mitigation requirements described in the previous paragraph. Though there are no restoration and preservation goals for the nonriparian habitat affected, the commitment to transplant shrubs and plant additional elderberry seedlings and associated natives would, together with the proposed restoration and protection of riparian (a higher quality habitat), would be more than adequate to compensate for the projects effects on the nonriparian habitat component of the modeled habitat for the species.

The project also includes commitments to implement AMM1 W*orker Awareness Training*, AMM2 C*onstruction Best Management Practices and Monitoring*, AMM3 *Stormwater Pollution Prevention Plan*, AMM4 *Erosion and Sediment Control Plan*, AMM5 *Spill Prevention, Containment, and Countermeasure Plan*, AMM6 *Disposal and Reuse of Spoils,* and AMM15 *Valley Elderberry Longhorn Beetle*. AMM15 requires surveys for elderberry shrubs within 100 feet of any ground disturbing activities, the implementation of avoidance and minimize measures for any shrubs that are identified within this 100-foot buffer, and transplanting shrubs that can't be avoided. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and RTM storage sites.

Other factors relevant to effects on valley elderberry longhorn beetle include:

- Habitat loss is widely dispersed throughout the study area and would not be concentrated in any one location.
- There would be a temporal loss of riparian habitat, which is expected to result in a minimal effect on valley elderberry longhorn beetle because much of the riparian habitat in the project area is not known to be currently occupied by the species, because all elderberry shrubs that are suitable for transplantation would be moved to conservation areas in the project area, and because most of the affected community is composed of small patches of riparian scrub and herbaceous vegetation that are fragmented and distributed across the agricultural landscape of the project area and thus are likely to provide no or low-value habitat for the beetle.
- Temporarily disturbed areas would be restored within 1 year following completion of construction and management activities. Under AMM10, a restoration and monitoring plan would be developed prior to initiating any construction-related activities associated with the

Environmental Commitments or other project activities that would result in temporary effects on natural communities.

NEPA Effects: In the absence of actions to compensate and avoid and minimize effects, the losses of valley elderberry longhorn beetle habitat and potential for direct mortality of a special-status species associated with Alternative 4A would represent an adverse effect. However, with habitat protection and restoration associated with Environmental Commitment 7, Resource Restoration and Performance Principles VELB1 and VELB2, and by AMM1–AMM6, AMM10, and AMM15, the effects of Alternative 4A as a whole on valley elderberry longhorn beetle would not be adverse under NEPA.

CEQA Conclusion: Considering the protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for habitats lost to construction and restoration activities, together with Resource Restoration and Performance Principles VELB1 and VELB2, implementation of Alternative 4A as a whole would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the alternative would have a less-than-significant impact on valley elderberry longhorn beetle under CEQA.

Impact BIO-36: Indirect Effects on Valley Elderberry Longhorn Beetle and its Habitat

Construction activities associated with water conveyance facilities, habitat restoration, and habitat enhancement, as well as operation and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic post-construction disturbances with localized impacts on valley elderberry longhorn beetle. Construction related effects could result from ground-disturbing activities, stockpiling of soils, and maintenance and refueling of heavy equipment could result in dust and the inadvertent release of hazardous substances in areas where elderberry shrubs occur. A GIS analysis estimates that approximately 37 shrubs could be indirectly affected by conveyance facilities construction (see Section 12.3.2.3, *Methods Used to Assess Species Effects*, for a discussion of the methods used to make this estimate). Restoration activities could result in excavation or modification of channels, and type conversion from riparian and grasslands to other habitats, that occur within 100 feet of an elderberry shrubs. These potential effects would be minimized or avoided through AMM1–AMM6, AMM10, and AMM15.

NEPA Effects: With the implementation of AMM1–AMM6, AMM10, and AMM15 as part of Alternative 4A construction, operations, and maintenance, substantial adverse indirect effects on valley elderberry longhorn beetle would be avoided and minimized. The indirect effects on valley elderberry longhorn beetle as a result of implementing Alternative 4A environmental commitments would not have an adverse effect on valley elderberry longhorn beetle under NEPA.

CEQA Conclusion: With the implementation of AMM1–AMM6, AMM10, and AMM15 as part of Alternative 4A construction, operation, and maintenance, substantial adverse indirect effects on valley elderberry longhorn beetle would be avoided and minimized. Furthermore, the impacts from project would not result in a substantial reduction in numbers or a restriction in the range of valley elderberry longhorn beetle. Therefore, the indirect effects under this alternative would have a less-than-significant impact on valley elderberry longhorn beetle under CEQA.

Impact BIO-37: Periodic Effects of Inundation of Valley Elderberry Longhorn Beetle Habitat as a Result of Implementation of Alternative 4A

Alternative 4A would not result in periodic effects on valley elderberry longhorn beetle.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Nonlisted Vernal Pool Invertebrates

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of the environmental commitments, on nonlisted vernal pool invertebrates (Blennosperma vernal pool andrenid bee, hairy water flea, Ricksecker's water scavenger beetle, curved-foot hygrotus beetle, molestan blister beetle). Little is known about the range of these species so it is assumed that they have potential to occur in the same areas described by the vernal pool crustacean modeled habitat. That habitat model consists of: vernal pool complex, which consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly affected by agricultural or development practices; alkali seasonal wetlands in CZ 8; and degraded vernal pool complex, which consists of low-value ephemeral habitat ranging from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. For the purpose of the effects analysis, vernal pool complex is categorized as high-value and degraded vernal pool complex is categorized as low-value for these species. Alkali seasonal wetlands in CZ 8 were also included as high-value habitat for vernal pool crustaceans in the model. Also included as low-value for vernal pool habitat are areas along the eastern boundary of CZ 11 that are mapped as vernal pool complex because they flood seasonally and support typical vernal pool plants, but do not include topographic depressions that are characteristic of vernal pools.

Alternative 4A would result in permanent losses of habitat for nonlisted vernal pool invertebrates as indicated in Table 12-4A-14 and indirect conversions of vernal pool habitat. Alternative 4A would also include the following environmental commitments and associated Resource Restoration and Performance Principles that would benefit nonlisted vernal pool invertebrates.

- Protect up to 188 acres of existing vernal pool/alkali seasonal wetland complex (Environmental Commitment 3) in the greater Byron Hills area primarily in core vernal pool recovery areas identified in the *Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon* (U.S. Fish and Wildlife Service 2005) (Resource Restoration and Performance Principles VP/AW1)
- Restore vernal pool complex and alkali seasonal wetland suitable for vernal pool invertebrates to achieve no net loss of wetted acreage (Environmental Commitment 9, Resource Restoration and Performance Principles VP/AW2).
- Increase size and connectivity of protected vernal pool complexes and alkali seasonal wetlands in the greater Byron Hill area (Resource Restoration and Performance Principles VP/AW3).
- Provide appropriate seasonal flooding characteristics for supporting and sustaining vernal pool and alkali seasonal wetland complex species (Resource Restoration and Performance Principles VP/AW4).

As explained below, with the restoration and protection of these amounts of habitat, impacts on nonlisted vernal pool invertebrates would not be adverse for NEPA purposes and would be less-than significant for CEQA purposes.

Table 12-4A-14. Changes in Nonlisted Vernal Pool Invertebrate Habitat Associated with Alternative 4A (acres)[a]

Project Component	Habitat Type	Permanent	Temporary	Indirect
Water Conveyance Facilities	High-value (vernal pool complex and alkali seasonal wetland complex)	13	1	42
	Low-value (degraded vernal pool complex)	7	2	0
Total Impacts Water Conveyance Facilities		**20**	**3**	**41**
Environmental Commitments 4, 6–7, 9–11[a]	High-value (vernal pool complex and alkali seasonal wetland complex)	17	0	3
	Low-value (degraded vernal pool complex)	8	0	1
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**25**	**0**	**4**
TOTAL IMPACTS		**45**	**3**	**46**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-38: Loss or Conversion of Habitat for and Direct Mortality of Nonlisted Vernal Pool Invertebrates

Alternative 4A would result in the direct, permanent and temporary loss combined of 48 acres of vernal pool habitat from conveyance facilities construction and tidal restoration. In addition, conveyance construction and tidal restoration could result in the indirect conversion due to hydrologic alteration of an additional 46 acres of vernal pool complex. Construction of the water conveyance facilities may result in the modification of hardpan and changes to the perched water table, which could lead to alterations in the rate, extent, and duration of inundation of nearby vernal pool habitat. USFWS typically considers construction within 250 feet of vernal pools to constitute an indirect effect unless more detailed information is provided to further refine the limits of any such effects. For the purposes of this analysis, the 250-foot buffer was applied to the water conveyance facilities work areas where surface and subsurface disturbance activities would take place. Habitat enhancement and management activities (Environmental Commitment 11), which include disturbance or removal of nonnative vegetation, could result in local adverse habitat effects.

As specified in *AMM12 Vernal Pool Crustaceans* and *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, restoration projects would be designed such that no more than a total of 10 wetted acres of vernal pool crustacean habitat are permanently lost. AMM12 would also ensure that no more than 20 wetted acres of vernal pool crustacean habitat are indirectly affected by alterations to hydrology resulting from adjacent habitat restoration activities, in particular tidal restoration. *AMM30 Transmission Line Design and Alignment Guidelines* would ensure that transmission lines avoid removal of wetted acres of vernal pools and alkali seasonal wetlands wetted acres of aquatic habitats to the maximum extent feasible. The term wetted acres refers to an area that would be defined by the three parameter wetland delineation method used by the U.S. Army Corps of Engineers to determine the limits of a wetland, which involve an evaluation of wetland soil, vegetation, and hydrology characteristics. This acreage differs from vernal pool complex acreages in that a vernal pool complex is composed of individual wetlands (vernal pools) and those upland areas that are in between and surrounding them, which provide the supporting hydrology (surface runoff and groundwater input), organic and nutrient inputs, and refuge for the terrestrial phase of some vernal pool species.

A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation*: Construction of Alternative 4A conveyance facilities would result in the permanent and temporary combined loss of approximately 23 acres of vernal pool habitat, composed of 14 acres of high-value and 9 acres of low-value habitat (Table 12-4A-14). In addition, the conveyance facilities could result in the indirect conversion of 42 acres of vernal pool habitat in the vicinity of Clifton Court Forebay. The indirect effects would result from the construction of permanent transmission lines, from the storage of reusable tunnel material, and permanent access roads. *AMM30 Transmission Line Design and Alignment Guidelines* would ensure that temporary transmission lines are designed to avoid removal wetted acres of aquatic habitats to the maximum extent practicable. There are no records of these nonlisted vernal pool invertebrates at this location (California Department of Fish and Game 2013).

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Implementation would result in the conversion of an estimated 25 acres of modeled vernal pool habitat (17 acres of high-value and 8 acres low-value habitat). Tidal restoration would also result in the indirect conversion of an estimated 4 acres of modeled vernal pool habitat. The effects would take place in one or more of the ROAs established for tidal restoration (see Figure 12-1).

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Alternative 4A's restoration/creation of vernal pools to achieve no net loss and the protection of up to 188 acres of vernal pool/alkali seasonal wetland complex would benefit vernal pool invertebrates. A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in protected habitats may result in localized ground disturbances that could temporarily affect vernal pool invertebrate habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on vernal pool invertebrate habitat and are expected to result in overall improvements to and maintenance of vernal pool habitat values. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.

The following paragraphs summarize the combined effects discussed above and describe other environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

The proposed conservation efforts have been evaluated to determine whether they would provide sufficient habitat protection and restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA and would be less than significant under CEQA. Table 12-4A-14 above lists the impacts on nonlisted vernal pool invertebrate habitat that are based on the natural community mapping done within the study area. Table 12-4A-15 was prepared to further analyze the project's effects on vernal pool invertebrates using wetted acres of habitat in order to compare the effects of this alternative with the effect limits established in *AMM12 Vernal Pool Crustaceans*, which are measured in wetted acres of habitat. Wetted acres were estimated by using the BDCP's assumption that restored vernal pool complexes would have a 15% density of vernal pools (i.e., of 100 acres of vernal pool complex 15 acres would constitute vernal pools and the remaining 85 acres supporting uplands). Based on an informal evaluation of aerial photographs of the project area, it is likely that the actual densities within the project area are approximately 10%, but the 15% density value was chosen as a conservative estimate for determining effects.

Table 12-4A-15. Estimated Effects on Wetted Vernal Pool Crustacean Habitat under Alternative 4A (acres)

	Direct Loss	Indirect Conversion
AMM 12 Impact Limit	10	20
Water Conveyance Facilities[a]	3.45	6.30
Environmental Commitments 4, 6–7, 9–11	3.75	0.60
Total	**7.2**	**6.9**

[a] These acreages were generated by assuming that the modeled habitat identified in Table 12-4A-14 has densities of wetted habitat at 15%. The direct effects numbers include permanent and temporary impacts.

Typical NEPA and CEQA project-level mitigation ratios for loss of vernal pools affected by Alternative 4A would be 1:1 for restoration and 2:1 for protection. Typically, indirect conversion impacts are mitigated by protecting vernal pools at a 2:1 ratio. Using these typical ratios would indicate that 7.2 wetted acres of vernal pool habitat (48 acres of vernal pool/alkali seasonal wetland complex) should be restored and 28.2 wetted acres of vernal pool habitat (188 acres of vernal pool/alkali seasonal wetland complex) protected to mitigate Alternative 4A's direct and indirect effects on nonlisted vernal pool species habitat. With the implementation of AMM30, the effects on aquatic habitat would be avoided to the maximum extent feasible during the designing of the transmission line west of Clifton Court Forebay.

Project proponents would commit to protecting 188 acres of vernal pool/alkali seasonal wetland complex by protecting at least 2 wetted acres of vernal pools protected for each wetted acre directly or indirectly affected. Alternative 4A also includes a commitment to restore or create vernal pools such that the project would result in no net loss of vernal pool acreage. The amount of restoration would be determined during implementation based on the following criteria, which would satisfy Resource Restoration and Performance Principle VP/AW2.

- If restoration is completed (i.e., restored natural community meets all success criteria) prior to impacts, then 1.0 wetted acre of vernal pools would be restored for each wetted acre directly affected (1:1 ratio).
- If restoration takes place concurrent with impacts (i.e., restoration construction is completed, but restored habitat has not met all success criteria prior to impacts occurring), then 1.5 wetted acres of vernal pools would be restored for each wetted acre directly affected (1.5:1 ratio).

The protection and restoration would be achieved by implementation of the following the Resource Restoration and Performance Principles.

- Protect existing vernal pool complex in the greater Byron Hills area primarily in core vernal pool recovery areas identified in the *Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon* (U.S. Fish and Wildlife Service 2005) (Resource Restoration and Performance Principles VP/AW1).
- Increase size and connectivity of protected vernal pool complexes and alkali seasonal wetlands in the greater Byron Hill area (Resource Restoration and Performance Principles VP/AW3).
- Provide appropriate seasonal flooding characteristics for supporting and sustaining vernal pool and alkali seasonal wetland complex species (Resource Restoration and Performance Principles VP/AW4).

Alternative 4A also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM30 Transmission Line Design and Alignment Guidelines*. *AMM12 Vernal Pool Crustaceans*, though developed for vernal pool crustaceans, includes measures to avoid and minimize direct and indirect effects on vernal pools and would thus be applicable to nonlisted vernal pool invertebrates as well. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of vernal pool habitat under Alternative 4A would not be adverse under NEPA because project proponents would commit to avoiding and minimizing effects from and to restoring and protecting an acreage that meets the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles VP/AW1-VP/AW4, and by AMM1–AMM6, AMM10, AMM12, and AMM30, which would be in place throughout the time period of construction and operations. Considering these commitments, losses and conversions of nonlisted vernal pool invertebrates habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on nonlisted vernal pool invertebrate habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of actions to compensate, avoid, and minimize impacts. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 9, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principles VP/AW1-VP/AW4, and by AMM1–AMM6, AMM10, AMM12, and AMM30, which would be in place throughout the period of construction and operations. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of nonlisted vernal pool invertebrates. Therefore, Alternative 4A would have a less-than-significant impact on nonlisted vernal pool invertebrates under CEQA.

Impact BIO-39: Indirect Effects of Alternative 4A on Nonlisted Vernal Pool Invertebrates

Construction and maintenance activities associated with water conveyance facilities, and restoration actions could indirectly affect nonlisted vernal pool invertebrates and their habitat in the vicinity of construction and restoration areas, and maintenance activities. Ground-disturbing activities, stockpiling of soils, and maintenance and refueling of heavy equipment could result in the inadvertent release of sediment and hazardous substances into this habitat. Vernal pools could be periodically indirectly affected by maintenance activities at water conveyance facilities. Embankment maintenance activities around Clifton Court Forebay could result in the inadvertent discharge of sediments and hazardous materials into nonlisted vernal pool invertebrate habitat that occurs along the southern and western boundaries of the forebays.

NEPA Effects: Water conveyance facilities construction and restoration activities could indirectly affect nonlisted vernal pool invertebrates and their habitat in the vicinity of construction areas. These potential effects would be avoided and minimized through AMM1–AMM6, and AMM10 which would be in effect throughout the period of construction and operations. The indirect effects of Alternative 4A on nonlisted vernal pool invertebrates would not be adverse under NEPA.

CEQA Conclusion: Construction and maintenance activities associated with water conveyance facilities, and restoration actions could indirectly impact nonlisted vernal pool invertebrates and their habitat in the vicinity of construction and restoration areas, and maintenance activities. These potential impacts would be minimized or avoided through AMM1–AMM6, and AMM10, which would be in effect throughout period of construction and operations. The indirect impacts of Alternative 4A on nonlisted vernal pool invertebrates would be less than significant under CEQA.

Impact BIO-40: Periodic Effects of Inundation of Nonlisted Vernal Pool Invertebrates' Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on nonlisted vernal pool invertebrates.

***NEPA Effects*:** No effect.

CEQA Conclusion: No impact.

Sacramento and Antioch Dunes Anthicid Beetles

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of the Environmental Commitments, on Sacramento and Antioch Dunes anthicid beetles. Potential habitat in the study area includes the inland dune scrub at Antioch Dunes NWR, sand bars along the Sacramento and San Joaquin Rivers, and sandy dredge spoil piles (California Department of Fish and Game 2006c and 2006d).

The construction, and operations and maintenance of the water conveyance facilities under Alternative 4A would not likely affect Sacramento and Antioch Dunes anthicid beetles. The construction of the water conveyance structure and associated infrastructure would generally avoid affects to channel margins where sand bars are likely to form. Conveyance construction would not affect inland dune scrub habitat at Antioch Dunes NWR. No dredge spoil areas that could be occupied by Sacramento anthicid beetle were identified within conveyance facilities footprints during a review of Google Earth imagery. Also, a review of the locations of the Alternative 4A water intake facilities on aerial imagery did not reveal any sandbars along the channel margins. These portions of the Sacramento River have steep, riprap lined channel banks that are likely not conducive to the formation of sandbars.

Implementation of Alternative 4A restoration measures could affect habitat for Sacramento and Antioch Dunes anthicid beetles. Both species are known to utilize interior sand dunes and sandbar habitat. The only interior sand dune habitat within the project area is at Antioch Dunes, which would not be impacted by the Alternative 4A Environmental Commitments. Both species are known to occur along the Sacramento River and San Joaquin Rivers. The implementation of Alternative 4A restoration actions could affect habitat for Sacramento and Antioch Dunes anthicid beetles along channels throughout the project area; however the extent of these habitats in the project area is unknown because these areas were not identified at the scale of mapping done within the study area. Because of current and historic channel modifications (channel straightening and dredging) and levee construction throughout the Delta, sandbar habitat is likely very limited and restricted to channel margins. The implementation of *Environmental Commitment 4 Tidal Natural Communities*

Restoration and *Environmental Commitment 6 Channel Margin Enhancement* could impact sandbar habitat along the river channels and possibly sandy, dredge piles on Delta islands.

Alternative 4A would likely result in beneficial effects on Sacramento and Antioch Dunes anthicid beetles. The following Alternative 4A Environmental Commitments would generally increase opportunities for the formation of sandbars in the project area.

- As stated in Environmental Commitment 6, 4.6 miles of channel margin habitat would be enhanced.
- Restore up to 251 acres of riparian habitat (Environmental Commitment 7).
- Protect up to 103 acres of riparian habitat (Environmental Commitment 3).

These measures would improve shoreline conditions by creating benches along levees, shallow habitat along margins, and increasing shoreline vegetation, all of which would likely contribute to the formation of sandbars along Delta river channels where these measures would be implemented. Increasing the structural diversity of Delta river channel margins would create opportunities for sand to be deposited and for sandbars to subsequently form. As explained below, potential impacts on Sacramento and Antioch Dunes anthicid beetle would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-16. Changes in Sacramento and Antioch Dunes Anthicid Beetles' Habitat Associated with Alternative 4A (acres)[a]

Project Component	Permanent	Temporary
Total Impacts Water Conveyance Facilities	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]	Unknown	Unknown
TOTAL IMPACTS	**Unknown**	**Unknown**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-41: Loss or Conversion of Habitat for and Direct Mortality of Sacramento and Antioch Dunes Anthicid Beetles

Implementation of Alternative 4A Environmental Commitments could affect Sacramento and Antioch Dunes anthicid beetles and their habitat. As mentioned above, the full extent of this habitat in the study area is unknown but it is assumed that sand bars likely occur to some degree along the Sacramento and San Joaquin Rivers and that some islands in the Delta may contain sandy dredge spoil piles. A review of Google Earth imagery in the north Delta did identify three general areas that appear to have accumulations of sandy soils (with some vegetation), possibly from dredge disposal, are Decker Island, the western portion of Bradford Island, and the southwestern tip of Grand Island. A review of Google Earth imagery in the south Delta did identify sandbar habitat along the San Joaquin River from the southern end of the project area downstream to an area just west of Lathrop. An additional area along Paradise Cut was identified just north of I-5. Environmental Commitments that could result in impacts on Sacramento and Antioch Dunes anthicid beetles are tidal habitat restoration (Environmental Commitment 4) and channel margin enhancement (Environmental Commitment 6). In addition, maintenance activities associated with the long-term operation of the water conveyance facilities could degrade or eliminate habitat for Sacramento and Antioch Dunes anthicid beetles. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal natural communities restoration could impact the areas of sandy soils identified from aerial photographs on Decker Island, the western portion of Bradford Island, and on the southwestern tip of Grand Island because these areas fall within the West Delta Restoration Opportunity Area (ROA). The methods and techniques for tidal restoration may include the recontouring of lands so that elevations are suitable for the establishment of marsh plains and the eventual breaching of levees. There are three CNDDB records of Sacramento anthicid beetle (just north of Rio Vista, one just south of Rio Vista along the west shore of the Sacramento River, and one on Grand Island) and one CNDDB record of Antioch Dunes anthicid beetle (just north of Rio Vista) that fall within the West Delta ROA (California Department of Fish and Wildlife 2013). Tidal restoration actions in the West Delta ROA may eliminate potential habitat and impact occupied habitat of both Sacramento and Antioch Dunes anthicid beetles.
- *Environmental Commitment 6 Channel Margin Enhancement*: Channel margin enhancement could result in impacts on 4.6 miles of channel margin that could contain sandbars.

The following paragraphs summarize the combined effects discussed above and describe other Environmental Commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Alternative 4A could result in substantial effects on Sacramento and Antioch Dunes anthicid beetles because all of the habitat identifiable from aerial photo review falls within either the West Delta ROA, which may be considered for tidal restoration (Environmental Commitment 4). Furthermore, three of the records for Sacramento anthicid beetle within the study area fall within areas being considered for tidal restoration (Environmental Commitment 4), which represents approximately one quarter of the extant records for this species range wide (3 of 13). The only extant record for Antioch Dunes anthicid beetle, which represents one of five extant records range wide, falls within the West Delta ROA that is just north of Rio Vista. These occurrences could be affected if tidal restoration occurs in these areas. However, considering all of the Environmental Commitments under Alternative 4A, Sacramento and Antioch Dunes anthicid beetles would likely benefit from the project. Under Alternative 4A, Environmental Commitment 6, and Environmental Commitment 7, would generally contribute to the formation of sandbar habitat in the project area. These measures would improve shoreline conditions by creating benches along levees (Environmental Commitment 6) and increasing shoreline vegetation (Environmental Commitment 7), all of which would likely contribute to the formation of sandbars along Delta river channels where these measures would be implemented. Increasing the structural diversity of Delta river channel margins would create areas of slow water that would allow for sand to be deposited and for sandbars to subsequently form.

NEPA Effects: The potential impacts on Sacramento and Antioch Dunes anthicid beetles associated with Alternative 4A as a whole would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of other means to compensate for, avoid, and/or minimize impacts. However, considering the implementation of restoration associated with Environmental Commitment 6 and Environmental Commitment 7 the effects of Alternative 4A as a whole on Sacramento and Antioch Dunes anthicid beetles would not be adverse under NEPA.

CEQA Conclusion: Alternative 4A would potentially impact Sacramento and Antioch Dunes anthicid beetles' habitat and could impact three occurrences of Sacramento anthicid beetle and one occurrence of Antioch Dunes anthicid beetle. However, the implementation of the Environmental Commitments would likely benefit Sacramento and Antioch Dunes anthicid beetles. Environmental

Commitment 6 and Environmental Commitment 7 would generally contribute to the formation of sandbar habitat in the project area. Alternative 4A as a whole would not result in a substantial adverse effect though habitat modification and would not substantially reduce the number or restrict the range of these species. Therefore, the alternative would have a less-than-significant impact on Sacramento and Antioch Dunes anthicid beetles under CEQA.

Delta Green Ground Beetle

Suitable habitat in the study area would be vernal pool complexes and annual grasslands in the general Jepson Prairie area. The construction, and operations and maintenance of the water conveyance facilities under Alternative 4A would not affect delta green ground beetle because the facilities and construction area are outside the known range of the species. Implementation of Alternative 4A could affect delta green ground beetle through the potential protection of grasslands (Environmental Commitment 3) in the vicinity of Jepson Prairie and the subsequent implementation of habitat enhancement and management actions (Environmental Commitment 11) in these areas. In addition, tidal natural communities restoration (Environmental Commitment 4) and vernal pool and alkali seasonal wetland complex restoration (Environmental Commitment 9) could result in potential impacts on delta green ground beetle and its habitat. Alternative 4A could result in beneficial effects on delta green ground beetle through the protection of grasslands it occurs in CZ 1.

These areas could contain currently occupied habitat for delta green ground beetle and/or create conditions suitable for eventual range expansion. As explained below, potential impacts on delta green ground beetle would be adverse for NEPA purposes and would be significant for CEQA purposes. Mitigation Measure BIO-42 would reduce the effects under NEPA and reduce the impacts to a less-than-significant level under CEQA.

Table 12-4A-17. Changes in Delta Green Ground Beetle Habitat Associated with Alternative 4A (acres)[a]

Project Component	Permanent	Temporary
Total Impacts Water Conveyance Facilities	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]	Unknown	Unknown
TOTAL IMPACTS	**Unknown**	**Unknown**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-42: Loss or Conversion of Habitat for and Direct Mortality of Delta Green Ground Beetle

Alternative 4A Environmental Commitments could result in the conversion of habitat and/or direct mortality to delta green ground beetle. Environmental Commitments that could affect delta green ground beetle include tidal natural communities habitat restoration (Environmental Commitment 4), vernal pool and alkali seasonal wetland complex restoration (Environmental Commitment 9),and habitat enhancement and management activities (Environmental Commitment 11) in CZ 1. CZ 1 is the only portion of the project area that contains occupied and potential habitat for delta green ground beetle. The range of the delta green ground beetle is currently believed to be generally bound by Travis Air Force Base to the west, Highway 113 to the east, Hay Road to the north, and Creed Road to the south (Arnold and Kavanaugh 2007; U.S. Fish and Wildlife Service 2009a). Further discussion of this potential effect is provided below, and NEPA and CEQA conclusions follow.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal restoration in the Cache Slough ROA could result in the loss of delta green ground beetle habitat if restoration is planned in areas known to be or potentially occupied by the species. The tidal restoration methods and techniques identified in Environmental Commitment 4 include excavating channels; modifying ditches, cuts, and levees to encourage tidal circulation; and scalping higher elevation areas to create marsh plains. These disturbances could affect delta green ground beetle through habitat modification, either directly or indirectly through hydrologic modifications, and/or result in direct mortality to the species.

- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: Vernal pool restoration may occur in CZ 1 and could result in disturbance to delta green ground beetle habitat if restoration is implemented in areas known to be or potentially occupied by the species. These restoration activities would most likely take place in areas that were historically vernal pool complexes that have since been highly degraded, but which are suitable for vernal pool restoration. These areas would not likely provide habitat for delta green ground beetle. However, if these activities take place in areas more suitable, then disturbances could result in direct mortality of the species. Nevertheless, restoration ultimately would expand habitat available to the species.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Grasslands would potentially be protected in CZ 1. Potential effects from Environmental Commitment 11 could include direct mortality to larvae and adults from the implementation of grassland management techniques, which may include livestock grazing, prescribed burning, and mowing. In addition to these grassland management actions, Environmental Commitment 11 also includes guidelines and techniques for invasive plant control, which may include manual control (hand-pulling and digging), mechanical control (large equipment), and chemical control, though some of these methods would be restricted in areas where rare plants occur or in critical habitat for vernal pool species.

NEPA Effects: The potential protection of grassland in CZ 1 (Environmental Commitment 3) could benefit delta green ground beetle if these areas occur within the range of the species. Tidal natural communities restoration (Environmental Commitment 4), and vernal pool and alkali seasonal wetland complex restoration (Environmental Commitment 9) could impact delta green ground beetle. The management of these grasslands according to *Environmental Commitment 11 Natural Communities Enhancement and Management* has a potential to affect this species. Direct mortality and the affects on delta green ground beetle habitat would be an adverse effect under NEPA. Implementation of mitigation measure BIO-42, *Avoid Impacts on Delta Green Ground Beetle and its Habitat*, would reduce this effect.

CEQA Conclusion: The implementation of grassland protection (Environmental Commitment 3), tidal natural communities restoration (Environmental Commitment 4), and vernal pool and alkali seasonal wetland complex restoration (Environmental Commitment 9) could impact delta green ground beetle. Tidal restoration projects around Calhoun Cut and possible Lindsey Slough could affect habitat and result in direct mortality to the species from excavating channels; modifying ditches, cuts, and levees to encourage tidal circulation; and scalping higher elevation areas to create marsh plains. Potential impacts from Environmental Commitment 11 could include direct mortality to larvae and adults resulting from grassland management techniques, which may include livestock grazing, prescribed burning, and mowing. Environmental Commitment 11 also includes guidelines and techniques for invasive plant control, which may include manual control (hand-pulling and digging), mechanical control (large equipment), and chemical control, though some of these methods would be restricted in areas where rare plants occur and in critical habitat for vernal pool species. These actions could result in adverse effects through habitat modification and a possible reduction in the number of the species or restrict its range, and therefore result in significant impacts on delta green ground beetle. Implementation of Mitigation Measure BIO-42, *Avoid Impacts on Delta Green Ground Beetle and its Habitat*, would reduce these potential impacts to a less-than-significant level.

Mitigation Measure BIO-42: Avoid Impacts on Delta Green Ground Beetle and its Habitat

As part of the design and development of management plans for conservation areas in the area of Jepson Prairie, the project proponents will implement the following measures to avoid effects on delta green ground beetle.

- If habitat restoration or protection is planned for the lands adjacent to Calhoun Cut and noncultivated lands on the western side of Lindsey Slough, these area will be evaluated by a USFWS approved biologist for potential delta green ground beetle habitat (large playa pools, or other similar aquatic features, with low growing vegetation or bare soils around the perimeter). The biologist will have previous experience with identifying suitable habitat requirements for delta green ground beetle.
- Any suitable habitat identified by the biologist (with previous experience with delta green ground beetle) within the species current range will be considered potentially occupied and all ground disturbing activities in these areas will be avoided, which for the project area is generally the area west of State Route 113.
- Any other areas identified as suitable habitat outside of the current range of the species will be surveyed by a biologist with previous experience in surveying for and identifying delta green ground beetle. No ground disturbing activities will be implemented in areas identified as occupied by delta green ground beetle.
- Based on the results of the habitat evaluations and surveys and site-specific restoration and management plans will be developed so that they don't conflict with the recovery goals for delta green ground beetle in the USFWS's 2005 *Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon* (U.S. Fish and Wildlife Service 2005). Plans will include measures to protect and manage for delta green ground beetle so that they continue to support existing populations or allow for future colonization.

Callippe Silverspot Butterfly

This section describes the effects of Alternative 4A on callippe silverspot butterfly. Suitable habitats are typically in areas influenced by coastal fog with hilltops that support the specie's host-plant, Johnny jump-ups. Preferred nectar flowers used by adults include thistles, blessed milk thistle, and coyote wild mint. Other native nectar sources include hairy false goldenaster, coast buckwheat, mourning bride, and California buckeye. Suitable habitat in the study area is located in CZ 11 in the Cordelia Hills west of I-680 and in the Potrero Hills on the northern edge of Suisun Marsh. The construction, and operations and maintenance of the water conveyance facilities under Alternative 4A would not result in impacts on callippe silverspot butterfly or its habitat. If Cordelia Hills and Potrero Hills are identified for grassland protection opportunities as part of *Environmental Commitment 3 Natural Communities Protection and Restoration* and the subsequent implementation of *Environmental Commitment 11 Natural Communities Enhancement and Management,* could affect callippe silverspot butterfly. Callippe silverspot butterfly has been documented in the western most portion of the project area (CZ 11) in the Cordelia Hills (Solano County Water Agency 2009). Potential habitat for the species (grassy hills with *Viola pedunculata*) is present in the Potrero Hills, but it has not been observed there (EDAW 2005, California Department of Fish and Wildlife 2013). Alternative 4A would protect up to 1,060 acres of grassland, some of which may occur in areas in CZ 11 that contain habitat for callippe silverspot butterfly. As explained below, potential impacts on callippe silverspot would be adverse for NEPA purposes and would be significant for CEQA purposes. Mitigation Measure BIO-43 would reduce the effects under NEPA and reduce the impacts to a less-than-significant level under CEQA.

Table 12-4A-18. Changes in Callippe Silverspot Butterfly Habitat Associated with Alternative 4A (acres)[a]

Project Component	Permanent	Temporary
Total Impacts Water Conveyance Facilities	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]	Unknown	Unknown
TOTAL IMPACTS	**Unknown**	**Unknown**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-43: Loss or Conversion of Habitat for and Direct Mortality of Callippe Silverspot Butterfly

Alternative 4A Environmental Commitments could result in the conversion of habitat and/or direct mortality to callippe silverspot butterfly. Only one Environmental Commitment was identified as potentially affecting Callippe silverspot butterfly, *Environmental Commitment 11 Natural Communities Enhancement and Management*, which could result in the disturbance of callippe silverspot butterfly habitat if such areas are acquired as part of grassland protection under *Environmental Commitment 3 Natural Communities Protection and Restoration*. Further discussion of this potential effect is provided below and NEPA and CEQA conclusions follow.

Up to 1,060 acres of grasslands would be protected in the project area, some of which may occur in CZ 11. If areas chosen for protection include Cordelia Hills or Potrero Hills, where there is known and potential habitat, respectively, then grassland enhancement and management actions could affect the callippe silverspot butterfly. Potential effects from Environmental Commitment 11 could include the loss of larval host and nectar sources and direct mortality to larvae and adults from the installation of artificial nesting burrows and structures and the implementation of grassland management techniques, which may include livestock grazing, prescribed burning, and mowing. In addition to these grassland management actions, Environmental Commitment 11 also includes guidelines and techniques for invasive plant control, which may include manual control (hand-pulling and digging), mechanical control (large equipment), and chemical control. Several of the preferred nectar sources are thistles, some of which have been identified by the California Invasive Plant Council as having limited to moderate ecological impacts (California Invasive Plant Council 2006).

NEPA Effects: The protection of up to 1,060 acres of grassland some of which may occur within CZ 11 could benefit callippe silverspot butterfly if these protected areas include occupied and potential habitat on the hill tops in Cordelia Hills and Potrero Hills. However, the management of these grasslands according to *Environmental Commitment 11 Natural Communities Enhancement and*

Management also has a potential to adversely affect this species. Direct mortality and/or the removal of larval host plants and nectar sources for adults would be an adverse effect under NEPA. Implementation of Mitigation Measure BIO-43, *Avoid and Minimize Loss of Callippe Silverspot Butterfly Habitat*, would ensure the effect is not adverse under NEPA.

CEQA Conclusion: If grasslands within the Cordelia Hills and Potrero Hills are protected as part of *Environmental Commitment 3 Natural Communities Protection and Restoration* then the subsequent management of these grasslands according to *Environmental Commitment 11 Natural Communities Enhancement and Management* has a potential to affect this species. These actions could result in adverse effects through habitat modification and a possible reduction in the number of the species or restrict its range and would therefore result in significant impact on the species under CEQA. However, callippe silverspot butterfly could benefit from the protection of occupied and potential habitat for the species with the implementation of Mitigation Measure BIO-43, which would avoid and minimize effects from management actions and thus reduce the potential impact to a less-than-significant level under CEQA.

Mitigation Measure BIO-43: Avoid and Minimize Loss of Callippe Silverspot Butterfly Habitat

As part of the development of site-specific management plans on protected grasslands in the Cordelia Hills and/or Potrero Hills, project proponents will implement the following measures to avoid and minimize the loss of callippe silverspot habitat.

- Hilltops in Cordelia Hills and Potrero Hills will be surveyed for callippe silverspot larval host plants (Johnny jump-ups) by a biologist familiar with identifying this plant species. These surveys should occur during the plant's blooming period (typically early January through April)
- If larval host plants are present, then presence/absence surveys for callippe silverspot butterfly larvae will be conducted according to the most recent USFWS approved survey methods by a biologist with previous experience in surveying for and identifying callippe larvae and/or signs of larval presence. These surveys should be conducted prior to the adult flight season, which usually starts in mid-May.
- If larvae are detected then no further surveys are necessary. If larvae are not detected then surveys for adults will be conducted by a biologist familiar with surveying for and identifying callippe silverspot. Surveys typically start in mid-May and continue weekly for 8 to 10 weeks.
- If callippe silverspot butterflies are detected, then the site-specific management plans will be written to include measures to protect and manage for larval host plants and nectar sources so that they continue to support existing populations and/or allow for future colonization. Mapping of both larval host plants and nectar sources will be incorporated into the management plans.

California Red-Legged Frog

Modeled California red-legged frog habitat in the study area is restricted to freshwater aquatic and grassland habitat, and immediately adjacent cultivated lands along the study area's southwestern edge in CZ 7, CZ 8, CZ 9, and CZ 11. Pools in perennial and seasonal streams and stock ponds provide potential aquatic habitat for this species. While stock ponds are underrepresented as a modeled habitat, none is expected to be affected by project actions.

Alternative 4A would result in both temporary and permanent losses of California red-legged frog modeled habitat as indicated in Table 12-4A-19. Factors considered in assessing the value of affected habitat for the California red-legged frog, to the extent that information is available, are presence of limiting habitat (aquatic breeding habitat), known occurrences and clusters of occurrences, proximity of the affected habitat to existing protected lands, and the overall degraded or fragmented nature of the habitat. The study area represents the extreme eastern edge of the species' coastal range, and species' occurrences are reported only from CZ 8 and CZ 11.

Alternative 4A would include the following Environmental Commitments and associated Resource Restoration and Performance Principles to benefit the California red-legged frog.

- Protect and improve habitat linkages that allow terrestrial species to move between protected habitats within and adjacent to the project area (Resource Restoration and Performance Principle L2).
- Protect up to 647 acres of grassland in the Byron Hills area where practicable and/or in other appropriate locations (Environmental Commitment 3, Resource Restoration and Performance Principle G10).
- Protect up to 188 acres and restore up to 48 acres of existing vernal pool/alkali seasonal wetlands complexes in the greater Byron Hills including associated grasslands (Environmental Commitment 3, Environmental Commitment 9, and Resource Restoration and Performance Principle VP/AW1) with the grassland portions expected to benefit California red-legged frog.
- Increase burrow availability for burrow-dependent species in grasslands surrounding all suitable aquatic habitat including stock ponds and vernal pool/alkali seasonal wetland complexes (Resource Restoration and Performance Principles G5, VP/AW6).
- Increase native species diversity and relative cover of native plant species, and reduce the introduction and proliferation of nonnative species (Resource Restoration and Performance Principle L3).
- Protect up to 6 acres of stock ponds and other aquatic features within protected grasslands to provide aquatic breeding habitat for native amphibians and aquatic reptiles (Resource Restoration and Performance Principle G2).
- Maintain and enhance aquatic features in protected grasslands to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding for amphibian and aquatic reptile species (Resource Restoration and Performance Principle G7).

As explained below, with the restoration and protection of these amounts of habitat, in addition to implementation of AMMs to reduce potential effects, impacts on California red-legged frog would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-19. Changes in California Red-Legged Frog Modeled Habitat Associated with Alternative 4A (acres)

TOTAL IMPACTS		**33**	**32**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-44: Loss or Conversion of Habitat for and Direct Mortality of California Red-Legged Frog

Alternative 4A water conveyance facilities construction and Environmental Commitments would result in the permanent and temporary loss combined of up to 1 acre of modeled aquatic habitat and 64 acres of modeled upland habitat for California red-legged frog (Table 12-4A-19). Construction activities associated with the water conveyance facilities, including operation of construction equipment, could result in permanent and temporary effects on, as well as injury and mortality of, California red-legged frogs. In addition, natural enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. Maintenance activities associated with the long-term operation of the water conveyance facilities and other project facilities could degrade or eliminate California red-legged frog habitat including injury and mortality of California red-legged frogs. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual activity discussions.

- *Water Facilities and Operation*: Construction of Alternative 4A would result in the permanent loss of up to 1 acre of aquatic habitat and 21 acres of upland habitat for California red-legged frog in CZ 8 (Table 12-4A-19). Permanent effects would be associated with RTM, grading, paving, excavating, extension and installation of cross culverts, installation of structural hardscape, and installation and relocation of utilities. Construction-related effects would temporarily disturb 32 acres of upland habitat for the California red-legged frog (Table 12-4A-19). Although there are no California red-legged frog occurrences that overlap with the water conveyance facilities construction footprint there are a number of occurrences approximately 0.5 mile to the west of Clifton Court Forebay.

- *Environmental Commitment 11 Natural Communities Enhancement and Management* Protection of up to 647 acres of grassland, protection of up to 188 acres and restoration of up to 48 acres of existing vernal pool/alkali seasonal wetlands complexes in the greater Byron Hills including associated grasslands, and protection and restoration of up to 6 acres of aquatic habitat would benefit California red-legged frog. Activities associated with natural communities enhancement and management in protected California red-legged frog habitat, such as ground disturbance or herbicide use to control nonnative vegetation, could result in local adverse habitat effects on, and injury or mortality of, California red-legged frogs. These effects would be avoided and minimized with implementation of the AMMs discussed below. Herbicides would only be used in

California red-legged frog habitat in accordance with the written recommendation of a licensed, registered pest control advisor and in conformance with label precautions and federal, state, and local regulations in a manner that avoids or minimizes harm to the California red-legged frog. *AMM14 California Red-Legged Frog* would be implemented to ensure that California red-legged frog upland and aquatic habitats are avoided, as described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*.

- Critical habitat: Several Environmental Commitments would be implemented in California red-legged frog habitat and designated critical habitat in CZ 8 and CZ 11. Approximately 2,460 acres of designated critical habitat for the California red-legged frog overlaps with the study area along the western edge of CZ 11 in critical habitat unit SOL-1. An additional 862 acres of designated critical habitat is also present along the western edge of CZ 8 in critical habitat unit ALA-2. Environmental Commitments to protect and enhance grassland habitat for wildlife species, including California red-legged frog in CZ 8 could include acquisition and enhancement of designated critical habitat for the California red-legged frog and California tiger salamander. Any habitat enhancement actions for these species in designated critical habitat are expected to enhance the value of any affected designated critical habitat for conservation of California red-legged frog. These actions would result in an overall benefit to California red-legged frog within the study area through protection and management of grasslands with associated intermittent stream habitat and through restoration of vernal pool complex habitat and its associated grassland habitat.

- Operations and maintenance: Ongoing water conveyance facilities operation and maintenance is expected to have little if any adverse effect on the California red-legged frog. Postconstruction operation and maintenance of the above-ground water conveyance facilities could result in ongoing but periodic postconstruction disturbances that could affect California red-legged frog use of the surrounding habitat. Operation of maintenance equipment, including vehicle use along transmission corridors in CZ 8, could also result in injury or mortality of California red-legged frogs if present in work sites. Implementation environmental commitments and AMM1–AMM6, AMM10, and AMM14 would reduce these effects.

- Injury and direct mortality: Construction activities associated with the water conveyance facilities, stock pond and vernal pool complex restoration, and habitat and management enhancement-related activities, including operation of construction equipment, could result in injury or mortality of California red-legged frogs. Breeding, foraging, dispersal, and overwintering behavior may be altered during construction activities, resulting in injury or mortality of California red-legged frog. Frogs occupying burrows could be trapped and crushed during ground-disturbing activities. Degradation and loss of estivation habitat is also anticipated to result from the removal of vegetative cover and collapsing of burrows. Injury or mortality would be avoided and minimized through implementation of seasonal constraints and preconstruction surveys in suitable habitat, collapsing unoccupied burrows, and relocating frogs outside of the construction area as described in AMM1–AMM6, AMM10, and AMM14.

The following paragraphs summarize the combined effects discussed above and describe other Environmental Commitments and associated Resource Restoration and Performance Principles that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

There are approximately 159 acres of modeled aquatic habitat and 7,766 acres of modeled upland habitat for California red-legged frog in the study area. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 1 acre of aquatic habitat and 64 acres of upland habitat for California red-legged frog (less than 1% of the total aquatic habitat and total upland habitat in the study area).

These effects would result from construction of the water conveyance (54 acres) and other facilities (11 acres). The 1 acre of aquatic habitat that would be permanently lost is not known to be used for breeding. Most of the California red-legged frog upland habitat that would be removed consists of naturalized grassland or cultivated land in a highly disturbed or modified setting on lands immediately adjacent to Clifton Court Forebay. The removed upland cover and dispersal habitat is within 0.5 mile of a cluster of known California red-legged frog occurrences to the west. However, this habitat consists mostly of cultivated lands and small patches of grasslands, and past and current surveys in this area have not found any evidence that this habitat is being used (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*).

With full implementation of Alternative 4A up to 647 acres of grassland would be protected, 188 acres of vernal pool/alkali seasonal wetland complexes with associated grasslands would be protected and 48 acres would be restored, and up to 6 acres of aquatic habitat would be protected and restored in the greater Byron Hills in CZ 8. Protection of grassland in CZ 8 west of Byron Highway would benefit the California red-legged frog by providing habitat in the portion of the study area with the highest long-term conservation value for the species based on known species occurrences and large, contiguous habitat areas. Six acres of ponds in the grasslands would also be protected to provide aquatic habitat for this species, and the surrounding grassland would provide dispersal and aestivation habitat. Aquatic features in the protected grasslands in CZ 8 would be maintained and enhanced to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding California red-legged frogs. Additionally, livestock exclusion from streams and ponds and other measures would be implemented as described in Environmental Commitment 11 to promote growth of aquatic vegetation with appropriate cover characteristics favorable to California red-legged frogs. Lands protected in CZ 8 would connect with lands protected under the *East Contra Costa County HCP/NCCP* and the extensive Los Vaqueros Watershed lands, including grassland areas supporting this species. This would ensure that California red-legged frog upland and associated aquatic habitats would be protected and enhanced in the largest possible patch sizes adjacent to occupied habitat within and adjacent to the study area.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration and 1:1 for protection of nontidal wetlands and 2:1 for protection of grassland habitats. Using these ratios would indicate that 1 acre of aquatic habitat should be restored, 1 acre of aquatic habitat should be protected, and 128 acres of grassland should be protected for California red-legged frog.

Alternative 4A also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, AMM10 Restoration of Temporarily Affected Natural Communities,* and *AMM14 California Red-Legged Frog*. These AMMs include elements that avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: In the absence of actions to restore and protect habitat, the effects on California red-legged frog habitat from Alternative 4A would represent an adverse effect as a result of habitat modification and potential direct mortality of special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles L2, L3, VP/AW1, VP/AW6, G2, G7, and G10, and guided by AMM1–AMM6, AMM10, and AMM14, which would be in place throughout the construction period, the effects of Alternative 4A as a whole on California red-legged frog would not be an adverse effect.

CEQA Conclusion: In the absence of actions to restore and protect habitat, the effects on California red-legged frog habitat from Alternative 4A would represent a significant impact as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles L2, L3, VP/AW1, VP/AW6, G2, G7, and G10, and guided by AMM1–AMM6, AMM10, and AMM14, which would be in place throughout the construction period and operations, the impact of Alternative 4A as a whole on California red-legged frog would be less than significant.

Impact BIO-45: Indirect Effects of Alternative 4A on California Red-Legged Frog

Noise and visual disturbance including aritifical nighttime lighting outside the project footprint but within 500 feet of construction activities are indirect effects that could temporarily affect the use of California red-legged frog habitat, all of which is upland cover and dispersal habitat. The areas to be affected are near Clifton Court Forebay, and no California red-legged frogs were detected during recent surveys conducted by DWR in this area (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*).

Maintenance and refueling of heavy equipment could result in the inadvertent release of sediment and hazardous substances into species habitat. Increased sedimentation could reduce the suitability of California red-legged frog habitat downstream of the construction area by filling in pools and smothering eggs. Accidental spills of toxic fluids also could result in the subsequent loss of California red-legged frog if these materials enter the aquatic system. Hydrocarbon and heavy metal pollutants associated with roadside runoff also have the potential to enter the aquatic system, affecting water quality and California red-legged frog.

NEPA Effects: Implementation of AMM1–AMM6, AMM10, and AMM14 as part of implementing Alternative 4A would avoid the potential for adverse effects on California red-legged frogs, either indirectly or through habitat modifications. These AMMs would also avoid and minimize effects that could substantially reduce the number of California red-legged frogs, or restrict the species' range. Therefore, the indirect effects of Alternative 4A would not have an adverse effect on California red-legged frog.

CEQA Conclusion: Indirect effects from Environmental Commitment operations and maintenance, as well as construction-related noise and visual disturbances including artificial nighttime lighting, could impact California red-legged frog in aquatic and upland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could impact California red-legged frog or its prey. The inadvertent discharge of sediment or excessive dust adjacent to California red-legged frog habitat could also have a negative impact on the species or its prey. With implementation of AMM1–AMM6, AMM10, and AMM14, Alternative 4A construction, operation, and maintenance would avoid the potential for substantial adverse effects on California red-legged frog, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of California red-legged frogs. The indirect effects of Alternative 4A would have a less-than-significant impact on California red-legged frogs.

California Tiger Salamander

Modeled California tiger salamander habitat in the study area contains two habitat types: terrestrial cover and aestivation habitat, and aquatic breeding habitat and is restricted to CZ 1, CZ 2, CZ 4, CZ 5, CZ 7, CZ 8, and CZ 11 (Figure 12-14). Modeled terrestrial cover and aestivation habitat contains all grassland types and alkali seasonal wetland with a minimum patch size of 100 acres and within a geographic area defined by species records and areas most likely to support the species. Patches of grassland that were below the 100-acre minimum patch size but were contiguous with grasslands outside of the study area boundary were included. Modeled aquatic breeding habitat for the California tiger salamander includes vernal pools and seasonal and perennial ponds.

California tiger salamander occurs within the study area in CZ 8 west of Clifton Court Forebay and in CZ 11 in the Potrero Hills (Figure 12-14). Potential habitat exists in vernal pool habitats in Yolo and Solano Counties (CZs 1, 2, and 3) west of Liberty Island and in the vicinity of Stone Lakes and the Cosumnes River Preserve in Sacramento County (CZ 4). DWR found California tiger salamander west of Clifton Court Forebay in the same vicinity as several of the CNNDB (California Department of Fish and Wildlife 2013) records (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*). There is also a small, isolated population near Manteca, south of Highway 120 in CZ 7.

Construction and restoration associated with Alternative 4A would result in temporary and permanent losses of upland habitat that California tiger salamander uses for cover and dispersal (Table 12-4A-20). Potential aquatic habitat for this species would not be affected. Factors considered in assessing the value of affected habitat for California tiger salamander, to the extent that information is available, include presence of limiting habitat (aquatic breeding habitat), known occurrences and clusters of occurrences, proximity of the affected habitat to existing protected lands, and the overall degraded or fragmented nature of the habitat. While Environmental Commitments implemented in other CZs could have potential effects on California tiger salamander, those activities in CZ 8 and CZ 11 are considered to have a proportionately larger effect due to their closer proximity to known occurrences of the species.

Alternative 4A would include the following Environmental Commitments and associated Resource Restoration and Performance Principles to benefit the California tiger salamander (see Chapter 3, *Conservation Strategy*, of the BDCP).

- Protect and improve habitat linkages that allow terrestrial species to move between protected habitats within and adjacent to the project area (Resource Restoration and Performance Principle L2).
- Protect up to 647 acres of grassland in the Byron Hills area where practicable and/or in other appropriate locations (Environmental Commitment 3, Resource Restoration and Performance Principle G10).
- Protect up to 188 acres and restore up to 48 acres of existing vernal pool/alkali seasonal wetlands complexes in the greater Byron Hills including associated grasslands (Environmental Commitment 3,Environmental Commitment 9, and Resource Restoration and Performance Principle VP/AW1).

- Increase burrow availability for burrow-dependent species in grasslands surrounding all suitable aquatic habitat including stock ponds and vernal pool/alkali seasonal wetland complexes (Resource Restoration and Performance Principles G5, VP/AW6).
- Increase native species diversity and relative cover of native plant species, and reduce the introduction and proliferation of nonnative species (Resource Restoration and Performance Principle L3).
- Protect up to 6 acres of stock ponds and other aquatic features within protected grasslands to provide aquatic breeding habitat for native amphibians and aquatic reptiles (Resource Restoration and Performance Principle G2).
- Maintain and enhance aquatic features in protected grasslands to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding for amphibian and aquatic reptile species (Resource Restoration and Performance Principle G7).
- Increase the size and connectivity of protected vernal pool complex within the project area and increase connectivity with protected vernal pool complex adjacent to the project area (Resource Restoration and Performance Principle VP/AW3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to the implementation of AMMs, impacts on California tiger salamander would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-20. Changes in California Tiger Salamander Modeled Habitat Associated with Alternative 4A (acres)

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-46: Loss or Conversion of Habitat for and Direct Mortality of California Tiger Salamander

Alternative 4A would result in the permanent and temporary loss combined of up to 17 acres of aquatic habitat and 92 acres of modeled upland habitat for California tiger salamander (Table 12-4A-20). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of RTM and tidal restoration. In addition, natural enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. Maintenance activities associated with the long-term operation of the water conveyance facilities and other project facilities could degrade or eliminate California tiger salamander habitat including injury and mortality of California tiger salamanders. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual activity discussions.

- *Water Facilities and Operation*: Construction of Alternative 4A conveyance facilities, including transmission lines, would result in the permanent loss of 19 acres of upland habitat for California tiger salamander habitat, primarily in CZ 8 (Table 12-4A-20). No aquatic habitat would be affected. Permanent effects would be associated with RTM, grading, paving, excavating, extension and installation of cross culverts, installation of structural hardscape, and installation and relocation of utilities. Construction-related effects would temporarily disturb 32 acres of upland habitat for the California tiger salamander (Table 12-4A-20). There is one California tiger salamander occurrence just south of the City of Byron that overlaps with the area of temporary effects. The area that would be affected by conveyance facilities construction is south of Clifton Court Forebay, where modeled California tiger salamander habitat is of relatively low value in that it consists of fragmented patches of primarily terrestrial habitat surrounded by actively cultivated lands. The highest concentration of California tiger salamander occurrences are in CZ 8 and west of the conveyance facilities alignment, while lands to the east consist primarily of actively cultivated lands that are not suitable for the species. Habitat loss in this area is not expected to contribute to habitat fragmentation or impede important California tiger salamander dispersal.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: This activity would result in the permanent removal of an estimated 17 acres of aquatic and 24 acres of upland habitat for California tiger salamander. The effects would take place in one or more of the ROAs established for tidal restoration (see Figure 12-1).
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Protection of up to 647 acres of grassland, protection of up to 188 acres and restoration of up to 48 acres of existing vernal pool/alkali seasonal wetlands complexes in the greater Byron Hills including associated grasslands, and protection and restoration of up to 6 acres of aquatic habitat would benefit California tiger salamander. Habitat enhancement- and management-related activities in protected California tiger salamander habitats would result in overall improvements to and maintenance of California tiger salamander habitat values. Activities associated with natural communities enhancement and management in protected California tiger salamander habitat, such as ground disturbance or herbicide use to control nonnative vegetation, could result in local adverse habitat effects and injury or mortality of California tiger salamander and disturbance effects if individuals are present in work sites. Implementation of AMM1–AMM6, AMM10, and AMM13 would reduce these effects. Herbicides would only be used in California tiger salamander habitat in accordance with the written recommendation of a licensed, registered Pest Control Advisor and in conformance with label precautions and federal, state, and local regulations in a manner that avoids or minimizes harm to the California tiger salamander.
- Critical habitat: Approximately 1,781 acres of designated Critical Habitat Unit 2, Jepson Prairie Unit, for California tiger salamander overlap the study area in CZ 1. While this area is located within the Cache Slough Complex, it is not expected to be affected by project restoration actions.
- Operations and maintenance: Ongoing facilities operation and maintenance is expected to have little if any adverse effect on the California tiger salamander. Postconstruction operation and maintenance of the above-ground water conveyance facilities could result in ongoing but periodic disturbances that could affect California tiger salamander use of the surrounding

habitat. Operation of maintenance equipment, including vehicle use along transmission corridors in CZ 8, could also result in injury or mortality of California tiger salamanders if present in work sites. These effects, however, would be minimized with implementation of the California tiger salamander measures described in AMM1–AMM6, AMM10, and AMM13.

- Injury and direct mortality: Construction activities associated with the water conveyance facilities, stock pond and vernal pool complex restoration, and habitat and management enhancement-related activities, including operation of construction equipment, could result in injury or mortality of California tiger salamanders. Foraging, dispersal, and overwintering behavior may be altered during construction activities, resulting in injury or mortality of California tiger salamander if the species is present. Salamanders occupying burrows could be trapped and crushed during ground-disturbing activities. Degradation and loss of estivation habitat is also anticipated to result from the removal of vegetative cover and collapsing of burrows. Injury or mortality would be avoided and minimized through implementation of seasonal constraints and preconstruction surveys in suitable habitat, collapsing unoccupied burrows, and relocating salamanders outside of the construction area as described in AMM1–AMM6, AMM10, and AMM13.

The following paragraphs summarize the combined effects discussed above and describe other Environmental Commitments and associated Resource Restoration and Performance Principles that offset or avoid these effects. NEPA effects and CEQA conclusions are also included.

There are approximately 8,273 acres of aquatic and 29,459 acres of upland modeled habitat for California tiger salamander in the study area. Alternative 4A as a whole would result in the permanent loss of, and temporary effects combined on 17 acres of aquatic and 92 acres of upland habitat for California tiger salamander for the term of the plan (less than 1% of the total upland habitat in the study area). These effects would result from construction of the water conveyance facilities and tidal restoration.

With full implementation of Alternative 4A up to 647 acres of grassland would be protected, 188 acres of vernal pool/alkali seasonal wetland complexes with associated grasslands would be protected and 48 acres would be restored, and up to 6 acres of aquatic habitat would be protected and restored in the greater Byron Hills in CZ 8. Protection of grassland in CZ 8 west of Byron Highway would benefit the California tiger salamander by providing habitat in the portion of the study area with the highest long-term conservation value for the species based on known species occurrences and large, contiguous habitat areas. Six acres of ponds in the grasslands would also be protected or restored to provide aquatic habitat for this species, and the surrounding grassland would provide dispersal and aestivation habitat. Aquatic features in the protected grasslands in CZ 8 would be maintained and enhanced to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding California tiger salamanders. Additionally, livestock exclusion from streams and ponds and other measures would be implemented as described in Environmental Commitment 11 to promote growth of aquatic vegetation with appropriate cover characteristics favorable to California tiger salamanders. Lands protected in CZ 8 would connect with lands protected under the *East Contra Costa County HCP/NCCP* and the extensive Los Vaqueros Watershed lands, including grassland areas supporting this species. This would ensure that California tiger salamander upland and associated aquatic habitats would be protected and enhanced in the largest possible patch sizes adjacent to occupied habitat within and adjacent to the study area.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration and 1:1 for protection of nontidal wetlands and 2:1 for protection of grassland habitats. Using these ratios would indicate that 17 acres of aquatic habitat should be restored, 17 acres of aquatic habitat should be protected, and 184 acres of grassland should be protected for California tiger salamander.

Alternative 4A also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM13 California Tiger Salamander*. These AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: In the absence of actions to restore and protect habitat, the effects on California tiger salamander habitat from Alternative 4A would represent an adverse effect as a result of habitat modification and potential direct mortality of special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles L2, L3, VP/AW1, VP/AW3, VP/AW6, G2, G7, and G10, and guided by AMM1–AMM6, AMM10, and AMM13, which would be in place throughout the construction period and operations, the effects of Alternative 4A as a whole on California tiger salamander would not be an adverse effect.

CEQA Conclusion: In the absence of actions to restore and protect habitat, the effects on California tiger salamander habitat from Alternative 4A would represent a significant impact as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles L2, L3, VP/AW1, VP/AW3, VP/AW6, G2, G7, and G10, and by AMM1–AMM6, AMM10, and AMM13, which would be in place throughout the construction period and operations, the impact of Alternative 4A as a whole on California tiger salamander would be less than significant.

Impact BIO-47: Indirect Effects of Alternative 4A on California Tiger Salamander

Indirect effects could occur outside of the construction footprint but within 500 feet of California tiger salamander habitat. Activities associated with conveyance construction, restoration, and ongoing habitat enhancement, as well as operation and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances with localized effects on California tiger salamander and its habitat, and temporary noise and visual disturbances, including aritifical night lighting at a worksite. Most of the areas indirectly affected are associated with the construction of Byron Forebay in CZ 8.

Maintenance and refueling of heavy equipment could result in the inadvertent release of sediment and hazardous substances into species habitat. Increased sedimentation could reduce the suitability of California tiger salamander habitat downstream of the construction area by filling in pools and smothering eggs. Accidental spills of toxic fluids into the aquatic system could result in the subsequent loss of California tiger salamander habitat. Hydrocarbon and heavy metal pollutants associated with roadside runoff also have the potential to enter the aquatic system, affecting water quality and California tiger salamander.

NEPA Effects: Implementation of AMM1–AMM6, AMM10, and AMM13 under Alternative 4A would avoid or minimize the potential for adverse effects on California tiger salamanders, either indirectly or through habitat modifications. These AMMs would also avoid and minimize effects that could substantially reduce the number of California tiger salamanders or restrict the species' range. Therefore, the indirect effects of Alternative 4A would not have an adverse effect on California tiger salamander.

CEQA Conclusion: Indirect effects resulting from project operations and maintenance as well as construction-related noise and visual disturbances including artificial night lighting could impact California tiger salamander in aquatic and upland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could impact California tiger salamander or its prey. The inadvertent discharge of sediment or excessive dust adjacent to California tiger salamander habitat could also have a negative impact on the species or its prey. With implementation of AMM1–AMM6, AMM10, and AMM13 as part of Alternative 4A, the project would avoid the potential for substantial adverse effects on California tiger salamander, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of California tiger salamanders. The indirect effects of Alternative 4A would have a less-than-significant impact on California tiger salamander.

Impact BIO-48: Periodic Effects of Inundation of California Tiger Salamander Habitat as a Result of Implementation of Alternative 4A

There would be no periodic effects on California tiger salamander.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Giant Garter Snake

The habitat model used to assess effects for the giant garter snake is based on aquatic habitat and upland habitat. Modeled aquatic habitat is composed of tidal perennial aquatic, tidal freshwater perennial emergent wetland, nontidal freshwater emergent wetland, and nontidal perennial aquatic natural communities; rice fields; and artificial canals and ditches. Modeled upland habitat is composed of all nonwetland and nonaquatic natural communities (primarily grassland and cropland) within 200 feet of modeled aquatic habitat features. The modeled upland habitat is ranked as high-, moderate-, or low-value based on giant garter snake associations between vegetation and cover types (U.S. Fish and Wildlife Service 2012) and historical and recent occurrence records (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*), and presence of features necessary to fulfill the species' life cycle requirements. Modeled habitat is expressed in acres for aquatic and upland habitats, and in miles for linear movement corridors in aquatic habitat. Other factors considered in assessing the value of affected habitat for the giant garter snake, to the extent that information is available, are proximity to conserved lands and recorded occurrences of the species, proximity to giant garter snake subpopulations (Yolo Basin/Willow Slough and Coldani Marsh/White Slough) in the study area that are identified in the draft recovery plan for this species (U.S. Fish and Wildlife Service 1999b), and contribution to connectivity between giant garter snake subpopulations.

Construction and restoration associated with Alternative 4A would result in both temporary and permanent losses of giant garter snake modeled habitat as indicated in Table 12-4A-21. Alternative 4A would include the following Environmental Commitments and associated Resource Restoration and Performance Principles to benefit the giant garter snake.

- Increase native species diversity and relative cover of native plant species, and reduce the introduction and proliferation of nonnative species (Resource Restoration and Performance Principle L3).
- Protect up to 1,060 acres and restore up to 1,070 acres of grassland (Environmental Commitment 3 and Environmental Commitment 8).
- Protect up to 843 acres of high-value upland giant garter snake habitat adjacent to suitable aquatic habitat (Environmental Commitment 3, Resource Restoration and Performance Principle GGS4).
- Restore up to 255 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities, with suitable habitat characteristics for giant garter snake and western pond turtle in CZ 4 and CZ 5 (Environmental Commitment 10).
- Protect up to 11,870 acres of cultivated lands that provide suitable habitat for native wildlife species, of which 255 acres of rice land or equivalent-value habitat would be protected for giant garter snake and connected to the restored 255 acres of aquatic habitat in nontidal marsh for giant garter snake in CZ 4 or CZ 5 (Environmental Commitment 3, Resource Restoration and Performance Principles GGS1 and GGS3).
- Protect and improve habitat linkages that allow terrestrial species to move between protected habitats within and adjacent to the project area (Resource Restoration and Performance Principle L2)
- Target cultivated land conservation to provide connectivity between other conservation lands (Resource Restoration and Performance Principle CL2).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the conservation area, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Resource Restoration and Performance Principle CL1).
- Protect giant garter snakes on restored and protected nontidal marsh and adjacent uplands from incidental injury or mortality by establishing 200-foot buffers between protected giant garter snake habitat and roads (other than those roads primarily used to support adjacent cultivated lands and levees). Establish giant garter snake conservation area at least 2,500 feet from urban areas or areas zoned for urban development (Resource Restoration and Performance Principle GGS2).
- Create connections from the Coldani Marsh/White Slough subpopulation to other areas in the giant garter snake's historical range in the Stone Lakes vicinity by protecting 255 acres of rice land or equivalent-value habitat (e.g., perennial wetland) for the giant garter snake in CZ 4 and/or CZ 5. Any portion of the 255 acres may consist of muted tidal freshwater emergent wetland and may overlap with the 160 acres of tidally restored freshwater emergent wetland if

it meets specific giant garter snake habitat criteria (Resource Restoration and Performance Principle GGS5).

As explained below, with the restoration or protection of these amounts of habitat, in addition to the implementation of AMMs, impacts on giant garter snake would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-21. Changes in Giant Garter Snake Modeled Habitat Associated with Alternative 4A

Project Component	Habitat Type[b]	Permanent	Temporary
Water Conveyance Facilities	Aquatic (acres)	210	110
	Upland (acres)	408	206
	Aquatic (miles)3	11	6
Total Impacts Water Conveyance Facilities (acres)		**618**	**316**
Environmental Commitments 4, 6–7, 9–11[a]	Aquatic (acres)	3	0
	Upland (acres)	46	0
	Aquatic (miles)	2	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a] (acres)		49	0
TOTAL IMPACTS (acres)		**667**	**316**

[a] See discussion below for a description of applicable Environmental Commitments.
[b] Aquatic acres represent tidal and nontidal habitat combined, and upland acres represent low-, moderate-, and high-value acreages combined.

Impact BIO-49: Loss or Conversion of Habitat for and Direct Mortality of Giant Garter Snake

Alternative 4A would result in the permanent and temporary loss combined of up to 323 acres of modeled aquatic habitat (tidal and nontidal combined), up to 660 acres of modeled upland habitat, and up to 19 miles of channels providing aquatic movement habitat for the giant garter snake (Table 12-4A-21). Project measures that would result in these losses are water conveyance facilities and transmission line construction, geotechnical investigation, and establishment and use of RTM and tidal restoration. Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available giant garter snake habitat and are expected to result in overall improvements to and maintenance of giant garter snake habitat values. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities would degrade or eliminate giant garter snake habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual activity discussions.

- *Water Facilities and Operation*: Construction of Alternative 4A conveyance facilities would result in the permanent loss of approximately 618 acres of modeled giant garter snake habitat, composed of 210 acres of aquatic habitat and 408 acres of upland habitat (Table 12-4A-21). The 408 acres of upland habitat that would be removed for the construction of the conveyance facilities consists of 116 acres of high-, 262 acres of moderate-, and 30 acres of low-value habitat. In addition, approximately 11 miles of channels providing giant garter snake movement habitat would be removed as a result of conveyance facilities construction. Development of the water conveyance facilities would also result in the temporary removal of up to 110 acres of giant garter snake aquatic habitat and up to 206 acres of adjacent upland habitat in areas near construction and geotechnical investigation in CZ 5 and CZ 6 (see Table 12-4A-21 and Terrestrial Biology Mapbook). In addition, approximately 6 miles of channels providing giant garter snake movement habitat would be temporarily removed as a result of conveyance facilities construction. There are three giant garter snake occurrences in the vicinity of the water conveyance facilities construction footprint in Snodgrass Slough and Middle River.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal natural communities restoration would result in an estimated permanent loss of approximately 3 acres of aquatic habitat and 46 acres of upland habitat for the giant garter snake to tidal marsh. This estimate includes 15 acres of high-value, 27 acres of moderate-value, and 4 acres of low-value habitat. In addition, an estimated 2 miles of channels providing giant garter snake movement habitat would be removed as a result of tidal natural communities restoration. The effects would take place in one or more of the ROAs established for tidal restoration (see Figure 12-1).

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in protected habitats may result in localized ground disturbances that could temporarily remove small amounts of giant garter snake habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available giant garter snake habitat and are expected to result in overall improvements to and maintenance of giant garter snake habitat values. These effects cannot be quantified, but are expected to be minimal because vegetation removal would occur around existing infrastructure and roads where giant garter snake are not as likely to be present. Any of these minor impacts would be avoided and minimized by the AMMs listed below.

- Operations and maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect giant garter snake use of the surrounding habitat in the Cache Slough area, and the north and south Delta (CZ 1, CZ 2, CZ 3, CZ 4, CZ 5, CZ 6, CZ 7, and CZ 8). Maintenance activities would include vegetation management, levee and structure repair, and regrading of roads and permanent work areas. These effects, however, would be reduced by AMMs and environmental commitments as described below.

- Injury and direct mortality: Construction vehicle activity may cause injury or mortality of the giant garter snake. If snakes reside where activities take place (most likely in the vicinity of the Coldani Marsh/White Slough subpopulation [CZ 4]), the operation of equipment for land clearing, construction, conveyance facilities operation and maintenance, and habitat restoration, enhancement, and management could result in injury or mortality of giant garter snakes. This risk is highest from late fall through early spring, when the snakes are dormant. Increased vehicular traffic associated construction and restoration could contribute to a higher incidence of road kill. However, preconstruction surveys would be implemented after the project planning phase and prior to any ground-disturbing activity. Any disturbance to suitable aquatic and upland sites in or near the project footprint would be avoided to the extent feasible, and the loss of aquatic habitat and grassland vegetation would be minimized through adjustments to project design, as practicable. Construction monitoring and other measures would be implemented to avoid and minimize injury or mortality of this species during construction as described in *AMM16 Giant Garter Snake*.

The following paragraphs summarize the combined effects discussed above and describe other Alternative 4A Environmental Commitments that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

There are approximately 31,281 acres of aquatic and 53,285 acres of upland modeled habitat for giant garter snake in the study area. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 323 acres of aquatic habitat and 660 acres of upland habitat for giant garter snake during the term of the plan (1% of the total aquatic and upland modeled habitat in the study area).

With full implementation of Alternative 4A there would be protection of up to 1,060 acres and restoration of up to 1,070 acres of grassland, protection of up to 11,870 acres of cultivated lands, 119 acres of nontidal wetlands, and restoration of up to 832 acres of nontidal wetlands in the study area. Lands to be protected and restored specifically for the giant garter snake total 1,353 acres (255 acres nontidal marsh, 843 acres of grassland, 255 acres of cultivated lands (rice or habitat of equivalent value in CZ 4, and CZ 5). In addition to the 1,353 acres of high-value habitat targeted specifically for giant garter snake, the protection and restoration of other natural communities is expected to provide additional restoration and protection of garter snake habitat. An unknown number of irrigation and drainage ditches located in cultivated lands and suitable for giant garter snake movement would be maintained and protected within the conservation area, which would include isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands.

Protection and management of cultivated lands (Environmental Commitment 11) would also benefit the giant garter snake by providing connectivity and maintaining irrigation and drainage channels that provide aquatic habitat for the snake. Giant garter snake habitat would be restored and protected specifically to conserve and expand the Coldani Marsh/White Slough subpopulation of the giant garter snake. Protecting and expanding existing giant garter snake subpopulations, and providing connectivity between protected areas, is considered the most effective approach to giant garter snake conservation in the study area. The Coldani Marsh/White Slough and Yolo Basin/Willow Slough subpopulations are the only known subpopulations of giant garter snakes in the study area and are identified as important for the recovery of the species in the draft recovery plan for the species (U.S. Fish and Wildlife Service 1999b). Implementation actions that target giant garter snake habitat would focus on these two important subpopulations.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration and 1:1 for protection of aquatic habitats and 2:1 for protection of upland habitats. Using these ratios would indicate that 323 acres of aquatic habitat should be restored, 323 acres of aquatic habitat should be protected, and 1,320 acres of upland habitat should be protected for giant garter snake.

Alternative 4A also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan, AMM10 Restoration of Temporarily Affected Natural Communities,* and *AMM16 Giant Garter Snake*. All of these AMMs include elements that avoid or minimize the risk of activities affecting habitats and species adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: In the absence of actions to restore and protect habitat, the effects on giant garter snake habitat from Alternative 4A would represent an adverse effect as a result of habitat modification and potential direct mortality of special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles GGS1-GGS5, L2, L3, CL1, and CL2, and guided by AMM1–AMM7, AMM10, and AMM16, which would be in place throughout the construction period and operations, the effects of Alternative 4A as a whole on giant garter snake would not be an adverse effect.

CEQA Conclusion: In the absence of actions to restore and protect habitat, the effects on giant garter snake habitat from Alternative 4A would represent a significant impact as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles GGS1-GGS5, L2, L3, CL1, and CL2, and guided by AMM1–AMM7, AMM10, and AMM16, which would be in place throughout the construction period and operations, the impact of Alternative 4A as a whole on giant garter snake would not result in a substantial reduction in numbers or a restriction in the range of giant garter snakes. Therefore, the effects of Alternative 4A would have a less-than-significant impact on giant garter snakes.

Impact BIO-50: Indirect Effects of Alternative 4A on Giant Garter Snake

Construction activities outside the project footprint but within 200 feet of construction associated with water conveyance facilities, habitat restoration, and ongoing habitat enhancement, as well as operation and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances with localized effects on giant garter snake habitat, and temporary noise and visual disturbances. These potential effects would be minimized or avoided through AMM1–AMM7, AMM10, and AMM16, which would be in effect during all project activities.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect giant garter snake or its aquatic prey. The inadvertent discharge of sediment or excessive dust adjacent to giant garter snake habitat could also have a negative effect on the species or its prey. AMM1–AMM6 would minimize the likelihood of such spills and would ensure measures are in place to prevent runoff from the construction area and potential effects of sediment or dust on giant garter snake or its prey.

Project activities have the potential to exacerbate bioaccumulation of mercury in species that feed on aquatic species, including giant garter snake. The operational impacts of new flows under water conveyance facilities were analyzed to assess potential effects on mercury concentration and bioavailability. Results indicated that changes in total mercury levels in water and fish tissues due to future operational conditions were insignificant (see BDCP Appendix 5.D, *Contaminants).*

Marsh (tidal and nontidal) restoration also has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes. Thus, restoration activities that create newly inundated areas could increase bioavailability of mercury. Increased methylmercury associated with natural community restoration may indirectly affect giant garter snake, which feeds on small fishes, tadpoles, and small frogs, especially introduced species, such as small bullfrogs (*Rana catesbeiana*) and their larvae, carp (*Cyprinus carpio*), and mosquitofish (*Gambusia affinis*). In general, the highest methylation rates are associated with high tidal marshes that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). Along with minimization and mitigation measures and adaptive management and monitoring, *Environmental Commitment 12 Methylmercury Management* is expected to reduce the amount of methylmercury resulting from the restoration of natural communities.

Extant populations of giant garter snake within the study area are known only from the upper Yolo Basin and at the Coldani Marsh/White Slough area. Davis et al. (2007) found mercury concentrations in fish at White Slough (and the central Delta in general) to be relatively low compared to other areas of the Delta. No restoration activities involving flooding (and subsequent methylation of mercury) are planned within the known range of the Coldani Marsh/White Slough giant garter snake population. Yolo Basin is where some of the highest concentrations of mercury and methylmercury have been documented (Foe et al. 2008); however, there would be no construction or restoration in this area. Effects from exposure to methylmercury may include decreased predator avoidance, reduced success in prey capture, difficulty in shedding, and reduced ability to move between shelter and foraging or thermoregulation areas (Wylie et al. 2009). The potential mobilization or creation of methylmercury within the study area varies with site-specific conditions and would need to be assessed at the project level. Measures described in *Environmental Commitment 12 Methylmercury Management* include provisions for project-specific Mercury Management Plans. Along with avoidance and minimization measures and adaptive management and monitoring, Environmental Commitment 12 is expected to reduce the effects of methylmercury resulting from natural communities and floodplain restoration on giant garter snake.

***NEPA Effects*:** Implementation of the AMMs listed above and *Environmental Commitment 12 Methylmercury Management* as part of implementing Alternative 4A would avoid the potential for substantial adverse effects on giant garter snakes, either indirectly or through habitat modifications. These AMMs and Environmental Commitment would also avoid and minimize effects that could substantially reduce the number of giant garter snakes or restrict the species' range. Therefore, the indirect effects of Alternative 4A would not have an adverse effect on giant garter snake.

***CEQA Conclusion*:** Indirect effects from project operations and maintenance as well as construction-related noise and visual disturbances could impact giant garter snake in aquatic and upland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could impact giant garter snake or its prey. The inadvertent discharge of sediment or excessive dust adjacent to giant garter snake habitat could also have a negative impact on the species or its prey. With implementation of AMM1–AMM7, AMM10, and AMM16 and *Environmental Commitment 12 Methylmercury Management* as part of Alternative 4A construction, operation and maintenance, the project would avoid or minimize the potential for substantial adverse effects on giant garter snakes, either indirectly or through habitat modifications. Therefore, the indirect effects of Alternative 4A would have a less-than-significant impact on giant garter snakes.

Impact BIO-50a: Loss of Connectivity among Giant Garter Snakes in the Coldani Marsh/White Slough Subpopulation, Stone Lakes National Wildlife Refuge, and the Delta

Implementation of Alternative 4A would not introduce a substantial barrier to the movement among giant garter snakes in the Coldani Marsh/White Slough subpopulation, Stone Lakes NWR, and the Delta in the study area.

NEPA Effects: Alternative 4A would not adversely affect connectivity among giant garter snakes in the Coldani Marsh/White Slough subpopulation, Stone Lakes NWR, and the Delta in the study area.

CEQA Conclusion: Alternative 4A would have a less-than-significant impact on connectivity among giant garter snakes in the study area and therefore no mitigation is required.

Impact BIO-51: Periodic Effects of Inundation of Giant Garter Snake Habitat as a Result of Implementation of Alternative 4A

There would be no periodic effects on giant garter snake.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Western Pond Turtle

The habitat model used to assess effects on the western pond turtle is based on aquatic and upland nesting and overwintering habitat. Further details regarding the habitat model, including assumptions on which the model is based, are provided in BDCP Appendix 2.A, *Species Accounts*, Section 2A.29, *Western Pond Turtle.* The model quantified two types of upland nesting and overwintering habitat, including upland habitat in natural communities as well as upland in agricultural areas adjacent to aquatic habitats. Both of these upland habitat types are combined for this analysis. Factors considered in assessing the value of affected aquatic habitat are natural community type and availability of adjacent nesting and overwintering habitat. The highest value aquatic habitat types in the study area consist of nontidal freshwater perennial emergent wetlands and ponds adjacent to suitable nesting and overwintering habitat (Patterson pers. comm.). Less detail is provided on effects on dispersal habitat because, although dispersal habitat is important for maintaining and increasing distribution and genetic diversity, turtles have been known to travel over many different land cover types; therefore, this habitat type is not considered limiting. The value of dispersal habitat depends less on the habitat type itself than on the proximity of that habitat type to high-value aquatic and nesting and overwintering habitat.

Alternative 4A would result in both temporary and permanent losses of western pond turtle modeled habitat, as indicated in Table 12-4A-22. The majority of these losses would take place over an extended period of time as tidal marsh is restored in the study area.

Alternative 4A would include the following Environmental Commitments and Resource Restoration and Performance Principles to benefit the western pond turtle.

- Protect up to 103 acres and restore up to 251 acres of valley/foothill riparian habitat (Environmental Commitments 3 and 7).
- Protect up to 119 acres and restore up to 832 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities, which will include suitable habitat characteristics for western pond turtle (Environmental Commitments 3 and 10, Resource Restoration and Performance Principle WPT1).
- Protect up to 1,060 acres and restore up to 1,070 acres of grassland (Environmental Commitments 3 and 8).

- Protect up to 6 acres of stock ponds and other aquatic features within protected grasslands to provide aquatic breeding habitat for native amphibians and aquatic reptiles (Resource Restoration and Performance Principle G2).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the conservation area, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Resource Restoration and Performance Principle CL1).

As explained below, with the restoration and protection of these amounts of habitat, in addition to implementation of AMMs, impacts on western pond turtle would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-22. Changes in Western Pond Turtle Modeled Habitat Associated with Alternative 4A

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Aquatic (acres)	335	2,005
	Upland (acres)	261	84
	Aquatic (miles)	7	4
Total Impacts Water Conveyance Facilities (acres)		**596**	**2,089**
Environmental Commitments 4, 6–7, 9–11[a]	Aquatic (acres)	231	0
	Upland (acres)	38	0
	Aquatic (miles)	2	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a] (acres)		**269**	
TOTAL IMPACTS (acres)		**865**	**2,089**

[a] See discussion below for a description of applicable Environmental Commitments.
[b] Upland acres represent upland nesting and overwintering habitat acreages combined for both natural communities and agricultural lands adjacent to aquatic habitats.

Impact BIO-52: Loss or Conversion of Habitat for and Direct Mortality of Western Pond Turtle

Alternative 4A would result in the permanent and temporary loss of up to 2,363 acres of aquatic habitat and 383 acres of upland nesting and overwintering habitat (Table 12-4A-22). Activities that would result in the temporary and permanent loss of western pond turtle modeled habitat are conveyance facilities and transmission line construction, geotechnical investigations, and establishment and use of RTM, and tidal habitat restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11), such as ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate western pond turtle habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual activity discussions.

- Water Facilities and Operation: Construction of Alternative 4A conveyance facilities would result in the permanent loss of approximately 335 acres of aquatic habitat and 261 acres of upland nesting and overwintering habitat for the western pond turtle in the study area (Table 12-4A-22). Development of the water conveyance facilities would also result in the temporary removal of up to 2,005 acres of aquatic habitat and 84 acres of upland nesting and overwintering habitat for the western pond turtle in the study area (see Table 12-4A-22). Approximately 7 miles of channels providing western pond turtle movement habitat would be removed and 4 miles would be temporarily disturbed. There are four western pond turtle occurrences that overlap with the water conveyance facilities footprint in CZ 2, one occurrence that overlaps with an RTM area on the southern tip of Bouldin Island in CZ 5, and one occurrence that overlaps with an RTM area along Twin Cities Road in CZ 4.

Permanent effects on an estimated 162 of the total 596 aquatic and upland acres combined and 4 of the 7 miles would be lost as storage areas for RTM, which would likely be moved to other sites for use in levee build-up and restoration. The affected area would likely be restored. Although this effect is categorized as permanent because there is no assurance that the material would eventually be moved, the effect would likely be temporary. Furthermore, the amount of storage area needed for RTM is flexible and the footprint used in the effects analysis is based on a worst case scenario. The actual area to be affected by RTM storage would likely be less than the estimated acreage.

The majority of the permanent loss of aquatic habitat and upland nesting and overwintering habitat would be near Clifton Court Forebay in CZ 8. Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. The aquatic habitat in the Clifton Court Forebay area is considered to be of reasonably high-value because it consists of agricultural ditches in or near known species occurrences. The nesting and overwintering habitat that would be lost consists primarily of cultivated lands with some small portion of ruderal grassland habitat. Except for remnant, uncultivated patches, the cultivated lands are not suitable for nesting and overwintering unless left fallow. Construction of the water conveyance facilities would also affect dispersal habitat, which is primarily cultivated lands. Although there are western pond turtle occurrences scattered throughout CZ 3, CZ 4, CZ 5, and CZ 6, this effect would be widely dispersed because of the long, linear nature of the pipeline footprint.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal natural communities restoration would result in the conversion of an estimated 23 acres of aquatic habitat and 38 acres of upland nesting and overwintering habitat for western pond turtle to tidal marsh. Tidal habitat restoration is expected to change existing salinity and flow conditions rather than lead to complete loss of aquatic habitat. Restoration of tidal flow where habitat consists of the calm waters of managed freshwater ponds and wetlands could have an adverse effect on the western pond turtle. Tidal restoration is likely to create suitable, slow-moving freshwater slough and marsh habitat suitable for western pond turtle. The effects would take place in one or more of the ROAs established for tidal restoration (see Figure 12-1). Actual effects are expected to be lower because sites would be selected to minimize effects on western pond turtle habitat (see AMM17 in Appendix 3B, *Environmental Commitments, AMMs, and CMs*).

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in protected habitats may result in localized ground disturbances that could temporarily remove small amounts of western pond turtle habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor adverse effects on available western pond turtle habitat and are expected to result in overall improvements to and maintenance of western pond turtle habitat values. In addition, effects would be avoided and minimized by the AMMs listed below.

- Operations and maintenance: Ongoing maintenance of facilities is expected to have little if any adverse effect on the western pond turtle. Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect western pond turtle use where there is suitable habitat in the study area. Maintenance activities would include vegetation management, levee and structure repair, and regrading of roads and permanent work areas. These effects, however, would be minimized by AMMs and environmental commitments described below.

- Injury and direct mortality: Construction vehicle activity may cause injury to or mortality of western pond turtles. If turtles reside where Environmental Commitments are implemented (most likely in the vicinity of aquatic habitats in the study area), the operation of equipment for land clearing, construction, conveyance facilities operation and maintenance, and habitat restoration, enhancement, and management could result in injury or mortality of western pond turtles. However, to avoid injury or mortality, preconstruction surveys would be conducted in suitable aquatic or upland habitat for the western pond turtle, and turtles found would be relocated outside the construction areas, as required by the AMMs listed below.

The following paragraphs summarize the combined effects discussed above and describe other Environmental Commitments and Resource Restoration and Performance Principles that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

Based on the habitat model, the study area supports approximately 81,666 acres of aquatic and 28,864 acres of upland habitat for western pond turtle. Alternative 4A as a whole would remove 2,363 acres of aquatic habitat and 383 acres of upland nesting and overwintering habitat for western pond turtle (3% of the total aquatic habitat and 1% of the total upland habitat in the study area).

These effects would result from water conveyance facilities construction (2,340 acres of aquatic and 345 acres of upland habitats), tidal habitat restoration (Environmental Commitment 4, 23 acres of aquatic and 38 acres of upland habitat). Most of the impacts (2,005 acres) from water conveyance facilities would be temporary in the vicinity of Clifton Court Forebay and are expected to return to suitable aquatic habitat once construction is completed. Therefore the following analysis addresses the permanent loss of 358 acres of aquatic habitat.

Implementation of Alternative 4A as a whole would increase the extent and distribution of high-value aquatic and upland nesting and overwintering habitat for western pond turtle in the study area. The conservation strategy for western pond turtle involves restoration and protection of aquatic and adjacent upland habitat, and establishment of an interconnected conservation area that provides for western pond turtle dispersal. The project proponents have committed to protection and restoration of up to 957 acres of aquatic habitat including 951 acres of nontidal wetland and up to 6 acres of stock ponds. In addition, there would be 354 acres of valley/foothill riparian habitat and 2,130 acres of grasslands habitat. The most beneficial restoration would occur in the 832 acres of freshwater emergent wetland consisting of slow-moving slough and marsh adjacent to protected, undisturbed grassland of which 77 acres would be protected and 77 acres restored with suitable habitat characteristics for western pond turtle. Aquatic features (e.g., ditches and ponds) and adjacent uplands that are preserved and managed as part of the 11,870 acres of protected cultivated lands described above for giant garter snake are also expected to benefit the species and to help offset the loss of aquatic habitat. Additionally, basking platforms would be installed as needed in restored freshwater marsh to benefit the western pond turtle.

Riparian restoration would potentially increase the quantity and value of aquatic and nesting and overwintering habitat. Where riparian vegetation is restored adjacent to slower-moving channels, sloughs, and ponds, downed trees can provide important basking habitat and cover habitat for turtles. Riparian restoration in those more interior portions of Old and Middle Rivers that would be managed for riparian brush rabbit habitat have potential to benefit resident western pond turtles as riparian-adjacent grassland is an important habitat characteristic for the rabbit.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected for western pond would be 1:1 for restoration and 1:1 for protection of aquatic habitats and 2:1 for protection of upland habitats. Using these ratios would indicate that 358 acres of aquatic habitat should be restored, 358 acres of aquatic habitat should be protected, and 766 acres of upland habitat should be protected for western pond turtle. Alternative 4A also contains commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, AMM10 Restoration of Temporarily Affected Natural Communities, and AMM17 Western Pond Turtle*. These AMMs include elements that would avoid or minimize the risk of affecting habitats and species adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: In the absence of actions to restore and protect habitat, the effects on western pond turtle would represent an adverse effect as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles WPT1, G2, and CL1, and guided by AMM1–AMM6, AMM10, AMM17, and AMM 37, the effects of Alternative 4A as a whole on western pond turtle would not be an adverse effect.

CEQA Conclusion: In the absence of actions to restore and protect habitat, the effects on western pond turtle habitat from Alternative 4A would represent a significant impact as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles WPT1, G2, and CL1, and guided by AMM1–AMM6, AMM10, and AMM17, which would be in place throughout the construction period and operations, the impact of Alternative 4A as a whole on western pond turtle would be less than significant.

Impact BIO-53: Indirect Effects of Alternative 4A on Western Pond Turtle

Indirect effects on western pond turtle within 200 feet of construction activities could temporarily affect the use of aquatic habitat and upland nesting and overwintering habitat for the western pond turtle. Construction activities outside the construction footprint but within 200 feet of water conveyance facilities, habitat restoration, and ongoing habitat enhancement, as well as operation and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances with localized impacts on western pond turtle habitat, and temporary noise and visual disturbances.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect western pond turtle or its aquatic prey. The inadvertent discharge of sediment or excessive dust adjacent to western pond turtle aquatic habitat could also have a negative effect on the species or its prey. AMM1–AMM6, and

AMM10 would minimize the likelihood of such spills and would ensure measures are in place to prevent runoff from the construction area and potential effects of sediment or dust on western pond turtle or its prey.

NEPA Effects: With implementation of AMM1–AMM6, AMM10, and AMM17 as part of Alternative 4A, the project would avoid the potential for substantial adverse effects on western pond turtles, either directly or through habitat modifications. These AMMs would also avoid and minimize effects that could substantially reduce the number of western pond turtles or restrict the species range. Therefore, the indirect effects of Alternative 4A would not have an adverse effect on western pond turtle.

CEQA Conclusion: Indirect effects resulting from project operations and maintenance as well as construction-related noise and visual disturbances could impact western pond turtle in aquatic and upland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could affect western pond turtle or its prey. The inadvertent discharge of sediment or excessive dust adjacent to western pond turtle habitat could also have a negative effect on the species or its prey. With implementation of AMM1–AMM6, AMM10, and AMM17 as part of Alternative 4A construction, operation, and maintenance, Alternative 4A would avoid the potential for substantial adverse effects on western pond turtles, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of western pond turtles. The indirect effects of Alternative 4A would have a less-than-significant impact on western pond turtles.

Impact BIO-54: Periodic Effects of Inundation of Western Pond Turtle Habitat as a Result of Implementation of Alternative 4A

There would be no periodic effects on western pond turtle.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Silvery Legless Lizard, San Joaquin Coachwhip, and Blainville's Horned Lizard

This section describes the effects of Alternative 4A on the silvery legless lizard, San Joaquin coachwhip and Blainville's horned lizard (special-status reptiles). The habitat types used to assess effects on silvery legless lizard are limited to inland sand dunes near Antioch (CZ 9 and CZ 10) (Figure 12-17). There are isolated patches of sandy habitat in the vicinity of Oakley and along the railroad in the East Bay Regional Park Legless Lizard Preserve that are not shown in Figure 12-17 because project mapping was not available at this level of detail. Furthermore, none of these areas would be affected by construction or restoration activities and this species is not discussed any further.

The habitat types used to assess effects on the San Joaquin coachwhip are alkali seasonal wetland complex, grassland, and inland dune scrub west of Byron Highway (CZ 7)and west of Old River and West Canal (CZ 8). The habitat types used to assess effects on the Blainville's horned lizard are the same as those for the whipsnake in CZ 7 and CZ 8. There is also potential habitat for the horned lizard to occur in grassland habitat around Stone Lake (CZ 4). Although the expected range for San Joaquin coachwhip and Blainville's horned lizard extends into the study area, there are no records for either of these species within the study area (California Department of Fish and Wildlife 2013).

In addition, historic museum records show that Blainville's horned lizard occurrences could have been extirpated within the study area (Jennings and Hayes 1994).

Construction associated with Alternative 4A Environmental Commitments would result in both temporary and permanent removal of habitat that special-status reptiles use for cover and dispersal (Table 12-4A-23).

Alternative 4A would also include the following Environmental Commitments and associated Resource Restoration and Performance Principles to benefit special-status reptiles.

- Increase the size and connectivity of the conservation area by acquiring lands adjacent to and between existing conservation lands (Resource Restoration and Performance Principle L1).
- Increase native species diversity and relative cover of native plant species, and reduce the introduction and proliferation of nonnative species (Resource Restoration and Performance Principle L3).
- Protect and improve habitat linkages that allow native terrestrial species to move between protected habitats within and adjacent to the project area (Resource Restoration and Performance Principle L2).
- Protect up to 188 acres and restore up to 48 acres of existing vernal pool/alkali seasonal wetlands complexes in the greater Byron Hills including associated grasslands (Environmental Commitments 3 and 9).
- Protect up to 1,060 acres and restore up to 1,070 acres of grassland (Environmental Commitments 3 and 8).
- Increase the extent, distribution, and density of native perennial grasses intermingled with other native species, including annual grasses, geophytes, and other forbs (G4).
- Increase burrow availability for burrow-dependent species (G5)
- Increase prey abundance and accessibility, especially of small mammals and insects, for grassland-foraging species (G6)

As explained below, with the restoration or protection of these amounts of habitat, in addition to implementation of AMMs, impacts on special-status reptiles would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-23. Changes in Special-Status Reptile Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type[b]	Permanent	Temporary
Water Conveyance Facilities	Grassland	269	102
Total Impacts Water Conveyance Facilities		**269**	**102**
Environmental Commitments 4, 6–7, 9–11[a]	Grassland	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**269**	**102**

[a] See discussion below for a description of applicable Environmental Commitments.
[b] Grassland impacts include alkali seasonal wetland complex, grassland, and inland dune scrub natural communities.

Impact BIO-55: Loss or Conversion of Habitat for and Direct Mortality of Special-Status Reptiles

Alternative 4A would result in the permanent and temporary loss of 371 acres of habitat for special-status reptiles (Table 12-4A-23). Water conveyance facilities and transmission line construction, including establishment and use of RTM and geotechnical investigations would cause the loss of special-status reptile habitat. In addition, habitat enhancement and management activities (Environmental Commitment 11), such as ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects for special-status reptiles. For purposes of this analysis, the acres of total effect are considered the same for both San Joaquin coachwhip and Blainville's horned lizard, even though this assumption results in slightly more acres of permanent effect on the San Joaquin coachwhip resulting from water conveyance facilities activities in CZ 4 where it does not occur.

In addition to habitat loss and conversion, construction activities, such as grading, the movement of construction vehicles or heavy equipment, and the installation of water conveyance facilities components and new transmission lines, may result in the direct mortality, injury, or harassment of special-status reptiles, including the potential crushing of individuals and disruption of essential behaviors. Construction of access roads could fragment suitable habitat, impede upland movements in some areas, and increase the risk of road mortality. Construction activities related to Environmental Commitments could have similar effects. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual activity discussions.

- *Water Facilities and Operation*: Development of the conveyance facilities would result in the permanent loss of approximately 269 acres of habitat for special-status reptiles in the vicinity of Clifton Court Forebay. Construction-related effects would temporarily disturb 102 acres of suitable habitat for special-status reptiles in the study area. There are no occurrences of either species within the construction footprint for water conveyance facilities.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in *Environmental Commitment 11* that are designed to enhance wildlife values in protected habitats may result in localized ground disturbances that could temporarily remove small amounts of special-status reptile habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor adverse effects on available special-status reptile habitat and are expected to result in overall improvements to and maintenance of species habitat values. These effects cannot be quantified, but are expected to be minimal and would be reduced through implementation of Mitigation Measure BIO-55 *Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs.*
- Operations and maintenance: Ongoing facilities operation and maintenance is expected to have little if any adverse effect on special-status reptiles. Postconstruction operation and maintenance of the above-ground water conveyance facilities could result in ongoing but periodic disturbances that could affect special-status reptiles' use of suitable habitat in the study area. These effects, however, would be minimized with implementation of Mitigation Measure BIO-55*.*
- Injury and direct mortality: Construction vehicles may cause injury to or mortality of special-status reptiles. The operation of equipment for land clearing, construction, operation and

maintenance, and restoration, enhancement, and management activities could result in injury or mortality. This risk is highest from late fall through early spring, when special-status reptiles are not as active. However, the risk of crushing Blainville's horned lizard would not necessarily be lower during the active season, because the species uses crypsis to hide from predators and would be hard to spot from a moving vehicle. Seasonal risk reduction may be more appropriate for the coachwhip, but there is still a risk of crushing the horned lizard during the active season. In addition, both species would not be active under conditions of extreme temperatures and could be taking cover in burrows or crevices or under structures such as rocks or logs (Morey 2000). They could also burrow beneath the soil and be crushed by vehicles. Increased vehicular traffic associated with project actions could contribute to a higher incidence of road kill. However, conducting construction during the late-spring through early fall periods when feasible, and when temperatures are 67–100 degrees F, and implementation of Mitigation Measure BIO-55 would avoid and minimize injury or mortality of special-status reptiles during construction.

The following paragraphs summarize the combined effects discussed above and describe other Environmental Commitments and associated Resource Restoration and Performance Principles that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

Alternative 4A would remove 371 acres of grassland habitat for special-status reptiles as a result of water conveyance facilities.

Effects of water conveyance facilities construction on special-status reptiles would be offset through the project's protection of up to 1,060 acres and restoration of up to 1,070 acres of grassland, and grassland associated with protection and restoration of up to 198 acres of vernal pool/alkali seasonal wetland complex. Grassland protection would focus in particular on acquiring the largest remaining contiguous patches of unprotected grassland habitat, which are located south of SR 4 in CZ 8. This area connects to more than 620 acres of existing habitat that is protected under the East Contra Costa County HCP/NCCP. The projects commitment to protect the largest remaining contiguous habitat patches (including grasslands and the grassland component of vernal pool/alkali seasonal wetland complexes) in CZ 8 would sufficiently offset the adverse effects resulting from water conveyance facilities construction.

The typical NEPA and CEQA project-level mitigation ratio (2:1 for protection) for this natural community would indicate that 742 acres should be protected to offset water conveyance facilities losses.

NEPA Effects: In the absence of actions to restore and protect habitat, the effects on special-status reptile habitat from Alternative 4A would represent an adverse effect as a result of habitat modification and potential direct mortality of special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles L1-L3, and by Mitigation Measure BIO-55, which would be in place throughout the construction period and operations, the effects of Alternative 4A as a whole on special-status reptiles would not be an adverse effect.

CEQA Conclusion: In the absence of other actions to restore and protect habitat, the effects on special-status reptile habitat from Alternative 4A would represent a significant impact as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles L1-L3, and by Mitigation Measure BIO-55, which would be in place throughout the construction period and operations, the impact of Alternative 4A as a whole on special-status reptiles would be less than significant.

Mitigation Measure BIO-55: Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs

DWR will retain a qualified biologist to conduct a habitat assessment in construction and restoration areas that are relatively undisturbed or have a moderate to high potential to support Blainville's horned lizard and San Joaquin coachwhip in CZ 4, CZ 7, and CZ 8. The qualified biologist will survey for these reptiles in areas of suitable habitat concurrent with the preconstruction surveys for other special-status species in CZ 4, CZ 7, and CZ 8. If special-status reptiles are found in work areas, the biologist will first attempt to allow these species to move out of the work area on their own but if conditions do not allow this, individuals will be captured by the biologist and relocated to the nearest suitable habitat outside of the work area as determined in consultation with CDFW. To the extent feasible, work in areas with suitable habitat for Blainville's hornzed lizard and San Joaquin coachwhip should not be conducted during periods of cold and hot temperatures (below 67 degrees F and above 100 degrees F), because both species would be relatively inactive during these periods and could be taking cover in loose soil, in burrows or crevices, or under structures such as rocks or logs (Morey 2000). This would reduce the impact of being crushed by vehicles and equipment.

In addition, *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities*, will be implemented for all special-status reptiles adversely affected by the project to avoid, minimize, or compensate for impacts.

Impact BIO-56: Indirect Effects of Alternative 4A on Special-Status Reptile Species

Construction activities associated with water conveyance facilities, Environmental Commitments, and ongoing habitat enhancement, as well as operations and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances and noise with localized effects on special-status reptiles and their habitat.

In addition, construction activities could indirectly affect special-status reptiles if construction resulted in the introduction of invasive weeds that create vegetative cover that is too dense for the species to navigate. Construction vehicles and equipment can transport in their tires and various parts under the vehicles invasive weed seeds and vegetative parts from other regions to construction sites, resulting in habitat degradation. These potential effects would be reduced through implementation of AMM10. Water conveyance facilities operations and maintenance activities would include vegetation and weed control, ground squirrel control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. While maintenance activities are not expected to remove special-status reptile habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in injury or mortality of individual special-status reptiles, if present.

***NEPA Effects*:** Implementation of the Mitigation Measure BIO-55, *Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs* would avoid the potential for substantial adverse effects on these species, either indirectly or through habitat modifications. The mitigation measure would also avoid and minimize effects that could substantially reduce the number of special-status reptiles, or restrict either species' range. Therefore, with implementation of Mitigation Measure BIO-55, the indirect effects of Alternative 4A on special-status reptiles would not be adverse under NEPA.

CEQA Conclusion: Indirect effects from project operations and maintenance as well as construction-related noise and visual disturbances could impact special-status reptiles. In addition, construction activities could indirectly affect special-status reptiles if construction resulted in the introduction of invasive weeds that create vegetative cover that is too dense for the species to navigate. Water conveyance facilities operations and maintenance activities, such as vegetation and weed control, and road maintenance, are not expected to remove special-status reptile habitat, but operation of equipment could disturb small areas of vegetation around maintained structures and could result in injury or mortality of individual special-status reptiles, if present. These activities could result in a significant impact.

With implementation of Mitigation Measure BIO-55, *Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs* as part of Alternative 4A construction, operation, and maintenance, the project would avoid the potential for significant effects on special-status reptile species, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of either species. With implementation of Mitigation Measure BIO-55, the indirect effects of Alternative 4A would have a less-than-significant impact on special-status reptiles.

Mitigation Measure BIO-55: Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs

See description of Mitigation Measure BIO-55 under Impact BIO-55.

California Black Rail

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on California black rail. The habitat model used to assess effects for the California black rail is based on primary breeding habitat and secondary habitat. Primary (breeding) habitat for this species within the Delta includes all *Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acre (essentially instream islands of the San Joaquin River and its tributaries and White Slough Wildlife Area). In Suisun Marsh, primary habitat includes all *Schoenoplectus* and *Typha*-dominated, and *Salicornia*-dominated patches greater than 0.55 acre, with the exception that all low marsh habitats dominated by *Schoenoplectus acutus* and *S. californicus* and all managed wetlands, in general, are considered secondary habitat with lesser ecological value. Upland transitional zones that provide refugia during high tides within 150 feet of the tidal wetland edge were also included as secondary habitat. Secondary habitats generally provide only a few ecological functions such as foraging (low marsh and managed wetlands) or extreme high tide refuge (upland transition zones), while primary habitats provide multiple functions, including breeding, effective predator cover, and valuable foraging opportunities.

Alternative 4A would result in both temporary and permanent losses of California black rail modeled habitat as indicated in Table 12-4A-24. Full implementation of Alternative 4A would also include the following Resource Restoration and Performance Principles that would benefit the California black rail.

- At the ecotone that would be created between restored tidal wetlands and transitional uplands (Environmental Commitment 4), provide for at least 13.5 acres of California black rail habitat (*Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acres at a location subject to CDFW approval) consisting of shallowly inundated emergent vegetation at the upper edge of the marsh (within 50 meters of upland refugia habitat) with adjacent riparian or other shrubs that will provide upland refugia, and other moist soil perennial vegetation. If feasible, create the 13.5 acres of tidal habitat in a single patch in a location that is contiguous with occupied California black rail habitat (Resource Restoration and Performance Principle CBR1).
- Create topographic heterogeneity in restored tidal wetlands (Environmental Commitment 4, Resource Restoration and Performance Principle CBR2).

California black rail is a fully protected species and take of California black rail individuals is prohibited under Fish and Game Code Section 3511. With the implementation of *AMM38 California Black Rail*, construction activities would not result in take and effects on the species would be avoided. As explained below, with the restoration and protection of tidal wetland habitat, in addition to natural community enhancement and management commitments (including *Environmental Commitment 12 Methylmercury Management*) and implementation of AMM1–AMM7, *AMM38 California Black Rail*, and *AMM27 Selenium Management*, impacts on the California black rail would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-24. Changes in California Black Rail Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Primary	0.5	11
	Secondary	0	0
Total Impacts Water Conveyance Facilities		**0.5**	**11**
Environmental Commitments 4, 6–7, 9–11[a]	Primary	1	0
	Secondary	1	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**2.5**	**11**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-57: Loss or Conversion of Habitat for and Direct Mortality of California Black Rail

Alternative 4A would result in the combined permanent and temporary loss of 13.5 acres of modeled primary habitat for California black rail (Table 12-4A-24). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of RTM areas. Habitat enhancement and management activities (Environmental Commitment 11) which include ground disturbance or removal of nonnative vegetation could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other Alternative 4A physical facilities could degrade or eliminate California black rail habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities would result in the permanent loss of up to 0.5 acres and the temporary loss of up to 11 acres of modeled primary California black rail habitat (Table 12-4A-24). The construction of a temporary transmission line in the central Delta that extends from Bouldin Island to Victoria Island would impact modeled habitat on Mandeville Island, the north end of Bacon Island, and on in-channel islands along the transmission line alignment. Other temporary impacts on modeled habitat would result from a temporary barge unloading facility and a temporary access road along the north end of Bacon Island, and from a temporary work area on Mandeveille Island. Geotechnical exploration could also impact black rail habitat on an in-channel island east of Bacon Island. Less than 0.5 acres of habitat would be permanently lost from the construction of a permanent transmission line at the northeast corner of Clifton Court Forebay in CZ 8. The water conveyance facilities footprint intersects with one California black rail occurrence on Mandeville Island, from the footprint of the temporary transmission line.

  Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Up to 2 acres of California black rail modeled habitat (1 acre of primary habitat and 1 acre of secondary habitat) would be affected by tidal marsh restoration. The restoration of up to 13.5 acres of tidal wetlands would benefit California black rail. The primary habitat for the species in the Delta consists of in-channel islands, which are in areas that are most vulnerable to the effects of sea level rise in the study area. Tidal restoration under Environmental Commitment 4 would ensure that land is protected adjacent to current habitat in the delta with the consideration of sea level rise. Tidal restoration for the California black rail would include an ecotone between wetlands and transitional uplands which would provide upland refugia for the species.

- *Environmental Commitment 11 Natural Communities Enhancement and Management:* A variety of habitat management actions associated with natural communities enhancement, that are designed to enhance wildlife values in restored tidal wetland habitats may result in localized ground disturbances that could temporarily remove small amounts of California black rail habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities are expected to have minor adverse effects on available California black rail habitat and are expected to result in overall improvements and maintenance of California black rail habitat values. Noise and visual disturbances during implementation of habitat management actions could also result in temporary disturbances that affect California black rail use of the surrounding habitat. These effects cannot be quantified, but would be avoided and minimized by the AMMs listed below (AMMs are described in detail in Appendix 3B, *Environmental Commitments, AMMs, and CMs*). The implementation of *AMM38 California Black Rail* would avoid disturbance and take by requiring restrictions on construction activities during the breeding season and establishing nodisturbance buffers around California black rail territories. In addition, construction would be avoided altogether if breeding territories cannot be accurately delimited. Environmental Commitment 11 would also include the control of nonnative predators through habitat manipulation techniques or trapping to reduce nest predation on California black rail if needed.

  Water Facility Operations and Maintenance: Post construction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect California black rail use of the central Delta.

Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by the AMMs listed below. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Injury and Direct Mortality: California black rail is a fully protected species and take is prohibited under Section 3511 of the Fish and Game Code. If rails are present adjacent to project activities, the operation of equipment for land clearing, construction, conveyance facilities operation and maintenance, and habitat restoration, enhancement, and management could result in injury or take of California black rail. Increased vehicular traffic associated with construction and maintenance of water conveyance facilities could also contribute to a higher potential for take. The implementation of *AMM38 California Black Rail* would avoid disturbance and take of California black rail individuals by restricting construction activities during the breeding season and establishing 500-foot no-disturbance buffers around identified territorial calling centers. If the 500-foot buffer does not provide complete avoidance of take, a CDFW-approved biologist would monitor construction activities to ensure that black rail individuals are not harmed. If breeding territories cannot be accurately delimited construction would not occur in order to avoid impacts (*AMM38 California Black Rail* is described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*).

The following paragraphs summarize the combined effects discussed above and describe Environmental Commitments that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

The study area supports approximately 7,467 acres of primary and 17,915 acres of secondary habitat for California black rail. Alternative 4A would result in the permanent loss of 2.5 acre and temporary effects on up to 11 acres of primary California black rail habitat (much less than 1% of the total primary habitat in the study area) as a result of water conveyance facilities construction. The typical NEPA and CEQA project-level mitigation ratio for the tidal wetlands that would be affected by the project would be 1:1 for restoration/creation of tidal wetlands. Using this ratio would indicate that 13.5 acres of tidal freshwater emergent wetland should be restored/created to mitigate the losses of California black rail habitat.

The project includes measures to improve habitat for California black rail to offset the habitat that is permanently and temporarily lost. Conservation commitments under Alternative 4A through *Environmental Commitment 4 Tidal Natural Communities Restoration* would restore or create up to 13.5 acres of tidal wetlands at a location subject to CDFW approval.

Upland refugia for California black rail would be created between the restored tidal wetlands and transitional uplands to provide cover from predators (*Environmental Commitment 4 Tidal Natural Communities Restoration*/Resource Restoration and Performance Principle CBR1). In addition, nonnative predators would be controlled to reduce nest predation if necessary through *Environmental Commitment 11 Natural Communities Enhancement and Management*. These wetlands would consist of *Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acre, which would provide primary habitat for the black rail. If feasible, the 13.5 acres of tidal restoration would occur in a single patch at a location adjacent to occupied California black rail habitat. Upland refugia for California black rail would be created between the restored tidal freshwater emergent wetlands and transitional uplands to provide cover from predators (Environmental Commitment 4/Resource Restoration and Performance Principle

CBR1). In addition, nonnative predators would be controlled to reduce nest predation if necessary through *Environmental Commitment 11 Natural Communities Enhancement and Management*.

The project also includes commitments to implement the following avoidance and minimization measures that will help to avoid and minimize adverse effects on California black rail: *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM38 California Black Rail*. *AMM38 California Black Rail* requires surveys for California black rail and the implementation of avoidance and minimization measures including the establishment of a 500 foot no disturbance buffer around any identified calling stations. All of these AMMs include elements that avoid or minimize the risk of affecting habitat and avoid the risk of take of California black rail in or adjacent to work areas and RTM storage sites.

NEPA Effects: In the absence of Environmental Commitments and AMMs, the losses of California black rail habitat and potential for take of a special-status species associated with Alternative 4A would represent an adverse effect. However, with habitat protection and restoration associated with Environmental Commitment 4, guided by Resource Restoration and Performance Principles CBR1 and CBR2, and AMM1–AMM7 and *AMM38 California Black Rail*, the effects of Alternative 4A as a whole on California black rail would not be adverse under NEPA.

CEQA Conclusion: In the absence of Environmental Commitments and AMMs, the losses of California black rail habitat and potential for take of a special-status species associated with Alternative 4A would represent a significant impact. Considering the restoration provisions, which would provide acreages of new tidal marsh habitat in amounts necessary to compensate for habitats lost to construction and restoration activities guided by Resource Restoration and Performance Principles CBR1 and CBR2, and the implementation of AMM1–AMM7 and *AMM38 California Black Rail*, implementation of Alternative 4A as a whole would not result in a substantial adverse effect through habitat modifications and would avoid take of California black rail individuals. Therefore, the alternative would have a less-than-significant impact on California black rail under CEQA.

Impact BIO-58: Effects on California Black Rail Associated with Electrical Transmission Facilities

A variety of rail species are known to suffer take from transmission line collision, likely associated with migration and flights between foraging areas (Eddleman et al.1994). Due to their wing shape and body size, rails have low to moderate flight maneuverability (Bevanger 1998), increasing susceptibility to collision mortality. However, there are relatively few records of California black rail collisions with overhead wires.

California black rails exhibit daytime site fidelity and a lack of long-distance night migration, two factors which are associated with low collision risk in avian species (Eddleman et al. 1994). California black rail movements in the study area are likely short, seasonal, and at low altitudes, typically less than 16 feet (5 meters) (Eddleman et al, 1994). There are numerous occurrences within 1 mile of the proposed temporary transmission line which extends north-south between Bouldin Island and Clifton Court Forebay. However, although the species may have low to moderate flight maneuverability, the bird's behavior (e.g., sedentary, nonmigratory, ground-nesting and foraging, solitary, no flocking, secretive) reduces potential exposure to overheard wires and vulnerability to collision mortality (see BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). For example, Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. As described in *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters, which would greatly reduce the risk of California black rails colliding with project powerlines. There would be no take of California black rail from the project as defined under Section 86 of the California Fish and Game Code.

Transmission line poles and towers also provide perching substrate for raptors, which are predators on California black rail. Although there is potential for temporary transmission lines to increase perching opportunities for raptors and result in increased predation pressure on local black rails, little is currently known about the seasonal movements of black rails or the potential for increased predation on rails near power poles. Therefore, because of the limited area over which poles would be installed relative to the amount of California black rail habitat in the Delta, it is assumed that the increased risk of predation on California black rail from an increase in raptor perching opportunities would be negligible.

NEPA Effects**:** The construction and presence of new transmission lines would not represent an adverse effect because the risk of bird strike is considered to be minimal based on the species' flight behaviors. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would further reduce the risk of bird strike for California black rails from the project. The increased risk of predation on California black rail from an increase in raptor perching opportunities would be negligible because of the limited area over which poles would be installed relative to the amount of California black rail habitat in the Delta. Therefore, the construction and operation of new transmission lines would not result in an adverse effect on California black rail.

CEQA Conclusion**:** The construction and presence of new transmission lines would not result in "take" of California black rail pursuant to California Fish and Game Code Section 86 because the risk of bird strike is considered to be minimal based on the species' flight behaviors. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would further reduce the risk of bird strike for California black rails from the project. The increased risk of predation on California black rail from an increase in raptor perching opportunities would be negligible when considering the limited area over which poles would be installed relative to the amount of California black rail habitat in the Delta. Therefore, the construction and operation of new transmission lines under Alternative 4A would result in a less-than-significant impact on California black rail.

Impact BIO-59: Indirect Effects of Alternative 4A on California Black Rail

Indirect Construction-Related Effects: Both primary and secondary habitat for California black rail within the vicinity of proposed construction areas could be indirectly affected by construction activities. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 500 feet from the construction edge. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and Appendix 11F, *Substantive BDCP Revisions*). However, there is no available data to determine the extent to which these noise levels could affect California black rail. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect California black rail in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to California black rail habitat could also affect the species.

If construction occurs during the nesting season, these indirect effects could result in the loss or abandonment of nests, and take of any eggs and/or nestlings. The implementation of *AMM38 California Black Rail* would avoid disturbance and take of individuals by requiring preconstruction surveys of potential breeding habitat, establishment of a 500-foot no-disturbance buffer, and the presence of an onsite monitor during the breeding season (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). In addition, construction would be avoided altogether if breeding territories cannot be accurately delimited.

Salinity: Water operations ranging between Operational Scenarios H3 and H4 would have an effect on salinity gradients in Suisun Marsh. It is expected that the salinity of water in Suisun Marsh would generally increase as a result of water operations and operations of salinity-control gates to mimic a more natural water flow. This would likely encourage the establishment of tidal wetland plant communities tolerant of more brackish environments, which should be beneficial to California black rail because its historical natural Suisun Marsh habitat was brackish tidal marsh.

Methylmercury Exposure: The modeled primary habitat for California black rail includes tidal brackish emergent wetland and tidal freshwater emergent wetland in Suisun Marsh and the Delta west of Sherman Island, and instream islands and White Slough Wildlife Area in the central Delta. Black rails typically occur in the high marsh zone near the upper limit of tidal flooding in salt and brackish habitats. Low marsh, managed wetlands, and the upland fringe are considered secondary habitat. California black rails are a top predator in the benthic food chain; they nest and forage in dense vegetation and prey on isopods, insects and arthropods from the surface of mud and vegetation They also consume insects and seeds from bulrushes (*Schoenoplectus* spp.) and cattails (*Typha* spp.) (Eddleman et al. 1994).

Largemouth bass was used as a surrogate species for analysis (see Appendix 11F, *Substantive BDCP Revisions*). Results of the quantitative modeling of mercury effects on largemouth bass as a surrogate species would overestimate the effects on black rail. Organisms feeding within pelagic-based (algal) foodwebs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic foodwebs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009). Modeled effects of mercury concentrations from changes in operations of water conveyance facilities on largemouth bass did not differ substantially from existing conditions; therefore, results also indicate that black rail mercury tissue concentrations would not measurably increase as a result of water conveyance facilities implementation.

Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. In general, the highest methylation rates are associated with high tidal marshes (primary black rail habitat) that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury. Given that some species have existing elevated mercury tissue levels, these low level increases could result in some level of effects. Environmental Commitment 12 would be implemented to address this risk of low level increases in methylmercury which could add to the current elevated tissue concentrations.

Due to the complex and very site-specific factors that would determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management,* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This Environmental Commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability.
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and project activities have the potential to exacerbate bioaccumulation of selenium in avian species, including California black rail. Tidal and nontidal marsh restoration has the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, tidal marsh restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative.

There could be an effect on California black rail from increases in selenium associated with tidal restoration activities (Environmental Commitment 4); however, effects on the California black rail population would be expected to be minimal as the amount of tidal restoration would total up to 22 acres. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of project design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design.

NEPA Effects**:** Noise and visual disturbances related to construction-related activities from Environmental Commitments could reduce California black rail use of modeled habitat adjacent to work sites. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect use of the surrounding habitat by California black rail. Potential effects of noise and visual disturbances on California black rail individuals would be avoided with *AMM38 California Black Rail*. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of spills from occurring and ensure that measures were in place to prevent runoff from the construction area and to avoid negative effects of dust on habitat for the species.

Implementation of operations ranging between Operational Scenarios H3 and H4, including operation of salinity-control gates are expected to increase water salinity in Suisun Marsh because they will create conditions more similar to historic conditions.

Tidal habitat restoration could result in increased exposure of California black rail to selenium; however, the amount of tidal restoration would total up to 22 acres, and potential exposure to selenium resulting from these acres of restoration would not be expected to adversely affect the California black rail population. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Changes in water operations would not be expected to result in increased mercury bioavailability to California black rail. Restoration actions that would create high and low tidal marsh, which is California black rail habitat, could provide biogeochemical conditions for methylation of mercury in the newly inundated soils. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the amount of tidal restoration would total up to 22 acres, and potential exposure to methylmercury resulting from these acres of restoration would not be expected to adversely affect the California black rail population. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for any effects of increased methylmercury exposure.

With the above measures in place, the indirect effects of Alternative 4A implementation would not result in take of California black rail individuals, nor would it result in a substantial adverse effect on the species through habitat modification. Therefore, the indirect effects of Alternative 4A implementation would not have adverse effect on California black rail.

***CEQA Conclusion*:** Noise and visual disturbances related to construction-related activities and Environmental Commitments could reduce California black rail use of modeled habitat adjacent to work sites. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect use of the surrounding habitat by California black rail. Potential effects of noise and visual disturbance on California black rail individuals would be avoided with *AMM38 California Black Rail*. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of spills from occurring and ensure that measures were in place to prevent runoff from the construction area and to avoid negative effects on dust on habitat for the species.

Implementation of Operational Scenarios H3 and H4, including operation of salinity-control gates, are expected to increase water salinity in Suisun Marsh. These salinity gradient changes should have a beneficial impact on California black rail because they will create conditions more similar to historic conditions.

Tidal habitat restoration could result in increased exposure of California black rail to selenium; however, the amount of tidal restoration would total up to 22 acres, and potential exposure to selenium resulting from these acres of restoration would not be expected to adversely affect the California black rail population. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. With implementation of AMM27, potential for increased selenium exposure would result in no adverse effect on the species.

Changes in water operations would not be expected to result in increased mercury bioavailability to California black rail. Restoration actions that would create high and low tidal marsh, which is California black rail habitat, could provide biogeochemical conditions for methylation of mercury in the newly inundated soils. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the amount of tidal restoration would total up to 22 acres, and potential exposure to methylmercury resulting from these acres of restoration would not be expected to adversely affect the California black rail population. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for any effects of increased methylmercury exposure.

With these measures in place, indirect effects of Alternative 4A implementation would not result in take of California black rail individuals, nor would it result in a substantial adverse effect on the species through habitat modification. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on California black rail.

Impact BIO-60: Fragmentation of California Black Rail Habitat as a Result of Project Implementation

Restoration activities may temporarily fragment existing wetlands and could create temporary barriers to California black rail movements. Grading, filling, contouring and other initial ground-disturbing activities could remove habitat along movement corridors used by individuals and potentially temporarily reduce access to adjacent habitat areas. The temporary adverse effects of fragmentation of tidal freshwater emergent wetland habitat for California black rail or restoration activities resulting in barriers to movement would be minimized through sequencing of *Environmental Commitment 4 Tidal Natural Community Restoration* activities to allow for recovery of some areas before restoration actions are initiated in other areas. In addition, *AMM38 California Black Rail* would avoid and minimize effects on California black rail.

NEPA Effects: The fragmentation of existing wetlands and creation of temporary barriers to movement would not represent an adverse effect on California black rail as a result of habitat modification of a special-status species because *Environmental Commitment 4 Tidal Natural Communities Restoration* would be phased to allow for the recovery of some areas before restoration actions are initiated in other areas. In addition, *AMM38 California Black Rail* would avoid and minimize effects on California black rail.

CEQA Conclusion: The fragmentation of existing wetlands and creation of temporary barriers to movement would represent a less-than-significant impact on California black rail as a result of habitat modification of a special-status species because *Environmental Commitment 4 Tidal Natural Communities Restoration* would be phased to allow for the recovery of some areas before restoration actions are initiated in other areas. In addition, *AMM38California Black Rail* would avoid and minimize impacts on California black rail.

Impact BIO-61: Periodic Effects of Inundation of California Black Rail Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects of inundation on California black rail.

NEPA Effects: There would be no periodic effects of inundation on California black rail.

CEQA Conclusion: There would be no periodic impacts of inundation on California black rail.

California Clapper Rail [1]

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on California clapper rail. California clapper rail modeled habitat includes primarily middle marsh habitat with select emergent wetland plant alliances. High marsh is also used if it is of high value, and low marsh provides foraging habitat for the species. California clapper rail secondary habitats generally provide only a few ecological functions such as foraging (low marsh) or high-tide refuge (upland

[1] Based on recent genetic studies by Maley and Brumfield (2013) and Chesser et al. (2014), the "California" (*Rallus longirostris obsoletus*), "Yuma" (*R. l. yumanensis*), and "light-footed" (*R. l. levipes*) subspecies of clapper rail are now recognized by the American Ornithologists' Union (AOU) as a separate species: Ridgway's rail (*Rallus obsoletus*). Consequently, the taxon formerly known as California clapper rail (*R. l. obsoletus*) is now California Ridgway's rail (*R. o. obsoletus*). For the purposes of this document, the "California clapper rail" common name has been retained due to its use in previous BDCP documents.

transition zones), while primary habitats provide multiple functions including breeding, effective predator cover, and foraging opportunities.

Alternative 4A would occur outside of the current range of the species and would not result in effects on modeled California clapper rail habitat as indicated in Table 12-4A-25. There is no modeled habitat for the species in the water conveyance facilities footprint and tidal restoration under Alternative 4A would not take place in Suisun Marsh.

Table 12-4A-25. Changes in California Clapper Rail Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Primary	0	0
	Secondary	0	0
Total Impacts Water Conveyance Facilities		**0**	**0**
Environmental Commitments 4, 6–7, 9–11[a]	Primary	0	0
	Secondary	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**0**	**0**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-62: Loss or Conversion of Habitat for and Direct Mortality of California Clapper Rail

No habitat would be lost or converted and there would be no direct take of California clapper rail under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where the species is known to occur.

NEPA Effects: There would be no effects on California clapper rail habitat.

CEQA Conclusion: There would be no impacts on California clapper rail habitat.

Impact BIO-63: Indirect Effects of the Project on California Clapper Rail

No indirect effects on California clapper rail were identified under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where the species is known to occur.

NEPA Effects: There would be no indirect effects on California clapper rail.

CEQA Conclusion: There would be no indirect impacts on California clapper rail.

Impact BIO-64: Effects on California Clapper Rail Associated with Electrical Transmission Facilities

Isolated patches of suitable California clapper rail habitat may occur in the study area as far east as (but not including) Sherman Island. Home range and territory of the California clapper rail is not known, but in locations outside of California, clapper rail territory ranges 0.3 acre to 8 acres (0.1 to

3.2 hectares) (Rush et al. 2012), indicating that known occurrences are not likely to intersect with the proposed lines (BDCP Appendix 5.J, Attachment 5J.C*, Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). The location of the current population and suitable habitat for the species make collision with the proposed transmission lines highly unlikely.

NEPA Effects: The construction and presence of new transmission lines would not have an adverse effect on California clapper rail because the location of the current population and suitable habitat for the species would make collision with the proposed transmission lines highly unlikely.

CEQA Conclusion: The construction and presence of new transmission lines would have a less-than-significant impact on California clapper rail because the location of the current population and suitable habitat for the species would make collision with the proposed transmission lines highly unlikely.

Impact BIO-65: Fragmentation of California Clapper Rail Habitat as a Result of Project Implementation

No effects of fragmentation of California clapper rail were identified under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where the species is known to occur.

NEPA Effects: There would be no effects of fragmentation on California clapper rail habitat.

CEQA Conclusion: There would be no impacts of fragmentation on California clapper rail habitat.

California Least Tern

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on California least tern. California least tern modeled habitat identifies foraging habitat as all tidal perennial aquatic natural community in the study area. Breeding habitat is not included in the model because most of the natural shoreline in the study area that historically provided nesting sites has been modified or removed. Least terns currently nest on artificial fill adjacent to tidal perennial aquatic habitat in the vicinity of Suisun Marsh and west Delta, and additional nesting could occur at the edge of tidal perennial waters whenever disturbed or artificial sites mimic habitat conditions sought for nesting (i.e., sandy or gravelly substrates with sparse vegetation). The study area is outside of the primary range of California least tern, although there are two CNDDB occurrences, one in Suisun Marsh (CZ 11), and one in Pittsburg (CZ 10).

Alternative 4A would result in both temporary and permanent losses of California least tern modeled foraging habitat as indicated in Table 12-4A-26.

California least tern is a fully protected species and "take" of individuals, pursuant to California Fish and Game Code Section 86, is prohibited. With the implementation of *AMM20 Greater Sandhill Crane* and Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall be Avoided and Indirect Effects on Colonies will be Minimized,* construction activities would not result in take of the species, which would avoid take under Section 86 of the California Fish and Game Code[2]. As explained below, with the expansion of aquatic foraging habitat in Clifton Court Forebay, in addition to natural community enhancement and management commitments (including *Environmental Commitment 12 Methylmercury Management*) and implementation of AMM1–AMM7, *AMM27 Selenium Management*, and mitigation to avoid impacts on terns should they nest in the study area, impacts on the California least tern would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-26. Changes in California Least Tern Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Foraging	281	2,019
Total Impacts Water Conveyance Facilities		**281**	**2,019**
Environmental Commitments 4, 6–7, 9–11[a]	Foraging	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**281**	**2,019**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-66: Loss or Conversion of Habitat for and Direct Mortality of California Least Tern

Alternative 4A would result in the combined permanent and temporary loss of up to 2,300 acres of modeled foraging habitat for California least tern (Table 12-4A-26). The project components that would result in these losses are construction of water conveyance facilities and operation. Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could also result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities could degrade or eliminate California least tern foraging habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 2,300 acres of modeled California least tern aquatic foraging habitat (Table 12-4A-26). Of these acres, 281 acres would be a permanent loss the majority of which would occur where new facilities are constructed at Clifton Court Forebay. A smaller portion of the permanent loss would occur where Intakes 2, 3, and 5 encroach on the Sacramento River's east bank between Clarksburg and Courtland. Permanent losses would also occur where new control structures would be built into the California Aqueduct and the Delta Mendota Canal adjacent to Clifton Court Forebay where Clifton Court Forebay levees are modified. The temporary effects on tidal perennial aquatic habitats would occur at numerous locations, with the largest affect occurring at Clifton Court Forebay, where the entire forebay would be dredged to provide additional storage capacity. Other temporary effects would occur in the Sacramento River at Intakes 2, 3, and 5, and at temporary barge unloading facilities established at three locations along the tunnel route. The water conveyance facilities footprint does not overlap with any California least tern occurrences. Refer to the

[2] Section 86 of the California Fish and Game Code defines take as "hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill." The project proponents do not propose to hunt, pursue, catch, or capture California least tern. Killing would be avoided through AMM20.

Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 11 Natural Communities Enhancement and Management:* Noise and visual disturbances during implementation of habitat management actions could result in temporary disturbances that affect California least tern use of the surrounding habitat. These effects cannot be quantified, but are expected to be minimal because few management activities would be implemented in aquatic habitat and because terns are not expected to nest on protected lands. Surveys would be conducted prior to ground disturbance in any areas that have suitable nesting substrate for California least tern (flat, unvegetated areas near aquatic foraging habitat) and effects on nesting terns would be avoided and minimized by the AMMs and Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized*, described below.

- *Water Facilities Operations and Maintenance*: Post construction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic postconstruction disturbances, localized impacts on California least tern foraging habitat, and temporary noise and disturbances over the term of the project. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas which could be adjacent to California least tern foraging habitat. These effects, however, would be reduced by AMMs described below.

- Injury and Direct Mortality: California least terns currently nest in the vicinity of potential restoration sites in the west Delta area (CZ 10). New nesting colonies could establish if suitable nesting habitat is created during restoration activities (e.g., placement of unvegetated fill to raise surface elevations prior to breaching levees during restoration efforts). If nesting occurs where covered activities are undertaken, the operation of equipment for land clearing, construction, conveyance facilities operation and maintenance, and habitat restoration, enhancement, and management could result in injury or take of California least tern. Risk of injury or disturbance would be greatest to eggs and nestlings susceptible to land-clearing activities, abandonment of nests and nesting colonies, or increased exposure to the elements or to predators. Injury to adults or fledged juveniles is less likely as these individuals would be expected to avoid contact with construction equipment. However, injury or take would be avoided through planning and preconstruction surveys to identify nesting colonies, the design of projects to avoid locations with least tern colonies, and the provision for 500-foot buffers as required by Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized*.

The following paragraph summarizes the combined effects discussed above and describes Environmental Commitments and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

With Alternative 4A implementation, there would be a permanent loss of 281 acres of modeled foraging habitat for California least tern in the study area. The permanent loss would occur primarily from the expansion of the Clifton Court Forebay and, a lesser amount would be lost along the Sacramento River. In addition, 2,019 acres would be temporarily unavailable from the dredging of the Clifton Court Forebay. The temporary loss of habitat would not be expected to adversely affect California least tern as the impact area is outside of their primary range.

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected by water conveyance facilities would be 1:1 for restoration/creation of tidal perennial aquatic habitat. Using this ratio would indicate that 281 acres of the tidal perennial aquatic natural community should be restored/created to compensate for the permanent loss of potential California least tern habitat from the construction of the water conveyance facilities. Part of the project includes the permanent expansion of the Clifton Court Forebay, which would create approximately 450 acres of aquatic habitat, which would be available for the California least tern if they were to forage in the area. This habitat creation would occur within the same timeframe as the construction temporary and permanent losses, thereby avoiding adverse effects on California least tern from loss of foraging habitat. In addition, up to 295 acres of tidal natural communities would be restored in the Delta, which would provide foraging opportunities for the species.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils*, and *AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats at or adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Although nesting by California least tern is not expected to occur, restoration sites could attract individuals wherever disturbed or artificial sites mimic habitat conditions sought for nesting (i.e., sandy or gravelly substrates with sparse vegetation). If nesting were to occur, construction activities could have an adverse effect on California least tern. Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall be Avoided and Indirect Effects on Colonies Will be Minimized*, would be available to address this adverse effect on nesting California least terns.

NEPA Effects: The potential for effects on California least tern associated with Alternative 4A would represent an adverse effect in the absence of the mitigation measure and AMMs described below. Although nesting by California least tern is not expected to occur in the study area, restoration sites could attract individuals wherever disturbed or artificial sites mimic habitat conditions sought for nesting (i.e., sandy or gravelly substrates with sparse vegetation). If nesting were to occur, construction activities could have an adverse effect on California least tern. Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall be Avoided and Indirect Effects on Colonies will be Minimized*, would be available to address this effect on nesting California least terns. Temporary impacts on tidal perennial aquatic habitat in Clifton Court Forebay associated with dredging would not be expected to impact California least tern, as this region of the study area is outside of their primary range. The restoration of aquatic habitat associated with the expansion of the Clifton Court Forebay (water conveyance facilities), and Environmental Commitment 4 (tidal restoration) would be sufficient to compensate for permanent impacts on California least tern foraging habitat. With these acres of restoration, in addition to the implementation of *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils*, and *AMM7 Barge Operations Plan*, which would be in place during all project activities, the effects of Alternative 4A as a whole on California least tern would not be adverse.

CEQA Conclusion: The potential effects on California least tern associated with Alternative 4A would represent an adverse effect in the absence of the Mitigation Measure and AMMs described below as a result of potential for take of a special-status species. Although nesting by California least tern is not expected to occur in the study area, restoration sites could attract individuals wherever disturbed or artificial sites mimic habitat conditions sought for nesting (i.e., sandy or gravelly substrates with sparse vegetation). Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall be Avoided and Indirect Effects on Colonies will be Minimized*, would avoid the potential for take of California least tern individuals and reduce this effect to a less-than-significant impact.

Temporary impacts on tidal perennial aquatic habitat in Clifton Court Forebay associated with dredging would not be expected to impact California least tern, as this region of the study area is outside of their primary range. The restoration of aquatic habitat associated with the expansion of the Clifton Court Forebay (water conveyance facilities), and *Environmental Commitment 4 Tidal Natural Communities Restoration* would be sufficient to compensate for permanent impacts on California least tern foraging habitat. With these acres of restoration, in addition to the implementation of *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils*, and *AMM7 Barge Operations Plan*, which would be in place during all project activities, the effects of Alternative 4A as a whole on California least tern would not result in a substantial adverse effect through habitat modifications and would avoid take of individuals. Therefore, the implementation of Alternative 4A would have a less-than-significant impact on California least tern.

Mitigation Measure BIO-66: California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized

If suitable nesting habitat for California least tern (flat unvegetated areas near aquatic foraging habitat) is identified during planning level surveys, DWR will ensure that a qualified biologist with experience observing the species and its nests conducts at least three preconstruction surveys for this species during the nesting season. DWR will design projects to avoid the loss of California least tern nesting colonies. No construction will take place within 500 feet California least tern nests during the nesting season (April 15 to August 15 or as determined through surveys). Only inspection, maintenance, research, or monitoring activities may be performed during the least tern breeding season in areas within or adjacent to least tern breeding habitat with USFWS and CDFW approval under the supervision of a qualified biologist.

Impact BIO-67: Indirect Effects of the Project on California Least Tern

Indirect Construction- and Operation-Related Effects: Indirect effects associated with construction that could affect California least tern include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 500 feet from the construction edge. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and Appendix 11F, *Substantive BDCP Revisions*). However, there are no available data to determine the extent to which these noise levels could affect California least tern. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect California least tern or their prey species in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to foraging habitat could also affect the species. Noise and visual disturbance is not expected to have an adverse effect on California least tern foraging behavior. As described in Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized*, if least tern nests were found during planning or preconstruction surveys, no construction would take place within 500 feet of active nests. In addition, AMM1–AMM7, including construction best management practices, would minimize the likelihood of spills or excessive dust being created during construction. Should a spill occur, implementation of these AMMs would greatly reduce the likelihood of individuals being affected.

Methylmercury Exposure: Project activities have the potential to exacerbate the bioaccumulation of mercury in the California least tern. The operational impacts of new flows with water conveyance facilities were analyzed using a DSM-2 based model to assess potential effects on mercury concentration and bioavailability. Largemouth bass were used as a surrogate species for this analysis and results would be expected to be similar or lower for the California least tern. Results indicated that changes in total mercury levels in water and largemouth bass tissues were insignificant (see Appendix 11F, Section 11F.5.2, *Effects of Contaminants on Terrestrial Species*).

Marsh (tidal and nontidal) restoration also has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Increased methylmercury associated with natural community restoration may indirectly affect California least tern, via uptake through consumption of prey (as described in BDCP Appendix 5.D, *Contaminants*).

Schwarzbach and Adelsbach (2003) investigated mercury exposure in 15 species of birds inhabiting the Bay-Delta ecosystem. Among the species studied, the highest concentrations of mercury were found in the eggs of piscivorous birds (terns and cormorants) that bioaccumulate mercury from their fish prey. The very highest concentrations were found in Caspian and Forster's terns, especially those inhabiting South San Francisco Bay. Based on three California least tern eggs collected from Alameda Naval Air Station in the San Francisco Central Bay, concentrations in California least tern eggs were a third (0.3 ppm) those of the eggs of the other two terns. Because of the small sample size, there is a high degree of uncertainty regarding the levels of mercury that may be present in California least tern eggs. If the mercury levels measured at Alameda Naval Air Station are representative of the population in the San Francisco Bay, they would not be expected to result in adverse effects on tern hatchlings. Hatching and fledging success were not reduced in common tern eggs in Germany with mercury concentrations of 6.7 ppm (Hothem and Powell 2000).

Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury. Given that some species have elevated mercury tissue levels pre-Alternative 4A, these low level increases could result in some level of effects. Environmental Commitment 12, described below, would be implemented to address this risk of low level increases in methylmercury which could add to the current elevated tissue concentrations.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability.

- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and project activities have the potential to exacerbate bioaccumulation of selenium in avian species, including California least tern. Marsh (tidal and nontidal) restoration has the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with Environmental Commitment 4 would lead to adverse effects on California least tern.

Because of the uncertainty that exists with respect to specific siting of tidal restoration areas, there could be a substantial effect on California least tern from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Noise and visual disturbances within 500 feet of construction-related activities from the Environmental Commitments could disturb California least tern foraging habitat adjacent to work sites. Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized*, would avoid this potential adverse effect.

AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of spills from occurring and ensure that measures were in place to prevent runoff from the construction area and to avoid negative effects of dust on the species.

Tidal habitat restoration could result in increased exposure of California least tern to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Changes in water operations under water conveyance facilities would not be expected to result in increased mercury bioavailability or exposures to Delta foodwebs. Tidal habitat restoration could result in increased exposure of California least tern to methylmercury. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, it is unknown what concentrations of methylmercury are harmful to the species, and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

With AMM1–7, AMM12, AMM27, and Environmental Commitment 12 in place, in addition to the implementation of Mitigation Measure BIO-66, the indirect effects of Alternative 4A implementation would not result in an adverse effect on California least tern.

Mitigation Measure BIO-66, California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized

See Mitigation Measure BIO-66 under Impact BIO-66.

CEQA Conclusion: Noise and visual disturbances within 500 feet of construction-related activities from the Environmental Commitments would not be expected to disturb California least tern foraging habitat adjacent to work sites. If terns were to nest in newly graded restoration sites during construction activities, Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized*, would avoid the potential for disturbance and take of California least tern individuals.

AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of spills from occurring and ensure that measures were in place to prevent runoff from the construction area and to avoid negative effects of dust on the species.

Tidal habitat restoration could result in increased exposure of California least tern to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Changes in water operations under water conveyance facilities would not be expected to result in increased mercury bioavailability or exposures to Delta foodwebs. Tidal habitat restoration could result in increased exposure of California least tern to methylmercury. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, it is unknown what concentrations of methylmercury are harmful to the species, and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

With AMM1–7, AMM12, AMM27, and Environmental Commitment 12 in place, in addition to the implementation of Mitigation Measure BIO-66, the indirect effects of Alternative 4A implementation would not result in take of California least tern individuals, nor would it result in a substantial adverse effect on the species through habitat modification. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on California least tern.

Mitigation Measure BIO-66, California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized

See Mitigation Measure BIO-66 under Impact BIO-66.

Impact BIO-68: Effects on California Least Tern Associated with Electrical Transmission Facilities

The risk of take of California least tern from the construction of new transmission lines is considered to be minimal based on tern flight behaviors and its unlikely use of habitats near the transmission line corridors. Terns exhibit low wing loading and high aspect-ratio wings and as a result can maneuver relatively quickly around an obstacle such as a transmission line. Their wing structure and design allows for rapid flight and quick, evasive actions (see BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new project transmission lines would be fitted with flight diverters. Bird flight diverters would make transmission lines highly visible to California least terns and would further reduce the potential for powerline collisions. There would be no take of California least tern from the project purrsuant to California Fish and Game Code Section 86.

NEPA Effects: The construction and presence of new transmission lines would not represent an adverse effect on California least tern because they are uncommon in the vicinity of proposed transmission lines and because the probability of bird-powerline strikes is highly unlikely due to tern flight behaviors. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. By implementing *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines would not result in an adverse effect on California least tern.

CEQA Conclusion: The construction and presence of new transmission lines would not result in take of California least tern pursuant to California Fish and Game Section 86Code because they are uncommon in the vicinity of proposed transmission lines and because the probability of bird-powerline strikes is highly unlikely due to tern flight behaviors. *AMM20 Greater Sandhill Crane* contains the commitment for all new transmission lines constructed as a result of the project to be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. By implementing *AMM20 Greater Sandhill Crane*, there would be no take of California least tern from the project under California Fish and Game Code Section 86, and the construction and operation of transmission lines would result in a less-than-significant impact on California least tern.

Greater Sandhill Crane

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on greater sandhill crane. Greater sandhill cranes in the study area are almost entirely dependent on privately owned agricultural lands for foraging. Long-term sustainability of the species is thus dependent on providing a matrix of compatible crop types that afford suitable foraging habitat and maintaining compatible agricultural practices, while sustaining and increasing the extent of other essential habitat elements such as night roosting habitat. The habitat model for greater sandhill crane includes permanent and temporary "roosting and foraging" and "foraging" habitat. These habitat types include certain agricultural types, specific grassland types, irrigated pastures and hay crops, managed seasonal wetland, and other natural seasonal wetland. Roosting and foraging habitat includes known, traditional roost sites that also provide foraging habitat (see BDCP Appendix 2.A *Covered Species Accounts*). Both temporary and permanent roost sites were identified for greater Sandhill crane. Permanent roosting and foraging sites are those used regularly, year after year, while temporary roosting and foraging sites are those only used in some years. Factors included in assessing the loss of foraging habitat for the greater sandhill crane includes the relative habitat value of specific crop or land cover types, and proximity to known roost sites. Foraging habitat for greater sandhill crane included crop types and natural communities up to 4 miles from known roost sites, within the boundary of the winter crane use area (see BDCP Appendix 2.A).

Alternative 4A would result in both temporary and permanent losses of foraging and roosting habitat for greater sandhill crane as indicated in Table 12-4A-27. Full implementation of Alternative 4A would also include the following Resource Restoration and Performance Principles that would benefit the greater sandhill crane.

- Protect high- to very high-value habitat for greater sandhill crane, with at least 80% maintained in very high-value types in any given year. This protected habitat will be within 2 miles of known roosting sites in CZs 3, 4, 5, and/or 6 and will consider sea level rise and local seasonal flood events, greater sandhill crane population levels, and the location of foraging habitat loss. Patch size of protected cultivated lands will be at least 160 acres. [In order to offset the effects on foraging habitat for both greater and lesser sandhill cranes, foraging habitat will be replaced at a minimum of 1:1 based on the acreage of impact on either the greater or lesser sandhill crane foraging habitat, whichever is greater.] (Resource Restoration and Performance Principle GSC1).
- Create at least 320 acres of managed wetlands (part of the nontidal wetland restoration acreage) in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6, with consideration of sea level rise and local seasonal flood events. The wetlands will be located within 2 miles of existing permanent roost sites and protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of 2:1 upland to wetland to provide buffers around the wetlands (Resource Restoration and Performance Principle GSC2).

- Create at least two 90-acre wetland complexes within the Stone Lakes NWR project boundary. The complexes will be no more than 2 miles apart and will help provide connectivity between the Stone Lakes and Cosumnes River Preserve greater sandhill crane populations. Each complex will consist of at least three wetlands totaling at least 90 acres of greater sandhill crane roosting habitat, and will be protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of at least 2:1 uplands to wetlands (i.e., two sites with at least 90 acres of wetlands each). One of the 90-acre wetland complexes may be replaced by 180 acres of cultivated lands (e.g., cornfields) that are flooded following harvest to support roosting cranes and provide highest-value foraging habitat, provided such substitution is consistent with the long-term conservation goals of Stone Lakes NWR for greater sandhill crane (Resource Restoration and Performance Principle GSC3).
- Create an additional 95 acres of roosting habitat within 2 miles of existing permanent roost sites. The habitat will consist of active cornfields that are flooded following harvest to support roosting cranes and that provide highest-value foraging habitat. Individual fields will be at least 40 acres and can shift locations throughout the Greater Sandhill Crane Winter Use Area, but will be sited with consideration of the location of roosting habitat loss and will be in place prior to roosting habitat loss (Resource Restoration and Performance Principle GSC4).

Greater sandhill crane is a fully protected species and take of individuals, pursuant to Section 86 of the California Fish and Game Code, is prohibited. With the implementation of *AMM20 Greater Sandhill Crane*, construction activities would not result in take of the species and would avoid take pursuant to Section 86 of the California Fish and Game Code. As explained below, with the restoration and protection of these amounts of habitat, in addition to natural community enhancement and management commitments (including *Environmental Commitment 12 Methylmercury Management*) and implementation of AMM1–AMM6, *AMM20 Greater Sandhill Crane*, *AMM27 Selenium Management*, and *AMM30 Transmission Line Design and Alignment Guidelines*, impacts on the greater sandhill crane would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-27. Changes in Greater Sandhill Crane Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Roosting and Foraging–Permanent	0	4
	Roosting and Foraging–Temporary	16	71
	Foraging	1,695	772
Total Impacts Water Conveyance Facilities		**1,711**	**847**
Environmental Commitments 4, 6–7, 9–11[a]	Roosting and Foraging–Permanent	0	0
	Roosting and Foraging–Temporary	1	0
	Foraging	2,017	0
Total Impacts Environmental Commitments 4, 6–9–11[a]		**2,018**	**0**
Total Roosting/Foraging–Permanent		**0**	**4**
Total Roosting/Foraging–Temporary		**17**	**71**
Total Foraging		**3,712**	**772**
TOTAL IMPACTS		**3,729**	**847**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-69: Loss or Conversion of Habitat for and Direct Mortality of Greater Sandhill Crane

Alternative 4A would result in the combined permanent and temporary loss of up to 92 acres of modeled roosting and foraging habitat (17 acres of permanent loss, 75 acres of temporary loss) and 4,484 acres of foraging habitat for greater sandhill crane (3,712 of permanent loss, 772 acres of temporary loss; see Table 12-4A-27). Project measures that would result in these losses are water conveyance facilities and transmission line construction, establishment and use of reuseable tunnel material areas, *Environmental Commitment 4 Tidal Natural Communities Restoration*, *Environmental Commitment 8 Grassland Natural Communities Restoration*, *Environmental Commitment 10 Nontidal Marsh Natural Community Restoration*, and *Environmental Commitment 11 Natural Communities Enhancement and Management*. The majority of habitat loss would result from water conveyance facility construction and conversion of habitat to nontidal wetland through Environmental Commitment 10. Habitat enhancement and management activities through Environmental Commitment 11, which include ground disturbance or removal of nonnative vegetation, could also result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate greater sandhill crane modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities as they are currently designed would result in the combined permanent loss of up to 1,711acres of modeled greater sandhill crane habitat. This would consist of the permanent removal of 16 acres of temporary roosting and foraging habitat, and 1,695 acres of foraging habitat (Table 12-4A-27). Foraging habitat that would be permanently impacted by water conveyance construction would consist of 1,050 acres of very high-value, 29 acres of high-value, 199 acres of medium-value, and 492 acres of low-value foraging habitat (Table 12-4A-28). In addition, 4 acres of permanent roosting and foraging habitat, 71 acres of temporary roosting and foraging habitat, and 772 acres of foraging habitat would be temporarily removed (Table 12-4A-27, Table 12-4A-28). The temporarily removed habitat would consist primarily of cultivated lands and it would be restored within one year following construction; however, it would not necessarily be restored to its original topography and it could be restored as grasslands in the place of cultivated lands. Water conveyance facilities activities that would result in temporary impacts would include temporary access roads, reusable tunnel material sites, and work areas for construction.

  The acres of roosting and foraging habitat that would be removed would occur from the construction of a temporary transmission line on Zacharias Island, Bouldin Island, and Venice Island and from the construction of a temporary concrete batch plant and a permanent access road on Bouldin Island; however, the implementation of *AMM20 Greater Sandhill Crane* would require that water conveyance facilities activities be designed to avoid direct loss of crane roost sites. This includes a provision that the final transmission line alignment would be designed to avoid crane roost sites. Avoidance of crane roost sites would be accomplished either by siting activities outside of identified roost sites or by relocating the roost site if it consisted of cultivated lands (roost sites consisting of wetlands would not be subject to re-location). Relocated roost sites would be established prior to construction activities affecting the original roost site, as described in *AMM20 Greater Sandhill Crane* (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Therefore there would be no loss of crane roosting and foraging habitat as a result of water conveyance facility construction once the facilities were fully designed. The potential for greater sandhill crane bird strike on electrical transmission facilities is addressed below under Impact BIO-70.

Activities that would impact modeled greater sandhill crane foraging habitat consist of intermediate forebay and intake construction, construction and use of temporary access roads, and construction of temporary transmission lines. Loss of foraging habitat would also result from the construction of permanent and temporary access roads on Mandeville and Bacon Islands, and from construction of vent shafts on Staten and Bacon Island. Temporary impacts on foraging habitat would also result form geotechnical boring activities along the tunnel alignment. Approximately 1,502 acres of the permanent loss of foraging habitat would be from the storage of reusable tunnel material. This material would likely be moved to other sites for use in levee build-up and restoration, and the affected area would likely eventually be restored. This effect is categorized as permanent because there is no assurance that the material would eventually be moved. The implementation of *AMM6 Disposal and Reuse of Spoils* would require that the areas used for reusable tunnel material storage be minimized in crane foraging habitat and completely avoid crane roost sites (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*).

Construction-related activities would not be expected to result in take of greater sandhill crane if they were present in the study area, because cranes would be expected to avoid contact with construction and other equipment. The potential for greater sandhill crane bird strike on electrical transmission lines is discussed below under Impact BIO-70.

The effects of noise and visual disturbance from water conveyance facilities construction activities are discussed under Impact BIO-71. Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

Table 12-4A-28. Value of Greater Sandhill Crane Foraging Habitat affected by Alternative 4A

Foraging Habitat Value Class	Land Cover Type	Amount Affected by Water Conveyance Facilities permanent [temporary] (acres)	Amount Affected by Environmental Commitments (permanent acres)
Very high	Corn, rice	1,050 [216]	534
High	Wheat, managed wetlands,	0 [21]	226
Medium	Alfalfa and alfalfa mixtures, irrigated mixed pasture, irrigated native pasture, irrigated pasture, irrigated other pasture, grain and hay crops, miscellaneous grain and hay, mixed grain and hay, nonirrigated mixed grain and hay, other grain crops, sudan, miscellaneous grasses, grassland, alkali seasonal wetlands, vernal pool complex	180 [307]	648
Low	Other irrigated crops, idle cropland, blueberries, asparagus, clover, cropped within the last 3 years, grain sorghum, green beans, miscellaneous truck, miscellaneous field, new lands being prepped for crop production, nonirrigated mixed pasture, nonirrigated native pasture, onions, garlic, peppers, potatoes, safflower, sugar beets, tomatoes (processing), melons squash and cucumbers all types, artichokes, beans (dry), native vegetation	465 [229]	609
Total		**1,695 [772]**	**2,017**

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: This activity would result in the permanent loss or conversion of approximately 1 acre of temporary roosting and foraging habitat and 88 acres of greater sandhill crane foraging habitat in the north Delta. Loss of foraging habitat from Environmental Commitment 4 would consist of 23 acres of very high-value, 10 acres of high-value, 28 acres of medium-value, and 27 acres of low-value foraging habitat.
- *Environmental Commitment 7 Riparian Natural Communities Restoration*: This activity would result in the permanent loss of approximately 251 acres of greater sandhill crane foraging habitat. Loss of foraging habitat from Environmental Commitment 4 would consist of 66 acres of very high-value, 28 acres of high-value, 81 acres of medium-value, and 76 acres of low-value foraging habitat.
- *Environmental Commitment 8 Grassland Natural Communities Restoration*: This activity would result in the permanent loss or conversion of approximately 843 acres of cultivated lands that comprise greater sandhill crane foraging habitat. Loss of foraging habitat from Environmental Commitment 4 would consist of 222 acres of very high-value, 94 acres of high-value, 271 acres of medium-value, and 255 acres of low-value foraging habitat.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration would result in the permanent conversion of approximately 832 acres of modeled foraging habitat for the greater sandhill crane. Impacts would consist of approximately 219 acres of very high-value, 93 acres of high-value, 268 acres of medium-value, and 252 acres of low-value foraging habitat (Table 12-4A-28). A portion of the restored nontidal marsh would be expected to provide roosting and foraging habitat value for the greater sandhill crane. However, some of this

restored marsh would be unsuitable as it would lack emergent vegetation and consist of open water that would be too deep to provide suitable roosting or foraging habitat.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could permanently remove 3 acres of foraging habitat and temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values. The potential for these activities to result in take of greater sandhill crane would be minimized with the implementation of *AMM20 Greater Sandhill Crane*.
- *Water Facilities Operations and Maintenance:* Post construction operation and maintenance of the above-ground water conveyance facilities could result in ongoing but periodic disturbances that could affect greater sandhill crane use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects could be adverse as sandhill cranes are sensitive to disturbance. However, potential impacts would be reduced by the AMMs listed below. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

The following paragraphs summarize the combined effects discussed above and describe Alternative 4A Environmental Commitments that offset or avoid these effects. NEPA effects and CEQA conclusions are provided at the end of the section.

Alternative 4A would remove 92 acres roosting and foraging habitat (17 acres of permanent loss, 75 acres of temporary loss) from the construction of the water conveyance facilities. In addition, 4,484 acres of foraging habitat would be removed or converted (Water Conveyance Facilities—2,467 acres; *Environmental Commitment 4 Tidal Natural Communities Restoration*, *Environmental Commitment 7 Riparian Natural Communities Restoration, Environmental Commitment 8 Grassland Natural Communities Restoration,* and *Environmental Commitment 10 Nontidal Marsh Restoration*—2,017 acres). Of these acres of foraging habitat impact, 3,182 acres would be medium- to very high-value habitat (Table 12-4A-28).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 protection and 1:1 restoration for loss of roost sites and 1:1 protection of high- to very high-value foraging habitat for loss of foraging habitat. Using these ratios would indicate that 92 acres of greater sandhill crane roosting habitat should be restored/created and 92 acres should be protected to compensate for the losses of greater sandhill crane roosting and foraging habitat. In addition, 4,484 acres of high- to very high-value foraging habitat should be protected to mitigate the losses of greater sandhill crane foraging habitat.

The implementation of *AMM20 Greater Sandhill Crane* would require no direct impact of greater sandhill crane roost sites by project activities related to water conveyance facilities, including transmission lines and their associated footprints (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Therefore, there would be no loss of crane roosting and foraging habitat as a result of water conveyance facility construction once the facilities were fully designed, which would avoid the water conveyance facilities impact on 91 acres of roosting and foraging habitat. Indirect effects of construction-related noise and visual disturbance are discussed below under Impact BIO-71.

Under Alternative 4A, project proponents would commit to creating up to 95 acres of roosting habitat within 2 miles of existing permanent roost sites Resource Restoration and Performance Principle GSC4). These roosts would consist of active cornfields that are flooded following harvest to support roosting cranes and also provide the highest-value foraging habitat for the species. Individual fields would be at least 40 acres could shift locations throughout the Greater Sandhill Crane Winter Use Area, and would be in place prior to roosting habitat loss. In addition, 320 acres of roosting habitat would be created in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6 (Resource Restoration and Performance Principle GSC2). Restoration sites would be identified with consideration of sea level rise and local seasonal flood events. These wetlands would be created within 2 miles of existing permanent roost sites and protected in association with other protected natural community types at a ratio of 2:1 upland to wetland habitat to provide buffers that will protect cranes from the types of disturbances that would otherwise result from adjacent roads and developed areas (e.g., roads, noise, visual disturbance, lighting). The creation of 180 acres of crane roosting habitat would be constructed within the Stone Lakes NWR project boundary (see Figure 3.3-7 in the BDCP) and would be designed to provide connectivity between the Stone Lakes and Cosumnes greater sandhill crane populations (Resource Restoration and Performance Principle GSC3). The large patch sizes of these wetland complexes would provide additional conservation to address the threats of vineyard conversion, urbanization to the east, and sea level rise to the west of greater sandhill crane wintering habitat.

As directed by Resource Restoration and Protection Principle GSC1, at least 4,584 acres of cultivated lands that provide high- to very high-value foraging habitat would be protected. This habitat would occur within 2 miles of known roost sites and at least 80% would be maintained in very high-value habitat types in any given year (see Table 12-4-28 for greater sandhill crane foraging habitat values).

The project also includes commitments to implement the following avoidance and minimization measures that will help to avoid and minimize adverse effects on greater sandhill crane: *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils,* and *AMM30 Transmission Line Design and Alignment Guidelines*. All of these AMMs include elements that would avoid or minimize the risk of affecting greater sandhill crane habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of greater sandhill crane habitat under Alternative 4A would not be adverse under NEPA because Alternative 4A has committed the project proponents to avoiding and minimizing effects and to restoring and protecting acreages that are greater than the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles GSC1-GSC4, and by AMM1–AMM6, *AMM20 Greater Sandhill Crane*, and AMM30 *Transmission Line Design and Alignment Guidelines,* which would be in place during all project activities. Construction activities would not be expected to result in greater sandhill crane take because foraging and roosting individuals would be expected to temporarily avoid the increased noise and activity associated with construction areas. Considering these commitments, the implementation of Alternative 4A would not result in an adverse effect on greater sandhill crane.

CEQA Conclusion: The effects on greater sandhill crane habitat under Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species in the absence of other Environmental Commitments, Resource Restoration and Performance Principles GSC1-GSC4, and AMMs. However, the project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3 and Environmental Commitment 10 that are greater than the mitigation ratios described above. These conservation actions would be guided by AMM1–AMM6, *AMM20 Greater Sandhill Crane*, and *AMM30 Transmission Line Design and Alignment Guidelines*, which would be in place during all project activities. Construction activities would not be expected to result in greater sandhill crane take because foraging and roosting individuals would be expected to temporarily avoid the increased noise and activity associated with construction areas. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications. Therefore, Alternative 4A would have a less-than-significant impact on greater sandhill cranes under CEQA.

Impact BIO-70: Effects on Greater Sandhill Crane Associated with Electrical Transmission Facilities

Greater sandhill cranes are susceptible to collision with power lines and other structures during periods of inclement weather and low visibility (Avian Power Line Interaction Committee 1994, Brown and Drewien 1995, Manville 2005). There are extensive existing transmission and distribution lines in the sandhill crane winter use area. These include a network of distribution lines that are between 11- and 22-kV. In addition, there are two 115-kV lines that cross the study area, one that overlaps with the sandhill crane winter use area between Antioch and I-5 east of Hood, and one that crosses the northern tip of the sandhill crane winter use area north of Clarksburg. There are 69-kv lines within the study area that parallel Twin Cities Road, Herzog Road, Lambert Road, and the Southern Pacific Dredge Cut in the vicinity of Stone Lakes NWR. At the south end of the winter use area, there are three 230-kV transmission lines that follow I-5, and then cut southwest through Holt, and two 500-kV lines cross the southwestern corner of the winter use area. This existing network of power lines in the study currently poses a collision and electrocution risk for sandhill cranes, because they cross over or surround sandhill crane roost sites in the study area.

Both permanent and temporary electrical transmission lines would be constructed to supply construction and operational power to Alternative 4A facilities, as described below. The potential for birdstrikes could be exacerbated by construction-related effects, especially in low-visibility conditions. The potential take of greater sandhill crane in the area of the proposed transmission lines was estimated for the BDCP using collision mortality rates developed by Brown and Drewien (1995) and an estimate of potential crossings along the proposed lines (See BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*). This analysis concluded that risk of take could be substantially reduced by marking new transmission lines to increase their visibility to sandhill cranes.

Alternative 4A would substantially reduce the length of permanent and temporary transmission lines as compared with the BDCP, substantially reducing the likelihood of crane collisions. Under Alternative 4A, no permanent transmission lines would be constructed within the sandhill crane winter use area. In addition, no new transmission lines (permanent or temporary) would be constructed in the vicinity of Staten Island which is one of the most important wintering sites for greater sandhill cranes in the Delta. The Alternative 4A transmission line alignment within the sandhill crane winter use area would be limited to three segments of temporary transmission lines: a temporary 11-mile segment extending north and south between Intake 2 and the intermediate forebay, a temporary 9-mile segment extending east and west between the intermediate forebay and the SMUD/WAPA substation, and an 11-mile segment extending north and south between Bouldin Island and Victoria Island. These three temporary lines would be removed after construction of the water conveyance facilities, after 10–14 years. Limiting the proposed transmission line footprint to temporary lines and siting these lines away from the highest use areas by greater sandhill cranes, substantially reduces the potential for sandhill crane bird strike in Alternative 4A as compared to the BDCP.

AMM30 Transmission Line Design and Alignment Guidelines would require design features for the transmission line alignment, such as co-locating transmission lines when it would minimize effects on sandhill cranes, to avoid impacts on sensitive habitats to the maximum extent feasible. In addition, after the Draft EIR/EIS was issued in December 2013, additional avoidance features were added to *AMM20 Greater Sandhill Crane*. *AMM20 Greater Sandhill Crane* requires that Alternative 4A meets the performance standard of no take of greater sandhill crane associated with the new facilities. This would be achieved by implementing one or any combination of the following: 1) siting new transmission lines in lower bird strike risk zones; 2) removing, relocating or undergrounding existing lines where feasible; 3) using natural gas generators in lieu of installing transmission lines in high-risk zones of the sandhill crane winter use area; 4) undergrounding new lines in high-risk zones of the sandhill crane winter use area; 5) permanently installing flight diverters on existing lines over lengths equal to or greater than the length of the new temporary transmission lines in the crane winter use area; 6) for areas outside of the Stone Lakes NWR project boundary, shifting locations of flooded areas that provide crane roosts to lower risk areas. These measures are described in detail in *AMM20 Greater Sandhill Crane* in Appendix 3B, *Environmental Commitments, AMMs, and CMs*.

The implementation of the measures described above under *AMM20 Greater Sandhill Crane*, in addition to the project design changes to avoid high crane use areas, would not result in take of greater sandhill crane pursuant to California Fish and Game Code Section 86. Potential measures include using natural gas generators in lieu of transmission lines or undergrounding new lines in high-risk zones in the sandhill crane winter use area. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality, including for sandhill cranes (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new temporary transmission lines would be fitted with flight diverters. The installation of flight diverters on existing permanent lines would be prioritized in the highest risk zones for greater sandhill crane (as described in BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*) and diverters would be installed in a configuration that research indicates would reduce bird strike risk by at least 60%. The length of existing line to be fitted with bird strike diverters would be equal to the length of new transmission lines constructed for the project, in an area with the same or higher greater sandhill crane strike risk to provide a net benefit to the species. For optimum results, the recommended spacing distance for bird flight diverters is 15 to 16.5 feet (4.5 to 5 meters) (Avian Power Line Interaction Committee 1994). Placing diverters on existing lines would be expected to reduce existing take in the Plan Area and therefore result in a net benefit to the greater sandhill crane population because these flight diverters would be maintained in perpetuity. Considering that the temporary lines would be removed within the first 10–14 years of

Alternative 4A implementation, and with the implementation of one or a combination of the measures described under *AMM20 Greater Sandhill Crane*, there would be no take of greater sandhill crane from the project pursuant to California Fish and Game Code Section 86.

NEPA Conclusion: Sandhill cranes are known to be susceptible to collision with overhead wires. The existing network of power lines in the study area currently poses a risk for sandhill cranes. Under Alternative 4A, proposed transmission lines have been designed to substantially reduce the likelihood of a crane collision with transmission lines. New transmission lines constructed as part of the project would be limited to temporary lines which would be removed within the first 10–14 years of Alternative 4A implementation. In addition, no new transmission lines would be sited in the vicinity of Staten Island, which has the highest crane-use in the sandhill crane winter use area. *AMM30 Transmission Line Design and Alignment Guidelines* would require design features for the transmission line alignment, such as co-locating transmission lines when it would minimize effects on sandhill cranes, to avoid impacts on sensitive habitats to the maximum extent feasible. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. By incorporating *AMM30 Transmission Line Design and Alignment Guidelines* and one or a combination of the measures to greatly reduce the risk of bird strike described in *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines under Alternative 4A would not result in an adverse effect on greater sandhill crane.

CEQA Conclusion: Sandhill cranes are known to be susceptible to collision with overhead wires. The existing network of power lines in the study area currently poses a risk for sandhill cranes. Under Alternative 4A, proposed transmission lines have been designed to substantially reduce the likelihood of a crane collision with transmission lines. New transmission lines constructed as part of the project would be limited to temporary lines which would be removed within the first 10–14 years of Alternative 4A implementation. In addition, no new transmission lines would be sited in the vicinity of Staten Island, which has the highest crane-use in the sandhill crane winter use area. *AMM30 Transmission Line Design and Alignment Guidelines* would require design features for the transmission line alignment, such as co-locating transmission lines when it would minimize effects on sandhill cranes, to avoid impacts on sensitive habitats to the maximum extent feasible. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. By incorporating *AMM30 Transmission Line Design and Alignment Guidelines* and one or a combination of the measures to greatly reduce the risk of bird strike described in *AMM20 Greater Sandhill Crane*, there would be no take of greater sandhill crane from the project pursuant to California Fish and Game Code Section 86, and the construction and operation of transmission lines under Alternative 4A would have a less-than-significant impact on greater sandhill crane.

Impact BIO-71: Indirect Effects of the Project on Greater Sandhill Crane

Indirect Construction- and Operation-Related Effects: Sandhill cranes are sensitive to disturbance. Noise and visual disturbances from the construction of water conveyance facilities and Environmental Commitments could reduce greater sandhill crane use of modeled habitat adjacent to work areas. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet of the construction edge. Furthermore, maintenance of the aboveground water conveyance facilities could result in ongoing but periodic postconstruction noise and visual disturbances that could affect greater sandhill crane use of surrounding habitat. These effects could result from periodic vehicle use along the conveyance corridor, inspection and maintenance of aboveground facilities, and similar activities. These potential effects would be minimized with implementation of *AMM20 Greater Sandhill Crane*, described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*.

The BDCP includes an analysis of the indirect effects of noise and visual disturbance that would result from the construction of the Alternative 4 water conveyance facilities on greater sandhill crane (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). The analysis addressed the potential noise effects on cranes, and concluded that as much as 20,243 acres of crane habitat could potentially be affected by general construction noise (including pile driving) above baseline level (50–60 dBA; Table 12-4A-29). This would include 1,008 acres of permanent crane roosting habitat, 1,909 acres of temporary crane roosting habitat, and 17,327 acres of crane foraging habitat. The analysis was conducted based on the assumption that there would be direct line-of-sight from sandhill crane habitat areas to the construction site, and, therefore, provides a worst-case estimate of effects. In many areas the existing levees would partially or completely block the line-of-sight and would function as effective noise barriers, substantially reducing noise transmission. However, there is insufficient data to assess the effects that increased noise levels would have on sandhill crane behavior.

Table 12-4A-29. Greater Sandhill Crane Habitat Affected by General Construction and Pile Driving Noise Under Alternative 4A (acres)

	General Construction	
Habitat Type	Above 60 dBA	Above 50 dBA
Permanent Roosting	196	1,008
Temporary Roosting	810	1,909
Foraging	7,676	17,327
Total Habitat	**8,681**	**20,243**

Evening and nighttime construction activities would require the use of extremely bright lights. Nighttime construction could also result in headlights flashing into roost sites when construction vehicles are turning onto or off of construction access routes. Proposed surge towers would require the use of safety lights that would alert low-flying aircraft to the presence of these structures because of their height. Little data is available on the effects of impact of artificial lighting on roosting birds. Direct light from automobile headlights has been observed to cause roosting cranes to flush and it is thought that they may avoid roosting in areas where lighting is bright (see BDCP Chapter 5, *Effects Analysis*). If the birds were to roost in a brightly lit site, they may be vulnerable to sleep-wake cycle shifts and reproductive cycle shifts. Potential risks of visual impacts from lighting include a reduction in the cranes' quality of nocturnal rest, and effects on their sense of photo-period which might cause them to shift their physiology towards earlier migration and breeding (see BDCP Chapter 5). Effects such as these could prove detrimental to the cranes' overall fitness and reproductive success (which could in turn have population-level impacts). A change in photo-period interpretation could also cause cranes to fly out earlier from roost sites to forage and might increase their risk of power line collisions if they were to leave roosts before dawn (see BDCP Chapter 5).

The effects of noise and visual disturbance on greater sandhill crane would be minimized through the implementation of *AMM20 Greater Sandhill Crane* (see Appendix 3B, *Environmental*

Commitments, AMMs, and CMs). Activities within 0.75 mile of crane roosting habitat would reduce construction noise during night time hours (from one hour before sunset to one hour after sunrise) such that construction noise levels do not exceed 50 dBA L_{eq} (1 hour) at the nearest temporary or permanent roosts during periods when the roost sites are available (flooded). In addition, the area of crane foraging habitat that would be affected during the day (from one hour after sunrise to one hour before sunset) by construction noise exceeding 50 dBA L_{eq} (1 hour) would also be minimized. Unavoidable noise related effects would be compensated for by the enhancement of 0.1 acre of foraging habitat for every acre indirectly affected within the 50 dBA L_{eq} (1 hour) construction noise contour. With these measures in place, indirect effects of noise and visual disturbance from construction activities are not expected to reduce the greater sandhill crane population in the study area.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect greater sandhill crane in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to greater sandhill crane habitat could also affect the species. The implementation of AMM1–AMM6 would minimize the likelihood of such spills and ensure that measures were in place to prevent runoff from the construction area and negative effects of dust on foraging habitat (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*).

Methylmercury Exposure: Changes in water operations from the construction of the water conveyance facilities and the implementation of Environmental Commitment 10 (Nontidal Marsh Restoration) have the potential to exacerbate bioaccumulation of mercury in greater sandhill crane. Largemouth bass was used as a surrogate species for analysis of impacts from changes in operations from the construction of the water conveyance facilities (see Appendix 11F, *Substantive BDCP Revisions*). Results of the quantitative modeling of mercury effects on largemouth bass as a surrogate species overestimate the effects on greater sandhill crane because of their position in the foodweb. Organisms feeding within pelagic-based (algal) foodwebs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic foodwebs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009). Potential indirect effects of increased mercury exposure are likely low for greater sandhill crane because they primarily forage on waste grains and, to a lesser extent, invertebrates associated with cultivated crops. The modeled effects of mercury concentrations from changes in water operations with water conveyance facilities on largemouth bass did not differ substantially from existing conditions; therefore, results also indicate that greater sandhill crane tissue concentrations would not measurably increase as a result of water conveyance facilities construction.

Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Increased methylmercury associated with *Environmental Commitment 10 Nontidal Marsh Restoration* may indirectly affect greater sandhill crane via uptake in lower trophic levels (see Appendix 11F, Section 11F.5.2, *Effects of Contaminants on Terrestrial Species*). Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury.

Due to the complex and very site-specific factors that would determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This Environmental Commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and project activities have the potential to exacerbate bioaccumulation of selenium in avian species, including greater sandhill crane. Environmental Commitment 10 (Nontidal Marsh Restoration) has the potential to mobilize selenium, and therefore increase greater sandhill crane exposure from ingestion of prey items (waste grain and associated invertebrates) with elevated selenium levels. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related Environmental Commitments (Environmental Commitment 10) would lead to adverse effects on greater sandhill crane.

Because of the uncertainty that exists with respect to the location of nontidal restoration activities, there could be an effect on greater sandhill crane from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal and nontidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the restoration design.

***NEPA Effects*:** Crane habitat could potentially be affected by general construction noise above baseline level (50–60 dBA). Construction in certain areas would take place 7 days a week and 24 hours a day and evening and nighttime construction activities would require the use of extremely bright lights, which could adversely affect roosting cranes by impacting their sense of photo-period and by exposing them to predators. Effects of noise and visual disturbance could substantially alter the suitability of habitat for greater sandhill crane. *AMM20 Greater Sandhill Crane* would include requirements (described above) to minimize the effects of noise and visual disturbance on greater sandhill cranes and to compensate for affected habitat.

The implementation of *Environmental Commitment 10 Nontidal Marsh Restoration* could result in increased exposure of greater sandhill crane to methylmercury and selenium. The potential indirect effect of increased mercury exposure is likely low for greater sandhill crane because they primarily forage on cultivated crops and associated invertebrates. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure. The potential effect of selenium exposure would be addressed through the implementation of *AMM27 Selenium Management,* which would provide specific restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in restored habitats.

With AMM1–AMM6, *AMM20 Greater Sandhill Crane*, *AMM27 Selenium Management*, and Environmental Commitment 12 in place, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of greater sandhill cranes. Therefore, the indirect effects of Alternative 4A implementation on greater sandhill crane would not be adverse under NEPA.

With AMM1–AMM6, *AMM20 Greater Sandhill Crane*, *AMM27 Selenium Management*, and Environmental Commitment 12 in place, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of greater sandhill cranes. Therefore, the indirect effects of Alternative 4A implementation would not result in an adverse effect on greater sandhill crane under NEPA.

***CEQA Conclusion*:** Crane habitat could potentially be affected by general construction noise above baseline level (50–60 dBA). Construction in certain areas would take place 7 days a week and 24 hours a day and evening and nighttime construction activities would require the use of extremely bright lights, which could adversely affect roosting cranes by impacting their sense of photo-period and by exposing them to predators. Effects of noise and visual disturbance could substantially alter the suitability of habitat for greater sandhill crane. This would be a significant impact. *AMM20 Greater Sandhill Crane* would include requirements (described above) to minimize the effects of noise and visual disturbance on greater sandhill cranes and to mitigate impacts on affected habitat.

The implementation of *Environmental Commitment 10 Nontidal Marsh Restoration* could result in increased exposure of greater sandhill crane to methylmercury and selenium. This would be a significant impact. The potential indirect effect of increased mercury exposure is likely low for greater sandhill crane because they primarily forage on cultivated crops and associated invertebrates. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure. The potential effect of selenium exposure would be addressed through the implementation of *AMM27 Selenium Management,* which would provide specific restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in restored habitats.

With AMM1–AMM6, *AMM20 Greater Sandhill Crane*, *AMM27 Selenium Management*, and Environmental Commitment 12 in place, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of greater sandhill cranes. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on greater sandhill crane under CEQA.

Lesser Sandhill Crane

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on lesser sandhill crane. Lesser sandhill cranes in the study area are almost entirely dependent on privately owned agricultural lands for foraging. Long-term sustainability of the lesser sandhill crane is thus dependent on providing a matrix of compatible crop types that afford suitable foraging habitat and maintaining compatible agricultural practices, while sustaining and increasing the extent of other essential habitat elements such as night roosting habitat. The habitat model for lesser sandhill crane is limited to the sandhill crane winter use area (Figure 12-22) and includes "roosting and foraging" (known roost sites that also provide foraging habitat) and "foraging" habitat. Suitable roosting and foraging habitat in the study area includes certain agricultural types, specific grassland types, irrigated pastures and hay crops, managed seasonal wetland, and other natural seasonal wetland. Roosting and foraging habitat includes traditional roost sites that are known to be used by sandhill cranes (both greater and lesser) and that also provide foraging habitat. Detail regarding the roosting and foraging modeled habitat for both subspecies of sandhill crane is included in the BDCP (see BDCP Appendix 2.A, *Covered Species Accounts*). Both temporary and permanent roost sites were identified for sandhill cranes. Permanent roosting and foraging sites are those used regularly, year after year, while temporary roosting and foraging sites are those used in some years. Factors included in assessing the loss of foraging habitat for the lesser sandhill crane considers the relative habitat value of specific crop or land cover types. Although both the greater and the lesser sandhill crane use similar crop or land cover types, these provide different values of foraging habitat for the two subspecies based on proportional use of these habitats. Lesser sandhill cranes are less traditional than greater sandhill cranes and are more likely to move between different roost site complexes and different wintering regions (Ivey pers. comm.) The wintering range is ten times larger than the greater sandhill crane and their average foraging flight radius from roost sites is twice that of greater sandhill cranes. Because of this higher mobility, lesser sandhill cranes are more flexible in their use of foraging areas than the greater sandhill crane. Therefore, within the sandhill crane winter use area, there is more suitable foraging habitat modeled for lesser sandhill crane than for greater sandhill crane.

Alternative 4A would result in both temporary and permanent losses of foraging and roosting habitat for lesser sandhill crane as indicated in Table 12-4A-30. Full implementation of Alternative 4A would include the following Resource Restoration and Performance Principles for greater sandhill crane that would similarly benefit the lesser sandhill crane.

- Protect high- to very high-value habitat for greater sandhill crane, with at least 80% maintained in very high-value types in any given year. This protected habitat will be within 2 miles of known roosting sites in CZs 3, 4, 5, and/or 6 and will consider sea level rise and local seasonal flood events, greater sandhill crane population levels, and the location of foraging habitat loss. Patch size of protected cultivated lands will be at least 160 acres [In order to offset the effects on foraging habitat for both greater and lesser sandhill cranes, foraging habitat will be replaced at a minimum of 1:1 based on the acreage of impact on either the greater or lesser sandhill crane foraging habitat, whichever is greater.] (Resource Restoration and Performance Principles GSC1).

- Create at least 320 acres of managed wetlands in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6, with consideration of sea level rise and local seasonal flood events. The wetlands will be located within 2 miles of existing permanent roost sites and protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of 2:1 upland to wetland to provide buffers around the wetlands (Resource Restoration and Performance Principles GSC2).

- Create at least two 90-acre wetland complexes within the Stone Lakes NWR project boundary. The complexes will be no more than 2 miles apart and will help provide connectivity between the Stone Lakes and Cosumnes greater sandhill crane populations. Each complex will consist of at least three wetlands totaling at least 90 acres of greater sandhill crane roosting habitat, and will be protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of at least 2:1 uplands to wetlands (i.e., two sites with at least 90 acres of wetlands each). One of the 90-acre wetland complexes may be replaced by 180 acres of cultivated lands (e.g., cornfields) that are flooded following harvest to support roosting cranes and provide highest-value foraging habitat, provided such substitution is consistent with the long-term conservation goals of Stone Lakes NWR for greater sandhill crane (Resource Restoration and Performance Principles GSC3).

- Create an additional 95 acres of roosting habitat within 2 miles of existing permanent roost sites. The habitat will consist of active cornfields that are flooded following harvest to support roosting cranes and that provide highest-value foraging habitat. Individual fields will be at least 40 acres and can shift locations throughout the Greater Sandhill Crane Winter Use Area, but will be sited with consideration of the location of roosting habitat loss and will be in place prior to roosting habitat loss (Resource Restoration and Performance Principles GSC4).

As explained below, with the restoration and protection of these amounts of habitat, in addition to natural community enhancement and management commitments (including *Environmental Commitment 12 Methylmercury Management*) and implementation of AMM1–AMM7, *AMM20 Greater Sandhill Crane*, *AMM27 Selenium Management*, and *AMM30 Transmission Line Design and Alignment Guidelines*, impacts on the lesser sandhill crane would be less than significant for CEQA purposes, and would not be adverse for NEPA purposes.

Table 12-4A-30. Changes in Lesser Sandhill Crane Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Roosting and Foraging–Permanent	0	4
	Roosting and Foraging–Temporary	16	71
	Foraging	1,707	860
Total Impacts Water Conveyance Facilities		**1,723**	**935**
Environmental Commitments 4, 6––11[a]	Roosting and Foraging–Permanent	0	0
	Roosting and Foraging–Temporary	1	0
	Foraging	2,017	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,018**	**0**
Total Roosting/Foraging–Permanent		**0**	**4**
Total Roosting/Foraging–Temporary		**17**	**71**
Total Foraging		**3,724**	**860**
TOTAL IMPACTS		**3,741**	**935**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-72: Loss or Conversion of Habitat for and Direct Mortality of Lesser Sandhill Crane

Alternative 4A would result in the combined permanent and temporary loss of up to 92 acres of modeled roosting and foraging habitat (17 acres of permanent loss, 75 acres of temporary loss) and 4,584 acres of foraging habitat (3,724 acres of permanent loss, 860 acres of temporary loss, Table 12-4A-30). Project measures that would result in these losses are water conveyance facilities and transmission line construction, establishment and use of reusable tunnel material areas, *Environmental Commitment 4 Tidal Natural Communities Restoration*, *Environmental Commitment 7 Riparian Natural Communities Restoration*, *Environmental Commitment 8 Grassland Natural Communities Restoration*, *Environmental Commitment 10 Nontidal Marsh Restoration*, and *Environmental Commitment 11 Natural Communities Enhancement and Management*. The majority of habitat loss would result from water conveyance facility construction and conversion of foraging habitat to nontidal natural communities through Environmental Commitment 10. Habitat enhancement and management activities through Environmental Commitment 11, which include ground disturbance or removal of nonnative vegetation, could also result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate lesser sandhill crane modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities would result in the combined permanent loss of up to 1,723 acres of modeled lesser sandhill crane habitat. This would consist of the permanent removal of 16 acres of temporary roosting and foraging habitat, and 1,707 acres of foraging habitat. Foraging habitat that would be permanently impacted by water conveyance construction would consist of 1,018 acres of very high-value, 135 acres of high-value, and 301 acres of medium-value foraging habitat (Table 12-4A-31). In addition, 4 acres of permanent roosting and foraging habitat, 71 acres of temporary roosting and foraging habitat, and 860 acres of foraging habitat would be temporarily removed (Table

12-4A-30). The temporarily removed habitat would consist primarily of cultivated lands and it would be restored within 1 year following construction. However, it would not necessarily be restored to its original topography and it could be restored as grasslands. Water conveyance facilities activities that would result in temporary impacts would include temporary access roads, reusable tunnel material sites, and work areas for construction.

- The acres of roosting and foraging habitat that would be permanently removed is located on Bouldin Island, from the construction of a permanent access road. Temporary impacts on roosting and foraging habitat would occur on Bouldin Island from the construction of a temporary concrete batch plant and a fuel station. Temporary losses would also occur from the construction of temporary transmission lines between the Lambert Road vent shaft and the intermediate forebay, and on Venice Island. However, the implementation of *AMM20 Greater Sandhill Crane* would require that water conveyance facilities activities be designed to avoid direct loss of crane roost sites. This includes a provision that the final transmission line alignment would be designed to avoid crane roost sites. Avoidance of crane roost sites would be accomplished either by siting activities outside of identified roost sites or by relocating the roost site if it consisted of cultivated lands (roost sites consisting of wetlands would not be subject to re-location). Relocated roost sites would be established prior to construction activities affecting the original roost site, as described in *AMM20 Greater Sandhill Crane* (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Therefore, there would be no loss of crane roosting and foraging habitat as a result of water conveyance facility construction once the facilities were fully designed.

- Activities that would impact modeled lesser sandhill crane foraging habitat consist of intermediate forebay and intake construction, construction and use of temporary access roads, and construction of temporary transmission lines. Loss of foraging habitat would also result from the construction of permanent and temporary access roads on Mandeville and Bacon Islands, and from construction of vent shafts on Staten and Bacon Islands. Temporary impacts on foraging habitat would also result form geotechnical boring activities along the tunnel alignment. Approximately 1,502 acres of the permanent loss of foraging habitat would be from the storage of reusable tunnel material. This material would be stored on Bouldin Island, Zacharias Island and parcels south of Lambert Road and north of the Cosumnes River. The reusable tunnel material would likely be moved to other sites for use in levee build-up and restoration, and the affected areas would likely eventually be restored. This effect is categorized as permanent because there is no assurance that the material would eventually be moved. The implementation of *AMM6 Disposal and Reuse of Spoils* would require that the areas used for reusable tunnel material storage be minimized in crane foraging habitat and completely avoid crane roost sites (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*).

  Construction-related activities would not be expected to result in direct mortality of lesser sandhill crane if they were present in the study area, because cranes would be expected to avoid contact with construction and other equipment. The potential for lesser sandhill crane bird strike on electrical transmission lines is discussed below under Impact BIO-73.

The effects of noise and visual disturbance from water conveyance facilities construction activities are discussed under Impact BIO-74. Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

Table 12-4A-31. Value of Lesser Sandhill Crane Foraging Habitat Affected By Alternative 4A Water Conveyance Facilities

Foraging Habitat Value Class	Land Cover Type	Water Conveyance Facilities Permanent [Temporary] (acres)
Very high	Corn, alfalfa and alfalfa mixtures	1,018[319]
High	Mixed pasture, native pasture, other pasture, irrigated pasture, native vegetation, rice	135 [124]
Medium	Grain and hay crops, miscellaneous grain and hay, mixed grain and hay, unirrigated mixed grain and hay, other grain crops, miscellaneous grasses, grassland, wheat, other grain crops, managed wetlands	301 [201]
Low	Other irrigated crops, idle cropland, blueberries, asparagus, clover, cropped within the last 3 years, grain sorghum, green beans, miscellaneous truck, miscellaneous field, new lands being prepped for crop production, nonirrigated mixed pasture, nonirrigated native pasture, onions, garlic, peppers, potatoes, safflower, sudan, sugar beets, tomatoes (processing), melons squash and cucumbers all types, artichokes, beans (dry)	242 [205]
None	Vineyards, orchards	12 [10]

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: This activity would result in the permanent loss or conversion of approximately 1 acre of temporary roosting and foraging habitat and 88 acres of lesser sandhill crane foraging habitat in the north Delta.
- *Environmental Commitment 7 Riparian Natural Communities Restoration*: This activity would result in the permanent loss or conversion of approximately 251 acres of lesser sandhill crane foraging habitat in the north Delta.
- *Environmental Commitment 8 Grassland Natural Communities Restoration*: This activity would result in the permanent loss or conversion of approximately 843 acres of lesser sandhill crane foraging habitat in the north Delta.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration would result in the permanent conversion of approximately 832 acres of modeled foraging habitat for the lesser sandhill crane. A portion of the restored nontidal marsh would be restored to provide roosting and foraging habitat value for sandhill cranes. However, some of this restored marsh would be unsuitable as it would lack emergent vegetation and consist of open water that would be too deep to provide suitable roosting or foraging habitat.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in *Environmental Commitment 11* that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could permanently remove 3 acres of foraging habitat and temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values. The potential for these activities to

result in direct mortality of lesser sandhill crane would be minimized with the implementation of *AMM20 Greater Sandhill Crane*.

- *Water Facilities Operations and Maintenance*: Post construction operation and maintenance of the above-ground water conveyance facilities could result in ongoing but periodic disturbances that could affect lesser sandhill crane use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, could be adverse as sandhill cranes are sensitive to disturbance. However, potential impacts would be reduced by the AMMs listed below. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

The following paragraphs summarize the combined effects discussed above and describe Alternative 4A Environmental Commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA effects and CEQA conclusions are provided at the end of the section.

Alternative 4A would remove 92 acres roosting and foraging habitat (17 acres of permanent loss, 75 acres of temporary loss) from the construction of the water conveyance facilities. In addition, 4,584 acres of foraging habitat would be removed or converted (Water Conveyance Facilities—2,567 acres; *Environmental Commitment 4 Tidal Natural Communities Restoration, Environmental Commitment 7 Riparian Natural Communities Restoration, Environmental Commitment 8 Grassland Natural Communities Restoration* and *Environmental Commitment 10 Nontidal Marsh Restoration*—2,017 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 protection and 1:1 restoration for loss of roost sites and 1:1 protection for loss of foraging habitat. Using these ratios would indicate that 92 acres of sandhill crane roosting habitat should be restored/created and 92 acres should be protected to compensate for the losses of lesser sandhill crane roosting and foraging habitat. In addition, 4,584 acres of foraging habitat should be protected to mitigate the losses of lesser sandhill crane foraging habitat.

The implementation of *AMM20 Greater Sandhill Crane* would require no direct impacts on sandhill crane roost sites by project activities related to water conveyance facilities, including transmission lines and their associated footprints (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Therefore there would be no loss of crane roosting and foraging habitat as a result of water conveyance facility construction once the facilities were fully designed, which would avoid the water conveyance facilities impact on 91 acres of roosting and foraging habitat once the project design is final. Indirect effects of construction-related noise and visual disturbance are discussed below under Impact BIO-74.

Alternative 4A also includes the following performance standards for the greater sandhill crane which would also benefit the lesser sandhill crane, as they utilize similar habitats and face similar threats within their winter use areas.

Project proponents would commit to creating up to 95 acres of roosting habitat within 2 miles of existing permanent roost sites (Resource Restoration and Performance Principle GSC4). These roosts would consist of active cornfields that are flooded following harvest to support roosting cranes and also provide the highest-value foraging habitat for the species. Individual fields would be at least 40 acres could shift locations throughout the Greater Sandhill Crane Winter Use Area, and would be in place prior to roosting habitat loss. In addition, 320 acres of roosting habitat would be created in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6 (Resource Restoration and Performance Principle GSC2). Restoration sites would be identified with consideration of sea level rise and local seasonal flood events. These wetlands would be created within 2 miles of existing permanent roost sites and protected in association with other protected natural community types at a ratio of 2:1 upland to wetland habitat to provide buffers that would protect cranes from the types of disturbances that would otherwise result from adjacent roads and developed areas (e.g., roads, noise, visual disturbance, lighting). The creation of 180 acres of crane roosting habitat would be constructed within the Stone Lakes NWR project boundary (see Figure 3.3-7 in the BDCP) and would be designed to provide connectivity between the Stone Lakes and Cosumnes greater sandhill crane populations (Resource Restoration and Performance Principle GSC3). The large patch sizes of these wetland complexes would provide additional conservation to address the threats of vineyard conversion, urbanization to the east, and sea level rise to the west of sandhill crane wintering habitat.

As specified in GSC1, at least 4,584 acres of cultivated lands that provide high- to very high-valueforaging habitat for greater sandhill crane would be protected. This habitat would occur within 2 miles of known roost sites and at least 80% would be maintained in very high-value habitat types for greater sandhill crane in any given year (which would be high- to very high-value crop types for the lesser sandhill crane; see Table 12-4A-28 and Table 12-4A-31 for sandhill crane foraging habitat values). The remaining habitat protected could range between medium to very-high value habitat for lesser sandhill crane. The proposed project would also include commitments to implement the following avoidance and minimization measures that will help to avoid and minimize adverse effects on lesser sandhill crane: *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils*, and *AMM30 Transmission Line Design and Alignment Guidelines*. All of these AMMs include elements that would avoid or minimize the risk of affecting lesser sandhill crane habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of lesser sandhill crane habitat under Alternative 4A would not be adverse under NEPA because Alternative 4A has committed the project proponents to avoiding and minimizing effects and to restoring and protecting acreages that meet the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles GSC1-GSC4, and by AMM1–AMM6, *AMM20 Greater Sandhill Crane*, and *AMM30 Transmission Line Design and Alignment Guidelines,* which would be in place during all project activities. Considering these commitments, the implementation of Alternative 4A would not result in an adverse effect on lesser sandhill crane.

CEQA Conclusion: The effects on lesser sandhill crane habitat under Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species in the absence of Environmental Commitments, Resource Restoration and Performance Principles GSC1-GSC4 for greater sandhill crane (which would also benefit lesser sandhill crane), and AMMs. However, the project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3 and Environmental Commitment 10 that are greater than the mitigation ratios described above. These conservation actions would be guided by AMM1–AMM6, *AMM20 Greater Sandhill Crane*, and *AMM30 Transmission Line Design and*

Alignment Guidelines, which would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of lesser sandhill cranes. Therefore, Alternative 4A would have a less-than-significant impact on lesser sandhill cranes under CEQA.

Impact BIO-73: Effects on Lesser Sandhill Crane Associated with Electrical Transmission Facilities

Sandhill cranes are susceptible to collision with power lines and other structures during periods of inclement weather and low visibility (Avian Power Line Interaction Committee 1994, Brown and Drewien 1995, Manville 2005). There are extensive existing transmission and distribution lines in the sandhill crane winter use area. These include a network of distribution lines that are between 11- and 22-kV. In addition, there are two 115-kV lines that cross the study area, one that overlaps with the sandhill crane winter use area between Antioch and I-5 east of Hood, and one that crosses the northern tip of the sandhill crane winter use area north of Clarksburg. There are 69-kv lines within the study area that parallel Twin Cities Road, Herzog Road, Lambert Road, and the Southern Pacific Dredge Cut in the vicinity of Stone Lakes NWR. At the south end of the winter use area, there are three 230-kV transmission lines that follow I-5, and then cut southwest through Holt, and two 500-kV lines cross the southwestern corner of the winter use area. This existing network of power lines in the study currently poses a collision and electrocution risk for sandhill cranes, because they cross over or surround sandhill crane roost sites in the study area.

Both permanent and temporary electrical transmission lines would be constructed to supply construction and operational power to Alternative 4A facilities, as described below. The potential for birdstrikes could be exacerbated by construction-related effects, especially in low-visibility conditions. The potential mortality of greater sandhill crane in the area of the proposed transmission lines was estimated for the BDCP using collision mortality rates developed by Brown and Drewien (1995) and an estimate of potential crossings along the proposed lines (See BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*). This analysis concluded that mortality risk could be substantially reduced by marking new transmission lines to increase their visibility to sandhill cranes. Mortality risk would be similarly reduced for lesser sandhill cranes by marking new transmission lines.

The transmission line footprint for Alternative 4A was changed substantially from the BDCP to reduce potential risk of greater sandhill crane collisions. The following changes also reduce potential risk of lesser sandhill crane collisions:

Alternative 4A would substantially reduced the length of permanent and temporary transmission lines as compared with the BDCP, substantially reducing the likelihood of crane collisions. Under Alternative 4A, no permanent transmission lines would be constructed within the sandhill crane winter use area. In addition, no new transmission lines (permanent or temporary) would be constructed in the vicinity of Staten Island which is one of the most important wintering sites for greater sandhill cranes in the Delta. The Alternative 4A transmission line alignment within the sandhill crane winter use area would be limited to three segments of temporary transmission lines: a temporary 11-mile segment extending north and south between Intake 2 and the intermediate forebay, a temporary 9-mile segment extending east and west between the intermediate forebay and the SMUD/WAPA substation, and an 11-mile segment extending north and south between Bouldin Island and Victoria Island. These three temporary lines would be removed after construction of the water conveyance facilities, after 10–14 years. Limiting the proposed transmission line footprint to temporary lines and siting these lines away from the highest use areas by both greater and lesser sandhill cranes, substantially reduces the potential for sandhill crane bird strike in Alternative 4A as compared to the BDCP.

AMM30 Transmission Line Design and Alignment Guidelines would require design features for the transmission line alignment, such as co-locating transmission lines when it would minimize effects on sandhill cranes, to avoid impacts on sensitive habitats to the maximum extent feasible. In addition, after the Draft EIR/EIS was issued in December 2013, additional avoidance features were added to *AMM20 Greater Sandhill Crane*. *AMM20 Greater Sandhill Crane* requires that Alternative 4A meet the performance standard of no mortality of greater sandhill crane associated with the new facilities. This would be achieved by implementing one or any combination of the following: 1) siting new transmission lines in lower bird strike risk zones; 2) removing, relocating or undergrounding existing lines where feasible; 3) using natural gas generators in lieu of installing transmission lines in high-risk zones of the sandhill crane winter use area; 4) undergrounding new lines in high-risk zones of the sandhill crane winter use area; 5) permanently installing flight diverters on existing lines over lengths equal to or greater than the length of the new temporary transmission lines in the sandhill crane winter use area; 6) for areas outside of the Stone Lakes NWR project boundary, shifting locations of flooded areas that provide crane roosts to lower risk areas. These measures are described in detail in *AMM20 Greater Sandhill Crane* (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*).

The implementation of the measures described above under *AMM20 Greater Sandhill Crane*, in addition to the project design changes to avoid high crane use areas, would substantially reduce potential collisions of lesser sandhill cranes with transmission lines. Potential measures include using natural gas generators in lieu of transmission lines or undergrounding new lines in high-risk zones in the sandhill crane winter use area. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality, including for sandhill cranes (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new temporary transmission lines would be fitted with flight diverters. The installation of flight diverters on existing permanent lines would be prioritized in the highest risk zones for greater sandhill crane (as described in BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*) and diverters would be installed in a configuration that research indicates would reduce bird strike risk by at least 60% The length of existing line to be fitted with bird strike diverters would be equal to the length of new transmission lines constructed as a result of the project, in an area with the same or higher lesser sandhill crane strike risk to provide a net benefit to the species. For optimum results, the recommended spacing distance for bird flight diverters is 15 to 16.5 feet (4.5 to 5 meters) (Avian Power Line Interaction Committee 1994). Placing diverters on existing lines would be expected to reduce existing lesser and greater sandhill crane mortality in the Plan Area and, therefore, would result in a net benefit to the lesser sandhill crane population because these flight diverters would be maintained in perpetuity.

NEPA Conclusion: Sandhill cranes are known to be susceptible to collision with overhead wires. The existing network of power lines in the study area currently poses a risk for lesser sandhill cranes. Under Alternative 4A, proposed transmission lines have been designed to substantially reduce the likelihood of a crane collision with transmission lines. New transmission lines constructed as part of the project would be limited to temporary lines which would be removed within the first 10–14 years of Alternative 4A implementation. In addition, no new transmission lines would be sited in the vicinity of Staten Island, which has high use by wintering lesser sandhill cranes. *AMM30 Transmission Line Design and Alignment Guidelines* would require design features for the transmission line alignment, such as co-locating transmission lines when it would minimize effects on sandhill cranes, to avoid impacts on sensitive habitats to the maximum extent feasible. All new transmission lines constructed for the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. By incorporating *AMM30 Transmission Line Design and Alignment Guidelines* and one or a combination of the measures to greatly reduce the risk of bird strike described in *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines under Alternative 4A would not result in an adverse effect on lesser sandhill crane.

***CEQA Conclusion*:** Sandhill cranes are known to be susceptible to collision with overhead wires. The existing network of power lines in the study area currently poses a risk for lesser sandhill cranes. Under Alternative 4A, proposed transmission lines have been designed to substantially reduce the likelihood of a crane collision with transmission lines. New transmission lines constructed as part of the project would be limited to temporary lines which would be removed within the first 10–14 years of Alternative 4A implementation. In addition, no new transmission lines would be sited in the vicinity of Staten Island, which has high use by wintering lesser sandhill cranes. *AMM30 Transmission Line Design and Alignment Guidelines* would require design features for the transmission line alignment, such as co-locating transmission lines when it would minimize effects on sandhill cranes, to avoid impacts on sensitive habitats to the maximum extent feasible. All new transmission lines constructed for the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. By incorporating *AMM30 Transmission Line Design and Alignment Guidelines* and one or a combination of the measures to greatly reduce the risk of bird strike described in *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines under Alternative 4A would have a less-than-significant impact on lesser sandhill crane.

Impact BIO-74: Indirect Effects of the Project on Lesser Sandhill Crane

Indirect Construction- and Operation-Related Effects: Sandhill cranes are sensitive to disturbance. Noise and visual disturbances from the construction of water conveyance facilities and Environmental Commitments could reduce lesser sandhill crane use of modeled habitat adjacent to work areas. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet of the construction edge. Furthermore, maintenance of the aboveground water conveyance facilities could result in ongoing but periodic postconstruction noise and visual disturbances that could affect lesser sandhill crane use of surrounding habitat. These effects could result from periodic vehicle use along the conveyance corridor, inspection and maintenance of aboveground facilities, and similar activities. These potential effects would be minimized with implementation of *AMM20 Greater Sandhill Crane*, described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*.

The BDCP includes an analysis of the indirect effects of noise and visual disturbance that would result from the construction of the Alternative 4 water conveyance facilities on greater sandhill crane (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). The analysis addressed the potential noise effects on cranes, and concluded that as much as 20,243 acres of crane habitat could potentially be affected by general construction noise (including pile driving) above baseline level (50–60 dBA; Table 12-4A-29). This would include 1,008 acres of permanent crane roosting habitat, 1,909 acres of temporary crane roosting habitat, and 17,327 acres of crane foraging habitat. The analysis was conducted based on the assumption that there would be direct line-of-sight from sandhill crane habitat areas to the construction site, and, therefore, provides a worst-case estimate of effects. In many areas the existing levees would partially or completely block the line-of-sight and would function as effective noise barriers, substantially reducing noise transmission. However, there is insufficient data to assess the effects that increased noise levels would have on sandhill crane behavior. Similar acreages of lesser sandhill crane habitat would be expected to be indirectly affected. However, lesser sandhill cranes are less traditional in their winter roost sites and may be more likely to travel away from disturbed areas to roost and forage in more suitable habitat.

Evening and nighttime construction activities would require the use of extremely bright lights. Nighttime construction could also result in headlights flashing into roost sites when construction vehicles are turning onto or off of construction access routes. Proposed surge towers would require the use of safety lights that would alert low-flying aircraft to the presence of these structures because of their height. Little data is available on the effects of impact of artificial lighting on roosting birds. Direct light from automobile headlights has been observed to cause roosting cranes to flush and it is thought that they may avoid roosting in areas where lighting is bright (see BDCP Chapter 5, *Effects Analysis*). If the birds were to roost in a brightly lit site, they may be vulnerable to sleep-wake cycle shifts and reproductive cycle shifts, and be more vulnerable to predators. Potential risks of visual impacts from lighting include a reduction in the cranes' quality of nocturnal rest, and effects on their "sense of photo-period which might cause them to shift their physiology towards earlier migration and breeding." (see BDCP Chapter 5). Effects such as these could prove detrimental to the cranes' overall fitness and reproductive success (which could in turn have population-level impacts). A change in photo-period interpretation could also cause cranes to fly out earlier from roost sites to forage and might increase their risk of power line collisions if they were to leave roosts before dawn (see BDCP Chapter 5).

The effects of noise and visual disturbance on lesser sandhill crane would be minimized through the implementation of AMM20 (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Activities within 0.75 mile of crane roosting habitat would reduce construction noise during night time hours (from one hour before sunset to one hour after sunrise) such that construction noise levels do not exceed 50 dBA L_{eq} (1 hour) at the nearest temporary or permanent roosts during periods when the roost sites are available (flooded). In addition, the area of crane foraging habitat that would be affected during the day (from one hour after sunrise to one hour before sunset) by construction noise exceeding 50 dBA L_{eq} (1 hour) would also be minimized. Unavoidable noise related effects would be compensated for by the enhancement of 0.1 acre of foraging habitat for every acre indirectly affected within the 50 dBA L_{eq} (1 hour) construction noise contour. With these measures in place, indirect effects of noise and visual disturbance from construction activities are not expected to reduce the lesser sandhill crane population in the study area.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect lesser sandhill cranes in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to lesser sandhill crane habitat could also affect the subspecies. The implementation of AMM1–AMM6 would minimize the likelihood of such spills and ensure that measures were in place to prevent runoff from the construction area and negative effects of dust on foraging habitat (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*).

Methylmercury Exposure: Changes in water operations from the construction of the water conveyance facilities and the implementation of *Environmental Commitment 10 Nontidal Marsh Restoration* have the potential to exacerbate bioaccumulation of mercury in lesser sandhill cranes. Largemouth bass was used as a surrogate species for analysis of impacts from changes in operations from the construction of the water conveyance facilities (see Appendix 11F, *Substantive BDCP Revisions*). Results of the quantitative modeling of mercury effects on largemouth bass as a surrogate species overestimate the effects on lesser sandhill crane because of their position in the foodweb. Organisms feeding within pelagic-based (algal) foodwebs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic foodwebs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009). Potential indirect effects of increased mercury exposure are likely low for lesser sandhill cranes because they primarily forage on waste grains, other cultivated crops, and associated invertebrates. The modeled effects of mercury concentrations from changes in water conveyance facilities operations on largemouth bass did not differ substantially from existing conditions; therefore, results also indicate that lesser sandhill crane tissue concentrations would not measurably increase as a result of water conveyance facilities construction.

Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Increased methylmercury associated with *Environmental Commitment 10 Nontidal Marsh Restoration* may indirectly affect lesser sandhill crane via uptake in lower trophic levels (see Appendix 11F, Section 11F.5.2, *Effects of Contaminants on Terrestrial Species*). Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury.

Due to the complex and very site-specific factors that determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This Environmental Commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.

Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by

interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and project activities have the potential to exacerbate bioaccumulation of selenium in avian species, including the lesser sandhill crane. *Environmental Commitment 10 Nontidal Marsh Restoration* has the potential to mobilize selenium, and therefore increase lesser sandhill crane exposure from ingestion of prey items with elevated selenium levels. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related Environmental Commitments (Environmental Commitment 10) would lead to adverse effects on lesser sandhill crane.

Because of the uncertainty that exists with respect to the location of nontidal restoration activities, there could be an effect on lesser sandhill crane from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal and nontidal habitats (see 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the restoration design.

NEPA Effects: Crane habitat could potentially be affected by general construction noise above baseline level (50–60 dBA). However, lesser sandhill cranes are less traditional in their winter roost sites than greater sandhill cranes and may be more likely to travel away from disturbed areas to roost in more suitable habitat. Construction in certain areas would take place 7 days a week and 24 hours a day and evening and nighttime construction activities would require the use of extremely bright lights, which could adversely affect roosting cranes by impacting their sense of photo-period and by exposing them to predators. Effects of noise and visual disturbance could substantially alter the suitability of habitat for lesser sandhill crane. *AMM20 Greater Sandhill Crane* would include requirements (described above) to minimize the effects of noise and visual disturbance on sandhill cranes and to compensate for effects on habitat.

The implementation of *Environmental Commitment 10 Nontidal Marsh Restoration* could result in increased exposure of lesser sandhill crane to selenium which could result in the mortality of a special status species. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

The implementation of tidal natural communities restoration could result in increased exposure of lesser sandhill crane to methylmercury and selenium. methylmercury and selenium. The potential indirect effect of increased mercury exposure is likely low for lesser sandhill crane because they primarily forage on waste grains, other cultivated crops, and associated invertebrates. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure. The potential effect of selenium exposure would be addressed through the implementation of *AMM27 Selenium Management,* which would provide specific restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in restored habitats.

With AMM1–AMM6, *AMM20 Greater Sandhill Crane*, *AMM27 Selenium Management*, and Environmental Commitment 12 in place, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of lesser sandhill crane. Therefore, the indirect effects of Alternative 4A implementation on lesser sandhill crane would not be adverse under NEPA.

***CEQA Conclusion*:** Crane habitat could potentially be affected by general construction noise above baseline level (50–60 dBA). However, lesser sandhill cranes are less traditional in their winter roost sites and may be more likely to travel away from disturbed areas to roost in more suitable habitat. Construction in certain areas would take place 7 days a week and 24 hours a day and evening and nighttime construction activities would require the use of extremely bright lights, which could adversely affect roosting cranes by impacting their sense of photo-period and by exposing them to predators. Effects of noise and visual disturbance could substantially alter the suitability of habitat for lesser sandhill crane. This would be a significant impact. With *AMM20 Greater Sandhill Crane* in place, which would include requirements (described above) to minimize the effects of noise and visual disturbance on sandhill cranes and to mitigate for affected habitat, there would not be an adverse effect on lesser sandhill crane.

The implementation of *Environmental Commitment 10 Nontidal Marsh Restoration* could result in increased exposure of lesser sandhill crane to methylmercury and selenium. This would be a significant impact. The potential indirect effect of increased mercury exposure is likely low for lesser sandhill crane because they primarily forage on cultivated crops and associated invertebrates. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure. The potential effect of selenium exposure would be addressed through the implementation of *AMM27 Selenium Management,* which would provide specific restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in restored habitats.

With AMM1–AMM6, *AMM20 Greater Sandhill Crane*, *AMM27 Selenium Management*, and Environmental Commitment 12 in place, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of lesser sandhill cranes. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on lesser sandhill crane.

Least Bell's Vireo and Yellow Warbler

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on least Bell's vireo and yellow warbler. Least Bell's vireo and yellow warbler modeled habitat identifies suitable nesting and migratory habitat as those plant alliances from the valley/foothill riparian modeled habitat that contain a dense shrub component, including all willow-dominated alliances.

Alternative 4A would result in both temporary and permanent losses of least Bell's vireo and yellow warbler modeled habitat as indicated in Table 12-4A-32. Full implementation of Alternative 4A would also include the following Environmental Commitments and Resource Restoration and Performance Principles that would benefit least Bell's vireo and yellow warbler.

- Restore or create up to 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect up to 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).
- Maintain a single contiguous patch of 100 acres of mature riparian forest in either CZ 4 or CZ 7 (Resource Restoration and Performance Principle VFR2).
- The mature riparian forest will be intermixed with a portion of the early- to mid-successional riparian vegetation and will be a minimum width of 330 feet where practicable (Resource Restoration and Performance Principle VFR3).

As explained below, with the restoration and protection of these amounts of habitat, in addition to natural community enhancement and management commitments and implementation of AMM1–AMM7, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, and Mitigation Measure BIO-75, impacts on least Bell's vireo and yellow warbler would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-32. Changes in Least Bell's Vireo and Yellow Warbler Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Migratory and breeding	30	20
Total Impacts Water Conveyance Facilities		**30**	**20**
Environmental Commitments 4, 6–7, 9–11[a]	Migratory and breeding	10	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**10**	**0**
TOTAL IMPACTS		**40**	**20**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-75: Loss or Conversion of Habitat for and Direct Mortality of Least Bell's Vireo and Yellow Warbler

Alternative 4A would result in the combined permanent and temporary loss of 60 acres of modeled habitat (40 acres of permanent loss and 20 acres of temporary loss) for least Bell's vireo and yellow warbler (Table 12-4A-32). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas and *Environmental Commitment 4 Tidal Natural Communities Restoration*. Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could also result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate least Bell's vireo and yellow warbler habitat. Each of these individual activities is described below.

- *Water Facilities Construction:* Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 50 acres of modeled least Bell's vireo and yellow warbler habitat (Table 12-4A-32). Of the 50 acres of modeled habitat that would be removed for the construction of the conveyance facilities, 30 acres would be a permanent loss and 20 acres would be a temporary loss of habitat. Activities that would impact modeled habitat consist of the construction of tunnel, forebay, and intake construction, permanent and temporary access roads, construction of transmission lines, and temporary barge unloading facilities and work areas. Impacts from water conveyance facilities would occur in the central Delta in CZs 3, 4, 5, 6, and 8. Permanent habitat loss would result from the construction of Intakes 2, 3, and 5 on the east bank of the Sacramento River between Freeport and Courtland. Some habitat would also be impacted by the construction of a permanent access road from the new forebay west to an reusable tunnel material disposal area. Additional losses would also occur along Lambert Road where permanent utility lines would be installed and from the construction of an operable barrier at the confluence of Old River and the San Joaquin River. Temporary losses of habitat would resulted from the construction of a barge unloading facility west of the intermediate forebay in Snodgrass Slough and where temporary work areas surround intake sites. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities as described *in AMM10 Restoration of Temporarily Affected Natural Communities*. Although the effects are considered temporary, the restored riparian habitat would require at least four years for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. However, restored riparian vegetation can have the habitat structure to support breeding vireos within 3 to 5 years, particularly if the restored vegetation is adjacent to established riparian areas (Kus 2002), and similar habitat would be suitable for yellow warbler. The majority of the riparian vegetation to be temporarily removed is early- to mid-successional; therefore, the replaced riparian vegetation would be expected to have structural components comparable to the temporarily removed vegetation within the first 5 to 10 years after the initial restoration activities are complete. There are no occurrences of least Bell's vireo or yellow warbler that intersect with the water conveyance facilities footprint. Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove approximately 10 acres of modeled least Bell's vireo and yellow warbler habitat.

- *Environmental Commitment 6 Channel Margin Enhancement:* Channel margin habitat enhancement could result in removal of small amounts of valley/foothill riparian habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur along waterway margins where riparian habitat stringers exist, including levees and channel banks. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.
- *Environmental Commitment 11 Natural Communities Enhancement and Management:* Habitat protection and management activities that could be implemented in protected least Bell's vireo and yellow warbler habitats are expected to maintain and improve the functions of the habitat. Least Bell's vireo and yellow warbler would be expected to benefit from the increase in protected habitat, which would maintain conditions favorable for future species establishment in the study area. If least Bell's vireo and yellow warbler established breeding populations in restored riparian habitats in the study area, occupied habitat would be monitored to determine if there were a need to implement controls on brood parasites (brown-headed cowbird) or nest predators. If implemented, these actions would be expected to benefit the least Bell's vireo and yellow warbler by removing a potential stressor that could, if not addressed, adversely affect the stability of newly established populations.

  Habitat management- and enhancement-related activities could disturb least Bell's vireo and yellow warbler nests. If either species were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. The potential for these activities to result in direct mortality of least Bell's vireo or yellow warbler would be minimized with the implementation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*.
- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect least Bell's vireo and yellow warbler use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.
- Injury and Direct Mortality: Nesting of least Bell's vireo and yellow warbler has not been confirmed in the study area. Although there have been recent occurrences of least Bell's vireo in the Yolo Bypass and of both least Bell's vireo and yellow warbler at the San Joaquin River National Wildlife Refuge, the reestablishment of a breeding population of either species unlikely over the term of the project (14 years). If present in the study area, construction-related activities would not be expected to result in direct mortality of least Bell's vireo or yellow warbler because adults and fledged young would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. These effects would be avoided and minimized with the implementation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo.* In addition, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would be available to address adverse effects on nesting yellow warblers.

The following paragraphs summarize the combined effects discussed above and describe Environmental Commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

The study area supports approximately 14,850 acres of modeled habitat for least Bell's vireo and yellow warbler. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 60 acres of habitat for these species during the term of the Plan (<1% of the total habitat in the study area). These losses would occur from the construction of the water conveyance facilities and from *Environmental Commitment 4 Tidal Natural Communities Restoration*. The locations of these losses would be in fragmented riparian habitat throughout the study area.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration/creation and 1:1 protection of dense shrubby successional valley/foothill riparian habitat. Using these ratios would indicate that 60 acres of valley/foothill riparian habitat should be restored/created and 60 acres should be protected to compensate for the losses of least Bell's vireo and yellow warbler habitat.

Alternative 4A includes conservation commitments through *Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration* to restore or create up to 251 acres and protect up to 103 acres of valley/foothill riparian woodland. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1). A single, contiguous patch of 100 acres of mature riparian forest would be maintained within either CZ 4 (in the vicinity of Cosumnes River Preserve) or CZ 7 (in the vicinity of San Joaquin National Wildlife Refuge and Caswell State Memorial Park) (Resource Restoration and Performance Principle VFR2). The mature riparian forest would be intermixed with a portion of the early- to mid-successional riparian vegetation and would be a minimum width of 330 feet where practicable (Resource Restoration and Performance Principle VFR3).

The project also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of least Bell's vireo and yellow warbler habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects from and to restoring and protecting an acreage that meets the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles VFR1-VFR3, and by AMM1–AMM7, and AMM22. Mitigation Measure BIO-75 would be available to address potential adverse effects on nesting yellow warblers. Environmental commitments and AMMs would be in place during all project activities. However, neither species is an established breeder in the study area and impacts would likely be limited to loss of migratory habitat. Considering these commitments, losses and conversions of least Bell's vireo and yellow warbler habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The loss of least Bell's vireo and yellow warbler habitat from Alternative 4A would represent an adverse effect in the absence of other conservation actions as a result of habitat modification and potential for direct mortality of a special-status species. However, neither species is an established breeder in the study area and impacts would likely be limited to loss of migratory habitat. In addition, habitat protection and restoration associated with Environmental Commitment 3 and Environmental Commitment 7, guided by Resource Restoration and Performance Principles VFR1-VFR3 and by *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, would be in place during all project activities. Considering these commitments, in addition to Mitigation Measure BIO-75, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of least Bell's vireo or yellow warbler. Therefore, Alternative 4A would have a less-than-significant impact on least Bell's vireo and yellow warbler under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

To reduce impacts on nesting birds, DWR will implement the measures listed below prior to construction and operations and maintenance activities.

- To the maximum extent feasible, vegetation removal and trimming will be scheduled during the nonbreeding season of birds (September 1–January 31). If vegetation removal cannot be removed in accordance with this timeframe, preconstruction/preactivity surveys for nesting birds and additional protective measures will be implemented as described below.
- A qualified wildlife biologist with knowledge of the relevant species will conduct nesting surveys before the start of construction. A minimum of three separate surveys will be conducted within 30 days prior to construction, with the last survey within 3 days prior to construction. Surveys will include a search of all suitable nesting habitat in the construction area. In addition, a 500-foot radius around the construction area, where accessible, will be surveyed for nesting raptors and species of special concern (except the Modesto song sparrow), and an area within 50 feet of construction will be surveyed for other non-special status nesting birds or birds protected by the MBTA. If no active nests are detected during these surveys, no additional measures are required.
- If active nests are found in the survey area, no-disturbance buffers will be established around the nest sites to avoid disturbance or destruction of the nest site until the end of the breeding season (approximately September 1) or until a qualified wildlife biologist determines that the young have fledged and moved out of the project area (this date varies by species). A qualified wildlife biologist will monitor construction activities in the vicinity of the nests to ensure that construction activities do not affect nest success. The extent of the buffers will be determined by DWR biologists in consultation with USFWS and CDFW and will depend on the level of noise or construction disturbance, line-of-sight between the nest

and the disturbance, ambient levels of noise and other disturbances, and other topographical or artificial barriers. Suitable buffer distances may vary between species.

Impact BIO-76: Fragmentation of Least Bell's Vireo and Yellow Warbler Habitat

Grading, filling, contouring, and other initial ground-disturbing operations may temporarily fragment modeled least Bell's vireo and yellow warbler habitat. This could temporarily reduce the affected habitat's extent and functions, including exposure to cowbird parasitism, a nest parasite of both species. Preconstruction surveys under *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would identify any nesting pairs and the potential for habitat fragmentation to affect either species. If a nesting pairs of either species were detected where fragmentation has occurred, nests would be monitored for edge effects or other effects caused by the disturbance. The habitat would be adaptively managed to avoid or minimize impacts (e.g., cowbird control) under Environmental Commitment 11, which includes the control of nonnative predators through habitat manipulation techniques or trapping to reduce nest predation.

NEPA Effects**:** Because there are only two recent occurrences of least Bell's vireo within the study area, and no occurrences of yellow warbler breeding in the study area, habitat fragmentation resulting from ground-disturbing operations is not expected to affect either species. If nesting pairs of either species were detected where fragmentation has occurred, nests would be monitored for edge effects or other effects caused by the disturbance. The habitat would be adaptively managed to avoid or minimize impacts (e.g., cowbird control) under Environmental Commitment 11. Therefore, the effect of habitat fragmentation would not have an adverse effect on least Bell's vireo or yellow warbler.

CEQA Conclusion**:** Because there are only two recent occurrences of least Bell's vireo within the study area, and no occurrences of yellow warbler breeding in the study area, habitat fragmentation resulting from ground-disturbing operations would not be expected to substantially modify habitat or result in the direct mortality of special status species. If nesting pairs of either species were detected where fragmentation has occurred, nests would be monitored for edge effects or other effects caused by the disturbance. The habitat would be adaptively managed to avoid or minimize impacts (e.g., cowbird control) under Environmental Commitment 11. Therefore, the effect of habitat fragmentation, as a result of Alternative 4A would have a less-than-significant impact on least Bell's vireo and yellow warbler.

Impact BIO-77: Effects on Least Bell's Vireo and Yellow Warbler Associated with Electrical Transmission Facilities

Both least Bell's vireo and yellow warbler typically occur in early to mid-successional riparian habitat, which is used to meet all of its life requisites. Least Bell's vireo are rarely observed in open habitats away from riparian vegetation. Neither species form flocks and individuals generally remain at or below the riparian canopy, below the height of proposed transmission lines (see BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*). The behavior and habitat requirements of least Bell's vireo and yellow warbler make collision with the proposed transmission lines unlikely. *AMM30 Transmission Line Design and Alignment Guidelines* would ensure that the transmission lines are designed to avoid sensitive terrestrial habitats (including riparian) when siting poles and towers to the maximum extent feasible, which would minimize the potential for collision. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). For example, Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. As described in *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters, which would substantially reduce any potential for mortality of least Bell's vireo or yellow warbler individuals from powerline collisions.

NEPA Effects: Installation and presence of new transmission lines would not result in an adverse effect on least Bell's vireo or yellow warbler because the probability of bird-powerline strikes is unlikely due to the behavior and habitat requirements of these species. *AMM30 Transmission Line Design and Alignment Guidelines* would avoid impacts on riparian habitat to the maximum extent feasible, which will minimize the potential for collision. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would substantially reduce the risk of mortality from bird strike for least Bell's vireo and yellow warbler from the project. Therefore, the construction and operation of new transmission lines would not result in an adverse effect on least Bell's vireo or yellow warbler.

CEQA Conclusion: Installation and presence of new transmission lines would result in less-than-significant impact on least Bell's vireo or yellow warbler because the probability of bird-powerline strikes is unlikely due to the lack of occurrences in the study area and the behavior and habitat requirements of these species. *AMM30 Transmission Line Design and Alignment Guidelines* would avoid impacts on riparian habitat to the maximum extent feasible, which will minimize the potential for collision. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would substantially reduce the risk of mortality from bird strike for least Bell's vireo and yellow warbler from the project. Therefore, the construction and operation of new transmission lines would result in a less-than-significant impact on least Bell's vireo or yellow warbler.

Impact BIO-78: Indirect Effects of The Project on Least Bell's Vireo and Yellow Warbler

Indirect Construction- and Operation-Related Effects: If least Bell's vireo or yellow warbler were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). However, there are no available data to determine the extent to which these noise levels could affect least Bell's vireo or yellow warbler. *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would reduce the potential for adverse effects of construction-related activities on survival and productivity of nesting least Bell's vireo and a 500 foot no-disturbance buffer would be established around the active nest. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to reduce the potential for adverse effects of construction-related activities on nesting yellow warbler. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect least Bell's vireo and yellow warbler in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. *AMM2 Construction Best Management Practices and Monitoring* would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Methylmercury Exposure: Project activities have the potential to exacerbate bioaccumulation of mercury in avian species, including the least Bell's vireo and yellow warbler. Marsh (tidal and nontidal) restoration has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect least Bell's vireo and yellow warbler, via uptake in lower trophic levels (as described in Appendix 11F, *Substantive BDCP Revisions*).

The potential mobilization or creation of methylmercury within the study area varies with site-specific conditions and would need to be assessed at the project level. Due to the complex and very site-specific factors that would determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This Environmental Commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which

forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and project activities have the potential to exacerbate bioaccumulation of selenium in avian species, including least Bell's vireo and yellow warbler. Tidal and nontidal marsh restoration has the potential to mobilize selenium, and, therefore, increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, tidal marsh restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations are analyzed in Chapter 8, *Water Quality*, which concludes that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative.

There could be an effect on least Bell's vireo and yellow warbler from increases in selenium associated with tidal restoration activities (Environmental Commitment 4); however, effects on the species populations would be expected to be minimal because the amount of tidal restoration would total up to 22 acres. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of project design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design.

NEPA Effects: Impacts of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities on least Bell's vireo would not be adverse with the implementation of AMM1–AMM7, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo.* Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting yellow warblers.

Tidal habitat restoration could result in increased exposure of least Bell's vireo and yellow warbler to selenium; however, the amount of tidal restoration would total up to 22 acres, and potential exposure to selenium resulting from these acres of restoration would not be expected to adversely affect the species populations. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

The implementation of tidal natural communities restoration could result in increased exposure of least Bell's vireo and yellow warbler to methylmercury. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

CEQA Conclusion**:** Impacts of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would have an adverse effect on least Bell's vireo and yellow warbler in the absence of Environmental Commitments and AMMs as a result of habitat modification and potential for direct mortality of special-status species. With the implementation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and *AMM2 Construction Best Management Practices and Monitoring* in place, the effect would not be adverse.

Tidal habitat restoration could result in increased exposure of least Bell's vireo and yellow warbler to selenium; however, the amount of tidal restoration would total up to 22 acres, and potential exposure to selenium resulting from these acres of restoration would not be expected to adversely affect the species populations. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

The implementation of tidal natural communities restoration could result in increased exposure of least Bell's vireo and yellow warbler to methylmercury. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

With AMM1–AMM7, AMM22, and Environmental Commitment 12 in place, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of least Bell's vireo or yellow warbler. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on least Bell's vireo or yellow warbler.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-79: Periodic Effects of Inundation of Least Bell's Vireo and Yellow Warbler Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on least Bell's vireo or yellow warbler.

NEPA Effects: No effect.

CEQA Conclusion**:** No impact.

Suisun Song Sparrow and Saltmarsh Common Yellowthroat

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on Suisun song sparrow and saltmarsh common yellowthroat. The habitat model used to assess effects on Suisun song sparrow and saltmarsh common yellowthroat is based on primary breeding habitat and secondary habitat. Suisun song sparrow and saltmarsh common yellowthroat primary habitat consists of all *Salicornia*-

dominated tidal brackish emergent wetland and all *Typha*-, *Scirpus*-, and *Juncus*-dominated tidal freshwater emergent wetland in the study area west of Sherman Island, with the exception that *Scirpus acutus* and *S. californicus* plant communities (low marsh) and all of the plant communities listed below that occur in managed wetlands were classified as secondary habitat. Upland transitional zones, providing refugia during high tides, within 150 feet of the wetland edge were also included as secondary habitat. Secondary habitats generally provide only a few ecological functions such as foraging (low marsh and managed wetlands) or extreme high tide refuge (upland transition zones), while primary habitats provide multiple functions, including breeding, effective predator cover, and high-value forage.

Alternative 4A would result in no effects on modeled Suisun song sparrow and saltmarsh common yellowthroat modeled habitat as indicated in Table 12-4A-33. There is no modeled habitat for Suisun song sparrow and saltmarsh common yellowthroat in the water conveyance facilities footprint and tidal restoration under Alternative 4A would not take place in Suisun Marsh.

Table 12-4A-33. Changes in Suisun Song Sparrow Saltmarsh Common Yellowthroat Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Primary	0	0
	Secondary	0	0
Total Impacts Water Conveyance Facilities		**0**	**0**
Environmental Commitments 4, 6–7, 9–11[a]	Primary	0	0
	Secondary	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**0**	**0**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-80: Loss or Conversion of Habitat for and Direct Mortality of Suisun Song Sparrow and Saltmarsh Common Yellowthroat

No habitat would be lost or converted and there would be no direct mortality of Suisun song sparrow or saltmarsh common yellowthroat under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where the species are known to occur.

***NEPA Effects*: No effect.**

***CEQA Conclusion*: No impact.**

Impact BIO-81: Indirect Effects of Alternative 4A on Suisun Song Sparrow and Saltmarsh Common Yellowthroat

No indirect effects on Suisun song sparrow and saltmarsh common yellowthroat were identified under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where these species are known to occur.

NEPA Effects: No effect.

CEQA Conclusion: No Impact.

Impact BIO-82: Effects on Suisun Song Sparrow and Saltmarsh Common Yellowthroat Associated with Electrical Transmission Facilities

The range of the Suisun song sparrow extends eastward into the study area to approximately Kimball Island. There are several reported occurrences from Kimball Island, Browns Island, and in the Suisun Marsh in the western portion of the study area. The easternmost range of the saltmarsh common yellowthroat also ends in Suisun Marsh. These species ranges, along with areas of suitable habitat, are far from the proposed transmission line routes (BDCP Attachment 5.J-2*, Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Location of the current populations, species ranges, and suitable habitat in the study area make collision with the proposed transmission lines highly unlikely. Therefore the construction and presence of new transmission lines would not have an adverse effect on Suisun song sparrow and saltmarsh common yellowthroat.

NEPA Effects: The construction and presence of new transmission lines would not have an adverse effect on Suisun song sparrow and saltmarsh common yellowthroat because the location of the current populations, species ranges, and suitable habitat for the species make collision with the proposed transmission lines highly unlikely.

CEQA Conclusion: The construction and presence of new transmission lines would not be expected to have an adverse effect on Suisun song sparrow and saltmarsh common yellowthroat because the location of the current populations, species ranges, and suitable habitat for the species make collision with the proposed transmission lines highly unlikely. Therefore, the construction and presence of new transmission lines under Alternative 4A would have a less-than-significant impact on Suisun song sparrow and saltmarsh common yellowthroat.

Swainson's Hawk

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on Swainson's hawk. The habitat model used to assess impacts on Swainson's hawk includes plant alliances and land cover types associated with Swainson's hawk nesting and foraging habitat. Alternative 4A would result in both temporary and permanent losses of Swainson's hawk modeled habitat as indicated in Table 12-4A-34. The majority of the losses would occur from the construction of the water conveyance facilities. Although protection and restoration for the loss of nesting and foraging habitat would be initiated in the same timeframe as the losses, it could take one or more decades (for nesting habitat) for restored habitats to replace the functions of habitat lost. This time lag between impacts and restoration of habitat function would be minimized through specific requirements of *AMM18 Swainson's Hawk*, including transplanting mature trees in the first 10 years. Full implementation of Alternative 4A would also include the following Environmental Commitments and Resource Restoration and Performance Principles which would benefit the Swainson's hawk.

- Restore or create up to 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect up to 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).

- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principles VFR1).
- Maintain a single contiguous patch of 100 acres of mature riparian forest in either CZ 4 or CZ7. The mature riparian forest intermixed with a portion of the early- to mid-successional riparian vegetation will be a minimum width of 330 feet where practicable (Resource Restoration and Performance Principles VFR1 and VFR2).
- Conserve 1 acre of Swainson's hawk foraging habitat for each acre of lost foraging habitat in minimum patch sizes of 40 acres (Resource Restoration and Performance Principle SH1).
- Protect Swainson's hawk foraging habitat above 1 foot above mean sea level with at least 50% in very high-value habitat (see Table 12-4A-35 for a definition habitat value) production (Resource Restoration and Performance Principle SH2).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands within the conservation area, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Resource Restoration and Performance Principle CL1).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for the species and implementation of AMM1–AMM7, *AMM10 Restoration of Temporarily Affected Natural Communities,* and *AMM18 Swainson's Hawk* to minimize potential effects, impacts on Swainson's hawk would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-34. Changes in Swainson's Hawk Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary

Total Foraging		**5,665**	**1,052**
TOTAL IMPACTS		**5,686**	**1,062**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-83: Loss or Conversion of Habitat for and Direct Mortality of Swainson's Hawk

Alternative 4A would result in the combined permanent and temporary loss of up to 6,748 acres of modeled habitat (31 acres of nesting habitat and 6,717 acres of foraging habitat) for Swainson's hawk (Table 12-4A-34). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, tidal habitat restoration (Environmental Commitment 4), riparian restoration, (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could also result in local habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could affect Swainson's hawk modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A water conveyance facilities would result in the combined permanent and temporary loss of up to 26 acres of Swainson's hawk nesting habitat (16 acres of permanent loss habitat and 10 acres of temporary loss). In addition, 4,290 acres of foraging habitat would be removed (3,238 acres of permanent loss, 1,052 acres of temporary loss; Table 12-4A-34). Activities that would impact modeled Swainson's hawk habitat consist of tunnel, forebay, and intake construction, temporary access roads, and construction of transmission lines. Most of the permanent loss of nesting habitat would occur where Intakes 2, 3, and 5 impact the Sacramento River's east bank between Freeport and Courtland. The riparian areas here are very small patches, some dominated by valley oak and others by nonnative trees. Some nesting habitat would be lost due to construction of a permanent access road from the new forebay west to an reusable tunnel material disposal area. Permanent losses would also occur along Lambert Road where permanent utility lines would be installed and from the construction of an operable barrier at the confluence of Old River and the San Joaquin River. Temporary losses of nesting habitat would result from the construction of a barge unloading facility west of the intermediate forebay in Snodgrass Slough and where temporary work areas surround intake sites. The riparian habitat in these areas is also composed of very small patches or stringers bordering waterways, which are composed of valley oak and scrub vegetation. There are at least 12 occurrences of nesting Swainson's hawk that overlap with the construction footprint of water conveyance facilities, primarily from the construction of intakes 2, 3, and 5, and the construction footprint for the permanent and temporary transmission lines. The implementation of *AMM18 Swainson's Hawk*, would minimize the effects of construction on nesting Swainson's hawks if present in the area (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS). Impacts on foraging habitat would occur throughout the central Delta in CZs 3–6, and CZ 8. Permanent foraging habitat impacts would include 849 acres of very high-value habitat (Table 12-4A-35). Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

Table 12-4A-35. Acres of Impacted Foraging Habitat by Value Classes for Swainson's Hawk

Foraging Habitat Value Class	Cultivated Land and Other Land Cover Types	Water Conveyance Facilities Permanent (temporary)	Environmental Commitments Permanent (temporary)
Very high	Alfalfa hay	849 (128)	681 (0)
Moderate	Irrigated pasture, other hay crops	745 (350)	752 (0)
Low	Other irrigated field and truck/berry crops	668 (234)	551 (0)
Very low	Safflower, sunflower, corn, grain sorghum	977 (340)	443 (0)

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 5 acres of Swainson's hawk nesting habitat and 254 acres of foraging habitat. Because the species is highly mobile and wide-ranging, habitat fragmentation is not expected to reduce the use of remaining cultivated lands or preclude access to surrounding lands. Trees would not be actively removed but tree mortality would be expected over time as areas became tidally inundated.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 251 acres of Swainson's hawk foraging habitat.
- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would convert approximately 1,070 acres of cultivated lands that provide Swainson's hawk foraging habitat to grassland.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 832 acres of Swainson's hawk foraging habitat.
- *Environmental Commitment 11 Natural Communities Enhancement and Management:* Habitat management- and enhancement-related activities could disturb Swainson's hawk nests if they were present near work sites. A variety of habitat management actions that are designed to enhance wildlife values in Alternative 4A-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of Swainson's hawk habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available Swainson's hawk habitat and are expected to result in overall improvements to and maintenance of habitat values. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.
- Permanent and temporary nesting habitat losses from the above Environmental Commitments would primarily consist of small, fragmented riparian stands. Temporarily affected nesting habitat would be restored as riparian habitat within 1 year following completion of construction activities as described in *AMM10 Restoration of Temporarily Affected Natural Communities*. The restored riparian habitat would require 1 to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by Swainson's hawks. *AMM18 Swainson's Hawk* contains actions described below to reduce the effect of temporal loss of nesting habitat, including the transplanting of mature trees and planting of trees near high-value foraging habitat. The functions of cultivated lands and grassland communities that provide foraging habitat for Swainson's hawk are expected to be restored relatively quickly (within 10–14 years of Alternative 4A implementation).
- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect Swainson's hawk use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7 and *AMM18 Swainson's Hawk* described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged Swainson's hawk if they were present in the study area, because they would be expected to avoid contact with construction and other equipment. However, if Swainson's hawk were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could affect nests or lead to their abandonment, potentially resulting in mortality of eggs and nestlings. These effects would be avoided and minimized with the incorporation of *AMM18 Swainson's Hawk* into Alternative 4A.

The following paragraphs summarize the combined effects discussed above and describe Environmental Commitments and Resource Restoration and Performance Principles that offset or avoid these effects. NEPA and CEQA conclusions are also provided at the end of the section.

The study area supports approximately 9,796 acres of modeled nesting habitat and 477,879 acres of modeled foraging habitat for Swainson's hawk. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 31 acres of potential nesting habitat (<1% of the potential nesting habitat in the study area) and 6,748 acres of foraging habitat (1% of the foraging habitat in the study area).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for nesting habitat, and 1:1 protection for foraging habitat. Using these ratios would indicate that 31 acres of nesting habitat should be restored/created and 31 acres should be protected to compensate for the losses of Swainson's hawk nesting habitat. In addition, 6,748 acres of foraging habitat should be protected to mitigate the losses of Swainson's hawk foraging habitat.

Project proponents would commit to conserving 1 acre of Swainson's hawk foraging habitat for every acre of lost foraging habitat (Resource Restoration and Performance Principle SH1). These acres of cultivated lands and grasslands would be located above 1 foot above sea level, and at least 50% would be in very high-value production (Resource Restoration and Performance Principle SH2). These Resource Restoration and Performance Principles would be associated with Environmental Commitment 3 and would occur in the same timeframe as the construction and early restoration losses.

Alternative 4A includes conservation commitments through *Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration* to restore or create up to 251 acres and protect up to 103 acres of valley/foothill riparian woodland, which would provide nesting habitat for Swainson's hawk. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs. A single, contiguous patch of 100 acres of mature riparian forest would be maintained in either CZ 4 or CZ 7, ensuring that acres of restored and protected habitat provide habitat for nesting raptors. In addition, small but essential nesting habitat for Swainson's hawk associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Environmental Commitment 3).

The 251 acres of restored riparian habitat would be initiated in the first 10 years to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by Swainson's hawks. This time lag between the removal and restoration of nesting habitat could have a substantial impact on Swainson's hawk in the first 10 years. Nesting habitat is limited throughout much of the study area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active Swainson's hawk nests within the study area until restored riparian habitat is sufficiently developed.

AMM18 Swainson's Hawk would implement a program to plant large mature trees, including transplanting trees scheduled for removal, to compensate for the temporal loss of Swainson's hawk nest sites, defined as a 125-acre area where more than 50% of suitable nest trees (20 feet or taller) within the 125-acre block are removed. These mature trees would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least 5 trees (5-gallon container size) would be planted for every tree removed by construction that was suitable for nesting by Swainson's hawks (20 feet or taller). A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Trees would be planted in areas that support high-value Swainson's hawk foraging habitat to increase nest sites, or within riparian plantings as a component of riparian restoration (Environmental Commitment 7) where they are in close proximity to suitable foraging habitat. Replacement trees that were incorporated into the riparian restoration would not be clustered in a single region of the study area, but would be distributed throughout the lands protected as foraging habitat for Swainson's hawk. Swainson's hawk foraging habitat would be protected within 3 miles of a known Swainson's hawk nest tree and within 50 miles of the project footprint on land not subject to threat of seasonal flooding, construction disturbances, or other conditions that would reduce the foraging value of the land. Further details of AMM18 are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of Swainson's hawk nesting and foraging habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects from and to restoring and protecting an acreage that meets or exceeds the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles VFR1, VFR2, SH1, SH2, and CL1, and by AMM1–AMM7, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM18 Swainson's Hawk*, which would be in place during all project activities. Considering these commitments, losses and conversions of Swainson's hawk habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on Swainson's hawk habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of Environmental Commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 7, and Environmental Commitment 11 that meet or exceed the typical mitigation ratios described above. These conservation activities would be guided by Resource Restoration and Performance Principles VFR1, VFR2, SH1, SH2, and CL1s, and by AMM1–AMM6, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM18 Swainson's Hawk*, which would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of Swainson's hawk. Therefore, Alternative 4A would have a less-than-significant impact on Swainson's hawk under CEQA.

Impact BIO-84: Effects on Swainson's Hawk Associated with Electrical Transmission Facilities

New transmission lines would increase the risk that Swainson's hawks could be subject to power line strikes, which could result in injury or mortality of Swainson's hawks. However, this species would be at low risk of bird strike mortality based on factors assessed in the bird strike vulnerability analysis (BDCP Attachment 5.J-2, *Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Factors analyzed include the height of the new transmission lines and the flight behavior of the species. The existing network of transmission lines in the study area currently poses the same small risk for Swainson's hawk, and any incremental risk associated with the new power line corridors would also be expected to be low. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new project transmission lines would be fitted with flight diverters. Bird flight diverters would make transmission lines highly visible to Swainson's hawks and would further reduce any potential for powerline collisions.

NEPA Effects: New transmission lines would minimally increase the risk for Swainson's hawk power line strikes. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. With implementation of *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines would not result in an adverse effect on Swainson's hawk.

CEQA Conclusion: New transmission lines would minimally increase the risk for Swainson's hawk power line strikes. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. With implementation of *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines would result in a less-than-significant impact on Swainson's hawk.

Impact BIO-85: Indirect Effects of The Project on Swainson's Hawk

Noise and visual disturbances from the construction of water conveyance facilities and Environmental Commitments could reduce Swainson's hawk use of modeled habitat adjacent to work areas. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4). However, there are no available data to determine the extent to which these noise levels could affect Swainson's hawk. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect Swainson's hawk use of the surrounding habitat. Swainson's hawks are seasonally abundant across much of the study area wherever adequate nest trees occur within a cultivated landscape that supports suitable foraging habitat. There would be a potential for noise and visual disturbances associated with Alternative 4A actions to temporarily displace Swainson's hawks and temporarily reduce the use of suitable habitat adjacent to construction areas. These adverse effects would be minimized with the implementation of *AMM18 Swainson's Hawk*.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect Swainson's hawk foraging in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. *AMM2 Construction Best Management Practices and Monitoring* would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on habitat.

***NEPA Effects*:** Noise and visual disturbances from the construction of water conveyance facilities could reduce Swainson's hawk use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect Swainson's hawk use of the surrounding habitat. Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would not have an adverse effect on Swainson's hawk with the implementation of AMM1–AMM7, and *AMM18 Swainson's Hawk.*

***CEQA Conclusion*:** Noise and visual disturbances from the construction of water conveyance facilities could reduce Swainson's hawk use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect Swainson's hawk use of the surrounding habitat. The effects of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would result in a less-than-significant impact on Swainson's hawk with the implementation of AMM1–AMM7, and *AMM18 Swainson's Hawk.*

Impact BIO-86: Periodic Effects of Inundation of Swainson's Hawk Nesting and Foraging Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on Swainson's hawk.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Tricolored Blackbird

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on tricolored blackbird. The habitat model used to assess effects for tricolored blackbird is based on breeding habitat and nonbreeding habitat. Although nesting colonies have been documented along the fringe of Suisun Marsh, in the Yolo Bypass, along the southwestern perimeter of the study area, and in the southeast corner of the study area near the San Joaquin River, breeding colonies are uncommon in the study area. Modeled breeding habitat includes bulrush/cattail wetlands and shrub communities that may provide suitable nesting substrate, and adjacent high-value foraging areas that occur within 5 miles of nesting colonies documented in the study area. The nesting component consists of nontidal freshwater perennial emergent marsh, and valley foothill riparian natural communities that occur within 5 miles of breeding colonies documented between 1998 and 2012. The foraging component includes cultivated lands and noncultivated land cover types known to support abundant insect populations such as grasslands, pasturelands (including alfalfa), natural seasonal wetlands, and sunflower croplands. The Delta is recognized as a major wintering area for tricolored blackbird (Hamilton 2004, Beedy 2008). Modeled nonbreeding habitat includes emergent wetlands and shrub stands that provide suitable roosting habitat, as well as cultivated lands and noncultivated lands that provide foods sought by tricolored blackbirds during the winter. Outside of the breeding season, tricolored blackbirds are primarily granivores that forage opportunistically across the study area in grasslands, pasturelands, croplands, dairies, and livestock feed lots. Factors considered in assessing the value of affected habitat for the tricolored blackbird, include patch size, suitability of vegetation, and proximity to recorded occurrences.

Alternative 4A would result in both temporary and permanent losses of tricolored blackbird modeled breeding and nonbreeding habitat as indicated in Table 12-4A-36. Full implementation of Alternative 4A would also include the following Environmental Commitments and Resource Restoration and Performance Principles to benefit the tricolored blackbird.

- Protect and manage occupied or recently occupied (within the last 15 years) tricolored blackbird nesting habitat located within 3 miles of high-value foraging habitat in Conservation Zones 1, 2, 8, or 11. Nesting habitat will be managed to provide young, lush stands of bulrush/cattail emergent vegetation and prevent vegetation senescence, or other non-marsh nesting habitat suitable for the species. If sufficient acres of protection are not available, create suitable nesting habitat at a ratio of 1:1 (Resource Restoration and Performance Principle TB1).
- Protect high- to very high-value breeding-foraging habitat (as defined in Table 12-4A-37) (within 5 miles of occupied or recently occupied) (within the last 15 years) tricolored blackbird nesting habitat. At least 130 acres will be within 3 miles of the 38 acres of nontidal wetland nesting habitat protected (Resource Restoration and Performance Principle TB2).
- Protect moderate-, high-, or very high-value cultivated lands (as defined in Table 12-4A-37) as nonbreeding foraging habitat, at least 50% of which is of high- or very high-value (Resource Restoration and Performance Principle TB3).
- Protect up to 119 acres and restore up to 832 acres of nontidal wetland (Environmental Commitment 3 and Environmental Commitment 10).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species and implementation of AMM1–AMM7 and *AMM21 Tricolored Blackbird,* impacts on tricolored blackbird would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-36. Changes to Tricolored Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type		Permanent	Temporary
Water Conveyance Facilities	Breeding	Nesting	15	4
		Foraging-cultivated	1,389	172
		Foraging-noncultivated	290	105
	Non-breeding	Roosting	9	21
		Foraging-cultivated	1,047	487
		Foraging-noncultivated	179	53
Total Impacts Water Conveyance Facilities			**2,929**	**842**

		Foraging-cultivated	806	0
		Foraging-noncultivated	58	0
	Non-breeding	Roosting	17	0
		Foraging-cultivated	1,502	0
		Foraging-noncultivated	23	0
Total Impacts Environmental Commitments 4, 6–7, 9–12, and 15–16[a]			**2,405**	**0**
Total Breeding			**2,558**	
Total Nonbreeding			**2,777**	
TOTAL IMPACTS			**5,335**	**842**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-87: Loss or Conversion of Habitat for and Direct Mortality of Tricolored Blackbird

Alternative 4A would result in the combined permanent and temporary loss of up to 6,177 acres of modeled habitat (2,839 acres of breeding habitat and up to 3,338 acres of nonbreeding habitat) for tricolored blackbird (Table 12-4A-36). Project components that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, tidal habitat restoration (Environmental Commitment 4), riparian restoration (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate tricolored blackbird habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A water conveyance facilities would result in the permanent loss of 1,694 acres of tricolored blackbird breeding habitat (15 acres nesting habitat, 1,389 acres of cultivated lands, and 290 acres of noncultivated lands suitable for foraging) and 1,235 acres of nonbreeding habitat (9 acres roosting habitat, 1,047 acres of cultivated lands, and 179 acres of noncultivated lands suitable for foraging, Table 12-4A-36).

Approximately 796 of the 1,757 acres permanently impacted would be lost as reusable tunnel material storage areas, which would likely be moved to other sites for use in levee build-up and restoration, and the affected area would likely be restored. This effect is categorized as permanent because there is no assurance that the material would eventually be moved. In addition, water conveyance facilities would result in the temporary removal of 281 acres of breeding habitat (4 acres nesting habitat, 172 acres of cultivated lands, and 105 acres of noncultivated lands suitable for foraging) and 561 acres of nonbreeding habitat (21 acres roosting habitat, 487 acres of cultivated lands, and 53 acres of noncultivated lands suitable for foraging, Table 12-4A-36). *AMM21 Tricolored Blackbird* would minimize the effects of construction on nesting tricolored blackbirds if present in the area (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within 10–14 years.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal natural communities restoration would result in the inundation of approximately 116 acres of breeding habitat and 116 acres of nonbreeding habitat. No nesting habitat would be removed as a result of tidal natural communities restoration.
- *Environmental Commitment 7 Riparian Natural Communities Restoration*: Riparian natural communities restoration could remove approximately 5 acres of breeding habitat and 246 acres of nonbreeding habitat.
- *Environmental Commitment 8 Grassland Natural Communities Restoration*: Grassland natural communities restoration would convert approximately 407 acres of breeding foraging habitat and 663 acres of nonbreeding foraging habitat consisting of cultivated lands and grasslands. Grassland provides high-value foraging habitat for tricolored blackbird during the breeding season. Therefore, while impacted habitat may be temporarily unavailable, restored grasslands would be expected to provide foraging habitat for the species if in the vicinity of breeding colonies.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Marsh restoration activities would result in the permanent removal or conversion of approximately 316 acres of breeding foraging habitat and 516 acres of nonbreeding foraging habitat (all cultivated lands suitable for foraging). Some portion of the restored nontidal marsh would be open water, and the remainder would support emergent wetland vegetation that could provide roosting habitat for tricolored blackbird depending on vegetation density and composition.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions that are designed to enhance wildlife values in protected habitats could result in localized ground disturbances that could permanently remove 20 acres of tricolored blackbird breeding habitat and temporarily remove small amounts of tricolored blackbird habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, would be expected to have minor effects on available tricolored blackbird habitat and are expected to result in overall improvements to and maintenance of tricolored blackbird habitat values. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect tricolored blackbird use of the surrounding habitat in or adjacent to work areas. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.

- Injury and Direct Mortality: Operation of construction equipment may cause injury to or mortality of tricolored blackbirds. Risk would be greatest to eggs and nestlings susceptible to land clearing activities, nest abandonment, or increased exposure to the elements or to predators. Injury to or mortality of adults and fledged juveniles would not be expected as individuals would be expected to avoid contact with construction equipment. Construction activities could temporarily fragment existing tricolored blackbird habitat during grading, filling, contouring, and other initial ground-disturbing operations that could temporarily reduce the extent and functions supported by the affected habitat. Construction activities would avoid active tricolored blackbird nesting colonies and associated habitat during the breeding season (generally March 15–July 31). Avoidance measures would include relocating project activities away from the nesting colonies and associated habitat to the maximum extent practicable. To the maximum extent practicable, construction activity will be avoided up to 1,300 feet, but not less than a minimum of 250 feet, from an active tricolored blackbird nesting colony. If monitoring determines an activity is adversely affecting a nesting colony, construction will be modified, as practicable, by either delaying construction until the colony site is abandoned or until the end of the breeding season, whichever occurs first, by temporarily relocating staging areas, or temporarily rerouting access to the construction site. Construction and restoration projects would also be designed, in consultation with CDFW, to avoid construction activity within at least 300 feet from occupied active tricolored blackbird roosting habitat. These measures to avoid injury or mortality of nesting and roosting tricolored blackbirds are described in *AMM21 Tricolored Blackbird* (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*).

The following paragraphs summarize the combined effects discussed above and describe other Environmental Commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Table 12-4A-37. Tricolored Blackbird Foraging Habitat Value Classes

Foraging Habitat Value Class	Agricultural Crop Type/Habitats	
	Breeding Season[a] Foraging Habitat	Nonbreeding Season Foraging Habitat
Very high	Native pasture, nonirrigated native pasture, annual grasslands, vernal pool grasslands, alkali grasslands, unsprayed alfalfa, unsprayed sunflower, unsprayed mixed alfalfa	Livestock feed lots
High	Sunflower, alfalfa and mixed alfalfa, mixed pasture, induced high water table native pasture, nonirrigated mixed pasture, dairies,	Corn, sunflower, alfalfa and mixed alfalfa, mixed pasture, native pasture, nonirrigated native pasture, rice, dairies, annual grasslands, vernal pool grasslands, alkali grasslands
Moderate	Miscellaneous grasses, fallow lands cropped within 3 years, new lands prepped for crop production, livestock feed lots, organic rice	Miscellaneous grass pasture, nonirrigated mixed pasture, fallow lands cropped within 3 years, new lands prepped for crop production
Low	Mixed grain and hay crops, farmsteads, non-irrigated mixed grain and hay, rice	Wheat, oats, mixed grain and hay, farmsteads, unirrigated mixed grain and hay, and non-irrigated misc. grain and hay

[a] Generally March through August; occasional breeding in fall (September through November).

Based on the habitat model, the study area approximately 164,947 acres of breeding and 259,093 acres of nonbreeding habitat for tricolored blackbird. The Delta is an important wintering area for the tricolored blackbird (Hamilton 2004, Beedy 2008). Although there is a large acreage of modeled breeding habitat available, the study area does not currently support many nesting tricolored blackbirds with the exception of a few occurrences on the fringes of the Suisun Marsh, in the Yolo Bypass, and along the southwestern perimeter of the study area. Alternative 4A would result in the combined permanent and temporary loss of up to 6,177 acres of modeled habitat (2,839 acres of breeding habitat and up to 3,338 acres of nonbreeding habitat) for tricolored blackbird (2% of the total breeding habitat in the study area and 1% of the total nonbreeding habitat in the study area). These impacts would consist of 19 acres of nesting habitat, 47 acres of roosting habitat, 708 acres of noncultivated foraging habitat, and 5,403 acres of cultivated lands suitable for foraging.

Typical NEPA and CEQA project-level mitigation ratios would be 2:1 for protection of nesting habitat, 1:1 creation and 1:1 protection of roosting wetland habitat, 2:1 protection for loss of noncultivated lands suitable for foraging (for the breeding and nonbreeding season), and 1:1 protection for the loss of cultivated lands.

Project proponents would commit to protecting and managing 38 acres of occupied or recently occupied (within the last 15 years) tricolored blackbird nesting habitat located within 3 miles of high-value foraging habitat in Conservation Zones 1, 2, 8, or 11. Nesting habitat would be managed to provide young, lush stands of bulrush/cattail emergent vegetation and prevent vegetation senescence, or other non-marsh nesting habitat suitable for the species (Resource Restoration and Performance Principle TB1). These acres would compensate for impacts on 19 acres of tricolored blackbird nesting habitat. An additional 47 acres of nontidal wetland would be protected and 47 acres would be restored which would provide sufficient compensation for impacts on 47 acres of roosting habitat. Alternative 4A would also commit to protecting 1,416 acres of high- to very high-value breeding-foraging habitat (as defined in Table 4A-38) within 5 miles of occupied or recently occupied - within the last 15 years - tricolored blackbird nesting habitat. At least 130 acres would be within 5 miles of the 38 acres of nontidal wetland nesting habitat protected (Resource Restoration and Performance Principle TB2). In addition, 5,403 acres of moderate-, high-, or very high-value cultivated lands (as defined in Table 4A-38) would be protected as nonbreeding foraging habitat, at least 50% of which would be of high- or very high-value (Resource Restoration and Performance Principle TB3). These acres would be sufficient to compensate for impacts on tricolored blackbird foraging habitat.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils*, and *AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of tricolored blackbird breeding and nonbreeding habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting acreages that meets the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles TB1-TB4, and by AMM1–AMM7, and *AMM21 Tricolored Blackbird*, which would be in place during all project activities. Considering these commitments, losses and conversions of tricolored blackbird habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on tricolored blackbird habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of Environmental Commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 10, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principles TB1-TB4, and by AMM1–AMM6, and *AMM21 Tricolored Blackbird*, which would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of tricolored blackbird. Therefore, Alternative 4A would have a less-than-significant impact on tricolored blackbird under CEQA.

Impact BIO-88: Effects on Tricolored Blackbird Associated with Electrical Transmission Facilities

New transmission lines would increase the risk that tricolored blackbirds could be subject to power line strikes, which could result in injury or mortality of individuals. Tricolored blackbirds would have the potential to intersect the proposed transmission lines largely due to winter movements throughout the study area, when individuals are migrating in large flocks and dense fog is common in the area. Although migratory movements and daily flights between roosting and foraging habitat make tricolored blackbird vulnerable to collision with transmission lines, daily flights associated with winter foraging likely occurs in smaller flocks at heights that are lower than the transmission lines (BDCP Attachment 5.J-2, *Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). For example, Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. As described in *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters, which would further reduce any potential for tricolored blackbird collision with transmission lines.

Transmission line poles and towers provide perching substrate for raptors, which are predators on tricolored blackbird. Although there is potential for transmission lines to result in increased perching opportunities for raptors and result in increased predation pressure on tricolored blackbirds, the existing network of transmission lines in the study area currently poses these risks and any incremental risk associated with the new power line corridors would not be expected to affect the study area population. Therefore, it is assumed that the increased risk of predation on tricolored blackbird from an increase in raptor perching opportunities would be minimal.

***NEPA Effects*:** New transmission lines would increase the risk for tricolored blackbird powerline strikes, primarily in winter during daily flights between roosting and foraging sites and during migration movements. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would reduce the potential impact of the construction of new transmission lines on tricolored blackbird. The increased risk of predation on tricolored blackbird from an increase in raptor perching opportunities would be minimal. Therefore, the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on tricolored blackbird.

***CEQA Conclusion*:** New transmission lines would increase the risk for tricolored blackbird powerline strikes, primarily in winter during daily flights between roosting and foraging sites and during migration movements. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would reduce the potential impact of the construction of new transmission lines on tricolored blackbird. The increased risk of predation on tricolored blackbird from an increase in raptor perching opportunities would be minimal. The construction and operation of new transmission lines under Alternative 4A would not substantially reduce the number or restrict the range of the species and would therefore result in a less-than-significant impact on tricolored blackbird.

Impact BIO-89: Indirect Effects of the Project on Tricolored Blackbird

Indirect Construction- and Operation-Related Effects: Tricolored blackbird nesting habitat within the vicinity of proposed construction areas that could be indirectly affected by construction activities. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). However, there are no available data to determine the extent to which these noise levels could affect tricolored blackbird. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet from the construction edge. Construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. *AMM21 Tricolored Blackbird* would require preconstruction surveys, and if detected, project activities would be avoided within a minimum 250 feet of an active nesting colony and up to 1,300 feet where practicable until breeding has ceased. In addition, monitoring would be implemented to ensure that construction does not adversely affect the nesting colony. If a colony appears to be affected, the activity would be modified, as practicable, by either delaying construction until the colony abandons the site or until the end of the breeding season, whichever occurs first, temporarily relocating staging areas, or temporarily rerouting access to the construction site. Construction and restoration projects would also be designed, in consultation with CDFW, to avoid construction activity within at least 300 feet from occupied active tricolored blackbird roosting habitat. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect tricolored blackbird in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to tricolored blackbird habitat could also affect the species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Methylmercury Exposure: Project activities have the potential to exacerbate bioaccumulation of mercury in avian species, including tricolored blackbird. Tidal and nontidal marsh restoration also have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury.

Breeding tricolored blackbirds are not thought to be highly susceptible to methylmercury exposure because tidal wetlands are not expected to be a major foraging area for the species. However, species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects and increased methylmercury associated with natural community restoration could indirectly affect tricolored blackbird, via uptake in lower trophic levels (as described in BDCP Appendix 5.D, *Contaminants*). A detailed review of the methylmercury issues associated with implementation of Alternative 4A is contained in Appendix 11F, *Substantive BDCP Revisions*,. The review includes an overview of the project-related mechanisms that could result in increased mercury in the foodweb, and how exposure of individual species to mercury may occur based on feeding habits and where species habitat overlaps with the areas where mercury bioavailability could increase.

Due to the complex and very site-specific factors that would determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. On a project-specific basis, where high potential for methylmercury production is identified that restoration design and adaptive management cannot fully address while also meeting restoration objectives, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This Environmental Commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.

- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and project activities have the potential to exacerbate bioaccumulation of selenium in avian species, including tricolored blackbird. Tidal and nontidal marsh restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with Environmental Commitment 4 would lead to adverse effects on tricolored blackbird.

Because of the uncertainty that exists with respect to the location of tidal restoration activities, there could be a substantial effect on tricolored blackbird from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: The effects of noise, potential spills of hazardous material, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would not be adverse with the implementation of AMM1–AMM7 and *AMM21 Tricolored Blackbird*.

Tidal habitat restoration could result in increased exposure of tricolored blackbird to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

The implementation of tidal natural communities restoration could result in increased exposure of tricolored blackbird to methylmercury. It is unlikely that breeding tricolored blackbird would be highly susceptible to methylmercury exposure because tidal wetlands are not expected to be a major foraging area for the species. However, it is unknown what concentrations of methylmercury are harmful to this species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on tricolored blackbird.

CEQA Conclusion: Impacts of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would be less than significant with the implementation of *AMM21 Tricolored Blackbird* and AMM1–AMM7.

Tidal habitat restoration could result in increased exposure of tricolored blackbird to selenium. This impact would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

The implementation of tidal natural communities restoration could result in increased exposure of tricolored blackbird to methylmercury. It is unlikely that breeding tricolored blackbird would be highly susceptible to methylmercury exposure because tidal wetlands are not expected to be a major foraging area for the species. However, it is unknown what concentrations of methylmercury are harmful to this species. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on tricolored blackbird.

Therefore, with AMM1–AMM7, AMM21, AMM27, and Environmental Commitment 12 in place, the indirect effects of Alternative 4A implementation would not result in a substantial adverse effect through habitat modification or potential mortality. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on tricolored blackbird.

Impact BIO-90: Periodic Effects of Inundation of Tricolored Blackbird Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on tricolored blackbird.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Western Burrowing Owl

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on western burrowing owl. Western burrowing owl modeled habitat consisted of high- and low-value habitat for nesting and foraging. High-value habitat consists of plant alliances within the grassland and vernal pool natural communities and pasture. Low-value habitat includes plant alliances and crop types from managed wetland, alkali seasonal wetland, and cultivated lands. Value was determined through reported species use patterns from the literature.

Alternative 4A would result in both temporary and permanent losses of western burrowing owl modeled habitat as indicated in Table 12-4A-38. Full implementation of Alternative 4A would also include the following Environmental Commitment and Resource Restoration and Performance Principle that would benefit the western burrowing owl.

- Protect up to 1,060 acres of grassland and 11,870 acres of cultivated lands (Environmental Commitment 3). The following Swainson's hawk Resource Restoration and Performance Principles would be implemented as part of these acres and would also benefit western burrowing owl:
  - Conserve 1 acre of Swainson's hawk foraging habitat for each acre of lost foraging habitat in a minimum of 40-acre patches (Resource Restoration and Performance Principle SH1).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for the species and implementation of AMM1–AMM7, and *AMM23 Western Burrowing Ow*l, impacts on western burrowing owl would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-38. Changes in Western Burrowing Owl Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	High-value	863	314
	Low-value	2,294	559
Total Impacts Water Conveyance Facilities		**3,157**	**873**
Environmental Commitments 4, 6–7, 9–11[a]	High-value	521	0
	Low-value	1,902	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,423**	**0**
Total High-value		**1,384**	**314**
Total Low-value		**4,196**	**559**
TOTAL IMPACTS		**5,580**	**873**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-91: Loss or Conversion of Habitat for and Direct Mortality of Western Burrowing Owl

Alternative 4A would result in the combined permanent and temporary loss of up to 6,453 acres of modeled habitat for western burrowing owl (of which 1,698 acres is of high-value and 4,755 acres is of low value, Table 12-4A-38). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, *Environmental Commitment 4 Tidal Natural Communities Restoration*, *Environmental Commitment 7 Riparian Natural Community Restoration*, *Environmental Commitment 8 Grassland Restoration*, *Environmental Commitment 10 Nontidal Marsh Restoration*, and *Environmental Commitment 11 Natural Communities Enhancement and Management.* Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate western burrowing owl habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A water conveyance facilities would result in the combined permanent and temporary loss of up to 1,177 acres of acres of modeled high-value western burrowing owl habitat (863 acres of permanent loss, 314 acres of temporary loss) from CZs 3–6 and CZ 8. In addition, 2,853 acres of low-value burrowing owl habitat would be removed (2,294 acres of permanent loss, 559 acres of temporary loss). The majority of high-value grassland habitat that would be removed would be in CZ 8, from the construction of the new forebay in CZ 8. There is a high concentration of CNDDB and DHCCP survey records for western burrowing owls in CZ 8 to the west and the south of the Clifton Court Forebay. The loss of high-value habitat from facility construction and the establishment of the forebay reusable tunnel material storage area could remove occupied habitat, displace nesting and wintering owls, and fragment occupied burrowing owl habitat.
- The reusable tunnel material storage area overlaps with six occurrences of western burrowing owl and there are also several occurrences west of the new forebay control structure that could be indirectly affected by construction activities. The amount of storage area needed for reusable tunnel material is flexible (dependent on storage pile height and other factors) and the footprint used in the effects analysis is based on a worst case scenario. However, the actual area to be affected by reusable tunnel material storage would likely be less than the estimated acreage. The implementation of *AMM6 Disposal and Reuse of Spoils* and *AMM23 Western Burrowing Owl* would require that to the extent practicable, the reusable tunnel material storage area footprint avoided locations where active burrows are present. The footprints of a permanent transmission line and a permanent access road, both located west of the Clifton Court Forebay overlap with an additional 8 occurrences of western burrowing owl. Preconstruction surveys would be conducted prior to any construction activities under *AMM23 Western Burrowing Owl* during the nonbreeding and the breeding season. If avoidance was not possible, passive relocation would be considered in consultation with CDFW. If owls were to be excluded from existing burrows, artificial burrows would be used if it were possible for them to be installed within 100 meters from the existing burrows on protected lands. A substantial portion of the high-value grassland protection and enhancement under *Environmental Commitment 8 Grassland Natural Community Restoration* would be expected to occur to the west and to the south of these occurrences in CZ 8, which would provide high-value protected lands in close proximity to the disturbed habitat.
- Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 153 acres of high-value and 97 acres of low-value western burrowing owl habitat.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 1 acre of high-value and 250 acres of low-value western burrowing owl habitat.
- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would permanently remove approximately 235 acres of high-value and 835 acres of low-value western burrowing owl habitat.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Implementation would result in the permanent removal of 112 acres of high-value and 720 acres of low-value western burrowing owl habitat.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could permanently remove 20 acres of high-value western burrowing owl habitat and could temporarily remove small amounts of western burrowing owl habitat. The burrowing owl's fossorial habits make the species more sensitive to the effects of ground disturbance than other raptors. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available western burrowing owl habitat and would be expected to result in overall improvements to and maintenance of habitat values.
- Habitat management- and enhancement-related activities and equipment operation could destroy nests burrows, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. The potential for these activities to result in nest failure and mortality or other adverse effects on western burrowing owl would be avoided or minimized with the incorporation of *AMM23 Western Burrowing Owl* which would require surveys to determine presence or absence and the establishment of no-disturbance buffers around active sites.
- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect western burrowing owl use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.
- Injury and Direct Mortality: Construction would not be expected to result in direct mortality of western burrowing owl. However, if nest burrows were occupied in the vicinity of construction activities, equipment operation could destroy nests and noise and visual disturbances could lead to abandonment. *AMM23 Western Burrowing Owl* would ensure that preconstruction surveys detected any occupied burrows and no-disturbance buffers would be implemented.

The following paragraphs summarize the combined effects discussed above and describe other Environmental Commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Based on the habitat model, the study area supports approximately 152,014 acres of high-value and 254,352 acres of low-value habitat for western burrowing owl. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 1,698 acres of high-value habitat (1% of the habitat in the study area) and 4,755 acres of low-value western burrowing owl habitat (2% of the habitat in the study area). These effects would result from the construction of the water conveyance facilities and implementing *Environmental Commitment 4 Tidal Natural Communities Restoration, Environmental Commitment 7 Riparian Natural Communities Restoration, Environmental Commitment 8 Grassland Natural Communities Restoration*, and *Environmental Commitment 10 Nontidal Marsh Restoration*.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 2:1 protection of high-value habitat, and 1:1 protection of low-value habitat. Using these typical ratios would indicate that 3,396 acres should be protected to compensate for the loss of high-value habitat and 4,715 acres should be protected to compensate for the loss of low-value habitat.

Project proponents would commit to protect up to 1,060 acres of grassland and 11,870 acres of cultivated lands, which would be sufficient to compensate for impacts on western burrowing owl habitat. As part of these acres of protection, Alternative 4A would conserve 1 acre of Swainson's hawk foraging habitat for every acre of lost foraging habitat (which would also benefit western burrowing owl), which would total 6,805 acres. These acres would be sufficient to compensate for impacts on western burrowing owl habitat.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils*, and *AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of western burrowing owl habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects from and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principle SH1, and by AMM1–AMM7, and *AMM23 Western Burrowing Owl*, which would be in place during all project activities. Considering these commitments, losses and conversions of western burrowing owl habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on western burrowing owl habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of Environmental Commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3 and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principle SH1, and by AMM1–AMM6 and *AMM23 Western Burrowing Owl*, which would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of western burrowing owl. Therefore, with the implementation of Mitigation Measure BIO-75, Alternative 4A would have a less-than-significant impact on western burrowing owl under CEQA.

Impact BIO-92: Effects on Western Burrowing Owl Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes and/or electrocution, which could result in injury or mortality of western burrowing owl. The species is large-bodied but with relatively long and rounded wings, making it moderately maneuverable. While burrowing owls may nest in loose colonies, they do not flock or congregate in roosts or foraging groups. Collectively, the species' keen eyesight and largely ground-based hunting behavior make it a relatively low-risk species for powerline collision. While the species in not widespread in the study area, it may become more widely distributed as grassland enhancement improves habitat for the species. Even so, the risk of effects on the population are low, given its physical and behavioral characteristics (BDCP Attachment 5.J-2*, Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*) and new transmission lines would not be expected to have an adverse effect on the species. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new project transmission lines would be fitted with flight diverters. Bird flight diverters would make transmission lines highly visible to western burrowing owls and would further reduce any potential for powerline collisions.

NEPA Effects: The construction and presence of new transmission lines would not result in an adverse effect on western burrowing owl because the risk of bird strike is considered to be minimal based on the owl's physical and behavioral characteristics. All new transmission lines constructed as a result of the project would be fitted with bird diverters (*AMM20 Greater Sandhill Crane*), which have been shown to reduce avian mortality by 60% and which would further reduce any potential for powerline collisions.

CEQA Conclusion: The construction and presence of new transmission lines would have a less-than-significant impact on western burrowing owl because the risk of bird strike is considered to be minimal based on the owl's physical and behavioral characteristics. All new transmission lines constructed as a result of the project would be fitted with bird diverters (*AMM20 Greater Sandhill Crane*), which have been shown to reduce avian mortality by 60% and which would further reduce any potential for powerline collisions.

Impact BIO-93: Indirect Effects of the Project on Western Burrowing Owl

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect western burrowing owl use of up to 13,922 acres of modeled burrowing owl habitat (6,113 acres of high-value habitat) within 500 feet of project activities will temporarily be made less suitable as a result of construction noise and visual disturbances adjacent to proposed construction areas. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Any disturbance within 250 feet of a burrow occupied by burrowing owl during the breeding season (February 1–August 31) and within 160 feet during the nonbreeding season (September 1–January 31) could potential displace winter owls or cause abandonment of active nests. These potential effects would be minimized with incorporation of *AMM23 Western Burrowing Owl* into Alternative 4A, which would require preconstruction surveys and establish no-disturbance buffers around active burrows. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). However, there are no available data to determine the extent to which these noise levels could affect western burrowing owl.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect western burrowing owl in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to western burrowing owl habitat could also affect the species. AMM1–AMM7 in addition to *AMM23 Western Burrowing Owl* would minimize the likelihood of such spills and ensure that measures were in place to prevent runoff from the construction area and any adverse effects of dust on active nests.

***NEPA Effects*:** Indirect effects on western burrowing owl as a result of Alternative 4A implementation could have adverse effects on this species through the modification of habitat and potential for direct mortality. Construction of the new forebay in CZ 8 would have the potential to disrupt nesting owls or active burrows in the high-value grassland habitat surrounding Clifton Court Forebay and adjacent to work area. With the implementation of AMM1–AMM7, and *AMM23 Western Burrowing Owl*, the indirect effects from Alternative 4A implementation would not be adverse under NEPA.

***CEQA Conclusion*:** Indirect effects on western burrowing owl as a result of Alternative 4A implementation could have significant impacts on these species through the modification of habitat and potential for direct mortality. Construction of the new forebay in CZ 8 would have the potential to disrupt nesting owls or active burrows in the high-value grassland habitat surrounding Clifton Court Forebay and adjacent to work areas. With the implementation of AMM1–AMM7 and *AMM23 Western Burrowing Owl*, the indirect effects resulting from Alternative 4A implementation would have a less-than-significant impact on western burrowing owl.

Impact BIO-94: Periodic Effects of Inundation on Western Burrowing Owl Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on western burrowing owl.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Western Yellow-Billed Cuckoo

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on western yellow-billed cuckoo. The habitat model for western yellow-billed cuckoo includes potential breeding habitat, which includes plant alliances from the valley/foothill riparian modeled habitat that contain a dense forest canopy for foraging with understory willow for nesting, and a minimum patch size of 50 acres, and migratory habitat, which includes the same plant alliances as breeding habitat without the minimum 50 acres patch size requirement.

The western yellow-billed cuckoo is uncommon in the study area at present, and the likelihood that it would be found using the modeled habitat is low relative to more abundant riparian species. Nesting of the species in the study area has not been confirmed for approximately 100 years. Western yellow-billed cuckoo was detected in the study area during 2009 DHCCP surveys, but nesting was not confirmed and the bird is suspected to have been a migrant (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*). Alternative 4A would result in both temporary and permanent losses of Western yellow-billed cuckoo modeled habitat as indicated in Table 12-4A-39. Full implementation Alternative 4A would also include the following environmental commitments and Resource Restoration and Performance Principles which would benefit the western yellow-billed cuckoo.

- Restore or create up to 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect up to 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).
- Maintain a single contiguous patch of 100 acres of mature riparian forest in either CZ 4 or CZ 7. The mature riparian forest will be intermixed with a portion of the early- to mid-successional riparian vegetation and will be a minimum width of 330 feet where practicable (Resource Restoration and Performance Principles VFR2 and VFR3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species and implementation of AMM1–AMM7, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, impacts on Western yellow-billed cuckoo would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-39. Changes in Western Yellow-Billed Cuckoo Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Breeding	6	2
	Migratory	15	15
Total Impacts Water Conveyance Facilities		**21**	**17**
Environmental Commitments 4, 6–7, 9–11[a]	Breeding	2	0
	Migratory	7	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**9**	**0**
Total Breeding		**8**	**2**
Total Migratory		**22**	**15**
TOTAL IMPACTS		**30**	**17**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-95: Loss or Conversion of Habitat for and Direct Mortality of Western Yellow-Billed Cuckoo

Alternative 4A would result in the combined permanent and temporary loss of up to 47 acres of modeled habitat for western yellow-billed cuckoo (10 acres of breeding habitat, 37 acres of migratory habitat, Table 12-4A-39). Project components that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11) which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate western yellow-billed cuckoo modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 8 acres of breeding habitat (6 acres of permanent loss, 2 acres of temporary loss) for yellow-billed cuckoo. In addition, 30 acres of migratory habitat would be removed (15 acres of permanent loss, 15 acres of temporary loss, see Table 12-4A-39). Activities that would impact modeled habitat consist of tunnel, forebay, and intake construction, permanent and temporary access roads, construction of transmission lines, and temporary barge unloading facilities and work areas. Impacts from water conveyance facilities would occur in the central Delta in CZs 3–6, and 8. Permanent habitat loss would occur from the construction of Intakes 2, 3, and 5 on the east bank of the Sacramento River between Freeport and Courtland. Some habitat would also be impacted by the construction of a permanent access road from the new forebay west to an reusable tunnel material disposal area. Additional losses would also occur along Lambert Road where permanent utility lines would be installed and from the construction of an operable barrier at the confluence of Old River and the San Joaquin River. Temporary losses of habitat would result from the construction of a barge unloading facility west of the intermediate forebay in Snodgrass Slough and where temporary work areas surround intake sites. Permanent and temporary habitat losses from the Environmental Commitments would primarily consist of small, fragmented riparian stands in CZ 2–CZ 8 that do not provide high-value habitat for the species. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities as described in *AMM10 Restoration of Temporarily Affected Natural Communities*. Although the effects are considered temporary, the restored riparian habitat would require 5 years to several decades, for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. The majority of the riparian vegetation to be temporarily removed is early- to mid-successional; therefore, the replaced riparian vegetation would be expected to have structural components comparable to the temporarily removed vegetation within the first 5 to 10 years after the initial restoration activities are complete.

  There are no extant occurrences of yellow-billed cuckoo nests in the study area; however, habitat loss from the construction of water conveyance facilities would have the potential to displace individuals, if present, and remove the functions and value of modeled habitat for nesting, protection, or foraging. *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, would minimize the effects of construction on nesting cuckoos if present in the area (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 2 acres of modeled yellow-billed cuckoo breeding habitat and 7 acres of modeled migratory habitat. There are no extant nesting records of yellow-billed cuckoo in the study area. However, a yellow-billed cuckoo detection was recorded during DHCCP surveys in 2009 (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*) in CZ 5 between Twin Cities Road and Walnut Grove.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Habitat protection and management activities that could be implemented in protected western yellow-billed cuckoo habitats would maintain and improve the functions of the habitat. With conditions favorable for its future establishment in the study area, western yellow-billed cuckoo would be expected to benefit from the increase in protected habitat. However, habitat management- and enhancement-related activities could disturb western yellow-billed cuckoo nests if they were present near work sites. Environmental Commitment 11 actions designed to enhance wildlife values in restored riparian habitats may result in localized ground disturbances that could temporarily remove small amounts of western yellow-billed cuckoo habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available western yellow-billed cuckoo habitat and would be expected to result in overall improvements and maintenance of western yellow-billed cuckoo habitat values.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect western yellow-billed cuckoo use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.

- Injury and Direct Mortality: Western yellow-billed cuckoo nesting has not been confirmed in the Delta for approximately 100 years. However, an unconfirmed breeding detection during 2009 DHCCP surveys (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*) and the presence of suitable habitat indicate that the species is potentially breeding in the study area, or may nest there in the future. Construction-related activities would not be expected to result in direct mortality of adult or fledged western yellow-billed cuckoo if they were present in the study area, because they would be expected to avoid contact with construction and other equipment. Although there is minimal habitat in the Plan Area that is of appropriate width, and suitable understory to support nesting cuckoos, if western yellow-billed cuckoo were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. as described in *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, to the extent feasible, the contractor will employ best management practices to reduce construction noise during daytime and evening hours (7:00 a.m. to 10:00 p.m.) such that construction noise levels do not exceed 60 dBA (A-weighted decibel) Leq (1 hour) at the nearest western yellow-billed cuckoo migratory habitat during migration periods. Limit construction during nighttime hours (10:00 p.m. to 7:00 a.m.) such that construction noise levels do not exceed 50 dBA

Lmax[1] at the nearest residential land uses. Limit pile driving to daytime hours (7:00 a.m. to 7:00 p.m.). Locate, store, and maintain portable and stationary equipment as far as possible from suitable western yellow-billed cuckoo habitat. Employ preventive maintenance including practicable methods and devices to control, prevent, and minimize noise. Route truck traffic in order to reduce construction noise impacts and traffic noise levels within 1,200 feet of suitable western yellow-billed cuckoo migratory habitat during migration periods. Limit trucking activities (e.g., deliveries, export of materials) to the hours of 7:00 a.m. to 10:00 p.m. Screen all lights and direct them down toward work activities away from migratory habitat. A biological construction monitor will ensure that lights are properly directed at all times. Operate portable lights at the lowest allowable wattage and height, while in accordance with the National Cooperative Highway Research Program's Report 498: Illumination Guidelines for Nighttime Highway Work.

The following paragraphs summarize the combined effects discussed above and describe other Environmental Commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

The habitat model indicates that the study area supports approximately 12,395 acres of modeled breeding and migratory habitat for yellow-billed cuckoo. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 47 acres of modeled habitat (<1% of the modeled habitat in the study area). These losses would occur from the construction of the water conveyance facilities and from *Environmental Commitment 4 Tidal Natural Communities Restoration*. The locations of these losses would be in fragmented riparian habitat throughout the study area.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat. Using these ratios would indicate that 47acres of valley/foothill riparian habitat should be restored/created and 47acres should be protected to compensate for the losses of western yellow-billed cuckoo habitat.

Alternative 4A includes conservation commitments through *Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration* to restore or create up to 251 acres and protect up to 103 acres of valley/foothill riparian woodland. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1). A single, contiguous patch of 100 acres of mature riparian forest would be maintained within either CZ 4 (in the vicinity of Cosumnes River Preserve) or CZ 7 (in the vicinity of San Joaquin National Wildlife Refuge and Caswell State Memorial Park) to ensure that restored and protected riparian would be of sufficient size to provide suitable habitat for yellow-billed cuckoo (Resource Restoration and Performance Principle VFR2). The mature riparian forest would be intermixed with a portion of the early- to mid-successional riparian vegetation and would be a minimum width of 330 feet where practicable (Resource Restoration and Performance Principle VFR3).

The project also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM22 Suisun Song Sparrow, Yellow-*

Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of western yellow-billed cuckoo habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects from and to restoring and protecting an acreage that meets the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles VFR1-VFR3, and by AMM1–AMM7, AMM10, and AMM22. These environmental commitments and AMMs would be in place during all project activities. Considering these commitments, losses and conversions of western yellow-billed cuckoo habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The loss of western yellow-billed cuckoo habitat from Alternative 4A would represent an adverse effect in the absence of Environmental Commitments and AMMs as a result of habitat modification and potential for direct mortality of a special-status species. However, habitat protection and restoration associated with Environmental Commitment 3 and Environmental Commitment 7, guided by Resource Restoration and Performance Principles VFR1-VFR3 and by *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of western yellow-billed cuckoo. Therefore, Alternative 4A would have a less-than-significant impact on western yellow-billed cuckoo under CEQA.

Impact BIO-96: Fragmentation of Western Yellow-Billed Cuckoo Habitat as a Result of Constructing the Water Conveyance Facilities

Grading, filling, contouring, and other initial ground-disturbing operations for water conveyance facilities construction may temporarily fragment modeled western yellow-billed cuckoo habitat. This could temporarily reduce the extent and functions supported by the affected habitat. Because western yellow-billed cuckoo is not currently known to breed in the study area, and the protection and restoration of riparian habitat will expand contiguous habitat block requirements, habitat fragmentation would have a minimal effect on the species.

NEPA Effects: Because western yellow-billed cuckoo is not currently known to breed in the study area and the protection and restoration of riparian habitat will expand contiguous habitat block requirements, fragmentation of habitat would not have an adverse effect on western yellow-billed cuckoo.

CEQA Conclusion: Because western yellow-billed cuckoo is not currently known to breed in the study area and the protection and restoration of riparian habitat will expand contiguous habitat block requirements, fragmentation of habitat would have a less-than-significant impact on western yellow-billed cuckoo.

Impact BIO-97: Effects on Western Yellow-Billed Cuckoo Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of western yellow-billed cuckoo. Because the western yellow-billed cuckoo uses riparian forests to meet all of its breeding and wintering life requisites, the species remains primarily within the canopy of riparian forests and rarely ventures into open spaces except during migration, limiting its opportunity to encounter the proposed transmission lines. As a summer resident, if the species were to occur in the study area it would be during periods of relatively high visibility and clear weather conditions, thus further reducing collision risk from daily use patterns or seasonal migration flights. Finally, western yellow-billed cuckoo wing shape is characterized by low wing loading and a moderate aspect ratio, making the species moderately maneuverable and presumably able to avoid collisions, especially during high-visibility conditions (BDCP Attachment 5.J-2, *Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*).

Transmission line poles and towers also provide perching substrate for raptors, which are predators on western yellow-billed cuckoo. Although there is potential for transmission lines to result in increased perching opportunities for raptors, the existing network of transmission lines in the study area currently poses these risks and any incremental risk associated with the new power line corridors would not be expected to affect the population. In addition, the transmission lines that would be constructed in the vicinity of modeled western yellow-billed cuckoo habitat would be temporary and would be removed within 10–14 years of Alternative 4A implementation. Because there is low probability for the species to occur in the study area, and because the transmission lines that would be constructed near modeled habitat would be temporary, any increased risk of predation on western yellow-billed cuckoo from an increase in raptor perching opportunities would be minimal.

***NEPA Effects*:** The risk of bird-strike is considered to be minimal based on the species' rarity in the study area, its proclivity to remain in the riparian canopy, its presence in the study area during periods of relative high visibility, and its overall ability to successfully negotiate around overhead wires that it may encounter. Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure on western yellow-billed cuckoo. However, because there is a low probability for the species to occur in the study area, and because the transmission lines that would be constructed near modeled habitat would be temporary, any increased risk of predation on western yellow-billed cuckoo from an increase in raptor perching opportunities would be minimal. Therefore, the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on western yellow-billed cuckoo.

***CEQA Conclusion*:** The construction and presence of new transmission lines would have a less-than-significant impact on western yellow-billed cuckoo because the risk of bird-strike is considered to be minimal based on the species' rarity in the study area, its proclivity to remain in the riparian canopy, its presence during periods of relative high visibility, and its overall ability to successfully negotiate around overhead wires that it may encounter. Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure on western yellow-billed cuckoo. However, because there is a low probability for the species to occur in the study area, and because the transmission lines that would be constructed near modeled habitat would be temporary, any increased risk of predation on western yellow-billed cuckoo from an increase in raptor perching opportunities would be minimal. Therefore, the construction and operation of new transmission lines under Alternative 4A would result in a less-than-significant impact on western yellow-billed cuckoo.

Impact BIO-98: Indirect Effects of the Project on Western Yellow-Billed Cuckoo

Construction- and operation-related effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect western yellow-billed cuckoo use of modeled habitat adjacent to proposed construction areas. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). However, there are no available data to determine the extent to which these noise levels could affect western yellow-billed cuckoo. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet from the construction edge. If western yellow-billed cuckoo were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. These potential effects would be minimized with incorporation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* into Alternative 4A which would require a no disturbance buffer around nest sites durng the breeding season in addition to monitoring and noise reducing measures. To the extent feasible, the contractor will employ best practices to reduce construction noise during daytime and evening hours (7:00 a.m. to 10:00 p.m.) such that construction noise levels do not exceed 60 dBA (A-weighted decibel) Leq (1 hour) at the nearest western yellow-billed cuckoo migratory habitat during migration periods. Limit construction during nighttime hours (10:00 p.m. to 7:00 a.m.) such that construction noise levels do not exceed 50 dBA Lmax[1] at the nearest residential land uses. Limit pile driving to daytime hours (7:00 a.m. to 7:00 p.m.). Locate, store, and maintain portable and stationary equipment as far as possible from suitable western yellow-billed cuckoo habitat. Employ preventive maintenance including practicable methods and devices to control, prevent, and minimize noise. Route truck traffic in order to reduce construction noise impacts and traffic noise levels within 1,200 feet of suitable western yellow-billed cuckoo migratory habitat during migration periods. Limit trucking activities (e.g., deliveries, export of materials) to the hours of 7:00 a.m. to 10:00 p.m. Screen all lights and direct them down toward work activities away from migratory habitat. A biological construction monitor will ensure that lights are properly directed at all times. Operate portable lights at the lowest allowable wattage and height, while in accordance with the National Cooperative Highway Research Program's Report 498: Illumination Guidelines for Nighttime Highway Work.The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect western yellow-billed cuckoo in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to western yellow-billed cuckoo habitat could also affect the species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, in addition to *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would minimize the likelihood of such spills from occurring and ensure that measures were in place to prevent runoff from the construction area and any adverse effects of dust on active nests.

Methylmercury Exposure: The modeled primary habitat for western yellow-billed cuckoo includes tidal brackish emergent wetland and tidal freshwater emergent wetland in Suisun Marsh and the

Delta west of Sherman Island, and instream islands and White Slough Wildlife Area in the central Delta. Cuckoos typically occur in the high marsh zone near the upper limit of tidal flooding in salt and brackish habitats. Low marsh, managed wetlands, and the upland fringe are considered secondary habitat. Cuckoos are a top predator in the benthic food chain; they nest and forage in dense vegetation and prey on isopods, insects and arthropods from the surface of mud and vegetation They also consume insects and seeds from bulrushes (*Schoenoplectus* spp.) and cattails (*Typha* spp.) (Eddleman et al. 1994).

Largemouth bass was used as a surrogate species for analysis (see Appendix 11F, *Substantive BDCP Revisions*). Results of the quantitative modeling of mercury effects on largemouth bass as a surrogate species would overestimate the effects on yellow-billed cuckoo. Organisms feeding within pelagic-based (algal) foodwebs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic foodwebs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009). Modeled effects of mercury concentrations from changes in operations of water conveyance facilities on largemouth bass did not differ substantially from existing conditions; therefore, results also indicate that yellow-billed cuckoo mercury tissue concentrations would not measurably increase as a result of water conveyance facilities implementation.

Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. In general, the highest methylation rates are associated with high tidal marshes that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury. Given that some species have existing elevated mercury tissue levels, these low level increases could result in some level of effects. Environmental Commitment 12 would be implemented to address the risk that low level increases in methylmercury could add to the current elevated concentrations in tissue.

Because of the complex and very site-specific factors that would determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This Environmental Commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability.
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults,

and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and project activities have the potential to exacerbate bioaccumulation of selenium in avian species, including western yellow-billed cuckoo. Tidal and nontidal marsh restoration has the potential to mobilize selenium, and, therefore, increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, tidal marsh restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations are analyzed in Chapter 8, *Water Quality*, which concludes that, relative to Existing Conditions and the No Action Alternative, construction and operation of proposed water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative.

There could be an effect on western yellow-billed cuckoo from increases in selenium associated with tidal restoration activities (Environmental Commitment 4); however, effects on the western yellow-billed cuckoo population are expected to be minimal because the amount of tidal restoration would total up to 22 acres. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of project design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design.

NEPA Effects: Indirect effects on western yellow-billed cuckoo as a result of Alternative 4A implementation could have adverse effects on the species through the modification of habitat and potential for direct mortality. Changes in water operations would not be expected to result in increased mercury bioavailability to western yellow-billed cuckoo. Restoration actions that would create high and low tidal marsh, which is western yellow-billed cuckoo habitat, could provide biogeochemical conditions for methylation of mercury in the newly inundated soils. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the amount of tidal restoration would total up to 22 acres, and potential exposure to methylmercury resulting from these acres of restoration would not be expected to adversely affect the western yellow-billed cuckoo population. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for any effects of increased methylmercury exposure.

Tidal habitat restoration could result in increased exposure of western yellow-billed cuckoo to selenium; however, the amount of tidal restoration would total up to 22 acres, and potential exposure to selenium resulting from these acres of restoration would not be expected to adversely affect the western yellow-billed cuckoo population. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Because of the species' minimal presence in the study area, and with the incorporation of AMM1–AMM7, *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, and *AMM27 Selenium Management* into Alternative 4A, indirect effects would not have an adverse effect on western yellow-billed cuckoo.

CEQA Conclusion: Indirect effects on western yellow-billed cuckoo as a result of Alternative 4A implementation could have a significant impact on the species from modification of habitat. Changes in water operations would not be expected to result in increased mercury bioavailability to western yellow-billed cuckoo. Restoration actions that would create high and low tidal marsh could provide biogeochemical conditions for methylation of mercury in the newly inundated soils. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the amount of tidal restoration would total up to 22 acres, and potential exposure to methylmercury resulting from these acres of restoration would not be expected to adversely affect the western yellow-billed cuckoo population. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for any effects of increased methylmercury exposure.

Tidal habitat restoration could result in increased exposure of western yellow-billed cuckoo to selenium; however, the amount of tidal restoration would total up to 22 acres, and potential exposure to selenium resulting from these acres of restoration would not be expected to adversely affect the western yellow-billed cuckoo population. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

With the incorporation of AMM1–AMM7, *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, and *AMM27 Selenium Management* into Alternative 4A, indirect effects as a result of Alternative 4A implementation would have a less-than-significant impact on western yellow-billed cuckoo.

Impact BIO-99: Periodic Effects of Inundation of Western Yellow-Billed Cuckoo Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on western yellow-billed cuckoo.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

White-Tailed Kite

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on white-tailed kite. The habitat model used to assess impacts on white-tailed kite includes nesting habitat and foraging habitat. Most white-tailed kites in the Sacramento Valley are found in oak and cottonwood riparian forests, valley oak woodlands, or other groups of trees and are usually associated with compatible foraging habitat for the species in patches greater than 1,500 square meters (Erichsen et al. 1996). Modeled foraging habitat for white-tailed kite consists of pasture and hay crops, compatible row and grain crops and natural vegetation such as seasonal wetlands and annual grasslands (Erichsen et al. 1995).

Alternative 4A would result in both temporary and permanent losses of white-tailed kite modeled habitat as indicated in Table 12-4A-40. The majority of the losses would result from the construction of the water conveyance facilities. Although restoration for the loss of nesting and foraging habitat would be initiated in the same timeframe as the losses, it could take one or more decades (for nesting habitat) for restored habitats to replace the functions of habitat lost. This time lag between impacts and restoration of habitat function would be minimized by specific requirements of *AMM39 White-Tailed Kite*, including the planting of mature trees. Full implementation of Alternative 4A would also include the following Environmental Commitments and Resource Restoration and Performance Principles which would benefit the white-tailed kite.

- Restore or create up to 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect up to 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).
- Maintain a single contiguous patch of 100 acres of mature riparian forest in either CZ 4 or CZ 7.The mature riparian forest will be intermixed with a portion of the early- to mid-successional riparian vegetation will be a minimum width of 330 feet where practicable (Resource Restoration and Performance Principles VFR2 and VFR3).
- Protect up to 1,060 acres of grassland and 11,870 acres of cultivated lands (Environmental Commitment 3). The following Swainson's hawk Resource Restoration and Performance Principles would be implemented as part of these acres and would also benefit white-tailed kite:
    - Conserve 1 acre of Swainson's hawk foraging habitat for each acre of lost foraging habitat in minimum patch sizes of 40 acres (as part of the total cultivated lands protected) (Resource Restoration and Performance Principle SH1).

- Protect Swainson's hawk foraging habitat above 1 foot above mean sea level with at least 50% in very high-value habitat (see Table 12-4A-35 for a definition habitat value) (Resource Restoration and Performance Principle SH2).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands within the conservation area, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Resource Restoration and Performance Principle CL1).

White-tailed kite is a fully protected species and take of white-tailed kite individuals is prohibited under Section 3511 of the Fish and Game Code. With the implementation of *AMM39 White-Tailed Kite*, construction activities would not result in take, and effects on the species would be minimized. As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species and implementation of AMM1–AMM7, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM39 White-Tailed Kite,* impacts on white-tailed kite would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-40. Changes in White-Tailed Kite Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting	25	16
	Foraging	3,244	1,054
Total Impacts Water Conveyance Facilities		**3,269**	**1,070**

	Foraging	2,429	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,438**	**0**
Total Nesting		**34**	**16**
Total Foraging		**5,673**	**1,054**
TOTAL IMPACTS		**5,707**	**1,070**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-100: Loss or Conversion of Habitat for and Direct Mortality of White-Tailed Kite

Alternative 4A would result in the combined permanent and temporary loss of up to 6,777 acres of modeled habitat (50 acres of nesting habitat and 6,727 acres of foraging habitat) for white-tailed kite (Table 12-4A-40). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, tidal habitat restoration (Environmental Commitment 4), riparian restoration, (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could also result in local habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could affect white-tailed kite modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A water conveyance facilities would result in the combined permanent and temporary loss of up to 41 acres of white-tailed kite nesting habitat (25 acres of permanent loss and 16 acres of temporary loss). In addition, 2,298 acres of foraging habitat would be removed (3,244 acres of permanent loss, 1,054 acres of temporary loss). Activities that would impact modeled white-tailed kite habitat consist of tunnel, forebay, and intake construction, temporary access roads, and construction of transmission lines. Most of the permanent loss of nesting habitat would occur where Intakes 1–3 impact the Sacramento River's east bank between Freeport and Courtland. The riparian areas here are very small patches, some dominated by valley oak and others by nonnative trees. Some nesting habitat would be lost due to construction of a permanent access road from the new forebay west to an reusable tunnel material disposal area. Permanent losses would also occur along Lambert Road where permanent utility lines would be installed and from the construction of an operable barrier at the confluence of Old River and the San Joaquin River. Temporary losses of nesting habitat would result from the construction of a barge unloading facility west of the intermediate forebay in Snodgrass Slough and where temporary work areas surround intake sites. The riparian habitat in these areas is also composed of very small patches or stringers bordering waterways, which are composed of valley oak and scrub vegetation. There are no occurrences of nesting white-tailed kite that overlap with the construction footprint of water conveyance facilities. White-tailed kite is a fully protected species and take is prohibited under Section 3511 of the Fish and Game Code. If white-tailed kite were to nest in or adjacent to work areas, the implementation of *AMM39 White-Tailed Kite* would avoid disturbance and nest abandonment, mortality of eggs, nestlings, or fledglings by restricting construction activities during the breeding season or establishing suitable buffers around active nests (see Appendix3B, *Environmental Commitments, AMMs, and CMs*). Impacts on foraging habitat would occur throughout the central Delta in CZs 3–6, and CZ 8. Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 9 acres of white-tailed kite nesting habitat and 256 acres of foraging habitat. The conversion of cultivated lands to tidal wetlands over fairly broad areas within the tidal restoration footprints could result in the removal or abandonment of nesting territories that occur within or adjacent to the restoration areas. Trees would not be actively removed but tree mortality would be expected over time as areas became tidally inundated.

- *Environmental Commitment 7 Riparian Natural Community Restoration:* Riparian restoration would permanently remove approximately 251 acres of white-tailed kite foraging habitat.

- *Environmental Commitment 8 Grassland Natural Community Restoration:* Grassland restoration would permanently convert approximately 1,070 acres of cultivated lands suitable for foraging by white-tailed kite to grassland.

- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent conversion of 832 acres of cultivated lands to nontidal marsh. This would not result in a loss of foraging habitat as both natural communities are foraging habitat for white-tailed kite. Small patches of riparian vegetation that support

White-tailed kite nesting habitat may develop along the margins of restored nontidal marsh restoration would also provide foraging habitat for the species.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Habitat management- and enhancement-related activities could remove up to 20 acres of white-tailed kite foraging habitat. Activities could also disturb white-tailed kite nests if they were present near work sites. A variety of habitat management actions that are designed to enhance wildlife values in Alternative 4A-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of white-tailed kite habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available white-tailed kite habitat and are expected to result in overall improvements to and maintenance of habitat values. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS. The implementation of *AMM39 White-Tailed Kite* would avoid disturbance and nest abandonment by requiring restrictions on construction activities during the breeding season or establishing nodisturbance buffers.

- Permanent and temporary white-tailed kite nesting habitat losses from the above Environmental Commitments would primarily consist of small, fragmented riparian stands. Temporarily affected nesting habitat would be restored as riparian habitat within 1 year following completion of construction activities as described in *AMM10 Restoration of Temporarily Affected Natural Communities*. The restored riparian habitat would require 1 to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by white-tailed kite. *AMM39 White-Tailed Kite* contains actions described below to reduce the effect of temporal loss of nesting habitat, including the transplanting of mature trees and planting of trees near high-value foraging habitat. The functions of agricultural and grassland communities that provide foraging habitat for white-tailed kite are expected to be restored relatively quickly.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect white-tailed kite use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. Effects of operations and maintenance activities on active white-tailed kite nests would be avoided by the implementation of *AMM39 White-Tailed Kite* which would restriction activities during the breeding season or require a construction buffer to minimize disturbance. If emergency repairs were required during the breeding season that could potentially result in take, CDFW consultation would be initiated (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*).

- Injury and Direct Mortality: Construction-related activities would not be expected to result in take of adult or fledged white-tailed kite if they were present in the study area, because they would be expected to avoid contact with construction and other equipment. However, if white-tailed kite were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could affect nests or lead to their abandonment. White-tailed kite is a fully protected species and take is prohibited under Section 3511 of the Fish and Game Code. If active nests were present in or adjacent to work areas, the implementation of *AMM39 White-Tailed Kite*, would restrict construction activities during the breeding season, or require a construction buffer that would avoid disturbance and nest abandonment, mortality of eggs, nestlings, or fledglings (Appendix 3B, *Environmental Commitments, AMMs, and CMs*).

The following paragraphs summarize the combined effects discussed above and describe Environmental Commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

The study area supports approximately 14,069 acres of modeled nesting habitat and 507,922 acres of modeled foraging habitat for white-tailed kite. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 50 acres of potential nesting habitat (<1% of the potential nesting habitat in the study area) and the loss or conversion of 6,727 acres of foraging habitat (1% of the foraging habitat in the study area). The locations of these losses are described above in the analyses of individual Environmental Commitments.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for nesting habitat, and 1:1 protection for foraging habitat. Using these ratios would indicate that 50 acres of nesting habitat should be restored/created and 50 acres should be protected to mitigate the losses of white-tailed kite nesting habitat. In addition, 6,727 acres of foraging habitat of should be protected to compensate for the losses of white-tailed kite foraging habitat.

A total of 1,060 acres of grassland and 11,870 acres of cultivated lands would be protected through Alternative 4A. Project proponents would commit to conserving 1 acre of Swainson's hawk foraging habitat for every acre of lost foraging habitat which would protect up to a total of 6,805 acres of white-tailed kite foraging habitat (Resource Restoration and Performance Principle SH1). These acres of cultivated lands and grasslands would be located above -1 foot above mean sea level. At least 50% of these lands would be in very high-value production for the Swainson's hawk (alfalfa) (Resource Restoration and Performance Principle SH2). These Swainson's hawk Resource Restoration and Performance Principles would be associated with Environmental Commitment 3 and would occur in the same timeframe as the construction and early restoration losses and would compensate for effects on white-tailed kite foraging habitat.

Alternative 4A includes conservation commitments through *Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration* to restore or create up to 251 acres and protect up to 103 acres of valley/foothill riparian woodland, which would provide nesting habitat for white-tailed kite. Though this riparian restoration would remove foraging habitat for the species (cultivated lands) it would create nesting habitat, which is more of a limiting resource in the Delta. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1). A single, contiguous patch of 100 acres of mature, riparian forest would be maintained in either CZ 4 or CZ 7 (Resource Restoration and Performance Principle VFR2), as part of the acres of restoration and protection under Environmental Commitment 7. In addition, small but essential nesting habitat for white-tailed kite associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Environmental Commitment 3).

The 251 acres of restored riparian habitat would be initiated to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by white-tailed kite. This time lag between the removal and restoration of nesting habitat could have a substantial impact on white-tailed kite. Nesting habitat is limited throughout much of the study area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active white-tailed kite nests within the study area until restored riparian habitat is sufficiently developed.

AMM39 White-Tailed Kite would implement a program to plant large mature trees, including transplanting trees scheduled for removal, to compensate for the temporal loss of Swainson's hawk nest sites, defined as a 125-acre area where more than 50% of suitable nest trees (20 feet or taller) within the 125-acre block are removed. These mature trees would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the Alternative 4A conservation area for every tree 20 feet or taller removed by construction. A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Trees would be planted within the Alternative 4A conservation area in areas that support high-value foraging habitat to increase nest sites, or within riparian plantings as a component of the riparian restoration (Environmental Commitment 7) where they are in close proximity to suitable foraging habitat. Replacement trees that were incorporated into the riparian restoration would not be clustered in a single region of the study area, but would be distributed throughout the lands protected as foraging habitat for white-tailed kite. Further details of AMM39 are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan, and AMM10 Restoration of Temporarily Affected Natural Communities*. The implementation of these AMMs, in addition to *AMM39 White-Tailed Kite*, would avoid the risk of take of individuals in habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of white-tailed kite nesting and foraging habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects from and to restoring and protecting an acreage that meets the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles VFR1-VFR3, SH1, SH2, and CL1, AMM1–AMM7, AMM10, and *AMM39 White-Tailed Kite*, which would restrict construction activities during the breeding season and would avoid disturbance and nest abandonment, mortality of eggs, nestlings, or fledglings and would be in place during all project activities. Considering these commitments, losses and conversions of white-tailed kite habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on white-tailed kite habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for take in the absence of Environmental Commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 7, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principles VFR1-VFR3, SH1, SH2, and CL1, AMM1–AMM6, AMM10, and *AMM39 White-Tailed Kite*, which would restrict construction activities during the breeding season and which would avoid disturbance and nest abandonment, mortality of eggs, nestlings, or fledglings and would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not result in take of white-tailed kite pursuant to California Fish and Game Code Section 86. Therefore, Alternative 4A would have a less-than-significant impact on white-tailed kite under CEQA.

Impact BIO-101: Effects on White-Tailed Kite Associated with Electrical Transmission Facilities

There are several known occurrences of nesting white-tailed kite within 5 miles of the proposed transmission line alignment. While white-tailed kite flight behavior puts them regularly within the range of heights proposed for the new transmission lines (50 to 110 feet), their keen vision and high maneuverability substantially reduce powerline collision risk for the species. Like other diurnal raptors, white-tailed kites have highly developed eyesight (Jones et al. 2007), allowing them to detect small prey while hunting from relatively high altitudes. Keen eyesight also allows for detection and avoidance of other aerial objects, including above-ground utility lines. Like many other falcons, the white-tailed kite has long, narrow, tapered wings and body size that allow for efficient soaring flight and highly developed aerial maneuverability. White-tailed kite are at low risk of take from bird strike from the construction of new transmission lines based on its general maneuverability, its keen eyesight, and lack of flocking behavior (BDCP Attachment 5.J-2*, Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. With the implementation of *AMM20 Greater Sandhill Crane*, all new transmission lines would be fitted with flight diverters, which would substantially reduce the risk of collisions with lines.

***NEPA Effects*:** The construction and presence of new transmission lines would not represent an adverse effect because the risk of bird strike is considered to be minimal based on the species' general maneuverability, keen eyesight, and lack of flocking behavior. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would further reduce the risk of white-tailed kites colliding with project powerlines. Therefore, the construction and operation of new transmission lines would not result in an adverse effect on white-tailed kite.

***CEQA Conclusion*:** The construction and presence of new transmission lines would not result in take of white-tailed kite pursuant to California Fish and Game Code Section 86 because the risk of bird strike is considered to be minimal based on the species' general maneuverability, keen eyesight, and lack of flocking behavior. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would further reduce the risk of white-tailed kites colliding with project powerlines. Therefore, the construction and operation of new transmission lines would result in a less-than-significant impact on white-tailed kite.

Impact BIO-102: Indirect Effects of the Project on White-Tailed Kite

White-tailed kite nesting habitat within the vicinity of proposed construction areas could be indirectly affected by construction activities. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). However, there are no available data to determine the extent to which these noise levels could affect white-tailed kite. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet from the construction edge. If white-tailed kite were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. The implementation of *AMM39 White-Tailed Kite* would avoid the risk of take of individual white-tailed kites in habitats in or adjacent to work areas by restricting construction activities during the breeding season or establishing nodisturbance buffers around active nests. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect white-tailed kite in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to white-tailed kite habitat could also affect the species. AMM1–AMM7, and *AMM39 White-tailed Kite*, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Methylmercury Exposure: Project activities have the potential to exacerbate bioaccumulation of mercury in avian species, including white-tailed kite. Marsh (tidal and nontidal) an restoration also has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Increased methylmercury associated with natural community restoration may indirectly affect white-tailed kite (see BDCP Appendix 5.D, *Contaminants*). However, the potential mobilization or creation of methylmercury within the study area varies with site-specific conditions and would need to be assessed at the project level. Due to the complex and very site-specific factors that would determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This Environmental Commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.

Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and project activities have the potential to exacerbate bioaccumulation of selenium in avian species, including white-tailed kite. Marsh (tidal and nontidal) restoration has the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with Environmental Commitment 4 would lead to adverse effects on white-tailed kite.

Because of the uncertainty that exists with respect to the location of tidal restoration activities, there could be a substantial effect on white-tailed kite from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

***NEPA Effects*:** Noise and visual disturbances from the construction of water conveyance facilities could reduce white-tailed kite use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect use of the surrounding habitat by white-tailed kite. Noise, potential spills of hazardous materials, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 4A would not have an adverse effect on white-tailed kite with the implementation of AMM1–AMM7, and *AMM39 White-Tailed Kite* which would avoid the risk of take of individuals. Tidal habitat restoration could result in increased exposure of white-tailed kite to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The indirect effects associated with noise and visual disturbances, potential spills of hazardous material, and increased exposure to selenium from Alternative 4A implementation would not have an adverse effect on white-tailed kite. Tidal habitat restoration is unlikely to have an adverse effect on white-tailed kite through increased exposure to methylmercury, as kites currently forage in tidal marshes where elevated methylmercury levels exist. However, it is unknown what concentrations of methylmercury are harmful to the species and the potential for increased exposure varies substantially within the study area. Site-specific restoration plans in addition to monitoring and adaptive management, described in *Environmental Commitment 12 Methylmercury Management,* would address the uncertainty of methylmercury levels in restored tidal marsh. The site-specific planning phase of marsh restoration would be the appropriate place to assess the potential for risk of methylmercury exposure for white-tailed kite, once site specific sampling and other information could be developed.

***CEQA Conclusion*:** Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 4A would have a less-than-significant impact on white-tailed kite with the implementation of AMM1–AMM7, and *AMM39 White-Tailed Kite*, which would avoid the risk of take of individuals. Tidal habitat restoration could result in increased exposure of white-tailed kite to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The implementation of tidal natural communities restoration could result in increased exposure of white-tailed kite to methylmercury. However, it is unknown what concentrations of methylmercury are harmful to this species. *Environmental Commitment 12 Methylmercury Management* includes provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in Environmental Commitment 12, would better inform potential impacts and address the uncertainty of methylmercury levels in restored tidal marsh in the study area on white-tailed kite. With these measures in place, the indirect effects associated with noise and visual disturbances, potential spills of hazardous material, and increased exposure to selenium from Alternative 4A implementation would have a less-than-significant impact on white-tailed kite.

Impact BIO-103: Periodic Effects of Inundation of White-Tailed Kite Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on white-tailed kite.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Yellow-Breasted Chat

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on yellow-breasted chat. Yellow-breasted chat modeled habitat includes suitable nesting and migratory habitat as those plant alliances from the valley/foothill riparian modeled habitat that contain a shrub component and an overstory component. Primary nesting and migratory habitat is qualitatively distinguished from secondary habitat in Delta areas as those plant associations that support a greater percentage of a suitable shrub cover, particularly blackberry, and California wild rose, and have an open to moderately dense overstory canopy, using data from Hickson and Keeler-Wolf (2007). No distinction is made between primary and secondary habitat for Suisun Marsh/Yolo Basin habitats because supporting information is lacking.

Alternative 4A would result in both temporary and permanent losses of yellow-breasted chat modeled habitat as indicated in Table 12-4A-41. Full implementation of Alternative 4A would also include the following Environmental Commitments and Resource Restoration and Performance Principles which would benefit the yellow-breasted chat.

- Restore or create up to 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect up to 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species and implementation of AMM1–AMM7, *AMM10 Restoration of Temporarily Affected Natural Communities* and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, impacts on yellow-breasted chat would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-41. Changes in Yellow-Breasted Chat Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Nesting and Migratory Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Primary	15	10
	Secondary	15	9
Total Impacts Water Conveyance Facilities		**30**	**19**
Environmental Commitments 4, 6–7, 9–11[a]	Primary	6	0
	Secondary	4	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**10**	**0**
Total Primary		**21**	**10**
Total Secondary		**19**	**9**
TOTAL IMPACTS		**40**	**19**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-104: Loss or Conversion of Habitat for and Direct Mortality of Yellow-Breasted Chat

Alternative 4A would result in the combined permanent and temporary loss of up to 59 acres of modeled nesting and migratory habitat for yellow-breasted chat (40 acres of permanent loss, 19 acres of temporary loss, Table 12-4A-41). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11) which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate yellow-breasted chat habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 25 acres of primary habitat (15 acres of permanent loss, 10 acres of temporary loss). In addition, 24 acres of secondary habitat would be removed (15 acres of permanent loss, 9 acres of temporary loss, Table 12-4A-41). Activities that would impact modeled habitat consist of tunnel, forebay, and intake construction, permanent and temporary access roads, construction of transmission lines, barge unloading facilities and temporary work areas. Impacts from water conveyance facilities would occur in the central Delta in CZs 3–6, and 8. Most of the permanent loss of habitat would occur where Intakes 2, 3, and 5 impact the Sacramento River's east bank between Freeport and Courtland. The riparian areas here are very small patches, some dominated by valley oak and others by nonnative trees. Some habitat would be lost due to construction of a permanent access road from the new forebay west to an reusable tunnel material disposal area. Permanent habitat loss would also occur along Lambert Road where permanent utility lines would be installed and from the construction of an operable barrier at the confluence of Old River and the San Joaquin River. Temporary loss of habitat would occur from the construction of a barge unloading facility west of the intermediate forebay in Snodgrass Slough and where temporary work areas surround intake sites. The riparian habitat in these areas is also composed of very small patches or stringers bordering waterways, which are composed of valley oak and scrub vegetation.
- Habitat loss from water conveyance facilities activities would have the potential to displace individuals, if present, and remove the functions and value of modeled habitat for nesting, protection, or foraging. There are no occurrences of yellow-breasted chat that overlap with the water conveyance facilities construction footprint. The implementation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would minimize the effects of construction on nesting yellow-breasted chats if they were to occur in the area (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 6 acres of modeled yellowbreasted chat primary habitat and 4 acres of modeled yellow-breasted chat secondary habitat.
- *Environmental Commitment 11 Natural Communities Enhancement and Management:* Habitat protection and management activities that could be implemented in protected yellow-breasted

chat habitats would be expected to maintain and improve the functions of the habitat. Yellow-breasted chat would be expected to benefit from the increase in protected habitat, which would maintain conditions favorable for the chat's use of the study area.

Habitat management- and enhancement-related activities could disturb yellow-breasted chat nests if they are present near work sites. Equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would ensure that these activities do not result in direct mortality of yellow-breasted chat or other adverse effects.

Occupied habitat would be monitored to determine if there is a need to implement controls on brood parasites (brown-headed cowbird) or nest predators. If implemented, these actions would be expected to benefit the yellow-breasted chat by removing a potential stressor that could, if not addressed, adversely affect the stability of newly established populations.

A variety of habitat management actions included in *Environmental Commitment 11 Natural Communities Enhancement and Management* that are designed to enhance wildlife values in restored riparian habitats may result in localized ground disturbances that could temporarily remove small amounts of yellow-breasted chat habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, are expected to have minor adverse effects on available yellow-breasted chat habitat and are expected to result in overall improvements to and maintenance of yellow-breasted chat habitat values.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect yellow-breasted chat use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.

- Injury and Direct Mortality: Construction is not expected to result in direct mortality of yellow-breasted chat because adults and fledged young are expected to occur only in very small numbers and, if present, would avoid contact with construction and other equipment. If yellow-breasted chat were to nest in the vicinity of construction activities, equipment operation could destroy nests and noise and visual disturbances could lead to nest abandonment. *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would avoid and minimize this effect.

- Permanent and temporary habitat losses from the above Environmental Commitments would primarily consist of small, fragmented riparian stands in CZ 2–CZ 8 that do not provide high-value habitat for the species. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities as described in *AMM10 Restoration of Temporarily Affected Natural Communities*. Although the effects are considered temporary, the restored riparian habitat would require 5 years to several decades for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. The majority of the riparian vegetation to be temporarily removed is early- to mid-successional; therefore, the replaced riparian vegetation would be expected to have structural components comparable to the temporarily removed vegetation within the first 5 to 10 years after the initial restoration activities are complete.

The following paragraphs summarize the combined effects discussed above and describe Environmental Commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

The habitat model indicates that the study area supports approximately 14,547 acres of modeled nesting and migratory habitat for yellow-breasted chat. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 59 acres of modeled habitat (less than 1% of the modeled habitat in the study area). These losses would occur from the construction of the water conveyance facilities and from *Environmental Commitment 4 Tidal Natural Communities Restoration*. The locations of these losses would be in fragmented riparian habitat throughout the study area.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration/creation and 1:1 protection of dense shrubby successional valley/foothill riparian habitat. Using these ratios would indicate that 59 acres of valley/foothill riparian habitat should be restored/created and 59 acres should be protected to compensate for the losses of yellow-breasted chat habitat.

Alternative 4A includes conservation commitments through *Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration* to restore or create up to 251 acres and protect up to 103 acres of valley/foothill riparian woodland. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).

The project also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of yellow-breasted chat habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects from and to restoring and protecting an acreage that meets the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principle VFR1, and by AMM1–AMM7, AMM10, and AMM22. These environmental commitments and AMMs would be in place during all project activities. Considering these commitments, losses and conversions of yellow-breasted chat habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The loss of yellow-breasted chat habitat from Alternative 4A would represent an adverse effect in the absence of Environmental Commitments and AMMs as a result of habitat modification and potential for direct mortality of a special-status species. However, habitat protection and restoration associated with Environmental Commitment 3 and Environmental Commitment 7, guided by Resource Restoration and Performance Principle VFR1 and by *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3*

Stormwater Pollution Prevention Plan, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities* and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of yellow-breasted chat. Therefore, Alternative 4A would have a less-than-significant impact on yellow-breasted chat under CEQA.

Impact BIO-105: Fragmentation of Yellow-Breasted Chat Habitat as a Result of Constructing the Water Conveyance Facilities

Grading, filling, contouring, and other initial ground-disturbing activities for water conveyance facilities construction may temporarily fragment modeled yellow-breasted chat habitat. This could temporarily reduce the extent of and functions supported by the affected habitat. Any such habitat fragmentation is expected to have no or minimal effect on the species.

***NEPA Effects*:** Temporary fragmentation of habitat would not result in an adverse effect on yellow-breasted chat. Any such habitat fragmentation is expected to have no or minimal effect on the species.

***CEQA Conclusion*:** Temporary fragmentation of habitat would have a less-than-significant impact on yellow-breasted chat. Any such habitat fragmentation is expected to have no or minimal effect on the species.

Impact BIO-106: Effects on Yellow-Breasted Chat Associated with Electrical Transmission Facilities

Yellow-breasted chats are migratory and usually arrive at California breeding grounds in April from their wintering grounds in Mexico and Guatemala. Departure for wintering grounds occurs from August to September. These are periods of relative high visibility when the risk of powerline collisions will be low. The species' small, relatively maneuverable body; its foraging behavior; and its presence in the project area during the summer contribute to a low risk of collision with the proposed transmission lines (BDCP Attachment 5.J-2*, Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new project transmission lines would be fitted with flight diverters. Bird flight diverters would further reduce any potential for powerline collisions.

***NEPA Effects*:** The construction and presence of new transmission lines would not result in an adverse effect on yellow-breasted chat because the risk of bird strike is considered to be minimal based on the species' small, relatively maneuverable body; its foraging behavior; and its presence in the project area during the summer during periods of high visibility. Under *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with bird diverters, which would further reduce any potential for powerline collisions.

***CEQA Conclusion*:** The construction and presence of new transmission lines would have a less-than-significant impact on yellow-breasted chat because the risk of bird strike is considered to be minimal based on the species' small, relatively maneuverable body; its foraging behavior; and its presence in the project area during the summer during periods of high visibility. Under *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with bird diverters, which would further reduce any potential for powerline collisions.

Impact BIO-107: Indirect Effects of the Project on Yellow-Breasted Chat

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect yellow-breasted chat use of modeled habitat adjacent to proposed construction areas. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). However, there are no available data to determine the extent to which these noise levels could affect yellow-breasted chat. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet from the construction edge. If yellow-breasted chat were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. These potential effects would be minimized with incorporation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* into the Alternative 4A, which would ensure 250 foot no-disturbance buffers were established around active nests. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect yellow-breasted chat in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to yellow-breasted chat habitat could also affect the species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, in addition to *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would minimize the likelihood of such spills from occurring and ensure that measures were in place to prevent runoff from the construction area and any adverse effects of dust on active nests. If present, yellow-breasted chat individuals could be temporarily affected by noise and visual disturbances adjacent to water conveyance construction sites, reducing the use of an estimated 59 acres of modeled primary nesting and migratory habitat and 119 acres of secondary nesting and migratory habitat. *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would avoid and minimize this effect on the species.

Methylmercury Exposure: The modeled primary habitat for yellow-breasted chat includes tidal brackish emergent wetland and tidal freshwater emergent wetland in Suisun Marsh and the Delta west of Sherman Island, and instream islands and White Slough Wildlife Area in the central Delta. Chats typically occur in the high marsh zone near the upper limit of tidal flooding in salt and brackish habitats. Low marsh, managed wetlands, and the upland fringe are considered secondary habitat. Chats are a top predator in the benthic food chain; they nest and forage in dense vegetation and prey on isopods, insects and arthropods from the surface of mud and vegetation They also consume insects and seeds from bulrushes (*Schoenoplectus* spp.) and cattails (*Typha* spp.) (Eddleman et al. 1994).

Largemouth bass was used as a surrogate species for analysis (see Appendix 11F, *Substantive BDCP Revisions*). Results of the quantitative modeling of mercury effects on largemouth bass as a surrogate species would overestimate the effects on yellow-breasted chat. Organisms feeding within pelagic-based (algal) foodwebs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic foodwebs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009). Modeled effects of mercury concentrations from changes in operations of water conveyance facilities on largemouth bass did not differ substantially from existing conditions; therefore, results also indicate that yellow-breasted chat mercury tissue concentrations would not measurably increase as a result of water conveyance facilities implementation.

Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. In general, the highest methylation rates are associated with high tidal marshes that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury. Given that some species have existing elevated mercury tissue levels, these low level increases could result in some level of effects. Environmental Commitment 12 would be implemented to address the that risk low level increases in methylmercury could add to the current elevated concentrations in tissue.

Because of the complex and very site-specific factors that would determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This Environmental Commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability.
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and project activities have the potential to exacerbate bioaccumulation of selenium in avian species, including yellow-breasted chat. Tidal and nontidal marsh restoration has the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, tidal marsh restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations are analyzed in Chapter 8, *Water Quality*, which concludes that, relative to Existing Conditions and the No Action Alternative, construction and operation of proposed water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative.

There could be an effect on yellow-breasted chat from increases in selenium associated with tidal restoration activities (Environmental Commitment 4); however, effects on the yellow-breasted chat population would be expected to be minimal because the amount of tidal restoration would total up to 22 acres. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of project design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design.

NEPA Effects: The potential for noise and visual disturbance, hazardous spills, increased dust and sedimentation, and the potential impacts of operations and maintenance of the water conveyance facilities would not result in an adverse effect on yellow-breasted chat with the incorporation of AMM1–AMM7, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* into Alternative 4A.

Changes in water operations would not be expected to result in increased mercury bioavailability to yellow-breasted chat. Restoration actions that would create high and low tidal marsh, which is yellow-breasted chat habitat, could provide biogeochemical conditions for methylation of mercury in the newly inundated soils. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the amount of tidal restoration would total up to 22 acres, and potential exposure to methylmercury resulting from these acres of restoration is not expected to adversely affect the yellow-breasted chat population. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for any effects of increased methylmercury exposure.

Tidal habitat restoration could result in increased exposure of yellow-breasted chat to selenium; however, the amount of tidal restoration would total up to 22 acres, and potential exposure to selenium resulting from these acres of restoration would not be expected to adversely affect the yellow-breasted chat population. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

***CEQA Conclusion*:** The potential for noise and visual disturbance, hazardous spills, increased dust and sedimentation, and the potential impacts of operations and maintenance of the water conveyance facilities would have a less-than-significant impact on yellow-breasted chat with the incorporation of AMM1–AMM7, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* into Alternative 4A.

Changes in water operations would not be expected to result in increased mercury bioavailability to yellow-breasted chat. Restoration actions that would create high and low tidal marsh, which is yellow-breasted chat habitat, could provide biogeochemical conditions for methylation of mercury in the newly inundated soils. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the amount of tidal restoration would total up to 22 acres, and potential exposure to methylmercury resulting from these acres of restoration is not expected to adversely affect the yellow-breasted chat population. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for any effects of increased methylmercury exposure.

Tidal habitat restoration could result in increased exposure of yellow-breasted chat to selenium; however, the amount of tidal restoration would total up to 22 acres, and potential exposure to selenium resulting from these acres of restoration would not be expected to adversely affect the yellow-breasted chat population. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Impact BIO-108: Periodic Effects of Inundation of Yellow-Breasted Chat Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on yellow-breasted chat.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Cooper's Hawk and Osprey

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on Cooper's hawk and osprey. Although osprey often nest on manmade structures such as telephone poles, and Cooper's hawk will nest in more developed landscapes, modeled nesting habitat for these species is restricted to valley/foothill riparian forest.

Alternative 4A would result in both temporary and permanent losses of Cooper's hawk and osprey modeled habitat as indicated in Table 12-4A-42. Although restoration for the loss of nesting habitat would be initiated in the same timeframe as the losses, it could take one or more decades for restored habitats to replace the functions of habitat lost. This time lag between impacts and restoration of habitat function would be minimized by specific requirements of *AMM18 Swainson's Hawk*, including the planting of mature trees. Full implementation of Alternative 4A would include the following Environmental Commitments and Resource Restoration and Performance Principles which would also benefit Cooper's hawk and osprey.

- Restore or create up to 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect up to 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).
- Maintain a single contiguous patch of 100 acres of mature riparian forest in either CZ 4 or CZ 7 (Resource Restoration and Performance Principle VFR2).

As explained below, with the acres of restoration or protection included in the project, in addition to management activities to enhance natural communities for species and implementation of AMM1–AMM7, *AMM10 Restoration of Temporarily Affected Natural Communities, AMM18 Swainson's Hawk*, and Mitigation Measure BIO-75, impacts on Cooper's hawk and osprey would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-42. Changes in Cooper's Hawk and Osprey Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting	25	16
Total Impacts Water Conveyance Facilities		**25**	**16**
Environmental Commitments 4, 6–7, 9–11[a]	Nesting	9	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**9**	**0**
TOTAL IMPACTS		**34**	**16**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-109: Loss or Conversion of Habitat for and Direct Mortality of Cooper's Hawk and Osprey

Alternative 4A would result in the combined permanent and temporary loss of up to 50 acres (34 acres of permanent loss, 16 acres of temporary loss) of modeled nesting habitat for Cooper's hawk and osprey (Table 12-4A-42). Project measures that would result in these losses are water facilities and operation (which would involve construction of water conveyance facilities and transmission lines and establishment and use of reusable tunnel material areas), and tidal restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11), which would include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other Alternative 4A physical facilities could affect Cooper's hawk and osprey modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A water conveyance facilities would result in the combined permanent and temporary loss of up to 41 acres of modeled Cooper's hawk and osprey habitat (Table 12-4A-42). Of the 41 acres of modeled habitat that would be removed for the construction of the conveyance facilities, 25 acres would be a permanent loss and 16 acres would be a temporary loss of habitat. Activities that would impact modeled habitat consist of tunnel, forebay, and intake construction, permanent and temporary access roads, construction of transmission lines, barge unloading facilities and work areas. Most of the permanent loss of nesting habitat would occur where Intakes 1–3 impact the Sacramento River's east bank between Freeport and Courtland. The riparian areas here are very small patches, some dominated by valley oak and others by nonnative trees. Some nesting habitat would be lost due to construction of a permanent access road from the new forebay west to an reusable tunnel material disposal area. Permanent losses would also occur along Lambert Road where permanent utility lines would be installed and from the construction of an operable barrier at the confluence of Old River and the San Joaquin River. Temporary losses of nesting habitat would result from the construction of a barge unloading facility west of the intermediate forebay in Snodgrass Slough and where temporary work areas surround intake sites. The riparian habitat in these areas is also composed of very small patches or stringers bordering waterways, which are composed of valley oak and scrub vegetation. Impacts from water conveyance facilities would occur in the central Delta in CZ 3, CZ 4, CZ 5, CZ 6, and CZ 8. These losses would have the potential to displace individuals, if present, and remove the functions and value of potentially suitable habitat. There are no occurrences of Cooper's hawk or osprey that overlap with the construction footprint for water conveyance facilities; however, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize impacts on Cooper's hawk and osprey if they were to nest in the vicinity of construction activities. Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Tidal habitat restoration would permanently remove up to 9 acres of potential Cooper's hawk and osprey nesting habitat. Trees would not be actively removed but tree mortality would be expected over time as areas became tidally inundated.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Habitat management- and enhancement-related activities could disturb Cooper's hawk and osprey nests if they were present near work sites. A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in Alternative 4A-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of Cooper's hawk and osprey habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available Cooper's hawk and osprey habitat and are expected to result in overall improvements to and maintenance of habitat values. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

- Permanent and temporary habitat losses from the above Environmental Commitments would primarily consist of fragmented riparian stands. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities as described in *AMM10 Restoration of Temporarily Affected Natural Communities*. Although the effects are considered temporary, the restored riparian habitat would require 1 to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by Cooper's hawk or osprey. *AMM18 Swainson's Hawk* contains actions described below to reduce the effect of temporal loss of nesting habitat, including the transplanting of mature trees.
- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect Cooper's hawk or osprey use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged Cooper's hawk or osprey if they were present in the project area, because they would be expected to avoid contact with construction and other equipment. If Cooper's hawk or osprey were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could affect nests or lead to their abandonment, potentially resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these adverse effects on Cooper's hawk and osprey.

The following paragraphs summarize the combined effects discussed above and describe Environmental Commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

The study area supports approximately 14,069 acres of modeled nesting habitat for Cooper's hawk and osprey. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 50 acres of potential nesting habitat (less than 1% of the potential nesting habitat in the study area).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for nesting habitat. Using these ratios would indicate that 50 acres of nesting habitat should be restored/created and 50 acres should be protected to mitigate the losses of Cooper's hawk and osprey nesting habitat.

The 251 acres of restored riparian habitat would be initiated to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by Cooper's hawk or osprey. This time lag between the removal and restoration of nesting habitat could have a substantial impact on Cooper's hawk or osprey. Nesting habitat is limited throughout much of the study area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active Cooper's hawk or osprey nests within the study area until restored riparian habitat is sufficiently developed.

AMM18 Swainson's Hawk would implement a program to plant large mature trees, including transplanting trees scheduled for removal to compensate for the temporal loss of Swainson's hawk nest sites, defined as a 125-acre area where more than 50% of suitable nest trees (20 feet or taller) within the 125-acre block are removed. These mature trees would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the Alternative 4A conservation area for every tree 20 feet or taller removed by construction. A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Trees would be planted within the Alternative 4A conservation area in areas that support high-value Swainson's hawk foraging habitat to increase nest sites, or within riparian plantings as a component of the riparian restoration (Environmental Commitment 7). Further details of AMM18 are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan, and AMM10 Restoration of Temporarily Affected Natural Communities.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of Cooper's hawk and osprey nesting habitat from Alternative 4A would not be adverse under NEPA because project proponents committed to avoiding and minimizing effects from and to restoring and protecting an acreage that meets the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principle VFR1, and by AMM1–AMM7, AMM10, and *AMM18 Swainson's Hawk*, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, losses and conversions of Cooper's hawk and osprey habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on Cooper's hawk and osprey habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of Environmental Commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management and enhancement associated with Environmental Commitment 3, Environmental Commitment 7, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principle VFR1, and by AMM1–AMM6, AMM10, and *AMM18 Swainson's Hawk*, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of Cooper's hawk and osprey. Therefore, with the implementation of Mitigation Measure BIO-75, Alternative 4A would have a less-than-significant impact on Cooper's hawk and osprey under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-110: Effects on Cooper's Hawk and Osprey Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of Cooper's hawk and osprey. However, the flight behavior of these species, their keen vision, and high maneuverability substantially reduce the risk of powerline collisions. The existing network of transmission lines in the project area currently poses the same small risk for Cooper's hawk and osprey, and any incremental risk associated with the new power line corridors would also be expected to be low. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. With the implementation of *AMM20 Greater Sandhill Crane*, all new transmission lines would be fitted with flight diverters, which would further reduce any risk of collision with lines.

NEPA Effects: The construction and presence of new transmission lines would not represent an adverse effect because the risk of bird strike is considered to be minimal based on the flight behavior, the general maneuverability, and keen eyesight of Cooper's hawk and osprey. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would further reduce any risk of mortality from bird strike for Cooper's hawk and osprey from the project. Therefore, the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on Cooper's hawk and osprey.

CEQA Conclusion: The construction and presence of new transmission lines would not represent an adverse effect because the risk of bird strike is considered to be minimal based on the flight behavior, the general maneuverability, and keen eyesight of Cooper's hawk and osprey. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would further reduce any risk of mortality from bird strike for Cooper's hawk and osprey from the project. Therefore, the construction and operation of new transmission lines under Alternative 4A would result in a less-than-significant impact on Cooper's hawk and osprey.

Impact BIO-111: Indirect Effects of the Project on Cooper's Hawk and Osprey

Indirect Construction- and Operation-Related Effects: Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). However, there are no available data to determine the extent to which these noise levels could affect Cooper's hawk or osprey. If Cooper's hawk or osprey were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would avoid the potential for adverse effects of construction-related activities on survival and productivity of nesting Cooper's hawk and osprey. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect Cooper's hawk and osprey in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Methylmercury Exposure: Project activities have the potential to exacerbate bioaccumulation of mercury in avian species, including Cooper's hawk and osprey. Future operational impacts under water conveyance facilities were analyzed using a DSM-2 based model to assess potential effects on mercury concentration and bioavailability resulting from proposed flows. Subsequently, a regression model was used to estimate fish-tissue concentrations under these future operational conditions (evaluated starting operations or ESO). Results indicated that changes in total mercury levels in water and fish tissues due to ESO were insignificant (see BDCP Appendix 5.D, *Contaminants*, Tables 5D.4-3, 5D.4-4, and 5D.4-5).

Marsh (tidal and nontidal) restoration has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community restoration could indirectly affect cooper's hawk and osprey, via uptake in lower trophic levels (as described in BDCP Appendix 5.D, *Contaminants*).

The potential mobilization or creation of methylmercury within the project area varies with site-specific conditions and would need to be assessed at the project level. Due to the complex and very site-specific factors that will determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management,* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This Environmental Commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.

Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by

interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and project activities have the potential to exacerbate bioaccumulation of selenium in avian species, including Cooper's hawk and osprey. Tidal and nontidal marsh restoration has the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, tidal marsh restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations are analyzed in Chapter 8, *Water Quality*, which concludes that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative.

There could be an effect on Cooper's hawk and osprey from increases in selenium associated with tidal restoration activities (Environmental Commitment 4); however, effects on the species populations would be expected to be minimal because the amount of tidal restoration would total up to 22 acres. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of project design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design.

NEPA Effects: Noise and visual disturbances from the construction of water conveyance facilities could reduce Cooper's hawk and osprey use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could adversely affect Cooper's hawk and osprey use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, in addition to AMM1–AMM7, would be available to address this adverse effect.

Tidal habitat restoration could result in increased exposure of Cooper's hawk and osprey to selenium; however, the amount of tidal restoration would total up to 22 acres, and potential exposure to selenium resulting from these acres of restoration would not be expected to adversely affect species populations. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

The implementation of tidal natural communities restoration could result in increased exposure of Cooper's hawk or osprey to methylmercury, through the ingestion of fish or small mammals in tidally restored areas. However, it is currently unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on Cooper's hawk and osprey.

***CEQA Conclusion*:** Noise and visual disturbances from the construction of water conveyance facilities could reduce Cooper's hawk and osprey use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect Cooper's hawk and osprey use of the surrounding habitat. Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 4A would have a less-than-significant impact on Cooper's hawk and osprey with the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and AMM1–AMM7. The implementation of tidal natural communities restoration could result in increased exposure of Cooper's hawk or osprey to methylmercury, through the ingestion of fish or small mammals in tidally restored areas. This would be a significant impact. However, it is currently unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on Cooper's hawk and osprey.

Tidal habitat restoration also could result in increased exposure of Cooper's hawk and osprey to selenium; however, the amount of tidal restoration would total up to 22 acres, and potential exposure to selenium resulting from these acres of restoration would not be expected to adversely affect species populations. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

With AMM1–AMM7 and Environmental Commitment 12 in place, and with the implementation of Mitigation Measure BIO-75, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of Cooper's hawk or osprey. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on Cooper's hawk or osprey.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-112: Periodic Effects of Inundation of Cooper's Hawk and Osprey Nesting Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on Cooper's hawk and osprey.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Golden Eagle and Ferruginous Hawk

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on golden eagle and ferruginous hawk. Modeled foraging habitat for these species consists of grassland, alkali seasonal wetland, vernal pool complex, alfalfa, grain and hay, pasture, and idle cropland throughout the study area.

Alternative 4A would result in both temporary and permanent losses of golden eagle and ferruginous hawk modeled foraging habitat as indicated in Table 12-4A-43. Full implementation of Alternative 4A would include the following Environmental Commitments that would benefit golden eagles or ferruginous hawk.

- Protect up to 1,060 acres and restore up to 1,070 acres of grassland (Environmental Commitments 3 and Environmental Commitment 8).
- Protect up to 11,870 acres of cultivated lands (Environmental Commitment 3).
- Restore up to 48 acres and protect up to 188 acres of vernal pool/alkali seasonal wetland complex (Environmental Commitment 3 and Environmental Commitment 9).

Golden eagle is a fully protected species and California Fish and Game Code Section 86 prohibits take of individuals. With the implementation of *AMM20 Greater Sandhill Crane*, construction activities would not result in mortality of the species, which would avoid take pursuant to Section 86 of the California Fish and Game Code. As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities to enhance natural communities for species and implementation of AMM1–AMM7, impacts on golden eagle and ferruginous hawk would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-43. Changes in Golden Eagle and Ferruginous Hawk Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Foraging	1,978	537
Total Impacts Water Conveyance Facilities		**1,978**	**537**
Environmental Commitments 4, 6–7, 9–11[a]	Foraging	2,427	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,427**	**0**
TOTAL IMPACTS		**4,405**	**537**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-113: Loss or Conversion of Habitat for and Direct Mortality of Golden Eagle and Ferruginous Hawk

Alternative 4A would result in the combined permanent and temporary loss of up 4,942 acres of modeled foraging habitat for golden eagle and ferruginous hawk (4,405 acres of permanent loss and 537 of temporary loss, Table 12-4A-43). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, tidal habitat restoration (Environmental Commitment 4), riparian restoration, (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), vernal pool and alkalai seasonal wetland restoration (Environmental Commitment 9) and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11) could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate foraging habitat for both species. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 2,515 acres of modeled golden eagle and ferruginous hawk habitat (1,978 acres of permanent loss, 537 acres of temporary loss). Impacts would occur from the construction of Intakes 2, 3, and 5 and associated temporary work areas and access roads in CZ 4 between Clarksburg and Courtland; construction of the intermediate forebay; and from an reusable tunnel material storage area on Bouldin Island. The construction of the permanent and temporary transmission line corridors through CZs 4–6 and 9 would also remove suitable foraging habitat for the species. Approximately 1,115 acres would be affected by placement of an reusable tunnel material area west of the Clifton Court Forebay in CZ 8. In addition, permanent habitat loss would result from the construction of the new forebay south of the existing Clifton court Forebay in CZ 8. Some of the grassland habitat lost at the sites of new canals south of Clifton Court Forebay is composed of larger stands of ruderal and herbaceous vegetation and California annual grassland, which is also suitable foraging habitat for the species. There are no occurrences of golden eagle or ferruginous hawk that intersect with the water conveyance facilities footprint. Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 254 acres of modeled golden eagle and ferruginous hawk habitat. The majority of the acres lost would consist of cultivated lands in the West Delta ROA.

- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 251 acres of golden eagle and ferruginous hawk foraging habitat.

- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would convert approximately 1,070 acres of cultivated lands into grasslands. These acres may be temporarily unavailable for foraging raptors but would not permanently reduce foraging habitat for either species.

- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:* The intent of the Environmental Commitment is to match the acreage of restoration with the actual acreage lost to other project measures (primarily water conveyance facilities). The current estimate for vernal pool/alkali seasonal wetland complex restoration is 48 acres. The goal is for no net loss of this natural community, consistent with the project's Resource Restoration and Performance Principles. These acres may be temporarily unavailable for foraging raptors but the project would not permanently reduce foraging habitat for either species.

- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 832 acres of golden eagle and ferruginous hawk foraging habitat.
- *Environmental Commitment 11 Natural Communities Enhancement and Management:* A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could permanently remove 20 acres and temporarily remove small amounts of golden eagle and ferruginous hawk foraging habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities would be expected to have minor adverse effects on available habitat for these species.
- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect golden eagle and ferruginous hawk use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.
- Injury and Direct Mortality: Construction would not be expected to result in direct mortality of golden eagle and ferruginous hawk because foraging individuals would be expected to temporarily avoid the increased noise and activity associated with construction areas.

The following paragraphs summarize the combined effects discussed above and describe Environmental Commitments and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Alternative 4A would remove 4,942 acres of modeled golden eagle and ferruginous hawk foraging habitat. These effects would result from the construction of the water conveyance facilities and implementing *Environmental Commitment 4 Tidal Natural Communities Restoration, Environmental Commitment 7 Riparian Natural Communities Restoration, Environmental Commitment 8 Grassland Natural Communities Restoration*, and *Environmental Commitment 10 Nontidal Marsh Restoration*.

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 9,884 acres should be protected to compensate for the losses of golden eagle and ferruginous hawk habitat. Project proponents would commit to protect up to 1,060 acres of grassland, 188 acres of vernal pool/alkali seasonal wetland complex, and 11,870 acres of cultivated lands, and to restore up to 1,070 acres of grassland and 48 acres of vernal pool/alkali seasonal wetland complex which would provide suitable habitat for golden eagle and ferruginous hawk.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and

species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of golden eagle and ferruginous hawk foraging habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by and by AMM1–AMM7, which would be in place during all project activities. Considering these commitments, losses and conversions of mountain plover habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on golden eagle and ferruginous hawk foraging habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species in the absence of Environmental Commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3 and Environmental Commitment 11. These conservation activities would be guided by and by AMM1–AMM7, which would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications. Therefore, Alternative 4A would have a less-than-significant impact on golden eagle and ferruginous hawk under CEQA.

Impact BIO-114: Effects on Golden Eagle and Ferruginous Hawk Associated with Electrical Transmission Facilities

Golden eagle and ferruginous hawk would be at low risk of bird strike mortality from the construction of new transmission lines based on their maneuverability, their keen eyesight, their lack of flocking behavior, and other factors assessed in the bird strike vulnerability analysis (BDCP Attachment 5.J-2, *Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. With the implementation of *AMM20 Greater Sandhill Crane*, all new transmission lines would be fitted with flight diverters, which would substantially reduce the potential for powerline collisions.

NEPA Effects: Golden eagle and ferruginous hawk are already at a low risk of bird strike mortality based on their general maneuverability, keen eyesight and lack of flocking behavior. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. By implementing *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines would not result in an adverse effect on golden eagle or ferruginous hawk.

CEQA Conclusion: Golden eagle and ferruginous hawk are already at a low risk of bird strike mortality based on their general maneuverability, keen eyesight and lack of flocking behavior. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to fit new transmission lines constructed as a result of the project with bird diverters, which have been shown to reduce avian mortality by 60%. By implementing *AMM20 Greater Sandhill Crane*, there would be no take of golden eagle from the project pursuant to California Fish and Game Code Section 86, and the construction and operation of transmission lines would have a less-than-significant impact on golden eagle and ferruginous hawk.

Impact BIO-115: Indirect Effects of the Project on Golden Eagle and Ferruginous Hawk

Construction- and subsequent maintenance-related noise and visual disturbances could disrupt foraging, and reduce the functions of suitable foraging habitat for golden eagle and ferruginous hawk. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). However, there are no available data to determine the extent to which these noise levels could affect golden eagle or ferruginous hawk. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to golden eagle and ferruginous hawk grassland habitat could also have a negative effect on the species. However, AMM1–AMM7 would also ensure that measures would be in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

***NEPA Effects*:** Indirect effects on golden eagle and ferruginous hawk as a result of Alternative 4A implementation could have adverse effects on these species through the modification of habitat. With the incorporation of AMM1–AMM7 into Alternative 4A, indirect effects as a result of Alternative 4A implementation would not have an adverse effect on golden eagle and ferruginous hawk.

***CEQA Conclusion*:** Indirect effects on golden eagle and ferruginous hawk as a result of Alternative 4A implementation could have a significant impact on the species from modification of habitat. With the incorporation of AMM1–AMM7 into Alternative 4A, indirect effects as a result of Alternative 4A implementation would have a less-than-significant impact on golden eagle and ferruginous hawk.

Impact BIO-116: Periodic Effects of Inundation on Golden Eagle and Ferruginous Hawk Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on golden eagle and ferruginous hawk.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Cormorants, Herons and Egrets

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron. Modeled breeding habitat for these species consists of valley/foothill riparian forest.

Alternative 4A would result in both temporary and permanent losses of cormorant, heron, and egret modeled habitat as indicated in Table 12-4A-44. The majority of the losses would take place over an extended period of time as tidal marsh is restored in the study area. Although restoration for the loss of nesting habitat would be initiated in the same timeframe as the losses, it could take one or more decades for restored habitats to replace the functions of habitat lost. This time lag between impacts and restoration of habitat function would be minimized by specific requirements of *AMM18 Swainson's Hawk*, including the planting of mature trees. Full implementation of Alternative 4A would include the following Environmental Commitments and Resource Restoration and Performance Principles which would benefit cormorants, herons, and egrets.

- Restore or create up to 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect up to 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Protect up to 119 acres of nontidal wetlands and create up to 832 acres of nontidal wetlands (Environmental Commitment 3 and Environmental Commitment 10).
- Restore or create up to 295 acres of tidal wetlands in the Delta (Environmental Commitment 4)
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities to enhance natural communities for species and implementation of AMM1–AMM7, *AMM10 Restoration of Temporarily Affected Natural Communities, AMM18 Swainson's Hawk*, Mitigation Measure BIO-75, and Mitigation Measure BIO-117, impacts on cormorants, herons, and egrets would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-44. Changes in Cormorant, Heron and Egret Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting (Rookeries)	37	24
Total Impacts Water Conveyance Facilities		**37**	**24**
Environmental Commitments 4, 6–7, 9–11[a]	Nesting (Rookeries)	11	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**11**	**0**
TOTAL IMPACTS		**48**	**24**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-117: Loss or Conversion of Nesting Habitat for and Direct Mortality of Cormorants, Herons and Egrets

Alternative 4A would result in the combined permanent and temporary loss of up to 72 acres of modeled nesting habitat (48 acres of permanent loss, 24 acres of temporary loss) for double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron (Table 12-4A-44). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal natural communities restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11) which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate cormorant, heron, and egret modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A water conveyance facilities would result in the combined permanent and temporary loss of up to 61 acres of modeled nesting habitat for cormorants, herons, and egrets. (Table 12-4A-44). Of the 61 acres of modeled habitat that would be removed for the construction of the conveyance facilities, 37 acres would be a permanent loss and 24 acres would be a temporary loss of habitat. Activities that would impact modeled nesting habitat consist of tunnel, forebay, and intake construction, permanent and temporary access roads, construction of transmission lines, barge unloading facilities, and temporary work areas. Most of the permanent loss of nesting habitat would occur where Intakes 2, 3, and 5 impact the Sacramento River's east bank between Freeport and Courtland. The riparian areas here are very small patches, some dominated by valley oak and others by nonnative trees. Some nesting habitat would be lost as a result of construction of a permanent access road from the new forebay west to an reusable tunnel material disposal area. Permanent losses would also occur along Lambert Road where permanent utility lines would be installed and from the construction of an operable barrier at the confluence of Old River and the San Joaquin River. Temporary losses of nesting habitat would result from the construction of a barge unloading facility west of the intermediate forebay in Snodgrass Slough and where temporary work areas surround intake sites. The riparian habitat in these areas is also composed of very small patches or stringers bordering waterways, which are composed of valley oak and scrub vegetation. Impacts from water conveyance facilities would occur in the central Delta in CZs 3–6, and CZ 8. Habitat loss from water conveyance facilities activities would have the potential to displace individuals, if present, and remove the functions and value of potentially suitable habitat. There are no CNDDB or DHCCP occurrences of nesting cormorants, herons, or egrets that overlap with the construction footprint of water conveyance facilities; however, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds* and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries*, would be available to minimize impacts on cormorants, herons and egrets if they were to nest in the vicinity of construction activities. Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 11 acres of nesting habitat for cormorants, herons and egrets. Trees would not be actively removed but tree mortality would be expected over time as areas became tidally inundated. Depending on the extent and value of remaining habitat, this could reduce use of these habitats by these species.

- *Environmental Commitment 11 Natural Communities Enhancement and Management:* Habitat management- and enhancement-related activities could disturb cormorant, heron, and egret nests if they were present near work sites. A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in Alternative 4A-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of cormorant, heron, and egret habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available habitat for these species and are expected to result in overall improvements to and maintenance of habitat values. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

- Permanent and temporary habitat losses from the above Environmental Commitments would primarily consist of fragmented riparian stands. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities as described in *AMM10 Restoration of Temporarily Affected Natural Communities*. Although the effects are considered temporary, the restored riparian habitat would require years to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure for established rookeries. *AMM18 Swainson's Hawk* contains actions described below to reduce the effect of temporal loss of mature riparian habitat, including the transplanting of mature trees.

- *Construction Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect use of the surrounding habitat by cormorants, herons or egrets. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.

- The primary impact of concern regarding double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron is the loss of existing known nest trees, and other large trees associated with known nest sites. Because these species are highly traditional in their use of rookeries, the establishment of new nest sites is unpredictable. To avoid adverse effects on these species, existing known nest sites would have to be avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries,* would be available to address these adverse effects on cormorants, herons, and egrets.

- Injury and Direct Mortality: If birds were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could affect nests including any nests that are built on the ground (e.g. Cormorant nests that have been built on the ground after nest trees fall over or die from stress and guano produced by a rookery) or lead to their abandonment, potentially resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 and Mitigation Measure BIO-117 would be available to address these effects on cormorants, herons, and egrets.

The following paragraphs summarize the combined effects discussed above and describe Environmental Commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Based on modeled habitat, the study area supports approximately 17,966 acres of modeled nesting habitat for cormorants, herons, and egrets. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 72 acres of potential breeding habitat (<1% of the potential breeding habitat in the study area).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for nesting habitat. Using these ratios would indicate that 72 acres of nesting habitat should be restored/created and 72 acres should be protected to mitigate the losses of cormorant, heron, and egret nesting habitat.

The 251 acres of restored riparian habitat would be initiated in the first 10 years to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by cormorants, herons, and egrets. This time lag between the removal and restoration of nesting habitat could have a substantial impact on cormorants, herons, and egrets. Nesting habitat is limited throughout much of the study area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active cormorant, heron, and egret nests within the study area until restored riparian habitat is sufficiently developed.

AMM18 Swainson's Hawk would implement a program to plant large mature trees, including transplanting trees scheduled for removal, to compensate for the temporal loss of Swainson's hawk nest sites, defined as a 125-acre area where more than 50% of suitable nest trees (20 feet or taller) within the 125-acre block are removed. These mature trees would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the Alternative 4A conservation area for every tree 20 feet or taller removed by construction. A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Trees would be planted within the Alternative 4A conservation area to increase Swainson's hawk nest sites, or within riparian plantings as a component of the riparian restoration (Environmental Commitment 7). Further details of AMM18 are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan, and AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of cormorant, heron, and egret nesting habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that meets the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principle VFR1, and by AMM1–AMM7, AMM10, and *AMM18 Swainson's Hawk*, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 and Mitigation Measure BIO-117 would be available to address potential impacts on nesting individuals. Considering these commitments, losses and conversions of cormorant, heron, and egret habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on cormorant, heron, and egret habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of Environmental Commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 7, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principle VFR1, and by AMM1–AMM6, AMM10, and *AMM18 Swainson's Hawk*, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 and Mitigation Measure BIO-117 would be available to address potential impacts on nesting individuals. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of cormorants, herons, or egrets. Therefore, with the implementation of Mitigation Measure BIO-75 and Mitigation Measure BIO-117, Alternative 4A would have a less-than-significant impact on cormorants, herons, and egrets under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Mitigation Measure BIO-117: Avoid Impacts on Rookeries

Herons, egrets, and cormorants are highly traditional in their use of nest sites (rookeries); therefore, DWR will avoid direct impacts on rookeries and avoid or minimize indirect impacts on rookeries.

Impact BIO-118: Effects Associated with Electrical Transmission Facilities on Cormorants, Herons and Egrets

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of cormorants, herons and egrets. New transmission lines would increase the risk for bird-power line strikes. Waterbirds have a higher susceptibility to collisions than passerines, raptors, and other birds. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. With the implementation of *AMM20 Greater Sandhill Crane*, all new transmission lines constructed as a result of the project would be fitted with flight diverters, which would reduce bird strike risk of cormorants, herons, and egrets.

NEPA Effects: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of cormorants, herons, and egrets. The implementation of *AMM20 Greater Sandhill Crane* would require the installation of bird flight diverters on all new transmission lines, which could reduce bird strike risk of cormorants, herons, and egrets by 60%. With the installation of bird flight diverters, the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on cormorants, herons, and egrets.

CEQA Conclusion: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of cormorants, herons, and egrets. The implementation of *AMM20 Greater Sandhill Crane* would require the installation of bird flight diverters on all new transmission lines, which could reduce bird strike risk of cormorants, herons, and egrets by 60%. With the installation of bird flight diverters, the construction and operation of new transmission lines under Alternative 4A would a less-than-significant impact on cormorants, herons, and egrets.

Impact BIO-119: Indirect Effects of the Project on Cormorants, Herons and Egrets

Indirect Construction- and Operation-Related Effects: Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). However, there are no available data to determine the extent to which these noise levels could affect cormorants, herons, or egrets. If cormorants, herons or egrets were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries*, would avoid the potential for adverse effects of construction-related activities on survival and productivity of nesting cormorants, herons or egrets. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect cormorants, herons or egrets in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Methylmercury Exposure: Project activities have the potential to exacerbate bioaccumulation of mercury in avian species, including cormorants, herons or egrets. Future operational impacts under water conveyance facilities were analyzed using a DSM-2 based model to assess potential effects on mercury concentration and bioavailability resulting from proposed flows. Subsequently, a regression model was used to estimate fish-tissue concentrations under these future operational conditions (evaluated starting operations or ESO). Results indicated that changes in total mercury levels in water and fish tissues due to ESO were insignificant (see BDCP Appendix 5.D, *Contaminants*, Tables 5D.4-3, 5D.4-4, and 5D.4-5).

Marsh (tidal and nontidal) restoration has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, restoration activities that create newly inundated areas could increase bioavailability of mercury. Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community restoration could indirectly affect cormorants, herons or egrets, via uptake in lower trophic levels (as described in BDCP Appendix 5.D, *Contaminants*).

Due to the complex and very site-specific factors that determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management,* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This Environmental Commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and project activities have the potential to exacerbate bioaccumulation of selenium in avian species, including cormorants, herons, and egrets. Marsh (tidal and nontidal) restoration has the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with Environmental Commitment 4 would lead to adverse effects on cormorants, herons, and egrets.

Because of the uncertainty that exists with respect to the location of tidal restoration activities, there could be a substantial effect on cormorants, herons, and egrets from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Noise and visual disturbances from the construction of water conveyance facilities could reduce cormorant, heron, and egret use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect cormorant, heron, and egret use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries*, would be available to address adverse effects on nesting individuals in addition to AMM1–AMM7. Tidal habitat restoration could result in increased exposure of cormorants, herons, and egrets to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The implementation of tidal natural communities restoration could result in increased exposure of cormorants, herons or egrets to methylmercury through the ingestion of fish in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

CEQA Conclusion: Impacts of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would be less than significant with the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries*, and AMM1–AMM7. The implementation of tidal natural communities restoration could result in increased exposure of cormorants, herons or egrets to methylmercury, through the ingestion of fish in tidally restored areas. This would be a significant impact. However, it is unknown what concentrations of methylmercury are harmful to these species. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on cormorants, herons, and egrets. Tidal habitat restoration could result in increased exposure of cormorants, herons, and egrets to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

With AMM1–AMM7, AMM27, and Environmental Commitment 12 in place, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of cormorants, herons, and egrets. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on cormorants, herons, and egrets.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Mitigation Measure BIO-117: Avoid Impacts on Rookeries

Herons, egrets, and cormorants are highly traditional in their use of nest sites (rookeries), therefore all direct and indirect impacts on rookeries must be avoided.

Impact BIO-120: Periodic Effects of Inundation on Cormorants, Herons and Egrets as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on cormorants, herons, and egrets.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Short-Eared Owl and Northern Harrier

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on short-eared owl and northern harrier. Modeled habitat for short-eared owl and northern harrier include tidal brackish and freshwater emergent wetland, nontidal freshwater perennial emergent wetland, managed wetland, other natural seasonal wetland, grassland, alkali seasonal wetland, vernal pool complex, and selected cultivated lands (grain and hay crops, pasture [including alfalfa], rice, truck, nursery, and berry crops [including tomatoes and melons], beets, and idle lands).

Alternative 4A would result in both temporary and permanent losses of modeled habitat for short-eared owl and northern harrier as indicated in Table 12-4A-45. Full implementation of Alternative 4A would include the following Environmental Commitments and Resource Restoration and Performance Principles which would benefit short-eared owl and northern harrier.

- Restore or create up to 295 acres of tidal wetlands in the north Delta (Environmental Commitment 4).
- Restore or create up to 13.5 acres of *Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acres at a location subject to CDFW approval (Resource Restoration and Performance Principle CBR1).
- Protect up to 119 acres of nontidal wetlands and create up to 832 acres of nontidal wetlands (Environmental Commitment 3 and Environmental Commitment 10).
- Restore up to 1,070 acres of grasslands (Environmental Commitment 8).
- Restore up to 48 acres and protect up to 188 acres of vernal pool/alkali seasonal wetland complex (Environmental Commitment 3 and Environmental Commitment 9).
- Protect up to 1,060 acres of grassland and 11,870 acres of cultivated lands (Environmental Commitment 3). The following Swainson's hawk Resource Restoration and Performance Principles would be implemented as part of these acres:

- ○ Conserve 1 acre of Swainson's hawk foraging habitat for each acre of lost foraging habitat in patch sizes of a minimum of 40 acres (Resource Restoration and Performance Principle SH1).
- ○ Protect Swainson's hawk foraging habitat above 1 foot above mean sea level with at least 50% in very high-value habitat (see Table 12-4A-35 for a definition habitat value) (Resource Restoration and Performance Principle SH2).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for these species, AMM1–AMM7, *AMM27 Selenium Management* and Mitigation Measure BIO-75, impacts on short-eared owl and northern harrier would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-45. Changes in Short-Eared Owl and Northern Harrier Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting and Foraging	2,231	724
Total Impacts Water Conveyance Facilities		**2,231**	**724**
Environmental Commitments 4, 6–7, 9–11[a]	Nesting and Foraging	2,232	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,232**	**0**
TOTAL IMPACTS		**4,463**	**724**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-121: Loss or Conversion of Habitat for and Direct Mortality of Short-Eared Owl and Northern Harrier

Alternative 4A would result in the combined permanent and temporary loss of up to 5,187 acres of modeled habitat for short-eared owl and northern harrier (of which 4,463 acres would be a permanent loss and 724 acres would be a temporary loss of habitat, Table 12-4A-45). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4), riparian restoration, (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate short-eared owl and northern harrier modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction:* Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 2,955 acres of modeled short-eared owl and northern harrier habitat (2,231 acres of permanent loss, 745 acres of temporary loss) from CZs 3–6 and CZ 8. Activities that would impact modeled habitat include tunnel, forebay, and intake construction, permanent and temporary access roads, construction of transmission lines, and temporary work areas. The majority of habitat removed would consist of grassland and alfalfa fields. There are no CNDDB or DHCCP surveys records of occurrences of nesting short-eared owl that overlap with the construction footprint of water conveyance facilities. However, there are two DHCCP occurrences of northern harrier that overlap with the footprint of a shaft associated with the pumps at Clifton Court Forebay and a permanent transmission line north of the forebay. Two DHCCP occurrences also overlap with the temporary impact footprint from geotechnical explorations. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize impacts on short-eared owl and northern harrier if they were to nest in the vicinity of construction activities. Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal restoration actions through Environmental Commitment 4 would restore up to an estimated 253 acres of tidal natural communities. These restored wetland areas could provide suitable nesting habitat for short-eared owl and northern harrier. Consequently, although existing nesting habitat for short-eared owl and northern harrier would be removed, restoration of wetland habitats is expected to benefit marsh associated ground nesting birds by increasing the value of their nesting habitat.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 251 acres of short-eared owl and northern harrier foraging habitat.
- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would convert approximately 1,070 acres of cultivated lands into grasslands. These acres may be temporarily unavailable for foraging short-eared owl and northern harrier but would not permanently reduce foraging habitat for either species.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 832 acres of short-eared owl and northern harrier foraging habitat. Some portion of nontidal marsh restoration would be expected to provide habitat for both species.
- *Environmental Commitment 11 Natural Communities Enhancement and Management:* A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could permanently remove up to 20 acres and temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have adverse effects on available habitat but would be expected to result in overall improvements to and maintenance of habitat values. Habitat management- and enhancement-related activities could affect short-eared owl and northern harrier nests. If either species were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize these adverse effects.
- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect short-eared owl and northern harrier use of the surrounding habitat. Maintenance activities would include vegetation management, levee

and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7 and Mitigation Measure BIO-75 as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged short-eared owl and northern harrier if they were present in the project area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to minimize these adverse effects.

The following paragraphs summarize the combined effects discussed above and describe Environmental Commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

The study area supports approximately 406,784 acres of modeled nesting and foraging habitat for short-eared owl and northern harrier. Alternative 4A would result in the permanent loss of and temporary effects on 5,187 acres of modeled habitat for short-eared owl and northern harrier (<1% of the modeled habitat in the study area). Of the 5,187 acres of modeled habitat impacted, 77 acres consist of wetlands.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by water conveyance facilities would be 1:1 protection of non-wetland habitats and 1:1 protection and 1:1 restoration of wetland habitat. Using these typical ratios would indicate that 5,106 acres of grassland and cultivated lands should be protected, 81 acres of wetlands should be restored or created, and 81 acres of wetlands should be protected to compensate for the losses of short-eared owl and northern harrier habitat.

Short-eared owl and northern harrier nest in tidal brackish and freshwater emergent wetland, nontidal freshwater perennial emergent wetland, managed wetland, other natural seasonal wetland, grassland, alkali seasonal wetland, vernal pool complex, and selected cultivated lands, which includes alfalfa, irrigated pasture, and other grain fields. A total of 1,060 acres of grassland and 11,870 acres of cultivated lands would be protected through Alternative 4A. Within these acres of grassland and cultivated lands protection, project proponents would commit to conserving 1 acre of Swainson's hawk foraging habitat for every acre of lost foraging habitat (Resource Restoration and Performance Principle SH1), which would total 6,717 acres and would also be suitable foraging habitat for short-eared owl and northern harrier. These acres of cultivated lands and grasslands would be located above 1 foot above mean sea level and at least 50% of these lands would be in very high-value production for the Swainson's hawk (alfalfa) (Resource Restoration and Performance Principle SH2).

In addition, 295 acres of tidal natural communities would be restored or created, 119 acres of nontidal wetlands would be protected, 832 acres of nontidal wetlands would be created in the Delta, 1,070 acres of grassland would be restored, and 48 acres of vernal pool complex would be restored. The restored and protected acres described above would provide suitable nesting and foraging habitat for these species. Environmental Commitment 3, Environmental Commitment 4, Environmental Commitment 8, Environmental Commitment 9, and Environmental Commitment 10 would occur in the same timeframe as the construction and early restoration losses.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils*, and *AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

For the project to avoid adverse effects on individuals, preconstruction surveys would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

NEPA Effects: The loss of short-eared owl and northern harrier nesting habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles CBR1, SH1, and SH2, and by AMM1–AMM7, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, losses and conversions of short-eared owl and northern harrier habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on short-eared owl and northern harrier habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of Environmental Commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management and enhancement associated with Environmental Commitment 3, Environmental Commitment 4, Environmental Commitment 10, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principles CBR1, SH1, and SH2, and by AMM1–AMM7, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of short-eared owl and northern harrier. Therefore, with the implementation of Mitigation Measure BIO-75, Alternative 4A would have a less-than-significant impact on short-eared owl and northern harrier under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-122: Effects on Short-Eared Owl and Northern Harrier Associated with Electrical Transmission Facilities

New transmission lines would increase the risk that short-eared owl and northern harrier could be subject to power line strikes, which could result in injury or mortality of these species. Short-eared owl and northern harrier would be at low risk of bird strike mortality based on their keen eyesight and largely ground-based foraging behavior (BDCP Attachment 5.J-2, *Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). The existing network of transmission lines in the project area currently poses the same small risk for these species, and any incremental risk associated with the new power line corridors would also be expected to be low. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. With the implementation of *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters, which would further reduce any bird strike risk of short-eared owl and northern harrier.

NEPA Effects: The construction and presence of new transmission lines would not result in an adverse effect on short-eared owl or northern harrier because the risk of bird strike is considered to be low for both species based on their keen eyesight and behavioral characteristics. New transmission lines would minimally increase the risk for short-eared owl and northern harrier power line strikes. All new transmission lines constructed as a result of the project would be fitted with bird diverters (*AMM20 Greater Sandhill Crane*), which have been shown to reduce avian mortality by 60% amd which would further reduce any potential for powerline collisions. Therefore, the construction and operation of transmission lines under Alternative 4A would not result in an adverse effect on short-eared owl or northern harrier.

CEQA Conclusion: The construction and presence of new transmission lines would not result in a significant impact on short-eared owl or northern harrier because the risk of bird strike is considered to be low for both species based on their keen eyesight and behavioral characteristics. New transmission lines would minimally increase the risk for short-eared owl and northern harrier power line strikes. All new transmission lines constructed as a result of the project would be fitted with bird diverters (*AMM20 Greater Sandhill Crane*), which have been shown to reduce avian mortality by 60% and which would further reduce any potential for powerline collisions. Therefore, the construction and operation of transmission lines under Alternative 4A would result in a less-than-significant impact on short-eared owl or northern harrier.

Impact BIO-123: Indirect Effects of the Project on Short-Eared Owl and Northern Harrier

Indirect Construction- and Operation-Related Effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect short-eared owl and northern harrier use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). However, there are no available data to determine the extent to which these noise levels could affect short-eared owl or northern harrier. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring and would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Project activities have the potential to exacerbate bioaccumulation of mercury in avian species, including short-eared owl and northern harrier. Marsh (tidal and nontidal) restoration has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. A detailed review of the methylmercury issues associated with implementation of Alternative 4A are contained in Appendix 11F, *Substantive BDCP Revisions*, which includes an overview of the Alternative 4A-related mechanisms that could result in increased mercury in the foodweb, and how exposure of individual species to mercury may occur based on feeding habits and where species habitat overlaps with the areas where mercury bioavailability could increase. Increased methylmercury associated with natural community restoration could indirectly affect short-eared owl and northern harrier, via uptake in lower trophic levels (as described in BDCP Appendix 5.D, *Contaminants*).

Due to the complex and very site-specific factors that determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. On a project-specific basis, where high potential for methylmercury production is identified that restoration design and adaptive management cannot fully address while also meeting restoration objectives, alternate restoration areas will be considered. Environmental Commitment 12 will be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This Environmental Commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.

Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and project activities have the potential to exacerbate bioaccumulation of selenium in avian species, including short-eared owl and northern harrier. Marsh (tidal and nontidal) restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with Environmental Commitment 4 would lead to adverse effects on short-eared owl and northern harrier.

Because of the uncertainty that exists with respect to the location of tidal restoration activities, there could be a substantial effect on short-eared owl and northern harrier from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Indirect effects on short-eared owl and northern harrier as a result of constructing the water conveyance facilities could have adverse effects on these species in the absence of Environmental Commitments and AMMs. However, the implementation of AMM1–AMM7 would help to reduce this effect. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would also be available to address the adverse indirect effects of construction on active nests. Tidal habitat restoration could result in increased exposure of short-eared owl and northern harrier to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Increased methylmercury associated with natural community restoration could indirectly affect short-eared owl and northern harrier, via uptake in lower trophic levels (as described in BDCP Appendix 5.D, *Contaminants*). However, it is unknown what concentrations of methylmercury are harmful to the species, and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on short-eared owl and northern harrier.

CEQA Conclusion: Indirect effects of noise and visual disturbance, in addition to the potential for hazardous spills or increased dust on short-eared owl and northern harrier and their habitat as a result of Alternative 4A implementation would represent a substantial adverse effect in the absence of Environmental Commitments and AMMs. This impact would be significant. The incorporation of AMM1–AMM7 into Alternative 4A and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level. Tidal habitat restoration could result in increased exposure of short-eared owl and northern harrier to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

The implementation of tidal natural communities restoration could also result in increased exposure of short-eared owl and northern harrier to methylmercury in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on short-eared owl and northern harrier.

Indirect effects of Alternative 4A implementation would represent an adverse effect on short-eared owl and northern harrier in the absence of other Environmental Commitments. This would be a significant impact. With AMM1–AMM7 and Environmental Commitment 12 in place, and with the implementation of Mitigation Measure BIO-75, indirect effects of Alternative 4A implementation would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of either species. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on short-eared owl and northern harrier.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-124: Periodic Effects of Inundation on Short-Eared Owl and Northern Harrier as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on short-eared owl and northern harrier.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Redhead and Tule Greater White-Fronted Goose

Impacts, relevant protection and restoration actions, and mitigation requirements under CEQA are generally discussed for waterfowl in the *General Terrestrial Biology*, section under Impacts BIO-178 through BIO-183. Further details of the methods of analysis for waterfowl and shorebirds can be found in the *BDCP Waterfowl and Shorebird Effects Analysis* (Ducks Unlimited 2013). Tule greater white-fronted goose is currently only known to occur in Susiun Marsh and there are no proposed project activities that would affect habitats in Suisun Marsh under Alternative 4A.

Mountain Plover

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on mountain plover. Mountain plover does not breed in California, but winters in the study area. Modeled habitat for mountain plover include grassland, alkali seasonal wetland, vernal pool complex, alfalfa, grain and hay, pasture, and idle cropland throughout the study area.

Alternative 4A would result in both temporary and permanent losses of modeled habitat for mountain plover as indicated in Table 12-4A-46. Full implementation of Alternative 4A would include the following Environmental Commitments which could benefit the mountain plover.

- Protect up to 1,060 acres and restore up to 1,070 acres of grassland (Environmental Commitments 3 and Environmental Commitment 8).
- Protect up to 11,870 acres of cultivated lands (Environmental Commitment 3).
- Restore up to 48 acres and protect up to 188 acres of vernal pool/alkali seasonal wetland complex (Environmental Commitment 3 and Environmental Commitment 9).

As explained below, with the restoration or protection of these amounts of habitat, in addition to AMM1-AMM7, management activities that would enhance these natural communities for the species, impacts on mountain plover would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-46. Changes in Mountain Plover Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Wintering	1,978	537
Total Impacts Water Conveyance Facilities		1,978	537
Environmental Commitments 4, 6–7, 9–11[a]	Wintering	2,427	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,427**	**0**
TOTAL IMPACTS		**4,405**	**537**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-125: Loss or Conversion of Habitat for and Direct Mortality of Mountain Plover

Alternative 4A would result in the combined permanent and temporary loss of up to 4,942 acres of modeled wintering habitat for mountain plover (4,405 acres of permanent loss and 537 of temporary loss, Table 12-4A-46). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4), riparian restoration, (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11) could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate mountain plover modeled wintering habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 2,515 acres of modeled mountain plover habitat (1,978 acres of permanent loss, 537 acres of temporary loss). Impacts would occur from the construction of Intakes 2, 3, and 5 and associated temporary work areas and access roads in CZ 4 between Clarksburg and Courtland; construction of the intermediate forebay; and from an reusable tunnel material storage area on Bouldin Island. The construction of the permanent and temporary transmission line corridors through CZs 4–6 and 9 would also remove suitable habitat for the species. Approximately 1,115 acres would be affected as a result of the placement of an reusable tunnel material area west of the Clifton Court Forebay in CZ 8. In addition, permanent habitat loss would result from the construction of the new forebay south of the existing Clifton court Forebay in CZ 8. There are no CNDDB occurrences of mountain plover that intersect with the water conveyance facilities footprint. However, the study area does overlap with the wintering range for the species. Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 254 acres of modeled mountain plover habitat. The majority of the acres lost would consist of cultivated lands in the West Delta ROA.

- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 251 acres of mountain plover wintering habitat.

- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would convert approximately 1,070 acres of cultivated lands into grasslands. These acres may be temporarily unavailable for mountain plover but would not permanently reduce foraging habitat for the species.

- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 832 acres of mountain plover wintering habitat.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could permanently remove 20 acres and temporarily remove small amounts of mountain plover habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities would be expected to have minor adverse effects on available mountain plover habitat. Management of grasslands and cultivated lands for mountain plover such as grazing or mowing would make habitat temporarily unavailable for the species but would ultimately make the habitat more suitable for mountain plover.

- *Water Conveyance Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect mountain plover use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.
- Injury and Direct Mortality: Construction would not be expected to result in direct mortality of mountain plover because foraging individuals would be expected to temporarily avoid the increased noise and activity associated with construction areas.

The following paragraphs summarize the combined effects discussed above and describe Environmental Commitments, AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Alternative 4A would remove 4,942 acres of modeled mountain plover wintering habitat. These effects would result from the construction of the water conveyance facilities and implementing *Environmental Commitment 4 Tidal Natural Communities Restoration, Environmental Commitment 7 Riparian Natural Communities Restoration, Environmental Commitment 8 Grassland Natural Communities Restoration*, and *Environmental Commitment 10 Nontidal Marsh Restoration*.

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 9,884 acres should be protected to compensate for the losses of mountain plover wintering habitat. Due to the conservative nature of the impact analysis, both grassland and cultivated lands were included in the impact model, however, only 686 acres of impact would be from loss of grasslands, some of which would be suitable for mountain plover. Project proponents would commit to protect up to 1,060 acres of grassland, 188 acres of vernal pool/alkali seasonal wetland complex, and 11,870 acres of cultivated lands, and to restore up to 1,070 acres of grassland and 48 acres of vernal pool/alkali seasonal wetland complex which could provide suitable wintering habitat for mountain plover. *Environmental Commitment 11 Natural Communities Enhancement and Management* would be implemented to ensure that sufficient acres of grassland and cultivated lands were managed to provide suitable habitat for mountain plover and other species with similar habitat requirements.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils*, and *AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of mountain plover wintering habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. AMM1–AMM7 would be in place during all project activities. Considering these commitments, losses and conversions of mountain plover habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on mountain plover wintering habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of Environmental Commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3 and Environmental Commitment 11. AMM1–AMM7 would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of mountain plover. Therefore, Alternative 4A would have a less-than-significant impact on mountain plover under CEQA.

Impact BIO-126: Effects on Mountain Plover Associated with Electrical Transmission Facilities

Mountain plovers congregate in flocks during the winter and travel between grasslands and cultivated lands that provide foraging habitat for the species. This flocking behavior puts them at risk of collisions with powerlines. However, plovers exhibit low wing loading and high aspect-ratio wings and as a result can maneuver relatively quickly around an obstacle such as a transmission line. Their wing structure and design allows for rapid flight and quick, evasive actions. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. Plovers are primarily visual foragers and therefore, the risk for collision would be further reduced by *AMM20 Greater Sandhill Crane*, which would require the installation of bird flight diverters on all new transmission lines in the study area.

NEPA Effects: New transmission lines are not expected to have an adverse effect on mountain plover because the probability of bird-powerline strikes is highly unlikely due to their flight behaviors. The implementation of *AMM20 Greater Sandhill Crane*, which would require the installation of bird flight diverters on all new transmission lines, would further reduce any potential for mortality. Therefore, the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on mountain plover.

CEQA Conclusion: New transmission lines would have a less-than-significant impact on mountain plover because the probability of bird-powerline strikes is highly unlikely due to their flight behaviors. The implementation of *AMM20 Greater Sandhill Crane,* which would require the installation of bird flight diverters on all new transmission lines, would further reduce any potential for mortality. Therefore, the construction and operation of new transmission lines under Alternative 4A would result in a less-than-significant impact on mountain plover.

Impact BIO-127: Indirect Effects of the Project on Mountain Plover

Construction- and subsequent maintenance-related noise and visual disturbances could disrupt foraging, and reduce the functions of suitable foraging habitat for mountain plover. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). However, there are no available data to determine the extent to which these noise levels could affect mountain plover. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7 would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to mountain plover wintering habitat could also have a negative effect on the species. However, AMM1–AMM7 would also ensure that measures would be in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

NEPA Effects**:** Indirect effects on mountain plover as a result of Alternative 4A implementation could have adverse effects on the species through the modification of habitat. With the implementation of AMM1–AMM7, indirect effects as a result of Alternative 4A implementation would not have an adverse effect mountain plover.

CEQA Conclusion: Indirect effects on mountain plover as a result of Alternative 4A implementation could have a significant impact on the species from modification of habitat. With the implementation of AMM1–AMM7, indirect effects as a result of Alternative 4A implementation would have a less-than-significant impact on mountain plover.

Impact BIO-128: Periodic Effects of Inundation on Mountain Plover as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on mountain plover.

NEPA Effects**:** No effect.

CEQA Conclusion**:** No impact.

Black Tern

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on black tern. Modeled nesting habitat for black tern in the study area is currently limited to rice in CZ 2.

Alternative 4A would not result in effects on modeled habitat for black tern as indicated in Table 12-4A-47. There is no modeled habitat for the species in the water conveyance facilities footprint and proposed areas of tidal restoration under Alternative 4A.

Table 12-4A-47. Changes in Black Tern Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting	0	0
Total Impacts Water Conveyance Facilities		**0**	**0**
Environmental Commitments 4, 6–7, 9–11[a]	Nesting	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**0**	**0**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-129a: Loss or Conversion of Habitat for and Direct Mortality of Black Tern

No habitat would be lost or converted and there would be no direct mortality of black tern under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Conservation Zone 2, which is the only portion of the study area where the species is known to occur.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Impact BIO-129b: Indirect Effects of the Project on Black Tern

No indirect effects on black tern were identified under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Conservation Zone 2, which is the only portion of the study area where the species is known to occur.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Impact BIO-129c: Periodic Effects of Inundation on Black Tern Nesting Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on black tern habitat under Alternative 4A.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

California Horned Lark and Grasshopper Sparrow

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on California horned lark and grasshopper sparrow. The primary impact of concern for grasshopper sparrow and California horned lark would be the loss of breeding habitat in the project area, which includes grassland vernal pool complex, and alkali seasonal wetland natural communities and selected cultivated lands including grain and hay crops and pasture. Alternative 4A would result in both temporary and permanent losses of modeled breeding habitat for California horned lark and grasshopper sparrow as indicated in Table 12-4A-48. Full implementation of Alternative 4A would include the following Environmental Commitments which could benefit the California horned lark and the grasshopper sparrow.

- Protect up to 1,060 acres and restore up to 1,070 acres of grassland (Environmental Commitments 3 and Environmental Commitment 8).
- Protect up to 11,870 acres of cultivated lands (Environmental Commitment 3).
- Restore up to 48 acres and protect up to 188 acres of vernal pool/alkali seasonal wetland complex (Environmental Commitment 3 and Environmental Commitment 9).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for these species and implementation of AMM1–AMM7 and Mitigation Measure BIO-75, impacts on California horned lark and grasshopper sparrow would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-48. Changes in California Horned Lark and Grasshopper Sparrow Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Breeding	1,978	537
Total Impacts Water Conveyance Facilities		**1,978**	**537**
Environmental Commitments 4, 6–7, 9–11[a]	Breeding	2,427	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,427**	**0**
TOTAL IMPACTS		**4,405**	**537**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-130: Loss or Conversion of Habitat for and Direct Mortality of California Horned Lark and Grasshopper Sparrow

Alternative 4A would result in the combined permanent and temporary loss of up to 4,942 acres of modeled nesting habitat for California horned lark and grasshopper sparrow (of which 4,405 acres would be a permanent loss and 537 acres would be a temporary loss of habitat, Table 12-4A-48). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4), riparian restoration, (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11) could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate California horned lark and grasshopper sparrow modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 2,515 acres of modeled California horned lark and grasshopper sparrow habitat (1,978 acres of permanent loss, 537 acres of temporary loss). Impacts would result from the construction of Intakes 2, 3, and 5 and associated temporary work areas and access roads in CZ 4 between Clarksburg and Courtland; construction of the intermediate forebay; and from an reusable tunnel material storage area on Bouldin Island. The construction of the permanent and temporary transmission line corridors through CZs 4–6 and 9 would also remove suitable foraging habitat for the species. Approximately 1,115 acres would be affected as the result of the placement of an reusable tunnel material area west of the Clifton Court Forebay in CZ 8. In addition, permanent habitat loss would result from the construction of the new forebay south of the existing Clifton court Forebay in CZ 8. Grasshopper sparrows were detected in DHCCP surveys south of Byron Highway in CZ 8 (1 occurrence) and east of Intakes 2 and 3 (6 occurrences), in the Stone Lakes NWR. However, the water conveyance facilities footprint does not overlap with any grasshopper sparrow or California horned lark occurrences. Mitigation Measure BIO-75, *Conduct*

Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address adverse effects on nesting California horned larks or grasshopper sparrows. Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 254 acres of modeled California horned lark and grasshopper sparrow habitat. The majority of the acres lost would consist of cultivated lands in the West Delta ROA.

- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 251 acres of California horned lark and grasshopper sparrow habitat.

- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would convert approximately 1,070 acres of cultivated lands into grasslands. These acres may be temporarily unavailable for California horned lark and grasshopper sparrow during restoration, but would not permanently reduce habitat availability for either species.

- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 832 acres of California horned lark and grasshopper sparrow habitat.

- *Environmental Commitment 11 Natural Communities Enhancement and Management:* A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could permanently remove 20 acres and temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation (mechanical or grazing) and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values for California horned lark and grasshopper sparrow.

- Habitat management- and enhancement-related activities could disturb California horned lark and grasshopper sparrow nests. If either species were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these adverse effects.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect California horned lark and grasshopper sparrow use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7 and Mitigation Measure BIO-75 as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged California horned lark and grasshopper sparrow if they were present in the project area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these adverse effects.

The following paragraphs summarize the combined effects discussed above and describe Environmental Commitments and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Alternative 4A would remove 4,942 acres of modeled California horned lark and grasshopper sparrow habitat. These effects would result from the construction of the water conveyance facilities and implementing *Environmental Commitment 4 Tidal Natural Communities Restoration, Environmental Commitment 7 Riparian Natural Communities Restoration, Environmental Commitment 8 Grassland Natural Communities Restoration*, and *Environmental Commitment 10 Nontidal Marsh Restoration*.

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 9,884 acres should be protected to compensate for the losses of California horned lark and grasshopper sparrow habitat. Due to the conservative nature of the impact analysis, both grassland and cultivated lands were included in the impact model, however, only 686 acres of impact would be from loss of grasslands, some of which would be suitable for horned lark and grasshopper sparrow. Project proponents would commit to protect up to 1,060 acres of grassland, 188 acres of vernal pool/alkali seasonal wetland complex, and 11,870 acres of cultivated lands, and to restore up to 1,070 acres of grassland and 48 acres of vernal pool/alkali seasonal wetland complex, which could provide suitable habitat for California horned lark and grasshopper sparrow. *Environmental Commitment 11 Natural Communities Enhancement and Management* would be implemented to ensure that sufficient acres of grassland and cultivated lands were managed to provide suitable habitat for California horned lark, grasshopper sparrow, and other species with similar habitat requirements.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils*, and *AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of California horned lark and grasshopper sparrow habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. AMM1–AMM7 would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, losses and conversions of California horned lark and grasshopper sparrow under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on California horned lark and grasshopper sparrow habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of Environmental Commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3 and Environmental Commitment 11. AMM1–AMM7 would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of California horned lark and grasshopper sparrow. Therefore, with the implementation of Mitigation Measure BIO-75, Alternative 4A would have a less-than-significant impact on California horned lark and grasshopper sparrow under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-131: Effects on California Horned Lark and Grasshopper Sparrow and Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of grasshopper sparrow and California horned lark. *AMM20 Greater Sandhill Crane* would minimize the risk of bird strikes by installing flight-diverters on new and selected existing powerlines.

NEPA Effects: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of grasshopper sparrow and California horned lark. With the implementation of *AMM20 Greater Sandhill Crane*, the effect of new transmission lines on California horned lark and grasshopper sparrow would not be adverse.

CEQA Conclusion: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of grasshopper sparrow and California horned lark. With the incorporation of *AMM20 Greater Sandhill Crane*, new transmission lines would have a less-than-significant impact on grasshopper sparrow and California horned lark.

Impact BIO-132: Indirect Effects of the Project on California Horned Lark and Grasshopper Sparrow

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect California horned lark and grasshopper sparrow use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). However, there are no available data to determine the extent to which these noise levels could affect California horned lark or grasshopper sparrow. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills. The inadvertent discharge of sediment or excessive dust adjacent to California horned lark and grasshopper sparrow nesting habitat could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

***NEPA Effects*:** Indirect effects on California horned lark and grasshopper sparrow as a result of Alternative 4A implementation could have adverse effects on these species through the modification of habitat and potential for direct mortality. Potential mortality of California horned lark and grasshopper sparrow would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. In conjunction with AMM1–AMM7, Mitigation Measure BIO-75 *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this effect.

***CEQA Conclusion*:** Indirect effects on California horned lark and grasshopper sparrow as a result of Alternative 4A implementation could have a significant impact on these species. The incorporation of AMM1–AMM7 into Alternative 4A and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-133: Periodic Effects of Inundation on California Horned Lark and Grasshopper Sparrow as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on California horned lark or grasshopper sparrow.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Least Bittern and White-Faced Ibis

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on least bittern and white-faced ibis. Modeled breeding habitat for least bittern and white-faced ibis includes tidal freshwater, nontidal freshwater emergent wetlands, managed wetlands, and other natural seasonal wetlands in CZ 2, 4, and 11. Alternative 4A would result in both temporary and permanent losses of modeled habitat for least bittern and white-faced ibis as indicated in Table 12-4A-49. Full implementation of Alternative 4A would include the following Environmental Commitments and Resource Restoration and Performance Principles that would also benefit least bittern and white-faced ibis.

- Restore or create up to 13.5 acres of *Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acres in the central Delta (Environmental Commitment 4 and Resource Restoration and Performance Principle CBR1).

- Protect up to 119 acres of nontidal wetlands and create up to 832 acres of nontidal wetlands (Environmental Commitments 3 and 10).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for these species (including *Environmental Commitment 12 Methylmercury Management*) and implementation of AMM1–AMM7, and *AMM27 Selenium Management* and Mitigation Measure BIO-75, impacts on least bittern and white-faced ibis would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-49. Changes in Least Bittern and White-Faced Ibis Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting	1	3
Total Impacts Water Conveyance Facilities		**1**	**3**
Environmental Commitments 4, 6–7, 9–11[a]	Nesting	5	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**5**	**0**
TOTAL IMPACTS		**6**	**3**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-134: Loss or Conversion of Habitat for and Direct Mortality of Least Bittern and White-Faced Ibis

Alternative 4A would result in the combined permanent and temporary loss of up to 11 acres of modeled habitat for least bittern and white-faced ibis (6acres of permanent loss and 3 of temporary loss, Table 12-4A-49). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate least bittern and white-faced ibis habitat. Each of these individual activities is described below.

- *Water Facilities Construction:* Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 4 acres of modeled least bittern and white-faced ibis habitat (1 acre of permanent loss, 3 acres of temporary loss) from CZ 4. Permanent impacts on habitat would result from an reusable tunnel material storage site north of Twin Cities Road and east of the intermediate forebay. Temporary impacts would result from the construction of two temporary transmission lines, one extending east along Lambert Road from the Lambert Road Vent Shaft, and one extending south from the Lambert Road Vent Shaft to the intermediate forebay. The construction footprint for water conveyance facilities does not overlap with any occurrences of least bittern or white-faced ibis. However, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize effects on least bittern and white-faced ibis if they were to nest in the vicinity of the construction footprint. Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 5 acres of modeled least bittern and white-faced ibis habitat.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of least bittern and white-faced ibis habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available least bittern and white-faced ibis habitat.
- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect least bittern and white-faced ibis use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to further reduce effects.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of least bittern and white-faced ibis because adults and fledged young would be expected to avoid contact with construction and other equipment. However, if either species were to nest in the construction area, equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Construction-related activities could also flush least bittern adults from nests and lead to collision with man-made objects (Sterling 2008). Mitigation Measure BIO-75 would require preconstruction surveys in and adjacent to work areas and, if nests were present, nodisturbance buffers would be implemented.

The following paragraphs summarize the combined effects discussed above and describe Environmental Commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Alternative 4A would result in the permanent loss of and temporary effects on 9 acres (6 acres of permanent loss, 3 acres of temporary loss) of least bittern and white-faced ibis habitat.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 for restoration/creation and 1:1 protection of least bittern and white-faced ibis habitat. Using these ratios would indicate that 9 acres of habitat should be restored and 9 acres of habitat should be protected to compensate for the losses of least bittern and white-faced ibis habitat.

Alternative 4A includes the following conservation commitments: 13.5 acres of tidal freshwater emergent wetland would be restored or created (Resource Restoration and Performance Principle CBR1) and 119 acres of nontidal wetlands would be protected, and 832 acres of nontidal wetlands would be created. These would be implemented as part of Environmental Commitment 4, and Environmental Commitment 10 and would be more than sufficient to compensate for impacts on least bittern and white-faced ibis habitat.

The project also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.*

If least bittern or white-faced ibis were to nest in or adjacent to work areas, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address this potentially adverse effect.

- ***NEPA Effects***: The loss of least bittern and white-faced ibis nesting habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principle CBR1, and by AMM1–AMM7, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, losses and conversions of least bittern and white-faced ibis habitat under Alternative 4A would not be adverse.

CEQA Conclusion:

- The effects on least bittern and white-faced ibis habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of Environmental Commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 4, Environmental Commitment 10, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principle CBR1 and by AMM1–AMM7, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of least bittern and white-faced ibis. Therefore, with the implementation of Mitigation Measure BIO-75, Alternative 4A would have a less-than-significant impact on least bittern and white-faced ibis under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-135: Effects on Least Bittern and White-Faced Ibis Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of least bittern and white-faced ibis. Waterbirds have a higher susceptibility to collisions than passerines, raptors, and other birds. Bitterns and ibises have a high wing loading/low aspect ratio which limits their maneuverability and make them more vulnerable to collisions rather than more agile species (see BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new project transmission lines would be fitted with flight diverters which would reduce bird strike risk of least bittern and white-faced ibis.

***NEPA Effects*:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of least bittern and white-faced ibis. Bitterns and ibises have a high wing loading/low aspect ratio which limits their maneuverability and make them more vulnerable to collisions rather than more agile species. The implementation of *AMM20 Greater Sandhill Crane* would require the installation of bird flight diverters on all new transmission lines, which could reduce bird strike risk of least bittern and white-faced ibis by 60%. With the installation of bird flight diverters, the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on least bittern and white-faced ibis.

***CEQA Conclusion*:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of least bittern and white-faced ibis. Bitterns and ibises have a high wing loading/low aspect ratio which limits their maneuverability and make them more vulnerable to collisions rather than more agile species. The implementation of *AMM20 Greater Sandhill Crane* would require the installation of bird flight diverters on all new transmission lines, which could reduce bird strike risk of least bittern and white-faced ibis by 60%. With the installation of bird flight diverters, the construction and operation of new transmission lines under Alternative 4A would result in a less-than-significant impact on least bittern and white-faced ibis.

Impact BIO-136: Indirect Effects of the Project on Least Bittern and White-Faced Ibis

Indirect Construction- and Operation-Related Effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect least bittern and white-faced ibis use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-44, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). However, there are no available data to determine the extent to which these noise levels could affect least bittern or white-faced ibis. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could adversely affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring and would ensure that measures were in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Marsh (tidal and nontidal) restoration has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. A detailed review of the methylmercury issues associated with implementation of Alternative 4A are contained in Appendix 11F, *Substantive BDCP Revisions.* The review includes an overview of the Alternative 4A-related mechanisms that could result in increased mercury in the foodweb, and how exposure of individual species to mercury may occur based on feeding habits and where species habitat overlaps with the areas where mercury bioavailability could increase. Increased methylmercury associated with natural community restoration could indirectly affect least bittern and white-faced ibis, via uptake in lower trophic levels (as described in BDCP Appendix 5.D, *Contaminants*).

Due to the complex and very site-specific factors that determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. On a project-specific basis, where high potential for methylmercury production is identified that restoration design and adaptive management cannot fully address while also meeting restoration objectives, alternate restoration areas will be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This Environmental Commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and project activities have the potential to exacerbate bioaccumulation of selenium in avian species, including least bittern and white-faced ibis. Marsh (tidal and nontidal) restoration has the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with Environmental Commitment 4 would lead to adverse effects on least bittern and white-faced ibis.

Because of the uncertainty that exists with respect to the location of tidal restoration activities, there could be a substantial effect on least bittern and white-faced ibis from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Indirect effects on least bittern and white-faced ibis as a result of constructing the water conveyance facilities could have adverse effects on these species in the absence of Environmental Commitments and AMMs. However, the implementation of AMM1–AMM7 would help to reduce this effect. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would also be available to address the adverse indirect effects of construction on active nests. Tidal habitat restoration could result in increased exposure of least bittern and white-faced ibis to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Increased methylmercury associated with natural community restoration could indirectly affect least bittern and white-faced ibis, via uptake in lower trophic levels (as described in BDCP Appendix 5.D, *Contaminants*). However, it is unknown what concentrations of methylmercury are harmful to the species, and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on least bittern and white-faced ibis.

CEQA Conclusion: Indirect effects of noise and visual disturbance, in addition to the potential for hazardous spills or increased dust on least bittern and white-faced ibis and their habitat as a result of Alternative 4A implementation, would represent a substantial adverse effect in the absence of other Environmental Commitments and AMMs. This impact would be significant. The incorporation of AMM1–AMM7 into Alternative 4A and the implementation of Mitigation Measure BIO-75, *Conduct*

Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would reduce this impact to a less-than-significant level. Tidal habitat restoration could result in increased exposure of least bittern and white-faced ibis to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The implementation of tidal natural communities restoration could result in increased exposure of least bittern and white-faced ibis to methylmercury in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on least bittern and white-faced ibis.

Indirect effects of Alternative 4A implementation would represent an adverse effect on least bittern and white-faced ibis in the absence of other Environmental Commitments. This would be a significant impact. With AMM1–AMM7, *AMM27 Selenium Management*, and Environmental Commitment 12 in place, and with the implementation of Mitigation Measure BIO-75, indirect effects of Alternative 4A implementation would not result in a substantial adverse effect through habitat modification and would not substantially reduce the number or restrict the range of either species. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on least bittern and white-faced ibis.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-137: Periodic Effects of Inundation on Least Bittern and White-Faced Ibis as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on least bittern or white-faced ibis.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Loggerhead Shrike

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on loggerhead shrike. Modeled habitat for loggerhead shrike includes both high-value and low-value modeled habitat. High-value habitat includes grassland, vernal pool complex and alkali seasonal wetland natural communities in addition to cultivated lands, including pasture and grain and hay crops. Breeding shrikes require shrubs and tall trees for perching and nest placement, and are generally associated with riparian edge grasslands (Humple 2008) or cultivated lands with associated trees and shrubs. Loggerhead shrike modeled habitat is overestimated as it does not differentiate between lands with or without associated nesting vegetation or nesting and perching vegetation structures. Low-value habitat includes row crops such as truck and berry crops and field crops which are not considered to be valuable habitat for the species but were included in the model as they may provide foraging opportunities.

Alternative 4A would result in both temporary and permanent losses of modeled habitat for loggerhead shrike as indicated in Table 12-4A-50. Full implementation of Alternative 4A would include the following Environmental Commitments and Resource Restoration and Performance Principles which would benefit loggerhead shrike.

- Protect up to 1,060 acres of grassland and 11,870 acres of cultivated lands (Environmental Commitment 3). The following Swainson's hawk Resource Restoration and Performance Principles would be implemented as part of these acres.
  - Conserve 1 acre of Swainson's hawk foraging habitat for each acre of lost foraging habitat in patch sizes of a minimum of 40 acres (Resource Restoration and Performance Principle SH1).
  - Protect Swainson's hawk foraging habitat above 1 foot above mean sea level with at least 50% in very high-value habitat (see Table 12-4A-35 for a definition habitat value) production (Resource Restoration and Performance Principle SH2).
- Of the 1,060 acres of grasslands protected, protect up to 227 acres of grasslands on the landward side of levees adjacent to restored floodplain to provide flood refugia and foraging habitat for riparian brush rabbit (Resource Restoration and Performance Principle RBR5).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the conservation area, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Resource Restoration and Performance Principle CL1).
- Restore up to 1,070 acres of grasslands (Environmental Commitment 8).
- Restore or create up to 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect up to 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for the species and implementation of AMM1–AMM7, AMM10, and Mitigation Measure BIO-75, impacts on loggerhead shrike would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-50. Changes in Loggerhead Shrike Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	High-value	1,978	537
	Low-value	1,269	441
Total Impacts Water Conveyance Facilities		**3,247**	**978**
Environmental Commitments 4, 6–7, 9–11[a]	High-value	2,239	0
	Low-value	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,239**	**0**
Total High-value		**4,217**	537
Total Low-value		**1,269**	441
TOTAL IMPACTS		**5,486**	**978**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-138: Loss or Conversion of Modeled Habitat for and Direct Mortality of Loggerhead Shrike

Alternative 4A would result in the combined permanent and temporary loss of up to 6,457 acres of modeled habitat for loggerhead shrike (of which 4,747 acres is of high-value and 1,710 acres is of low value, Table 12-4A-50). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4), riparian restoration, (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11) could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate loggerhead shrike modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction:* Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 2,515 acres of high-value loggerhead shrike habitat (1,978 acres of permanent loss, 537 acres of temporary loss). In addition, 1,710 acres of low-value habitat would be removed (1,269 acres of permanent loss, 441 acres of temporary loss). Impacts would occur from the construction of Intakes 2, 3, and 5 and associated temporary work areas and access roads in CZ 4 between Clarksburg and Courtland; construction of the intermediate forebay; and from a an reusable tunnel material storage area on Bouldin Island. The construction of the permanent and temporary transmission line corridors through CZs 4–6 and 9 would also remove suitable foraging habitat for the species. Approximately 1,115 acres would be affected by the placement of and reusable tunnel material area west of the Clifton Court Forebay in CZ 8. In addition, permanent habitat loss would result from the construction of the new forebay south of the existing Clifton court Forebay in CZ 8. Temporarily affected areas (grassland, cultivated lands, and associated shrubs or trees) would be restored within 1 year following completion of construction activities as described *in AMM10 Restoration of Temporarily Affected Natural Communities*.

Loggerhead shrikes nest in high abundance in shrubs associated with the grasslands to the south and to the west of Clifton Court Forebay. Shrikes were detected using this area at a much higher rate than other grasslands and areas in the Delta during DHCCP surveys (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*). Impacts from water conveyance facilities that overlap with recorded loggerhead shrike nest occurrences (from CNDDB and DHCCP surveys) include the construction of the new forebay (5 occurrences), the reusable tunnel material storage area north-west of the existing forebay (2 occurrences), permanent transmission line south of Clifton Court Road and west of the existing Clifton Court Forebay (1 occurrence), a permanent transmission line that extends along the northern extent of the reusable tunnel material storage areas west of the existing forebay (1 occurrence). Mitigation Measure BIO-75 *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address adverse effects on nesting loggerhead shrikes. Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 66 acres of high-value loggerhead shrike habitat.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 251 acres of high-value loggerhead shrike habitat.
- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would convert approximately 1,070 acres of cultivated lands into grasslands. These acres may be temporarily unavailable for loggerhead shrike but would not permanently reduce foraging habitat for the species.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 832 acres of high-value loggerhead shrike habitat.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could permanently remove 20 acres and temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values. Fences (e.g., barbed wire) installed as part of Environmental Commitment 11, in or adjacent to protected grasslands and cultivated lands could benefit loggerhead shrike by providing hunting perches and impalement opportunities.

Habitat management- and enhancement-related activities could disturb loggerhead shrike nests. If either species were to nest in the vicinity of a worksite, equipment operation could destroy nests if shrubs and trees in grasslands or cultivated lands were removed, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these adverse effects.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities could result in ongoing but periodic disturbances that could affect loggerhead shrike use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and Mitigation Measure BIO-75 as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged loggerhead shrike if they were present in the project area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these potential effects.

The following paragraphs summarize the combined effects discussed above and describe Environmental Commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Alternative 4A as a whole would result in the permanent loss of and temporary effects on 4,747 acres of high-value loggerhead shrike habitat and 1,710 acres of low-value loggerhead shrike habitat. These effects would result from the construction of the water conveyance facilities and implementing *Environmental Commitment 4 Tidal Natural Communities Restoration*, *Environmental Commitment 7 Riparian Natural Communities Restoration, Environmental Commitment 8 Grassland Natural Communities Restoration*, and *Environmental Commitment 10 Nontidal Marsh Restoration*. The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 protection of high-value habitat. Using this ratio would indicate that 9,494 acres should be protected to compensate for the loss of high-value habitat. The loss of low-value habitat would not require mitigation because a large proportion of the low-value habitat would result from the conversion and enhancement to high-value habitats. In addition, *AMM10 Restoration of Temporarily Affected Natural Communities* would require that temporary impacts on riparian habitat, grasslands with trees and shurbs available for nestings, and cultivated lands would be restored relatively quickly after completion of construction.

A total of 1,060 acres of grassland and 11,870 acres of cultivated lands would be protected and 1,070 acres of grassland would be restored through *Environemntal Commitment 3* and *Environmental Commitment 8*. As part of these acres of protection, project proponents would commit to conserving 1 acre of Swainson's hawk foraging habitat for every acre of lost foraging habitat, which would total 6,805 acres and would be located above 1 foot above mean sea level (Resource Restoration and Performance Principle SH1). At least 50% of protected Swainson's hawk foraging habitat would be in very high-value production (Resource Restoration and Performance Principle SH2) (alfalfa) which would also provide suitable high-value habitat for loggerhead shrike. Alternative 4A also contains Resource Restoration and Performance Principle CL1 to maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the conservation area, including isolated valley oak trees, trees and shrubs along field borders and roadsides which provide nesting habitat for loggerhead shrike. Resource Restoration and Performance Principal RBR5 would protect up to 227 acres of grasslands on the landward sides of levees adjacent to restored floodplain which would also benefit loggerhead shrike. These Resource Restoration and Performance Principles would be associated with Environmental

Commitment 3 and would occur in the same timeframe as the construction and early restoration losses and would benefit loggerhead shrike.

Alternative 4A also includes conservation commitments through *Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration* to restore or create up to 251 acres and protect up to 103 acres of valley/foothill riparian woodland. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs. *AMM18 Swainson's Hawk* includes a measure to plant large mature trees, including transplanting trees scheduled for removal. Trees would be planted in areas that support high-value Swainson's hawk foraging habitat within or adjacent to conserved cultivated lands, or as a component of the riparian restoration (Environmental Commitment 7) where they are in close proximity to suitable foraging habitat. Locating tree plantings and riparian restoration adjacent to Swainson's hawk foraging habitat would also provide suitable nesting habitat for loggerhead shrike.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and loggerhead shrike habitat adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Preconstruction surveys for loggerhead shrike would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

NEPA Effects: The loss of loggerhead shrike habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 7, Environmental Commitment 8, and Environmental Commitment 11. These conservation actions would be guided by Resource Restoration and Performance Principles SH1, SH2, CL1, RBR5, and VFR1, and by AMM1–AMM6, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM18 Swainson's Hawk*, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, losses and conversions of loggerhead shrike habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on loggerhead shrike habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of Environmental Commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement (including the maintenance of important habitat characteristics such as trees and shrubs) associated with Environmental Commitment 3, Environmental Commitment 7, Environmental Commitment 8, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principles SH1, SH2, CL1, RBR5, and VFR1, and by AMM1–AMM6, AMM1–AMM6, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM18*

Swainson's Hawk, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of loggerhead shrike. Therefore, with the implementation of Mitigation Measure BIO-75, Alternative 4A would have a less-than-significant impact on loggerhead shrike under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-139: Effects on Loggerhead Shrike Associated with Electrical Transmission Facilities

Loggerhead shrike's small, relatively maneuverable body; its lack of flocking behavior, and its diurnal foraging behavior, contribute to a low risk of collision with the proposed transmission lines. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). For example, Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. As described in *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters, which would substantially reduce any potential for mortality of loggerhead shrike individuals from powerline collisions.

NEPA Effects: Loggerhead shrike's small, relatively maneuverable body,; its lack of flocking behavior, and its diurnal foraging behavior contribute to a low risk of collision with the proposed transmission lines In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new transmission lines, which would substantially reduce the risk of bird strike for loggerhead shrike from the project. Therefore, the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on loggerhead shrike.

CEQA Conclusion: Loggerhead shrike's small, relatively maneuverable body, its lack of flocking behavior, and its diurnal foraging behavior contribute to a low risk of collision with the proposed transmission lines In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new transmission lines, which would substantially reduce the risk of bird strike for loggerhead shrike from the project. Therefore, the construction and operation of new transmission lines under Alternative 4A would result in a less-than-significant impact on loggerhead shrike.

Impact BIO-140: Indirect Effects of the Project on Loggerhead Shrike

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect loggerhead shrike use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). However, there are no available data to determine the extent to which these noise levels could affect loggerhead shrike. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Indirect effects from construction of the new forebay in CZ 8 could result in substantial effects on active loggerhead shrike nests. DHCCP surveys in 2009 detected 10 nest sites south-west of the Clifton Court Forebay (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*) and the large expanses of grassland in CZ 8 provide high-value nesting habitat for the species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills. The inadvertent discharge of sediment or excessive dust adjacent to loggerhead shrike nesting habitat could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

NEPA Effects: Indirect effects on loggerhead shrike as a result of Alternative 4A implementation could have adverse effects on these species through the modification of habitat and potential for direct mortality. Construction of the new forebay in CZ 8 would have the potential to disrupt nesting loggerhead shrikes in the highly suitable habitat surrounding Clifton Court Forebay and adjacent to work areas. The potential for mortality of loggerhead shrike would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. In conjunction with AMM1–AMM7, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

CEQA Conclusion: Indirect effects on loggerhead shrike as a result of Alternative 4A implementation could have a significant impact on these species. Construction of the new forebay in CZ 8 would have the potential to disrupt nesting loggerhead shrikes in the highly suitable habitat surrounding Clifton Court Forebay and adjacent to work areas. The incorporation of AMM1–AMM7 into Alternative 4A and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-141: Periodic Effects of Inundation on Loggerhead Shrike as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on loggerhead shrike.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Song Sparrow "Modesto" Population

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on Modesto song sparrow. The Modesto song sparrow is common and ubiquitous throughout the project area, excluding CZ 11, and modeled habitat for the species includes managed wetlands, tidal freshwater emergent, nontidal freshwater emergent, and valley/foothill riparian vegetation communities.

Alternative 4A would result in both temporary and permanent removal of Modesto song sparrow habitat in the quantities indicated in Table 12-4A-51. Full implementation of Alternative 4A would include the following Environmental Commitments and Resource Restoration and Performance Principles which would benefit Modesto song sparrow.

- Restore or create up to 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect up to 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore or create up to 295 acres of tidal wetlands in the north Delta (Environmental Commitment 4).
- Restore or create up to 13.5 acres of *Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acres at a location subject to CDFW approval (Resource Restoration and Performance Principle CBR1).
- Protect up to 119 acres of nontidal wetlands and create up to 832 acres of nontidal wetlands (Environmental Commitments 3 and 10).

As explained below, with the restoration or protection of these amounts of habitat, with AMM1–AMM7 and *AMM10 Restoration of Temporarily Affected Natural Communities* in place, and with the implementation of Mitigation Measure BIO-75, impacts on Modesto song sparrow would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-51. Changes in Modesto Song Sparrow Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting	56	63
Total Impacts Water Conveyance Facilities		**56**	**63**
Environmental Commitments 4, 6–7, 9–11[a]	Nesting	31	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**31**	**0**
TOTAL IMPACTS		**87**	**63**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-142: Loss or Conversion of Habitat for and Direct Mortality of Modesto Song Sparrow

Alternative 4A would result in the combined permanent and temporary loss of up to 150 acres of modeled habitat for Modesto song sparrow (87 acres of permanent loss and 63 acres of temporary loss, Table 12-4A-51). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate Modesto song sparrow modeled habitat. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities as described *in AMM10 Restoration of Temporarily Affected Natural Communities*. Although the effects are considered temporary, the restored riparian habitat would require a period of time for ecological succession to occur for restored riparian habitat to functionally replace habitat that has been affected. Each of these individual activities is described below.

- *Water Facilities Construction:* Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 119 acres of modeled Modesto song sparrow habitat (56 acres of permanent loss, 63 acres of temporary loss) from CZs 3–6 and CZ 8. The water conveyance facilities construction footprint overlaps with 77 Modesto song sparrow occurrences and the species is ubiquitous throughout the Delta. The reusable tunnel material storage areas throughout the central Delta overlap with 24 occurrences, shaft locations along the tunnel alignment overlap with 9 occurrences, the permanent transmission line overlaps with 6 occurrences, and 1 occurrence overlaps with the construction of the new forebay in CZ 8. In addition, areas temporarily affected overlap with species occurrences, including the construction of a transmission line (1 occurrence) and geotechnical exploration zones along the tunnel alignment (17 occurrences). Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address adverse effects on nesting Modesto song sparrows. Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Construction of the water conveyance facilities and the resultant impacts would occur within the first 10–14 years of Alternative 4A implementation.
- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would result in the conversion of an estimated 31 acres of Modesto song sparrow riparian habitat.
- *Environmental Commitment 6 Channel Margin Enhancement:* Channel margin habitat enhancement could result in removal of small amounts of valley/foothill riparian habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur along waterway margins where riparian habitat stringers exist, including levees and channel banks. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs. Some of the restored riparian habitat in the channel margin would be expected to support nesting habitat for Modesto song sparrow.
- *Environmental Commitment 11 Natural Communities Enhancement and Management:* A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values.

  Habitat management- and enhancement-related activities could affect Modesto song sparrow nests. If the individuals were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these adverse effects.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect Modesto song sparrow use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged Modesto song sparrow if they were present in the project area, because they would be expected to avoid contact with construction and other equipment. If the species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these effects.

The following paragraphs summarize the combined effects discussed above and describe Environmental Commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Alternative 4A would remove 150 acres of modeled habitat (87 permanent, 63 temporary) for Modesto song sparrow in the study area. These effects would result from the construction of the water conveyance facilities and implementing *Environmental Commitment 4 Tidal Natural Communities Restoration*.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration/creation and 1:1 protection of habitat. Using these ratios would indicate that 150 acres of suitable habitat should be restored/created and 150 acres should be protected to compensate for the losses of 150 acres of Modesto song sparrow habitat. Habitat that would be restored or protected to benefit Modesto song sparrow would include valley/foothill riparian and tidal and nontidal wetlands.

Alternative 4A includes conservation commitments through *Environmental Commitment 4 Tidal Natural Communities Restoration, Environmental Commitment 7 Riparian Natural Community Restoration*, and *Environmental Commitment 3 Natural Communities Protection and Restoration* to restore or create up to 251 acres and protect up to 103 acres of valley/foothill riparian woodland. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs. In addition, 295 acres of tidal wetlands would be restored or created, 119 acres of nontidal wetlands would be protected, and 832 acres of nontidal wetlands would be created.

The project also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils*, and *AMM7 Barge Operations Plan.*

If Modesto song sparrow were to nest in or adjacent to work areas, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address this potentially adverse effect.

NEPA Effects: The loss of Modesto song sparrow nesting habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principle CBR1, and by AMM1–AMM7, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, losses and conversions of Modesto song sparrow habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on Modesto song sparrow habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of other Environmental Commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 4, Environmental Commitment 7, Environmental Commitment 10, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principle CBR1, and by AMM1–AMM6, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of Modesto song sparrow. Therefore, with the implementation of Mitigation Measure BIO-75, Alternative 4A would have a less-than-significant impact on Modesto song sparrow under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-143: Effects on Modesto Song Sparrow Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of Modesto song sparrow. Existing lines currently pose this risk for Modesto song sparrow and the incremental increased risk from the construction of new transmission lines is not expected to adversely affect the population.

NEPA Effects: The incremental increased risk of bird-powerline strikes from the construction of new transmission lines would not adversely affect the Modesto song sparrow population.

CEQA Conclusion: The incremental increased risk of bird-powerline strikes from the construction of new transmission lines would have a less-than-significant impact on the Modesto song sparrow population.

Impact BIO-144: Indirect Effects of the Project on Modesto Song Sparrow

Indirect Construction- and Operation-Related Effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect Modesto song sparrow use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*). However, there are no available data to determine the extent to which these noise levels could affect Modesto song sparrow. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7 including *AMM2 Construction Best Management Practices and Monitoring* would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to Modesto song sparrow could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Marsh (tidal and nontidal) restoration has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community restoration could indirectly affect Modesto song sparrow, via uptake in lower trophic levels (as described in BDCP Appendix 5.D, *Contaminants*).

The potential mobilization or creation of methylmercury within the project area varies with site-specific conditions and would need to be assessed at the project level. Due to the complex and very site-specific factors that will determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This Environmental Commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and project activities have the potential to exacerbate bioaccumulation of selenium in avian species, including Modesto song sparrow. Tidal and nontidal marsh restoration has the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, tidal marsh restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations are analyzed in Chapter 8, *Water Quality*, which concludes that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative.

There could be an effect on Modesto song sparrow from increases in selenium associated with tidal restoration activities (Environmental Commitment 4); however, effects on the Modesto song sparrow population would be expected to be minimal as the amount of tidal restoration would total up to 22 acres. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of project design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design.

NEPA Effects: Noise and visual disturbances from the construction of water conveyance facilities could reduce Modesto song sparrow use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could adversely affect

Modesto song sparrow use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, in addition to AMM1–AMM7, would be available to address this adverse effect.

Tidal habitat restoration could result in increased exposure of Modesto song sparrow to selenium; however, the amount of tidal restoration would total up to 22 acres, and potential exposure to selenium resulting from these acres of restoration would not be expected to adversely affect the Modesto song sparrow population. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

The implementation of tidal natural communities restoration could result in increased exposure of Modesto song sparrow to methylmercury in tidally restored areas. However, it is currently unknown what concentrations of methylmercury are harmful to the species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on Modesto song sparrow.

CEQA Conclusion: Noise and visual disturbances from the construction of water conveyance facilities could reduce Modesto song sparrow use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect Modesto song sparrow use of the surrounding habitat. Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 4A would have a less-than-significant impact on Modesto song sparrow with the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and AMM1–AMM7. The implementation of tidal natural communities restoration could result in increased exposure of Modesto song sparrow to methylmercury in tidally restored areas. This would be a significant impact. However, it is currently unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on Modesto song sparrow.

Tidal habitat restoration could result in increased exposure of Modesto song sparrow to selenium; however, the amount of tidal restoration would total up to 22 acres, and potential exposure to selenium resulting from these acres of restoration would not be expected to adversely affect the Modesto song sparrow population. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

With AMM1–AMM7 and Environmental Commitment 12 in place, and with the implementation of Mitigation Measure BIO-75, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of Modesto song sparrow. Therefore, with the implementation of Mitigation Measure BIO-75, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on Modesto song sparrow.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-145: Periodic Effects of Inundation on Modesto Song Sparrow as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on Modesto song sparrow.

NEPA Effects**:** No effect.

CEQA Conclusion**:** No impact.

Bank Swallow

This section describes the effects of Alternative 4A, including construction and implementation of Environmental Commitments, on bank swallow. Bank swallows nest in colonies along rivers, streams, or other water and require fine textured sandy soils in vertical banks to create their burrows. There is little suitable habitat for bank swallow in the study area because most of the erodible banks have been stabilized with of levee revetment. The placement of rock revetment prevents the lateral migration of rivers, removing the natural river process that creates vertical banks through erosion (Bank Swallow Technical Advisory Committee 2013, Stillwater Sciences 2007). An estimated 70–90% of the bank swallow population in California nests along the Sacramento and Feather Rivers (Bank Swallow Technical Advisory Committee 2013) upstream of the study area. However, there are three CNDDB records of bank swallow colonies in the study area: two in CZ 2 north of Fremont Weir, and one in CZ 5 on Brannan Island, just west of Twitchell Island.

The closest natural community to represent modeled habitat for bank swallow is valley foothill riparian. Although there are impacts to the valley foothill riparian natural community along the northeast corner of Clifton Court Forebay, at the intermediate forebay, and on Bouldin Island, it is highly unlikely that the habitat in these locations is suitable for bank swallow (alluvial soils that form steep, eroded banks that have not been stabilized with levee revetment). Reusable tunnel material areas are not expected to be colonized by nesting bank swallows, as it is unlikely that the substrate would provide suitable nesting habitat for the species. However, if reusable tunnel material areas were to become suitable for swallows over time, Mitigation Measure BIO-146 *Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized*, would avoid impacts on nesting bank swallows by requiring surveys to be conducted prior to the removal of reusable tunnel material. Alternative 4A would not result in the direct loss of modeled habitat for bank swallow. However, indirect effects of noise and visual disturbance from *Environmental Commitment 4 Tidal Natural Communities Restoration* could impact bank swallow colonies if they were present near work areas. In addition, there is uncertainty with respect to how water flows upstream of the study area would affect bank swallow habitat.

As explained below, impacts on bank swallow under Alternative 4A would not be adverse for NEPA purposes and would be less than significant for CEQA purposes with the implementation of mitigation measures to monitor colonies and address the uncertainty of upstream operations on the species.

Table 12-4A-52. Changes in Bank Swallow Modeled Habitat Associated with Alternative 4A (acres)[a]

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting	0	0
Total Impacts Water Conveyance Facilities		**0**	**0**
Environmental Commitments[b]	Nesting	0	0
Total Impacts Environmental Commitments		**0**	**0**
TOTAL IMPACTS		**0**	**0**

[a] See Appendix 12E, *Detailed Accounting of Direct Effects of Alternatives on Natural Communities and Covered Species*, for a detailed breakdown of Environmental Commitments' effects.
[b] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-146: Indirect Effects of Implementation of Alternative 4A on Bank Swallow

Noise and visual disturbances during restoration activities from *Environmental Commitment 4 Tidal Natural Communities Restoration* including operation of earthmoving equipment and human activities at work sites, could result in temporary disturbances that cause bank swallow to abandon active nest burrows adjacent to construction areas. Bank swallow colonies with occupied burrows have been recorded in CZ 5 and construction-related disturbances could result in an adverse effect on individuals. Various activities related to *Environmental Commitment 11 Natural Communities Enhancement and Management* could also have indirect impacts on bank swallow.

NEPA Effects: Construction activities associated with habitat restoration could adversely affect bank swallow colonies in the absence of other measures. Noise and visual disturbances could result in adverse effects on bank swallows including abandonment of nests if active colonies were present within 500 feet of work areas. Mitigation Measure BIO-146, *Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized*, would be available to address this effect.

CEQA Conclusion: Construction activities associated with habitat restoration could represent an adverse effect on bank swallow colonies as a result of modification of habitat and potential mortality of special status species in the absence of other measures. This impact would be significant. Noise and visual disturbances could result in significant impacts on bank swallows if active colonies were present within 500 feet of work areas. Implementation of Mitigation Measure BIO-146, *Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized*, would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-146: Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized

To the extent practicable, project proponents will not conduct restoration activities during the bank swallow nesting season (April 1 through August 31). If restoration activities cannot be avoided during nesting season, a qualified biologist will conduct preconstruction surveys to determine if active bank swallow nesting colonies are present within 500 feet of work areas. If no active nesting colonies are present, no further mitigation is required. Reusable tunnel material areas are not expected to be colonized by nesting bank swallows, as it is unlikely that the substrate would provide suitable nesting habitat for the species. However, reusable tunnel material sites could become suitable for swallows over time. Surveys of reusable tunnel material areas that have been present for at least 1 year, allowing the substrate to stabilize, will be conducted prior to the removal of reusable tunnel material.

If active colonies are detected, DWR will establish a nondisturbance buffer (determined by DWR in consultation with CDFW and the Bank Swallow Technical Advisory Committee) around the colony during the breeding season. In addition, a qualified biologist will monitor any active colony within 500 feet of construction to ensure that construction activities do not affect nest success.

Impact BIO-147: Effects of Upstream Reservoir and Water Conveyance Facilities Operations on Bank Swallow

Bank swallows are a riparian species that have evolved to deal with a dynamic system that changes with annual variation in variables such as rainfall, or late snowpack runoff. The primary threat to the species is loss of nesting habitat from the placement of rock revetment for levee stabilization. Because of this limited available habitat, and the reduction of natural river process, the species is highly sensitive to 1) reductions in winter flows which are necessary to erode banks for habitat creation, and 2) high flows during the breading season. The potential impacts of changes in upstream flows during the breeding season on bank swallows are the flooding of active burrows and destruction of burrows from increased bank sloughing. Bank swallows arrive in California and begin to excavate their burrows in March, and the peak egg-laying occurs during April and May (Bank Swallow Technical Advisory Committee 2013). Therefore, increases in flows after the swallows have nested and laid eggs in the burrows could result in the loss of nests. On the Sacramento River, breeding season flows between 14,000 and 30,000 cfs have been associated with localized bank collapses that resulted in partial or complete colony failure (Stillwater Sciences 2007).

The CALSIM II modeling results of mean monthly flow were analyzed for three flow gauge stations on the Sacramento River (Sacramento River at Keswick, Sacramento River upstream of Red Bluff, Sacramento River at Verona) and two flow gauge stations on the Feather River (Feather River high-flow channel at Thermalito Dam, and Feather River at the confluence with the Sacramento River). Flows were estimated for wet years, above normal years, below normal years, dry years, and critical years. An average also was estimated (see Chapter 5, Section 5.3.1, *Methods for Analysis*, a description of the model).

On the Sacramento River at the Keswick and Red Bluff gauges, mean monthly flows under Alternative 4A could increase between April and August in below normal, dry, and critical years based on modeling assumptions and output (see Table 1 in Section 11C.4.1.1 and Table 3 in Section 11C.4.1.2 of Appendix 11C, *CALSIM II Model Results Utilized in the Fish Analysis*). The increased flows could lead to inundation of active colonies. However, model outputs indicate that flows under Existing Conditions and the predicted flows in year 50 without the project (NAA) also show increases in flows during the breeding season (April through August) in these water year types. Similar trends are shown for the Feather River (see Table 15 in Section 11C.4.1.8 and Table 17 in Section 11C.4.1.9 of Appendix 11C). In addition, at the Verona flow gauge on the Sacramento River in average water years (see Table 7 in Section 11C.4.1.4 of Appendix 11C) flows are predicted to be greater than 14,000 cfs during the breeding season (April through August,) which could lead to bank collapse. However, flows of this height are recorded under Existing Conditions at this flow gage and are also predicted at year 50 without the project (NAA).

NEPA Effects: High spring flows on the Sacramento and Feather Rivers may already be impacting bank swallow colonies during the breeding season, and predicted flows under Alternative 4A would not differ substantially from those under the No Action Alternative. However, because of the complexity of variables that dictate suitable habitat for the species, there is uncertainty regarding the potential for and magnitude of impacts on bank swallow from changes in upstream operations. Soil type, high winter flows, and low spring flows all contribute to successful nesting of bank swallow, and even moderate changes in seasonal flows could have an adverse effect on breeding success for the species. Mitigation Measure BIO-147, *Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area*, would be available to address the uncertainty of potential adverse effects of upstream operations on bank swallow.

CEQA Conclusion: High spring flows on the Sacramento and Feather Rivers may already be impacting bank swallow colonies during the breeding season, and predicted flows under Alternative 4A would not differ substantially from those under Existing Conditions. However, because of the complexity of variables that dictate suitable habitat for the species, there is uncertainty regarding the potential for and magnitude of impacts on bank swallow from changes in upstream operations. There are many variables that dictate suitable habitat for the species that cannot be clearly quantified, and seasonal changes in flow could increase or decrease suitable habitat for bank swallow depending on soil type and location of current colonies. Implementation of Mitigation Measure BIO-147, *Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area*, would address this potential significant impact and further determine if additional mitigation is required for bank swallow.

Mitigation Measure BIO-147: Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area

To address the uncertainty of the impact of upstream spring flows on existing bank swallow habitat, DWR will continue to support annual monitoring[3] of existing colonies upstream of the study area. DWR will collect data to be used for quantifying the magnitude of flows that would result inloss of active nest sites or degradation of available nesting habitat, and the extent to which changes in SWP operations attributable solely to the California WaterFix are the cause of such impacts. If DWR determines that changes in SWP operations attributable solely to the California WaterFix have caused loss of active nest sites or degradation of available nesting habitat, replacement habitat will be established at a minimum of 2:1 for the length of bank habitat affected. Replacement habitat will consist of removing bank revetment to create habitat for bank swallow at a location subject to CDFW approval (Bank Swallow Technical Advisory Committee 2013).

Yellow-Headed Blackbird

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of Environmental Commitments, on yellow-headed blackbird. The

[3] Bank swallow colonies have historically been and are currently monitored by DWR, USFWS, and CDFW in association with the Bank Swallow Technical Advisory Committee, which is a diverse coalition of state and federal agency and nongovernmental organization personnel, created in response to the continued decline of bank swallow populations on the Sacramento River.

habitat model used to assess impacts on yellow-headed blackbird includes nesting habitat and foraging habitat. Modeled nesting habitat includes tidal freshwater emergent wetland, other natural seasonal wetland, nontidal freshwater perennial emergent wetland, and managed wetland. These natural communities support aquatic insects which are important prey items for yellow-headed blackbird young (Beedy 2008). Modeled foraging habitat for yellow-headed blackbird consists of cultivated lands and noncultivated land cover types known to support abundant insect populations, including corn, pasture, and feedlots.

Alternative 4A would result in both temporary and permanent losses of yellow-headed blackbird modeled habitat as indicated in Table 12-4A-53. Full implementation of Alternative 4A would include the following Environmental Commitments and Resource Restoration and Performance Principles which would also benefit yellow-headed blackbird.

- Restore or create up to 295 acres of tidal wetlands in the north Delta (Environmental Commitment 4).
- Restore or create up to 13.5 acres of *Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acres at a location subject to CDFW approval (Environmental Commitment 4 and Resource Restoration and Performance Principle CBR1)
- Protect up to 119 acres of nontidal wetlands and create up to 832 acres of nontidal wetlands (Environmental Commitments 3 and 10).
- Protect up to 1,060 acres of grassland and 11,870 acres of cultivated lands (Environmental Commitment 3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities to enhance habitats for the species and implementation of AMM1–AMM7, *AMM27 Selenium Management*, Environmental Commitment 12, and Mitigation Measure BIO-75, impacts on yellow-headed blackbird would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-53. Changes in Yellow-Headed Blackbird Modeled Habitat Associated with Alternative 4A

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting	19	39
	Foraging	2,652	656
Total Impacts Water Conveyance Facilities		**2,671**	**695**
Environmental Commitments 4, 6–7, 9–11[a]	Nesting	21	0
	Foraging	2,239	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,260**	**0**
Total Nesting		**40**	**39**
Total Foraging		**4,891**	**656**
TOTAL IMPACTS		**4,931**	**695**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-148: Loss of Habitat for and Direct Mortality of Yellow-Headed Blackbird

Alternative 4A would result in the combined permanent and temporary loss of up to 5,626 acres of modeled habitat (79 acres of nesting habitat and 5,547 acres of foraging habitat) for yellow-headed blackbird (Table 12-4A-53). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4), riparian restoration, (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate yellow-headed blackbird suitable habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A water conveyance facilities would result in the combined permanent and temporary loss of up to 58 acres of yellow-headed blackbird nesting habitat (19 acres of permanent loss and 39 acres of temporary loss). In addition, 3,308 acres of foraging habitat would be removed (2,652 acres of permanent loss, 656 acres of temporary loss). Activities that would impact suitable yellow-headed blackbird habitat consist of tunnel, forebay, and intake construction, temporary access roads, and construction of transmission lines. The largest losses of foraging habitat would occur from loss of corn. There are no occurrences of yellow-headed blackbird that overlap with the construction footprint for water conveyance facilities. However, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would be available to address adverse effects on nesting yellow-headed blackbirds. Impacts from water conveyance facilities would occur in the central Delta in CZs 3–6, and CZ 8. Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Site preparation and inundation from Environmental Commitment 4 would permanently remove or convert an estimated 21 acres of nesting habitat and 66 acres of foraging habitat.

- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 251 acres of yellow-headed blackbird foraging habitat.

- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would convert approximately 1,070 acres of cultivated lands into grasslands. These acres may be temporarily unavailable for yellow-headed blackbird but would not permanently reduce foraging habitat for the species.

- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 832 acres of yellow-headed blackbird foraging habitat. Resulting nontidal marsh creation could benefit yellow-headed blackbird by creating breeding habitat that also supports aquatic insects for foraging.

- *Environmental Commitment 11 Natural Communities Enhancement and Management:* Habitat management- and enhancement-related activities could disturb yellow-headed blackbird nests if they were present near work sites. A variety of habitat management actions included in

Environmental Commitment 11 that are designed to enhance wildlife values in protected habitats may result in localized ground disturbances that could temporarily remove small amounts of yellow-headed blackbird habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, would be expected to have minor effects on available yellow-headed blackbird habitat. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect yellow-headed blackbird use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged yellow-headed blackbird if they were present in the study area, because they would be expected to avoid contact with construction and other equipment. If yellow-headed blackbird were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these adverse effects on yellow-headed blackbird.

The following paragraphs summarize the combined effects discussed above and describe other Environmental Commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Alternative 4A would remove 5,626 acres (79 acres of nesting habitat and 5,547 acres of foraging habitat) of yellow-headed blackbird nesting habitat in the study area. These effects would result from the construction of the water conveyance facilities (58 acres of nesting habitat, 3,308 acres of foraging habitat), and implementing other Environmental Commitments (*Environmental Commitment 4 Tidal Natural Communities Restoration*, *Environmental Commitment 7 Riparian Natural Community Restoration*, *Environmental Commitment 8 Grassland Natural Community Restoration*, and *Environmental Commitment 10 Nontidal Marsh Restoration*, 21 acres of nesting habitat and 2,239 acres of foraging habitat).Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by water conveyance facilities would be 1:1 for restoration/creation and 1:1 protection of nesting habitat, and 1:1 protection of foraging habitat. Using these ratios would indicate that 79 acres of nesting habitat should be restored/created and 79 acres should be protected to compensate for the water conveyance facilities losses of 79 acres of yellow-headed blackbird nesting habitat. In addition, 5,547 acres of foraging habitat should be protected to compensate for the losses of yellow-headed blackbird foraging habitat.

Project proponents would commit to creating or restoring 295 acres of tidal wetlands, creating 832 acres of nontidal wetlands, and protecting 119 acres of nontidal wetlands. These acres of restoration and protection would be more than sufficient to compensate for impacts on 79 acres of yellow-headed blackbird nesting habitat. Alternative 4A would also protect up to 1,060 acres of grassland

and 11,870 acres of cultivated lands, which would provide suitable foraging habitat for yellow-headed blackbird.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils*, and *AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

For the project to avoid adversely affecting individuals, preconstruction surveys for avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

NEPA Effects**:** The loss of yellow-headed blackbird nesting and foraging habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principle CBR1, and by AMM1–AMM7, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, losses and conversions of yellow-headed blackbird habitat under Alternative 4A would not be adverse.

CEQA Conclusion**:** The effects on yellow-headed blackbird habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of Environmental Commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 4, Environmental Commitment 10, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principle CBR1, and by AMM1–AMM7, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of yellow-headed blackbird. Therefore, with the implementation of Mitigation Measure BIO-75, Alternative 4A would have a less-than-significant impact on yellow-headed blackbird under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-149: Effects on Yellow-Headed Blackbird Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of yellow-headed blackbirds. Yellow-headed blackbirds are colonial and have the potential to collide with the proposed transmission lines when migrating in large flocks. However, similar to tricolored blackbird behavior, daily flights associated with foraging likely occur in smaller flocks at heights that are lower than the transmission lines (BDCP Attachment 5.J-2, *Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). For example, Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. As described in *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters, which reduce the potential for yellow-headed blackbird collision with transmission lines.

Transmission line poles and towers also provide perching substrate for raptors, which are predators on yellow-headed blackbird. Although there is potential for transmission lines to result in increased perching opportunities for raptors and result in increased predation pressure on yellow-headed blackbirds, the existing network of transmission lines in the study area currently poses this risk for yellow-headed blackbirds, and any incremental risk associated with the new transmission line corridors would not be expected to affect the study area population. Therefore, it is assumed that the increased risk of predation on yellow-headed blackbird from an increase in raptor perching opportunities would be minimal.

***NEPA Effects*:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of yellow-headed blackbird. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would reduce the potential impact of the construction of new transmission lines on yellow-headed blackbird. The increased risk of predation on yellow-headed blackbird from an increase in raptor perching opportunities would be minimal. Therefore, the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on yellow-headed blackbird.

***CEQA Conclusion*:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of yellow-headed blackbird. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would reduce the potential impact of the construction of new transmission lines on yellow-headed blackbird. The increased risk of predation on yellow-headed blackbird from an increase in raptor perching opportunities would be minimal. The construction and operation of new transmission lines under Alternative 4A would not substantially reduce the number or restrict the range of the species and would therefore result in a less-than-significant impact on yellow-headed blackbird.

Impact BIO-150: Indirect Effects of the Project on Yellow-Headed Blackbird

Indirect Construction- and Operation-Related Effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect yellow-headed blackbird use of suitable habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4, and EIR/EIS Appendix 11F, *Substantive BDCP Revisions*), although there are no available data to determine the extent to which these noise levels could affect yellow-headed blackbird. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect the species in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to yellow-headed blackbird habitat could also have a negative effect on the species. Where nests are located above open water, impacts of contamination, dust, and sediment in water could impact fledglings directly, or affect aquatic insect prey, which is important for feeding young. AMM1–AMM7 would minimize the likelihood of spills from occurring and ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Project activities have the potential to exacerbate bioaccumulation of mercury in avian species, including yellow-headed blackbird. Marsh (tidal and nontidal) restoration has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. A detailed review of the methylmercury issues associated with implementation of Alternative 4A are contained in Appendix 11F, *Substantive BDCP Revisions*. The review includes an overview of the project-related mechanisms that could result in increased mercury in the foodweb, and how exposure of individual species to mercury may occur based on feeding habits and where the species habitat overlaps with the areas where mercury bioavailability could increase. Increased methylmercury associated with natural community restoration could indirectly affect yellow-headed blackbird, via uptake in lower trophic levels (as described in BDCP Appendix 5.D, *Contaminants*).

Due to the complex and very site-specific factors that determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. On a project-specific basis, where high potential for methylmercury production is identified that restoration design and adaptive management cannot fully address while also meeting restoration objectives, alternate restoration areas will be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This Environmental Commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and project activities have the potential to exacerbate bioaccumulation of selenium in avian species, including yellow-headed blackbird. Tidal and nontidal marsh restoration has the potential to mobilize selenium, and, therefore, increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, tidal marsh restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations are analyzed in Chapter 8, *Water Quality*, which concludes that, relative to Existing Conditions and the No Action Alternative, construction and operation of proposed water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative.

There could be an effect on yellow-headed blackbird from increases in selenium associated with tidal restoration activities (Environmental Commitment 4); however, effects on the yellow-headed blackbird population would be expected to be minimal because the amount of tidal restoration would total up to 22 acres. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of project design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design.

NEPA Effects**:** Noise and visual disturbances from the construction of water conveyance facilities could reduce yellow-headed blackbird use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect yellow-headed blackbird use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting individuals in addition to AMM1–AMM7.

Tidal habitat restoration could result in increased exposure of yellow-headed blackbird to selenium; however, the amount of tidal restoration would total up to 22 acres, and potential exposure to selenium resulting from these acres of restoration would not be expected to adversely affect the yellow-headed blackbird population. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

The implementation of tidal natural communities restoration could result in increased exposure of yellow-headed blackbird to methylmercury in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on yellow-headed blackbird.

CEQA Conclusion: In the absence of AMMs, noise and visual disturbance, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 4A would represent an adverse effect. This impact would be significant. The implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and AMM1–AMM7, would reduce this impact to a less-than-significant level.

The implementation of tidal natural communities restoration could result in increased exposure of yellow-headed blackbird to methylmercury in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on yellow-headed blackbird.

Tidal habitat restoration could result in increased exposure of yellow-headed blackbird to selenium; however, the amount of tidal restoration would total up to 22 acres, and potential exposure to selenium resulting from these acres of restoration would not be expected to adversely affect the yellow-headed blackbird population. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Indirect effects of Alternative 4A implementation would represent an adverse effect on yellow-headed blackbird in the absence of other Environmental Commitments. This would be a significant impact. With AMM1–AMM7 and Environmental Commitment 12 in place, and with the implementation of Mitigation Measure BIO-75, indirect effects of Alternative 4A implementation would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, indirect effects of

Alternative 4A implementation would have a less-than-significant impact on yellow-headed blackbird.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-151: Periodic Effects of Inundation of Yellow-Headed Blackbird Nesting Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on yellow-headed blackbird.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Riparian Brush Rabbit

The habitat model used to assess effects on the riparian brush rabbit consists of 38 vegetation associations within the valley/foothill riparian natural community and adjacent grasslands. The vegetation associations were selected based on a review of understory and overstory composition from Hickson and Keeler-Wolf (2007) and species habitat requirements.

Just until recently, the only known naturally occurring populations of riparian brush rabbits were confined to Caswell Memorial State Park (MSP), a 258-acre park supporting riparian oak woodland on the Stanislaus River immediately southeast of the study area, and in the south Delta southwest of Lathrop, which is within the study area (Williams and Basey 1986; Williams et al. 2002) (Figure 12-46). On October 11, 2012 a single female riparian brush rabbit was captured near Durham Ferry Road in riparian habitat along the San Joaquin River between Caswell MSP and Lathrop (Bradbury pers. comm.). This is only the 2nd naturally occurring population documented outside of Caswell MSP. Factors considered in assessing the value of adversely affected habitat for riparian brush rabbit, to the extent information was available, included size and degree of isolation of habitat patches, proximity to recorded species occurrences, and adjacency to conserved lands.

Alternative 4A would result in both temporary and permanent losses of riparian brush rabbit modeled habitat as indicated in Table 12-4A-54. Alternative 4A would include the following Environmental Commitments and associated Resource Restoration and Performance Principles to benefit the riparian brush rabbit.

- Increase the size and connectivity of the conservation area by acquiring lands adjacent to and between existing conservation lands (Resource Restoration and Performance Principle L1).
- Of the 103 acres of protected valley/foothill riparian natural community, protect and maintain 19 acres of early- to mid-successional riparian habitat that meets the ecological requirements of the riparian brush rabbit and that is within or adjacent to or that facilitates connectivity with existing occupied or potentially occupied habitat (Environmental Commitment 3 and Resource Restoration and Performance Principle RBR1).
- Of the 251 acres of restored valley/foothill riparian natural community, restore and maintain 19 acres of early- to mid-successional riparian habitat that meets the ecological requirements of the

riparian brush rabbit and that is within or adjacent to or that facilitates connectivity with existing occupied or potentially occupied habitat (Environmental Commitment 7 and Resource Restoration and Performance Principle RBR2).

- Create and maintain high-water refugia in the 19 acres of restored riparian brush rabbit habitat and the 19 acres of protected riparian brush rabbit habitat, through the retention, construction and/or restoration of high-ground habitat on mounds, berms, or levees, so that refugia are no further apart than 66 feet (Resource Restoration and Performance Principle RBR3).
- In protected riparian areas that are occupied by riparian brush rabbit, monitor for and control nonnative predators that are known to prey on riparian brush rabbit (Resource Restoration and Performance Principle RBR4).
- Of the 1,060 acres of grasslands protected, protect up to 227 acres of grasslands on the landward side of levees adjacent to restored floodplain to provide flood refugia and foraging habitat for riparian brush rabbit (Resource Restoration and Performance Principle RBR5).

As explained below, with the restoration and protection of these amounts of habitat, in addition to the AMMs to reduce potential effects, impacts on riparian brush rabbit would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-54. Changes in Riparian Brush Rabbit Modeled Habitat Associated with Alternative 4A (acres)

TOTAL IMPACTS		**178**	**71**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-152: Loss or Conversion of Habitat for and Direct Mortality of Riparian Brush Rabbit

Alternative 4A would result in the permanent and temporary loss of up to 17 acres of riparian habitat and 232 acres of associated grassland habitat for the riparian brush rabbit in the study area (Table 12-4A-54). Environmental commitments that would result in these losses are conveyance facilities construction and geotechnical investigation. Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual activity discussions.

- *Water Facilities and Operation*: Development of Alternative 4A water conveyance facilities would result in the permanent removal of approximately 14 acres of riparian habitat and 164 acres of associated grassland habitat and in the temporary removal of 3 acre of riparian habitat and 68 acres of grassland habitat for riparian brush rabbit in CZ 8 (Table 12-4A-54). There are no riparian brush rabbit occurrences in the water conveyance facilities construction footprint. The riparian habitat that would be removed is of low value for the riparian brush rabbit as it consists of several small, isolated patches surrounded by agricultural lands northeast of Clifton Court Forebay. The associated grasslands are also of low value for the species: They consist of long, linear strips that abut riparian habitat, but extend several miles from the riparian habitat and, therefore, provide few if any opportunities for adjacent cover. Trapping efforts conducted for the riparian brush rabbit in this area were negative (see Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*, in the BDCP). Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Protection of up to 227 acres of grassland and 19 acres of riparian habitat, as well as restoration of up to 19 acres of riparian habitat would benefit riparian brush rabbit (Table 12-4A-54). A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in protected habitats may result in localized ground disturbances that could temporarily remove small amounts of riparian brush rabbit habitat. Enhancement and management actions in riparian brush rabbit habitat within the conservation area may include invasive plant removal, planting and maintaining vegetation to improve and sustain habitat characteristics for the species, and creating and maintaining flood refugia. These activities are expected to have minor adverse effects on available riparian brush rabbit habitat and are expected to result in overall improvements to and maintenance of riparian brush rabbit habitat values over time. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized through the AMMs listed below.

- Operations and maintenance: Ongoing maintenance of project facilities are not expected to adversely affect the riparian brush rabbit because the species is not expected to occur in the vicinity of proposed facilities.

- Injury and direct mortality: Water conveyance facility construction is not is not likely to result in injury or mortality of individual riparian brush rabbit because the species is not likely to be present in the areas that would be affected by this activity, based on live trapping results (see Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*, in the BDCP). Valley foothill/riparian natural communities restoration would not result in injury or mortality of the riparian brush rabbit because restoration projects would be designed to avoid occupied riparian brush rabbit habitat and, if that is not possible, rabbits would be trapped and relocated as described in AMM25 (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*).

The following paragraphs summarize the combined effects discussed above and describe other Environmental Commitments and AMMs that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

There are 6,012 acres of modeled riparian brush rabbit habitat in the study area, consisting of 2,909 acres of riparian habitat and 3,103 acres of associated grassland habitat. Alternative 4A would result in permanent and temporary effects combined on 17 acres of modeled riparian habitat (less than 1% of the habitat in the study area) and 232 acres of modeled grassland habitat (less than 1% of habitat in the study area) for riparian brush rabbit in CZ 6, CZ 7, and CZ 8.

These effects would result from the construction of the water conveyance facilities. The habitat would be lost in the valley/foothill riparian and grassland natural communities. Most of the loss of riparian brush rabbit habitat would be in an area unlikely to be occupied by the species in CZ 8. Habitat loss in CZ 7, in areas known or likely to be occupied, would also occur. Riparian restoration would be phased to minimize temporal habitat loss. Alternative 4A includes a commitment to protect up to 464 acres of grassland and 17 acres of riparian habitat, and to restore up to 17 acres of riparian habitat for riparian brush rabbit. The conserved habitat would also be part of a larger, more contiguous, and less patchy area of protected and restored riparian natural community than what currently exists in CZ 7 and would be contiguous with existing modeled riparian brush rabbit habitat. The conserved habitat would also provide more specific ecological requirements of riparian brush rabbit, including large patches of dense riparian brush; ecotonal edges that transition from brush species to grasses and forbs, scaffolding plants to support vines that grow above flood levels; a tree canopy that is open, if present; and high-ground refugia from flooding.

The project would also protect grasslands adjacent to suitable riparian vegetation in areas outside the floodplain levees. These grasslands are expected to provide additional foraging opportunities for the riparian brush rabbit and upland refugia during flood events. Grasslands on the landward side of levees adjacent to restored floodplain will be restored or protected as needed to provide flood refugia and foraging habitat for riparian brush rabbit.

Additionally, nonnative predators that are known to prey on riparian brush rabbit (e.g., feral dogs and cats) would be monitored in protected and restored riparian and grassland areas that are occupied by riparian brush rabbit and controlled as needed (Environmental Commitment 11).

Typical NEPA and CEQA project-level mitigation ratios for loss of riparian and grassland habitats affected by water conveyance facilities would be 1:1 for restoration and protection of the valley/foothill riparian natural community, and 2:1 for protection of grassland for riparian brush rabbit. Using these ratios would indicate that 17 acres of riparian habitat should be restored, 17 acres of riparian habitat should protected, and 464 acres of grassland should be protected for riparian brush rabbit.

The project also contains commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan, AMM10 Restoration of Temporarily Affected Natural Communities,* and *AMM25 Riparian Woodrat and Riparian Brush Rabbit*. These AMMs contain elements that avoid or minimize the risk of project activities affecting habitats and species adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: The loss of riparian brush rabbit habitat and potential mortality under Alternative 4A would not be an adverse effect because there is little likelihood of riparian brush rabbits being present and because the project proponents have committed to protecting and restoring the acreage required to meet the typical mitigation ratios described above. This habitat protection, restoration, and enhancement would be guided by species-specific Resource Restoration and Performance Principles L1 and RBR1-RBR5, and by AMM1–AMM6, AMM10, and AMM25, which would be in place throughout the period of construction and operations. Considering these commitments, the effects of Alternative 4A as a whole on riparian brush rabbit would not be an adverse effect.

CEQA Conclusion: Considering Alternative 4A's commitment to the protection, restoration, and management of riparian brush rabbit habitat, Resource Restoration and Performance Principles L1 and RBR1-RBR5, and with the implementation of AMM1–AMM7, AMM10, and AMM25, the loss of habitat or direct mortality of riparian brush rabbit as a result of implementing Alternative 4A would not represent a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the loss of habitat and potential mortality under this alternative would have a less-than-significant impact on riparian brush rabbit under CEQA.

Impact BIO-153: Indirect Effects of Alternative 4A on Riparian Brush Rabbit

Noise, lighting, and visual disturbances adjacent to construction activities could indirectly affect the use of modeled riparian brush rabbit riparian habitat and of associated grassland habitat in the study area. These construction activities would include water conveyance, geotechnical investigation, and restoration activities. Water conveyance facilities construction would potentially affect acres of adjacent riparian habitat and of associated grassland habitat: this construction would occur in CZ 8 where there is suitable habitat for the species but surveys by ESRP did not indicate the species is present in this area; therefore, the potential for adverse noise, lighting, and visual effects from conveyance facility construction would be minimal. The use of mechanical equipment during construction might cause the accidental release of petroleum or other contaminants that would affect the riparian brush rabbit in adjacent habitat, if the species is present.

NEPA Effects: Implementation of AMM1–AMM7, AMM10, and AMM25, as part of implementing Alternative 4A would avoid the potential for substantial adverse effects on riparian brush rabbits, either indirectly or through habitat modifications or result in a substantial reduction in numbers or a restriction in the range of riparian brush rabbits. Therefore, indirect effects of Alternative 4A would not have an adverse effect on riparian brush rabbit.

CEQA Conclusion: Indirect effects from operations and maintenance as well as construction-related noise, lighting, visual disturbances could affect riparian brush rabbit in riparian and grassland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could affect riparian brush rabbit. The inadvertent discharge of sediment or excessive dust adjacent to riparian brush rabbit habitat could also have a negative effect on the species. With implementation of AMM1–AMM7, AMM10, and AMM25 as part of Alternative 4A, the project would avoid and minimize the potential for substantial adverse effects on riparian brush rabbits, either indirectly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of riparian brush rabbits. Indirect effects of Alternative 4A would have a less-than-significant impact on riparian brush rabbit.

Impact BIO-154: Periodic Effects of Inundation of Riparian Brush Rabbit Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on riparian brush rabbit.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Riparian Woodrat

The habitat model used to assess effects for the riparian woodrat consists of selected plant alliances from the valley/foothill riparian natural community, geographically constrained to the south Delta portion of the study area in CZ 7, south of State Route 4 and Old River Pipeline along the Stanislaus, San Joaquin, Old, and Middle Rivers. Valley/foothill riparian areas along smaller drainages (Paradise Cut, Tom Paine Slough), and some larger streams in the northern portion of CZ 7 were excluded from the riparian woodrat habitat model due to a lack of trees or riparian corridors that were too narrow. Factors considered in assessing the value of affected habitat for the riparian woodrat, to the extent that information is available, include habitat patch size and connectivity.

The riparian woodrat is not known to occur in the study area. The only verified extant population of riparian woodrats rangewide is 2 miles east of the southern end of the study area in Caswell Memorial State Park along the Stanislaus River (Williams 1986:1–112; Williams 1993). Riparian woodrat may occur in small patches of valley oak riparian forest along the San Joaquin River from the southern tip of the study area north to approximately the Interstate 5 overcrossing near Lathrop (Figure 12-47).

Alternative 4A would not result in losses of riparian woodrat modeled habitat as indicated in Table 12-4A-55. There is no modeled habitat for the species in either the water conveyance facilities or Environmental Commitment 4 (tidal restoration) footprint.

Table 12-4A-55. Changes in Riparian Woodrat Modeled Habitat Associated with Alternative 4A (acres)

Total Impacts Environmental Commitments 4, 6–7, 9–11	0	0
TOTAL IMPACTS	**0**	**0**

Impact BIO-155: Loss or Conversion of Habitat for and Direct Mortality of Riparian Woodrat

No habitat would be lost or converted and there would be no direct mortality of riparian woodrat under Alternative 4A.

***NEPA Effects*:** No effect.

CEQA Conclusion: No Impact.

Impact BIO-156: Indirect Effects of Alternative 4A on Riparian Woodrat

There would be no indirect effects on riparian woodrat from Alternative 4A.

***NEPA Effects*:** No effect.

CEQA Conclusion: No Impact.

Impact BIO-157: Periodic Effects of Inundation of Riparian Woodrat Habitat as a Result of Implementation of Alternative 4A

There would be no periodic inundation effects on riparian woodrat from Alternative 4A.

***NEPA Effects*:** No effect.

CEQA Conclusion: No Impact.

Salt Marsh Harvest Mouse

The habitat model used to assess effects for the salt marsh harvest mouse includes six habitat types: primary tidal marsh habitat, secondary tidal marsh habitat (low marsh), secondary upland habitat adjacent to tidal marsh habitat, primary habitat within managed wetlands, secondary habitat within managed wetlands (dominated by plants characteristic of low marsh), and upland habitats within managed wetland boundaries. The tidal and managed wetland habitats were discriminated recognizing that regardless of habitat value, managed wetlands are at high risk of catastrophic flooding and have lower long-term conservation value than tidal wetlands.

Alternative 4A would not result in effects on modeled salt marsh harvest mouse habitat as indicated Table 12-4A-56. There is no modeled habitat for the species in the water conveyance facilities footprint and tidal restoration under Alternative 4A would not take place in Suisun Marsh, which is the extent of known salt marsh harvest mouse habitat in the study area.

Table 12-4A-56. Changes in Salt Marsh Harvest Mouse Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Total Impacts Water Conveyance Facilities	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]	0	0
TOTAL IMPACTS	**0**	**0**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-158: Loss or Conversion of Habitat for and Direct Mortality of Salt Marsh Harvest Mouse

No habitat would be lost or converted and there would be no direct mortality of salt marsh harvest mouse under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where the species is known to occur.

***NEPA Effects*:** No effect.

CEQA Conclusion: No impact.

Impact BIO-159: Indirect Effects of Alternative 4A on Salt Marsh Harvest Mouse

No indirect effects on salt marsh harvest mouse were identified under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where the species is known to occur.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Suisun Shrew

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of the Environmental Commitments, on the Suisun shrew. Primary Suisun shrew habitat consists of all *Salicornia*-dominated natural seasonal wetlands and certain *Scirpus* and *Typha* communities found within Suisun Marsh only. Low marsh dominated by *Schoenoplectus acutus* and *S. californicus* and upland transitional zones within 150 feet of the tidal wetland edge were classified separately as secondary habitat because they are used seasonally (Hays and Lidicker 2000). All managed wetlands were excluded from the habitat model.

Alternative 4A would not result in effects on modeled Suisun shrew habitat as indicated in Table 12-4A-57. There is no modeled habitat for the species in the water conveyance facilities footprint and tidal restoration under Alternative 4A would not take place in Suisun Marsh.

Total Impacts Environmental Commitments 4, 6–7, 9–11[a]	0	0
TOTAL IMPACTS	**0**	**0**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-160: Loss or Conversion of Habitat for and Direct Mortality of Suisun Shrew

No habitat would be lost or converted and there would be no direct mortality of Suisun shrew under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where the species is known to occur.

NEPA Effects: No effect.

CEQA Conclusion: No Impact.

Impact BIO-161: Indirect Effects of Alternative 4A on Suisun Shrew

No indirect effects on Suisun shrew were identified under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where the species is known to occur.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

San Joaquin Kit Fox and American Badger

Within the study area, the modeled habitat for the San Joaquin kit fox and potential habitat for the American badger is restricted to 5,327 acres of grassland habitat west of Clifton Court Forebay along the study area's southwestern edge, in CZ 7–CZ 10. The study area represents the extreme northeastern corner of the San Joaquin kit fox's range in California, which extends westward and southward from the study area border. The northern range of the San Joaquin kit fox (including the study area) was most likely marginal habitat historically and has been further degraded due to development pressures, habitat loss, and fragmentation (Clark et al. 2007a). CNDDB (California Department of Fish and Wildlife 2013) reports twelve occurrences of San Joaquin kit foxes along the extreme western edge of the project area within CZ 8, south of Brentwood (Figure 12-49). However, Clark et al. (2007b) provide evidence that a number of CNDDB occurrences in the northern portion of the species' range may be coyote pups misidentified as San Joaquin kit foxes. Smith et al. (2006) suggest that the northern range may possibly be a population sink for the San Joaquin kit fox. There are five American badger records in the study area (California Department of Fish and Wildlife 2013). Two are from 1938 and no longer extant. The remaining three are all located in CZ 8, west of Clifton Court Forebay.

Alternative 4A would result in both temporary and permanent losses of San Joaquin kit and American badger habitat (Table 12-4A-58). Grassland restoration, and protection and management of natural communities could affect modeled San Joaquin San Joaquin kit fox habitat and potential American badger habitat. Alternative 4A would include the following Environmental Commitments and associated Resource Restoration and Performance Principles to benefit the San Joaquin kit fox which would also benefit American badger which uses similar habitat (see BDCP Chapter 3, *Conservation Strategy*). The conservation strategy for the San Joaquin kit fox involves protecting and enhancing habitat in the northern extent of the species' range to increase the likelihood that San Joaquin kit fox may reside and breed in the project area; and providing connectivity to habitat outside the project area.

- Protect and improve habitat linkages that allow native terrestrial species to move between protected habitats within and adjacent to the project area (Resource Restoration and Performance Principle L2).
- Protect up to 647 acres of grassland in the Byron Hills area where practicable and/or in other appropriate locations (Environmental Commitment 3 and Resource Restoration and Performance Principle G10).
- Protect up to 188 acres and restore up to 48 acres of existing vernal pool/alkali seasonal wetlands complexes in the greater Byron Hills including associated grasslands (Environmental Commitments 3 and 9, and Resource Restoration and Performance Principle VP/AW1).
- Increase burrow availability for burrow-dependent species in grasslands including grasslands surrounding restored and protected vernal pool and alkali seasonal wetland complexes (Resource Restoration and Performance Principle VP/AW6).
- Increase prey abundance and accessibility, especially small mammals and insects, for grassland-foraging species in grasslands and within restored and protected vernal pool and alkali seasonal wetland complex (Resource Restoration and Performance Principle VP/AW7).

As explained below, with the restoration and protection of these amounts of habitat, in addition to the AMMs to reduce potential effects, impacts on San Joaquin kit fox and American badger would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-58. Changes in San Joaquin Kit Fox Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary

Environmental Commitments 4, 6–7, 9–11[a]	Modeled Habitat	4	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**262**	**68**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-162: Loss or Conversion of Habitat for and Direct Mortality of San Joaquin Kit Fox and American Badger

Alternative 4A conveyance facilities construction would result in the permanent and temporary loss combined of 330 acres of grassland habitat for the San Joaquin kit fox in the study area (Table 12-4A-58). Because American badger uses grasslands for denning and foraging and may occupy the same range as the San Joaquin kit fox in the project area, effects are anticipated to be the same as those described for San Joaquin kit fox. Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual activity discussions.

- *Water Facilities and Operation*: Construction of the conveyance facilities would result in the permanent loss of approximately 258 acres and the temporary loss of 68 acres of modeled San Joaquin kit fox and American badger habitat. This habitat is located in areas of naturalized grassland in a highly disturbed or modified setting on lands immediately adjacent to Clifton Court Forebay, in CZ 8. There are 3 San Joaquin kit fox and no American badger occurrences that overlap with the water conveyance facilities footprint.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Protection of up to 647 acres of grassland would benefit San Joaquin kit fox and American badger individuals present in the area. A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values on protected lands may result in localized ground disturbances that could temporarily remove small amounts of San Joaquin kit fox and American badger habitat near Clifton Court Forebay, in CZ 8. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, are expected to have minor effects on available habitat and are expected to result in overall improvements to and maintenance of San Joaquin kit fox and badger habitat values. However, management activities could result in injury or mortality of San Joaquin kit fox or American badger if individuals were present in work sites or if dens were located in the vicinity of habitat management work sites. *AMM24 San Joaquin Kit Fox* and Mitigation Measure BIO-162: *Conduct Preconstruction Survey for American Badger* would be implemented to ensure

that San Joaquin kit fox and American badger dens are avoided. AMM24 is described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*.

- Operations and maintenance: Ongoing maintenance of project facilities would be expected to have little if any adverse effect on San Joaquin kit fox or American badger. Postconstruction operations and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect either species' use of the surrounding habitat near Clifton Court Forebay, in CZ 8. Maintenance activities would include vegetation management, levee and structure repair, and regrading of roads and permanent work areas. These effects, however, would be minimized with implementation of AMM1–AMM6, AMM10, and AMM24 and with preconstruction surveys for the American badger, as required by Mitigation Measure BIO-162, *Conduct Preconstruction Survey for American Badger*.
- Injury and direct mortality: Construction vehicle activity may cause injury to or mortality of either species. If San Joaquin kit fox or American badger reside where activities take place (most likely in the vicinity of Clifton Court Forebay, in CZ 8), the operation of equipment for land clearing, construction, operations and maintenance, and restoration, enhancement, and management activities could result in injury to or mortality of either species. Measures would be implemented to avoid and minimize injury to or mortality of these species as described in AMM1–AMM6, AMM10, and AMM24 (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*) and Mitigation Measure BIO-162.

The following paragraphs summarize the combined effects discussed above and describe other Environmental Commitments and associated Resource Restoration and Performance Principles that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

There are 5,327 acres of modeled San Joaquin kit fox habitat in the study area. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 330 acres of associated grassland habitat for San Joaquin kit fox and potential habitat for American badger, representing 6% of the modeled habitat. These effects would result from construction of the water conveyance facilities (326 acres) and natural communities enhancement and management activities (4 acres).

With full implementation of Alternative 4A, up to 647 acres of grassland would be protected in areas where the San Joaquin kit fox and American badger are most likely to occur in the study area. In addition, San Joaquin kit fox and American badger would benefit from the protection of up to 188 acres and restoration of up to 48 acres of existing vernal pool/alkali seasonal wetlands complexes in the greater Byron Hills. Because San Joaquin kit fox home ranges are large (varying from approximately 1 to 12 square miles; see Appendix 2.A, *Covered Species Accounts*, of the BDCP), habitat connectivity is key to the conservation of the species. Grasslands would be acquired for protection in locations that provide connectivity to existing protected breeding habitats in CZ 8 and to other adjoining San Joaquin kit fox and American badger habitat within and adjacent to the project area. Connectivity to occupied habitat adjacent to the project area would help ensure the movement of San Joaquin kit foxes and American badger, if present, to larger habitat patches outside of the project area in Contra Costa County. Grassland protection would focus in particular on acquiring the largest remaining contiguous patches of unprotected grassland habitat, which are located south of SR 4 in CZ 8 (see Appendix 2.A, *Covered Species Accounts*, of the BDCP). This area connects to more than 620 acres of existing habitat that was protected under the East Contra Costa County HCP/NCCP.

Grasslands in CZ 8 would also be managed and enhanced to increase prey availability and to increase mammal burrows, which could benefit the San Joaquin kit fox and American badger by increasing potential den sites, which are a limiting factor for the San Joaquin kit fox in the northern portion of its range. These management and enhancement actions are expected to benefit the San Joaquin kit fox as well as the American badger by increasing the habitat value of the protected grasslands.

CZ 8 supports 74% of the modeled San Joaquin kit fox grassland habitat in the study area, and the remainder of habitat consists of fragmented, isolated patches that are unlikely to support this species. The project's commitment to protect the largest remaining contiguous habitat patches (including grasslands and the grassland component of alkali seasonal wetland and vernal pool complexes) in CZ 8 and to maintain connectivity with the remainder of the satellite population in Contra Costa County would sufficiently offset the impacts resulting from water conveyance facilities construction.

Typical NEPA and CEQA project-level mitigation ratio for the natural community that would be affected would be 2:1 for protection of grassland. Using this ratio would indicate that 660 acres of grassland should be protected for San Joaquin kit fox and American badger.

Alternative 4A also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM24 San Joaquin Kit Fox.* These AMMs contain elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS. Remaining effects would be addressed by implementation of Mitigation Measure BIO-162, *Conduct Preconstruction Survey for American Badger*.

NEPA Effects: In the absence of the proposed Environmental Commitments, the effects on San Joaquin kit fox and American badger habitat from Alternative 4A would represent an adverse effect as a result of habitat modification and potential direct mortality of special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles L2, VP/AW1, VP/AW6, VP/AW7, and G10 and guided by AMM1–AMM6, AMM10, and AMM24, which would be in place throughout the construction period and operations, and with implementation of Mitigation Measure BIO-162, the effects of Alternative 4A as a whole on San Joaquin kit fox and American badger would not be an adverse effect.

CEQA Conclusion: In the absence of the proposed Environmental Commitments, the effects on San Joaquin kit fox and American badger habitat from Alternative 4A would represent a significant impact as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles L2, VP/AW1, VP/AW6, VP/AW7, and G10, and guided by AMM1–AMM6, AMM10, and AMM24, which would be in place throughout the time period of construction and operations, and with implementation of Mitigation Measure BIO-162, the impact of Alternative 4A as a whole on San Joaquin kit fox and American badger would be less than significant.

Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger

A qualified biologist provided by DWR will survey for American badger concurrent with the preconstruction survey for San Joaquin kit fox and burrowing owl. If badgers are detected, the biologist will passively relocate badgers out of the work area prior to construction if feasible. If an active den is detected within the work area, DWR will establish a suitable buffer distance and avoid the den until the qualified biologist determines the den is no longer active. Dens that are determined to be inactive by the qualified biologist will be collapsed by hand to prevent occupation of the den between the time of the survey and construction activities. In addition, ground disturbance within project-related conservation areas within 50 feet of active American badger dens would be prohibited.Existing trails would be closed within 250 feet of active natal/pupping dens until young have vacated, and within 50 feet of other active dens. No dogs would be allowed on conservation areas with active American badger populations. Rodent control would be prohibited on areas with American badger populations to ensure rodent prey availability. Mitigation Measure BIO-162 is applicable to all ground-disturbing activities related to construction, restoration, and operations and maintenance.

Impact BIO-163: Indirect Effects of Alternative 4A on San Joaquin Kit Fox and American Badger

Noise and visual disturbances outside the project footprint but within 250 feet of construction activities could temporarily affect modeled San Joaquin kit fox habitat and potential American badger. Water conveyance facilities operations and maintenance activities would include vegetation and weed control, rodent control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. Rodent control would be prohibited in areas with San Joaquin kit fox or American badger populations to ensure rodent prey availability. While maintenance activities are not expected to remove San Joaquin kit fox and badger habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in injury or mortality of individual foxes and badgers, if present. Given the remote likelihood of active San Joaquin kit fox or badger dens in the vicinity of the conveyance facility, the potential for this effect is small and would further be minimized with the implementation of seasonal no-disturbance buffers around occupied dens, if any, and other measures as described in AMM1–AMM6, AMM10, AMM24, and Mitigation Measure BIO-162.

***NEPA Effects*:** Implementation of AMM1–AMM6, AMM10, and AMM24,and Mitigation Measure BIO-162 *Conduct Preconstruction Survey for American Badger*, would avoid the potential for substantial adverse effects on San Joaquin kit fox or American badger, either indirectly or through habitat modifications. These measures would also avoid and minimize effects that could substantially reduce the number of San Joaquin kit fox or American badger, or restrict either species' range. Therefore, the indirect effects of Alternative 4A would not have an adverse effect on San Joaquin kit fox or American badger.

***CEQA Conclusion*:** Indirect effects from Environmental Commitment operations and maintenance as well as construction-related noise and visual disturbances could impact San Joaquin kit fox and American badger. With implementation of AMM1–AMM6, AMM10, and AMM24 as part of Alternative 4A construction, operation, and maintenance, the project would avoid the potential for significant adverse effects on either species, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of either species.

In addition, Mitigation Measure BIO-162 as described above, would further reduce of the potential for indirect effects of Alternative 4A on American badger to a less-than-significant level.

Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger

Please see Mitigation Measure BIO-162 under Impact BIO-162.

San Joaquin Pocket Mouse

Habitat for San Joaquin pocket mouse consists of the grassland natural community throughout the study area. The species requires friable soils for burrowing. Alternative 4A would result in both temporary and permanent losses of San Joaquin pocket mouse habitat as indicated in Table 12-4A-59. Alternative 4A would also include the following Environmental Commitments and associated Resource Restoration and Performance Principles that would likely benefit San Joaquin pocket mouse.

- Protect up to 1,060 acres of grasslands (Environmental Commitment 3).
- Restore up to 1,070 acres of grasslands (Environmental Commitment 8).
- Sustain a mosaic of grassland vegetation alliances, reflecting localized water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical states (Resource Restoration and Performance Principle G3).

As explained below, with protection and management of this amounts of habitat, Alternative 4A's impacts on San Joaquin pocket mouse would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-59. Changes in San Joaquin Pocket Mouse Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Grassland	467	158
Total Impacts Water Conveyance Facilities		**467**	**158**
Environmental Commitments 4, 6–7, 9–11[a]	Grassland	61	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**61**	**0**
TOTAL IMPACTS		**528**	**158**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-164: Loss or Conversion of Habitat for and Direct Mortality of San Joaquin Pocket Mouse

Alternative 4A would result in the combined permanent and temporary loss of up to 686 acres of habitat for San Joaquin pocket mouse, of which 528 acres would be a permanent loss and 158 acres would be a temporary loss of habitat (Table 12-4A-59). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of RTM areas, and *Environmental Commitment 4 Tidal Natural Communities Restoration*. The majority of habitat loss would result from water conveyance facilities. Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities could degrade or eliminate San Joaquin pocket mouse habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation*: Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 625 acres of potential San Joaquin pocket mouse habitat (467 acres of permanent loss, 158 acres of temporary loss) in CZ 3–CZ 6 and CZ 8. The majority of grassland that would be removed would be in CZ 8, from the modifications to Clifton Court Forebay. Refer to the Terrestrial Biology Mapbook for a detailed view of Alternative 4A construction locations. Construction of the forebay would affect the area where there is a record of San Joaquin pocket mouse (California Department of Fish and Game 2012).
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Implementation would permanently inundate or remove an estimated 40 acres of potential San Joaquin pocket mouse habitat. The losses would occur in one or more of the ROAs established for tidal restoration (see Figure 12-1).
- *Environmental Commitment 6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in removal of small amounts of potential San Joaquin pocket mouse habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur along waterway margins where grassland habitat stringers exist, including along levees and channel banks. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: Environmental Commitment 7 would permanently remove an estimated 1 acre of potential San Joaquin pocket mouse habitat.
- *Environmental Commitment 11 Natural Communities Enhancement and Management:* The protection of up to 1,060 acres of grassland for wildlife species is expected to benefit San Joaquin pocket mouse by protecting existing habitats from potential loss or degradation that otherwise could occur with future changes in existing land use. Habitat management and enhancement-related activities could cause disturbance or direct mortality to San Joaquin pocket mouse if they are present near work areas.
- A variety of habitat management actions included in *Environmental Commitment 11 Natural Communities Enhancement and Management* that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of San Joaquin pocket mouse habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on habitat and would be expected to result in overall improvements to and maintenance of habitat values. Noise and visual disturbance from management-related equipment operation could temporarily displace individuals or alter the behavior of the species if adjacent to work areas. Alternative 4A enhancement and management actions designed for western burrowing owl would also be expected to benefit San Joaquin pocket mouse.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect San Joaquin pocket mouse use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and environmental commitments as described below.
- Injury and Direct Mortality: Construction could result in direct mortality of San Joaquin pocket mouse if present in construction areas.

The following paragraphs summarize the combined effects discussed above and describe other Environmental Commitments that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

The habitat model indicates that the study area supports approximately 78,047 acres of potential habitat for San Joaquin pocket mouse. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 686 acres of grasslands that could be suitable for San Joaquin pocket mouse (1% of the habitat in the study area). These effects would result from the construction of the water conveyance facilities. Alternative 4A includes a commitment to protect up to 1,060 acres of grassland (Environmental Commitment 3) and restore up to 1,070 acres of grassland (Environmental Commitment 8). Alternative 4A's commitment to sustain a mosaic of grassland vegetation alliances, reflecting localized water availability, soil chemistry, soil texture, topography, and disturbance regimes would protect a diversity of habitats that San Joaquin pocket mouse could use. All protected habitat would be managed under *Environmental Commitment 11 Natural Communities Enhancement and Management*.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by the project would be 2:1 protection of grassland habitat. Using these typical ratios would indicate that 1,372 acres of grassland natural communities should be protected to mitigate the loss of 686 acres of grassland.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containments and Countermeasure Plan, and AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and RTM storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: In the absence of the Environmental Commitments, the effects on San Joaquin pocket mouse habitat and potential mortality of a special-status species resulting from Alternative 4A would represent an adverse effect. However, project proponents have committed to habitat protection and management associated with Environmental Commitment 3 and Environmental Commitment 11. This habitat protection and management would be guided by Resource Restoration and Performance Principle G3, and by AMM1–AMM6 and AMM10, which would be in place during construction. Considering these commitments, losses of San Joaquin pocket mouse and potential mortality under Alternative 4A would not be an adverse effect.

CEQA Conclusion: Considering Alternative 4A's commitment to the protection and management of grasslands and with the implementation of Resource Restoration and Performance Principle G3 and AMM1–AMM6 and AMM10, the loss of habitat or direct mortality through implementation of Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of San Joaquin pocket mouse. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on San Joaquin pocket mouse under CEQA.

Impact BIO-165: Indirect Effects of Alternative 4A on San Joaquin Pocket Mouse

Construction activities associated with water conveyance facilities, Environmental Commitments, and ongoing habitat enhancement, as well as operations and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances and noise with localized effects on San Joaquin kit pocket mouse and its habitat. These potential effects would be minimized and avoided through AMM1–AMM6, and AMM10, which would be in effect throughout the construction phase.

Water conveyance facilities operations and maintenance activities would include vegetation and weed control, ground squirrel control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. While maintenance activities are not expected to remove pocket mouse habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in injury or mortality of individual pocket mice, if present.

NEPA Effects: Implementation of the AMMs listed above would avoid the potential for substantial adverse effects on San Joaquin pocket mouse, either indirectly or through habitat modifications. These measures would also avoid and minimize effects that could substantially reduce the number of San Joaquin pocket mouse, or restrict the species' range. Therefore, the indirect effects of Alternative 4A would not have an adverse effect on San Joaquin pocket mouse.

CEQA Conclusion: Indirect effects from Environmental Commitment operations and maintenance as well as construction-related noise and visual disturbances could impact San Joaquin pocket mouse. With implementation of AMM1–AMM6, and AMM10, as part of Alternative 4A construction, operation, and maintenance, Alternative 4A would avoid the potential for adverse effects on either species, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of the species. Therefore, the indirect effects under this alternative would have a less-than-significant impact on San Joaquin pocket mouse under CEQA.

Special-Status Bat Species

Special-status bat species with potential to occur in the study area employ varied roost strategies, from solitary roosting in foliage of trees to colonial roosting in trees and artificial structures, such as tunnels, buildings, and bridges. Various roost strategies could include night roosts, maternity roosts, migration stopover, or hibernation. The habitat types used to assess effects for special-status bats roosting habitat includes valley/foothill riparian natural community, developed lands and landscaped trees, including eucalyptus, palms and orchards. Potential foraging habitat includes all riparian habitat types, cultivated lands, developed lands, grasslands, and wetlands.

There is potential for at least thirteen different bat species to be present in the study area (Figure 12-51), including four California species of special concern and nine species ranked from low to moderate priority by the Western Bat Working Group (see Appendix 12A, *Special-Status Species with Potential to Occur in the Study Area*, Table 12A-2). In 2009, DHCCP conducted a large-scale effort that involved habitat assessments, bridge surveys, and passive acoustic monitoring surveys for bats (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*, for details on methods and results, and Table 12A-2 in Appendix 12A). The majority of the parcels assessed during field surveys contained bat foraging and roosting features and were considered highly suitable habitat. At the time of the 2009 field surveys, DWR biologists initially identified 145 bridges in their survey area. Eleven of the 145 bridges were not accessible and thirteen were determined to not be suitable for bats. Evidence of bat presence was observed at six of the bridges and bat sign (guano, urine staining, odor, or vocalizations) was observed at 26 of the bridges. Biologists observed Mexican free-tailed bats at four of the bridges and unidentified species at the remaining two bridges. One of these bridges, over the Yolo Causeway, was used by approximately 10,000 Mexican free-tailed bats, indicating a maternity roost. A second roost site of about 50 individuals was observed under a bridge in eastern Solano County.

The remaining 89 bridges contained structural features that were considered conducive to maternity, solitary, day and/or night roosting. Night roosts may have crevices and cracks but more often have box beams or other less protected roosting spots where bats rest temporarily while feeding. Day roosts are commonly found in bridges with expansion joints, crevices, or cracks where bats are protected from predators and weather. Seventeen bridges in the survey area had no potential for roosting because they lacked surface features from which bats could hang and offered no protection from weather or predators.

Alternative 4A would result in both temporary and permanent losses of foraging and roosting habitat for special-status bats as indicated in Table 12-4A-60. Protection and restoration for special-status bat species focuses on habitats and does not include manmade structures such as bridges. Alternative 4A would include the following conservation and Resource Restoration and Performance Principles to benefit special-status bats.

- Protect up to 13,302 acres and restore up to 2,496 acres of high-value natural communities. This objective involves protecting and restoring a variety of habitat types described below that would also benefit special-status bats (see Table 3-9 in Chapter 3, *Description of Alternatives*).
- Protect up to 1,060 acres and restore up to 1,070 acres of grassland (Environmental Commitment 3 and Environmental Commitment 8).
- Restore grasslands to connect fragmented patches of protected grassland and to provide upland habitat (Resource Restoration and Performance Principal G1).
- Restore and sustain a mosaic of grassland vegetation alliances, reflecting localized water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical states (Resource Restoration and Performance Principal G3).
- Increase the extent, distribution, and density of native perennial grasses intermingled with other native species, including annual grasses, geophytes, and other forbs (Resource Restoration and Performance Principal G4).
- Protect up to 11,870 acres of cultivated lands (Environmental Commitment 3).

- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the conservation area, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Resource Restoration and Performance Principal CL1).
- Target cultivated land conservation to provide connectivity between other conservation lands wetlands (Resource Restoration and Performance Principal CL2).
- Restore up to 48 acres and protect up to 188 acres of vernal pool/alkali seasonal wetland complex (Environmental Commitment 3 and Environmental Commitment 9).
- Protect up to 119 acres and restore up to 832 acres of nontidal marsh (Environmental Commitment 3 and Environmental Commitment 10).
- Protect up to 6 acres of ponds (Resource Restoration and Performance Principle G2).
- Restore up to 295 acres of tidal natural communities (Environmental Commitment 4).
- Restore up to 251 acres and protect up to 103 acres of valley/foothill riparian natural community (Environmental Commitment 3 and Environmental Commitment 7).

As explained below, with the restoration and protection of these amounts of habitat, in addition to mitigation measures to reduce potential effects, impacts on special-status bats would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-60. Changes in Special-Status Bat Roosting and Foraging Habitat Associated with Alternative 4A

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Roosting	64	200
	Foraging	4,496	3,459

TOTAL IMPACTS		**4,565**	**3,659**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-166: Loss or Conversion of Habitat for and Direct Mortality of Special-Status Bats

Alternative 4A would result in the permanent and temporary loss combined of up to 264 acres of roosting habitat and 8,224 acres of foraging habitat for special-status bats from water conveyance facilities construction and from tidal restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11) could result in local adverse effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other project facilities could affect special-status bat roosting habitat. A summary of combined impacts and NEPA effects and a CEQA conclusion follows the individual activity discussions.

- *Water Facilities and Operation*: Construction of Alternative 4A conveyance facilities would result in the permanent loss of approximately 64 acres of roosting habitat and 4,496 acres of foraging habitat in the study area. Development of the water conveyance facilities would also result in the temporary removal of up to 200 acres of roosting habitat and up to 3,459 acres of foraging habitat for special-status bats in the study area (Table 12-4A-60). DWR identified two bridges with potential night roosting habitat in the forebay embankment area and tunnel muck area that could be permanently affected by construction for water conveyance facilities. Additional roosting habitat affected by construction and operations includes valley/foothill riparian natural community, developed lands and landscaped trees, including eucalyptus, palms and orchards.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would result in the loss of approximately 5 acres of roosting habitat. The roosting habitat that would be removed consists of relatively small and isolated patches along canals and irrigation ditches surrounded by cultivated lands in the Union Island and Roberts Island areas, and several small patches along the San Joaquin River. Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, requires that tidal natural communities restoration avoid effects on roosting special-status bats.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Implementation of Alternative 4A would result in an overall benefit to special-status bats within the study area through protection and restoration of their foraging and roosting habitats. The majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands. Restored foraging habitats primarily would replace agricultural lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats. Noise and visual disturbances during implementation of riparian habitat management actions could result in temporary disturbances that, if bat roost sites are present, could cause temporary abandonment of roosts. This effect would be minimized with implementation of Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*.
- Operations and maintenance: Ongoing facilities operation and maintenance is expected to have little if any adverse effect on special-status bats. Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect special-status bat use of the surrounding habitat in the Cache Slough area, and the north and south Delta (CZ 1, CZ 2, CZ 4, CZ 5, CZ 6, CZ 7, and CZ 8). Maintenance activities would include vegetation management, levee and structure repair, and regrading of roads and permanent work areas. These effects, however, would be minimized with implementation of the mitigation measures described below.
- Injury and direct mortality: In addition, to habitat loss and conversion, construction activities, such as grading, the movement of construction vehicles or heavy equipment, and the installation of water conveyance facilities components and new transmission lines, may result in the direct mortality, injury, or harassment of roosting special-status bats. Construction activities related to the Environmental Commitments could have similar affects. Preconstruction surveys would be conducted and if roosting or maternity sites are detected, seasonal restrictions would be placed while bats are present, as described below in the mitigation measures.

The following paragraphs summarize the combined effects discussed above and describe other Alternative 4A activities that offset or avoid these effects. NEPA effects and CEQA conclusions are also included.

Because the majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands this analysis focuses only on losses to roosting habitat resulting from water conveyance facilities and Environmental Commitment 4.

Alternative 4A would permanently or temporarily affect 269 acres of roosting habitat for special-status bats as a result of implementing water conveyance facilities (264 acres roosting habitat) and Environmental Commitment 4 (5 acres roosting habitat). Only 72 acres of the 269 acres of roosting habitat losses would be in valley/foothill riparian habitat Alternative 4A would restore up to 251 acres and protect up to 103 acres of valley/foothill riparian roosting habitat and 15,798 acres of additional foraging habitat in natural communities and developed lands. Restored foraging habitats would replace primarily cultivated lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats.

Implementation of Alternative 4A would result in an overall benefit to special-status bats within the study area through protection and restoration of approximately 15,798 acres of their foraging and roosting habitats. The target for total protected and restored acreage is based on the sum of all natural community acreage targets. Achieving this is intended to protect and restore natural communities, species-specific habitat elements, and species diversity on a landscape-scale. Achieving this is also intended to conserve representative natural and seminatural landscapes in order to maintain the ecological integrity of large habitat blocks, including desired ecosystem function, and biological diversity.

Should any of the special-status bat species be detected roosting in the study area, construction of water conveyance facilities and restoration activities would have an adverse effect on roosting special-status bats. Noise and visual disturbances and the potential for injury or mortality of individuals associated within implementation of the restoration activities on active roosts would be minimized with implementation of Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*. Environmental commitments would sufficiently offset the adverse effects resulting from effects from water conveyance facilities and Environmental Commitment 4.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected for roosting habitat would be 1:1 for restoration and protection of the valley/foothill riparian natural community. Using these ratios would indicate that 72 acres of riparian habitat should be restored and 72 acres of riparian habitat should be protected.

The project also contains commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities.* These AMMs include elements that avoid or minimize the risk of construction activity affecting habitat and species adjacent to work areas and storage sites. BDCP

Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EISS.

***NEPA Effects*:** The losses of roosting and foraging habitat for special-status bats associated with implementing Alternative 4A are not expected to result in substantial adverse effects on special-status bats, either directly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of special-status bats because the project proponents have committed to protecting the acreage required to meet the typical mitigation ratios described above. The losses of roosting and foraging habitat for special-status bats, in the absence of the Environmental Commitments, would represent an adverse effect as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection and restoration associated with the Environmental Commitments and Resource Restoration and Performance Principles, the implementation of AMM1–AMM6, and AMM10, and with implementation of Mitigation Measure BIO-166, the effects of Alternative 4A as a whole on special-status bats would not be adverse.

***CEQA Conclusion*:** The permanent loss of roosting habitat from Alternative 4A would be mitigated through implementation of Mitigation Measure BIO-166, which would ensure there is no significant impact under CEQA on roosting special-status bats, either directly or through habitat modifications and no substantial reduction in numbers or a restriction in the range of special-status bats. The project also contains commitments to implement habitat protection and restoration associated with the Environmental Commitments and Resource Restoration and Performance Principles,and AMM1–6 and AMM10, which would offset the loss of foraging habitat. These AMMs include elements that avoid or minimize the risk of project activities affecting habitat and species adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures

The following measure was designed to avoid and minimize adverse direct and indirect effects on special-status bats. However, baseline data are not available or are limited on how bats use the study area, and on individual numbers of bats and how they vary seasonally. Therefore, it is difficult to determine if there would be a substantial reduction in species numbers. Bat species with potential to occur in the study area employ varied roost strategies, from solitary roosting in foliage of trees to colonial roosting in trees and artificial structures, such as buildings and bridges. Daily and seasonal variations in habitat use are common. To obtain the highest likelihood of detection, preconstruction bat surveys will be conducted by DWR and will include these components.

- Identification of potential roosting habitat within project footprint.
- Daytime search for bats and bat sign in and around identified habitat.
- Evening emergence surveys at potential day-roost sites, using night-vision goggles and/or active full-spectrum acoustic monitoring where species identification is sought.
- Passive full-spectrum acoustic monitoring and analysis to detect bat use of the area from dusk to dawn over multiple nights.

- Additional on-site night surveys as needed following passive acoustic detection of special status bats to determine nature of bat use of the structure in question (e.g., use of structure as night roost between foraging bouts).
- Qualified biologists will have knowledge of the natural history of the species that could occur in the study area and experience using full-spectrum acoustic equipment. During surveys, biologists will avoid unnecessary disturbance of occupied roosts.

Preconstruction Bridges and Other Structure Surveys

Before work begins on the bridge/structure, qualified biologists will conduct a daytime search for bat sign and evening emergence surveys to determine if the bridge/structure is being used as a roost. Biologists conducting daytime surveys would listen for audible bat calls and would use naked eye, binoculars, and a high-powered spotlight to inspect expansion joints, weep holes, and other bridge features that could house bats. Bridge surfaces and the ground around the bridge/structure would be surveyed for bat sign, such as guano, staining, and prey remains.

Evening emergence surveys will consist of at least one biologist stationed on each side of the bridge/structure watching for emerging bats from a half hour before sunset to 1–2 hours after sunset for a minimum of two nights within the season that construction would be taking place. Night-vision goggles and/or full-spectrum acoustic detectors shall be used during emergence surveys to assist in species identification. All emergence surveys would be conducted during favorable weather conditions (calm nights with temperatures conducive to bat activity and no precipitation predicted).

Additionally, passive monitoring with full-spectrum bat detectors will be used to assist in determining species present. A minimum of four nights of acoustic monitoring surveys will be conducted within the season that the construction would be taking place. If site security allows, detectors should be set to record bat calls for the duration of each night. To the extent possible, all monitoring will be conducted during favorable weather conditions (calm nights with temperatures conducive to bat activity and no precipitation predicted). The biologists will analyze the bat call data using appropriate software and prepare a report with the results of the surveys. If acoustic data suggest that bats may be using the bridge/structure as a night roost, biologists will conduct a night survey from 1–2 hours past sunset up to 6 hours past sunset to determine if the bridge is serving as a colonial night roost.

If suitable roost structures would be removed, additional surveys may be required to determine how the structure is used by bats, whether it is as a night roost, maternity roosts, migration stopover, or for hibernation.

Preconstruction Tree Surveys

If tree removal or trimming is necessary, qualified biologists will examine trees to be removed or trimmed for suitable bat roosting habitat. High-value habitat features (large tree cavities, basal hollows, loose or peeling bark, larger snags, palm trees with intact thatch, etc.) will be identified and the area around these features searched for bats and bat sign (guano, culled insect parts, staining, etc.). Riparian woodland, orchards, and stands of mature broadleaf trees should be considered potential habitat for solitary foliage roosting bat species.

If bat sign is detected, biologists will conduct evening visual emergence survey of the source habitat feature, from a half hour before sunset to 1–2 hours after sunset for a minimum of two nights within the season that construction would be taking place. Methodology should follow that described above for the bridge emergence survey.

Additionally, if suitable tree roosting habitat is present, acoustic monitoring with a bat detector will be used to assist in determining species present. These surveys would be conducted in coordination with the acoustic monitoring conducted for the bridge/structure.

Protective Measures for Bats using Bridges/Structures and Trees

Avoidance and minimization measures shall be necessary if it is determined that bats are using the bridge/structure or trees as roost sites and/or sensitive bats species are detected during acoustic monitoring. Appropriate measures will be determined by DWR in consultation with CDFW and shall include, as applicable, the measures listed below.

- Ensure that bats are protected from noise, vibrations, and light that result from construction activities associated with water conveyance facilities, conservation components and ongoing habitat enhancement, as well as operations and maintenance of above-ground water conveyance facilities, including the transmission facilities. This would be accomplished by either directing noise barriers and lights inward from the disturbance or ensuring that the disturbances do not extend more than 300 feet from the point source.
- Disturbance of the bridge will be avoided between March 1 and October 31 (the maternity period) to avoid impacts on reproductively active females and dependent young.
- Installation of exclusion devices from March through October 31 to preclude bats from occupying the bridge during construction. Exclusionary devices will only be installed by or under the supervision of an experienced bat biologist.
- Tree removal will be avoided between April 15 and September 15 (the maternity period for bat species that use trees) to avoid impacts on pregnant females and active maternity roosts (whether colonial or solitary).
- Tree removal will be conducted between September 15 and October 31 to the maximum extent feasible, which corresponds to a time period when bats would not likely have entered winter hibernation and would not be caring for flightless young. If weather conditions remain conducive to regular bat activity beyond October 31, later tree removal may be considered in consultation with CDFW.
- Trees will be removed in pieces, rather than felling the entire tree.
- If a maternity roost is located, whether solitary or colonial, that roost will remain undisturbed with a buffer as determined in consultation with CDFW until September 15 or until a qualified biologist has determined the roost is no longer active.
- If a non-maternity roost is found, that roost will be avoided to the maximum extent feasible and an appropriate buffer established in consultation with CDFW. Every effort would be made to avoid the roost to the maximum extent feasible, as methods to evict bats from trees are largely untested. However, if the roost cannot be avoided, eviction would be attempted and procedures designed in consultation with CDFW to reduce the likelihood of mortality of evicted bats. In all cases:

- Eviction will not occur before September 15th and will match the timeframe for tree removal approved by CDFW.
- Qualified biologists will carry out or oversee the eviction tasks and monitor the tree trimming/removal.
- Eviction will take place late in the day or in the evening to reduce the likelihood of evicted bats falling prey to diurnal predators.
- Eviction will take place during weather and temperature conditions conducive to bat activity.
- Special-status bat roosts would not be disturbed.

Eviction procedures shall include but are not limited to:

- Pre-eviction surveys to obtain data to inform the eviction approach and subsequent mitigation requirements. Relevant data may include the species, sex, reproductive status and/or number of bats using the roost, and roost conditions themselves such as temperature and dimensions. Surveys may include visual emergence, night vision, acoustic, and/or capture.
- Structural changes may be made to the roost, performed without harming bats, such that the conditions in the roost are undesirable to roosting bats and the bats leave on their own (e.g., open additional portals so that temperature, wind, light and precipitation regime in the roost change).
- Noninjurious harassment at the roost site to encourage bats to leave on their own, such as ultrasound deterrents or other sensory irritants.

- Prior to removal/trimming, after other eviction efforts have been attempted, any confirmed roost tree would be shaken, repeatedly struck with a heavy implement such as an axe and several minutes should pass before felling trees or trimming limbs to allow bats time to arouse and leave the tree. The biologists should search downed vegetation for dead and injured bats. The presence of dead or injured bats would be reported to CDFW.

Compensatory mitigation at a 1:1 ratio for the loss of roosting habitat would be accomplished by the restoration of up to 251 acres and protection of up to 103 acres of valley/foothill riparian habitat. Compensation may include the construction and installation of suitable replacement roosting habitat onsite as described below. Depending on the species and type of roost lost, various roost replacement habitats have met with some success (e.g., bat houses, “bat bark,” planting cottonwood trees, leaving palm thatch in place rather than trimming). The creation of natural habitat onsite is generally preferable to artificial.

Artificial roosts are often unsuccessful, and care must be taken to determine as closely as possible the conditions in the natural roost to be replaced. Even with such care, artificial habitat may fail. Several artificial roosts have been highly successful in replacing bridge roost habitat when incorporated into new bridge designs. “Bat bark” has been successfully used by Arizona Department of Game and Fish to create artificial crevice-roosting bat habitat mounted on pine trees (Mering and Chambers 2012: 765). Bat houses have at best an inconsistent track record but information is mounting on how to create successful houses. There is no single protocol or recipe for bat-house success. Careful study of the roost requirements of the species in question; the particular conditions at the lost roost site including temperature, orientation of the openings, airflow, internal dimensions and structures (cavity vs. crevice, etc.) should increase the chances of designing a successful replacement.

Restoring riparian woodland with plantings shows signs of success in Colorado. Western red bat activity has been positively correlated with increased vegetation and tree growth, canopy complexity and restoration acreage at cottonwood-willow restoration sites along the Lower Colorado River (Broderick 2012: 39). These complex woodland areas would ultimately provide a wider range of bat species with preferred roost types, including both foliage-roosting and crevice-/cavity-roosting bats.

Impact BIO-167: Indirect Effects of Alternative 4A on Special-Status Bats

Construction activities associated with water conveyance facilities, restoration activities, and ongoing habitat enhancement, as well as operations and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic disturbances from light, vibrations, and noise with localized effects on special-status bats and their roosting habitat.

Water conveyance facilities operations and maintenance activities would include vegetation and weed control, ground squirrel control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. While maintenance activities are not expected to remove special-status bat habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in disturbances to roosting bats, if present. Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, is available to address these adverse effects.

Increased exposure to methylmercury associated with tidal natural communities restoration would potentially indirectly affect special-status bat species. *Environmental Commitment 12 Methylmercury Management* describes the process by which tidal natural communities restoration may increase methyl mercury levels in wetlands in the study area. Mercury has been found in high concentrations in some bat species, such as the Indiana bat. Many bat species forage heavily on aquatic insects, which might result in rapid bioaccumulation (Evers et al. 2012). Measures described in *Environmental Commitment 12 Methylmercury Management* are expected to reduce the effects of methylmercury on special-status bat species resulting from tidal natural communities restoration.

***NEPA Effects*:** Implementation of the Mitigation Measure BIO-166 for special-status bats would avoid the potential for substantial adverse effects on roosting special-status bats, either indirectly or through habitat modifications. This mitigation measure and *Environmental Commitment 12 Methylmercury Management* would also avoid and minimize effects that could substantially reduce the number of special-status bats, or restrict species' range. Therefore, the indirect effects of Alternative 4A would not have an adverse effect on special-status bats.

***CEQA Conclusion*:** Indirect effects from Environmental Commitments, operations and maintenance as well as construction-related noise and visual disturbances could have a significant impact on special-status bat species, either indirectly or through habitat modifications. Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, and *Environmental Commitment 12 Methylmercury Management* would reduce this impact to a less-than-significant level by reducing the likelihood for impacts to occur to roosting bats and would ensure Alternative 4A would not result in a substantial reduction in numbers or a restriction in the range of species.

Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures

See Mitigation Measure BIO-166 under Impact BIO-166.

Impact BIO-168: Periodic Effects of Inundation of Special-Status Bat Habitat as a Result of Implementation of Alternative 4A

There would be no periodic effects of inundation on special-status bats or their habitat.

***NEPA Effects*:** No effects.

***CEQA Conclusion*:** No impacts.

Plant Species

Vernal Pool Species

Seventeen special-status plant species occur in vernal pools in the study area (Tables 12-2 and 12-3, summarized in Table 12-4A-61). The vernal pool habitat model used for the impact analysis on vernal pool species was developed for the BDCP and was based on vegetation types and associations from various data sets. The model was used to create maps showing the distribution of vernal pool habitat in the study area according to three habitat types in which these species are known to occur, including vernal pool complex, degraded vernal pool complex, and alkali seasonal wetland habitat. Vernal pool complex habitat consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Degraded vernal pool complex habitat consists of habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, discing, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. Because wetlands in the degraded vernal pool complex are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or small populations of species that are found in vernal pools and swales. However, they do not possess the full complement of ecosystem and community characteristics of natural vernal pools, swales and their associated uplands and they are generally ephemeral features that are eliminated during the course of normal agricultural practices. A small amount of alkali seasonal wetland habitat was included in the model because alkaline vernal pools are also present in some areas mapped as alkali seasonal wetland.

Because each of the vernal pool species addressed in this EIR/EIS have specific microhabitat affinities, and because vernal pool habitat within the study area is highly heterogeneous with respect to habitat parameters such as soil type and pool depth, the vernal pool habitat model greatly overestimates the extent of habitat in the study area occupied by each species. However, the vernal pool habitat model is likely to encompass all or most of the potential area within which special-status vernal pool plant species would occur. Therefore, it is not likely to underestimate the extent of occupied habitat or to underestimate the effects of Alternative 4A.

Full implementation of Alternative 4A and compliance with Resource Restoration and Performance Principle VPS1 would include the following conservation commitment to benefit special-status vernal pool plant species

- Protect at least two currently unprotected occurrences of alkali milk-vetch in the Altamont Hills or Jepson Prairie core recovery areas (Resource Restoration and Performance Principle VPS1).

The construction activities proposed under Alternative 4A could have impacts on special-status vernal pool plant species. Modeled habitat is within the proposed footprint for the Alternative 4A water conveyance facilities. One known occurrence of a special-status plant species is within the proposed footprint for the Alternative 4A water conveyance facilities. Table 12-4A-61 summarizes the acreage of modeled vernal pool habitat in the study area and the number of occurrences of each special-status vernal pool species in the study area.

1 **Table 12-4A-61. Summary of Impacts on Vernal Pool Plant Species under Alternative 4A**

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Vernal pool complex	9,557	29	–	–	Potential habitat loss from construction of the water conveyance facilities and tidal wetland restoration
Degraded vernal pool complex	2,576	17	–	–	Potential habitat loss from construction of the water conveyance facilities and tidal wetland restoration
Alkali Seasonal Wetland	188	2	–	–	Potential habitat loss from construction of the water conveyance facilities and tidal wetland restoration
Total	12,321	49	–	–	Potential habitat loss from construction of the water conveyance facilities and tidal wetland restoration
Species					
Alkali milk-vetch	–	–	16	1	Population loss from construction of the water conveyance facilities
Dwarf downingia	–	–	12	0	None
Boggs Lake hedge-hyssop	–	–	1	0	None
Legenere	–	–	8	0	None
Heckard's peppergrass	–	–	4[a]	0	None
Ferris' milk-vetch	–	–	6	0	None
Vernal pool smallscale	–	–	2	0	None
Hogwallow starfish	–	–	0	0	None
Ferris' goldfields	–	–	4	0	None
Contra Costa goldfields	–	–	7	0	None
Cotula-leaf navarretia	–	–	5	0	None
Baker's navarretia	–	–	3	0	None
Colusa grass	–	–	1	0	None
Bearded popcorn-flower	–	–	4	0	None
Delta woolly marbles	–	–	3	0	None
Saline clover	–	–	9	0	None
Solano grass	–	–	1	0	None

[a] One additional occurrence is in alkali seasonal wetlands.

2

Impact BIO-169: Effects on Habitat and Populations of Vernal Pool Plants

Under Alternative 4A, construction of the water conveyance facilities would affect habitat for special-status vernal pool species and one occurrence of a special-status vernal pool species.

- *Water Facilities and Operations*: Twenty-three acres of modeled vernal pool habitat, 19.4 acres of critical habitat for Contra Costa goldfields, and one known occurrence of the 17 vernal pool species are within the proposed footprint for the Alternative 4A water conveyance facilities. One occurrence of alkali milk-vetch in CZ 8 would be crossed by an electric transmission line. Under Alternative 4A, construction and operation of the water conveyance facilities could affect undiscovered occurrences of the seventeen special-status plant species.
- The east-west transmission line would not affect four special-status vernal pool species that occur in the study area. One occurrence each of dwarf downingia, legenere, Heckard's peppergrass, and Boggs Lake hedge-hyssop are within the east-west transmission line study area. However, the transmission line would not cross any of the occurrences.
- *Environmental Commitment 3 Natural Communities Protection and Restoration*: Alternative 4A proposes to benefit special-status vernal pool plants by protecting 188 acres of vernal pool complex and alkali seasonal wetland complex. The protected vernal pool habitat would be managed and enhanced to sustain populations of native vernal pool species.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration is estimated to result in the inundation of 26 acres of modeled habitat for vernal pool species and could, therefore, potentially affect special-status vernal pool plants. However, under this Environmental Commitment, no tidal habitat restoration would be implemented in habitat for special-status plant species. No known occurrences of special-status vernal pool species would be affected by tidal restoration.
- *Environmental Commitment 6 Channel Margin Enhancement*: No vernal pool habitat or occurrences of special-status vernal pool plant species are present within the general areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on special-status vernal pool species.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: No vernal pool habitat or occurrences of special-status vernal pool plant species are present within the general areas proposed for riparian habitat enhancement. Therefore, riparian habitat enhancement would have no impacts on special-status vernal pool species.
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: If, through unforeseen circumstances, construction of the water conveyance facilities results in the net loss of vernal pool habitat, environmental commitments would be implemented to compensate for that loss. Because vernal pool complex restoration would focus on habitat that had been cleared and leveled but maintained an intact duripan or claypan, the likelihood of affecting any special-status vernal pool plant species would be low. However, vernal pool restoration could adversely affect remnant populations of special-status vernal pool species or affect vernal pool habitat adjacent to the restoration areas.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid vernal pool habitat and would have no impacts on special-status vernal pool plant species.

- *Avoidance and Minimization Measures*: Effects on special-status vernal pool plant species potentially resulting from implementation of Alternative 4A would be avoided or minimized though *AMM11 Covered Plant Species*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM12 Vernal Pool Crustaceans, and AMM30 Transmission Line Design and Alignment Guidelines.* AMM11 prohibits ground disturbance or hydrologic disturbance within 250 feet of existing vernal pools. In addition, AMM11 specifies that individual projects be designed to avoid critical habitat for listed plant and wildlife vernal pool species. AMM12 limits the direct removal of vernal pool crustacean habitat to no more than 10 wetted acres and the indirect effect to no more than 20 wetted acres. AMM12 also requires that that tidal natural communities restoration or other ground-disturbing project activities in Conservation Zones 1 and 11 not result in the adverse modification of primary constituent elements of critical habitat for vernal pool fairy shrimp, conservancy fairy shrimp, and vernal pool tadpole shrimp. These protections would also apply to critical habitat for Contra Costa goldfields, where it overlaps with critical habitat for these vernal pool crustaceans. AMM30 specifies that the alignment of proposed transmission lines will be designed to avoid sensitive terrestrial and aquatic habitats when siting poles and towers, to the maximum extent feasible. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

In addition, Environmental Commitment 3 includes Resource Restoration and Performance Principle VPS1 to protect two occurrences of alkali milk-vetch.

In summary, no adverse effects on special-status vernal pool plants would be expected from implementing Alternative 4A. Construction of the water conveyance facilities could affect one species, alkali milk-vetch, although adverse effects on this species would be avoided or minimized though implementation of AMM11 and AMM30. No other known occurrences of special-status vernal pool species would be affected under Alternative 4A. Beneficial effects on special-status vernal pool plants could occur by protecting 188 acres of vernal pool complex and by protecting occurrences of alkali milk-vetch.

The GIS analysis estimated that up to 49 acres of vernal pool habitat could be adversely affected by proposed activities. Under *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration,* up to 49 acres of vernal habitat would be restored to compensate for the loss. However, the actual effect on habitat for special-status vernal pool plant species is expected to be much less than the estimated impact because Alternative 4A limits the total loss of wetted vernal pool habitat resulting from specific projects to 10 acres (approximately 67 acres of vernal pool complex) (AMM12). At the proposed restoration ratios of 1:1 (prior to impact) and 1.5:1 (concurrent with impact), between 49 and 73.5 acres of vernal pool complex restoration would be required to compensate for the loss of modeled habitat for special-status vernal pool plants. This would be consistent with typical NEPA and CEQA project-level mitigation ratios for vernal pool impacts.

NEPA Effects: The loss of modeled habitat for vernal pool plant species would be minimized by AMM12 and offset through the environmental commitments, and effects of constructing the water conveyance facilities on one occurrence of alkali milk-vetch would be avoided through AMM30. Therefore, Alternative 4A would not result in adverse effects on federally listed vernal pool plant species.

CEQA Conclusion: Because loss of modeled habitat for vernal pool plant species would be offset through restoration, and because impacts on occurrences of special-status vernal pool plant species would be avoided, implementation of Alternative 4A would not result in a reduction in the range or numbers of 17 special-status vernal pool plant species in the study area. Therefore, impacts on special-status vernal pool plant species would be less than significant. No mitigation is required.

Alkali Seasonal Wetland Species

Eight special-status plant species occur in alkali seasonal wetlands in the study area (Tables 12-2, 12-3, summarized in Table 12-4A-62). Alkali seasonal wetland habitat was modeled separately for four plant species occurring in seasonal alkali wetlands. Because this analysis relies on the data developed for the BDCP, models were only available for species covered under the BDCP. Habitat models were not developed for the four alkali seasonal wetland species not proposed for coverage under the BDCP.

The San Joaquin spearscale habitat model approximated the distribution of suitable San Joaquin spearscale habitat in the study area according to the species' preferred habitat types, intersected with soil series and slope position. Historical and current records of San Joaquin spearscale in the study area indicate that its current distribution is limited to alkaline soil areas with shallow basin or swale microtopography along the western border of the study area. The vegetation cover of the alkaline soils is typically a combination of alkaline soil-adapted species and annual grasses, including annual ryegrass and Mediterranean barley. Habitat types used for the model included alkali seasonal wetlands, vernal pool complex, and grasslands. Soil series used in the model consisted of either clays or clay loams with alkaline horizons. San Joaquin spearscale typically occurs in swales or in level terrain but occasionally occurs on the lower slopes adjacent to streams or swales or where seeps are present. Because some of the soil series with which San Joaquin spearscale is associated can occur on hillsides, slope was used to limit the extent of the model to the toe of the slope where these soils occur by excluding areas with slope greater than 1%. Land uses that are incompatible with the species' habitat requirements, such as modeled habitat polygons falling on leveled or developed lands, were removed from the model.

Modeled habitat for brittlescale was mapped as hydrologic features such as stream corridors and playa pools located on alluvium associated with the Montezuma Block along the western boundary of the study area or on alluvium associated with tertiary formations located along the southwest boundary of the study area. Stream corridors (intermittent and perennial) that intersected these geologic units were selected and truncated at the point at which they encountered the upper elevation of intertidal marsh. The corridors were buffered 50 feet (15.2 meters) on either side of their centerlines to capture the estimated maximum extent of alluvium deposits in proximity to the streams. Mapped habitat that was occupied by urban or intensive agricultural uses was removed from the model.

The habitat model for heartscale was based on the species distribution in the study area (Solano and Yolo Counties) and on the soil types and plant communities within which it occurs. Potential habitat was determined by intersecting the GIS coverage for three parameters: 1) Yolo and Solano County boundaries; 2) Solano, Pescadero, and Willows soils; and 3) grassland, alkali seasonal wetland, and vernal pool complex natural communities. The model excluded areas that have been developed or cultivated, i.e., where the topography, soils, and hydrology have been substantially altered.

Delta button-celery habitat was modeled as alkali seasonal wetland complex, vernal pool complex, other natural seasonal wetland, and grassland occurring on Brentwood, Grangerville, Marcuse, Solano, and Vernalis soil map units within the San Joaquin Basin (i.e., south of the mainstem San Joaquin River). For this species, land cover north of the Discovery Bay area where intensive agriculture was classified as annual grassland were manually deleted from the area of predicted habitat. Additionally, other areas of potential habitat that have been developed were also manually deleted.

Full implementation of Alternative 4A and compliance with Resource Restoration and Performance Principle ASWS1 would include Environmental Commitments to benefit special-status alkali seasonal wetland species.

- Protect two currently unprotected occurrences of San Joaquin spearscale in Conservation Zones 1, 8, or 11 (Resource Restoration and Performance Principle ASWS1).

Modeled habitat for Delta button-celery would be adversely affected by construction of the Alternative 4A water conveyance facilities. One population of crownscale also would be adversely affected by construction of the water conveyance facilities. No adverse effects on palmate-bracted bird's-beak or recurved larkspur would be expected. Table 12-4A-62 summarizes the acreage of modeled alkali seasonal wetland habitat in the study area and the number of occurrences of each special-status alkali seasonal wetland plant species in the study area.

Table 12-4A-62. Summary of Impacts on Seasonal Alkali Wetland Plant Species under Alternative 4A

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
San Joaquin spearscale modeled habitat	14,933	96	–	–	Potential habitat loss from construction of water conveyance facilities and tidal wetlands restoration
Brittlescale modeled habitat	451	1	–	–	Potential habitat loss from tidal wetlands restoration
Heartscale modeled habitat	6,528	14	–	–	Potential habitat loss from tidal wetlands restoration
Delta button-celery modeled habitat	3,361[a]	97	–	–	Habitat loss from construction of water conveyance facilities
Alkali seasonal wetlands	3,723	2	–	–	Potential habitat loss from construction of water conveyance facilities and tidal wetlands restoration
Species					
San Joaquin spearscale	–	–	19	1	Population loss from construction of water conveyance facilities
Brittlescale	–	–	8	0	None
Heartscale	–	–	3	0	None
Delta button-celery	–	–	1[b]	0	None
Heckard's peppergrass	–	–	1[c]	0	
Crownscale	–	–	17	1	Population loss from construction of water conveyance facilities
Palmate-bracted bird's-beak	–	–	1	0	None
Recurved larkspur	–	–	4	0	None

[a] A portion of this acreage consists of riparian habitat.
[b] A second occurrence in study area is in riparian habitat.
[c] Four additional occurrences of Heckard's peppergrass are associated with vernal pools.

Impact BIO-170: Effects on Habitat and Populations of Alkali Seasonal Wetland Plants

Alternative 4A would have potential adverse effects on modeled habitat for San Joaquin spearscale, brittlescale, heartscale, and Delta button-celery. It would also have adverse effects on occurrences of San Joaquin spearscale and crownscale. Under Alternative 4A, construction of the Clifton Court Forebay would permanently remove 75 acres of modeled habitat for San Joaquin spearscale and 97 acres of modeled habitat for Delta button-celery. This could be an adverse effect, depending on whether or not the affected modeled habitat is actually occupied by the species. Modeled habitat is assumed to encompass all potential habitat for a species and may therefore overestimate the area actually occupied. One known occurrence of San Joaquin spearscale near the forebay would be affected by facilities construction. Delta button-celery is not known to occur in CZ 8; the nearest known occurrence, in CZ 9, would not be affected. Construction of the water conveyance facilities would permanently remove about 1.5 acre of habitat occupied by crownscale at the Clifton Court Forebay. All or most of the occurrence would be directly affected. Construction of the water conveyance facilities would not affect brittlescale, heartscale, Heckard's peppergrass, palmate-bracted bird's-beak, or recurved larkspur.

- *Environmental Commitment 3 Natural Communities Protection and Restoration*: Alternative 4A would benefit alkali seasonal wetland plants by including alkali seasonal wetland in the 188 acres of vernal pool complex habitat that would be protected and 48 that would be restored. The protected alkali seasonal wetland habitat would be managed and enhanced to sustain populations of native plant species.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration is estimated to result in the inundation of modeled habitat for brittlescale (1 acre), heartscale (14 acres), and San Joaquin spearscale (21 acres), potentially affect special-status vernal pool plants. However, under this Environmental Commitment, no tidal habitat restoration would be implemented in habitat for special-status plant species. Therefore, tidal habitat restoration would not affect special-status alkali seasonal wetland species.
- *Environmental Commitment 6 Channel Margin Enhancement*: No alkali seasonal wetland habitat or occurrences of special-status alkali seasonal wetland plant species are present within the general areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on special-status alkali seasonal wetland species.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: No alkali seasonal wetland habitat or occurrences of special-status alkali seasonal wetland plant species are present within the general areas proposed for riparian habitat enhancement. Therefore, riparian habitat enhancement would have no impacts on special-status alkali seasonal wetland species.
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: Although some vernal pools are alkaline, alkali seasonal wetlands in the study area consist of alkali grassland, alkali meadow, or iodine bush scrub. Therefore, vernal pool restoration would avoid alkali seasonal wetland habitat and would have no impacts on special-status alkali seasonal wetland plants. In addition, the Environmental Commitments would compensate for the loss of alkali seasonal wetlands resulting from other Environmental Commitments by restoring vernal pool complex that includes alkali seasonal wetlands to achieve no net loss of this habitat.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid alkali seasonal wetland habitat and would have no impacts on special-status alkali seasonal wetland plant species.

Avoidance and Minimization Measures: Effects on special-status alkali seasonal wetland plants potentially resulting from implementation of the water conveyance facilities would be avoided or minimized through *AMM2 Construction Best Management Practices and Monitoring, AMM11 Covered Plant Species,* and *AMM30 Transmission Line Design and Alignment Guidelines*. Under AMM11, surveys for special-status plant species would be performed during the planning phase of projects, and any impacts on populations of special-status species would be avoided through project design or subsequently minimized though AMM2. In addition, AMM11 prohibits ground disturbance or hydrologic disturbance within 250 feet of existing vernal pools, which would protect those species with modeled habitat that includes vernal pool complex. Occurrences of special-status species in vernal pools near tidal wetlands would not be affected by tidal habitat restoration where critical habitat for vernal pool species is present and would be avoided under AMM11. AMM30 requires that transmission line construction avoid any losses of alkali seasonal wetland complex natural community. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

In summary, only one known occurrence of a special-status alkali seasonal wetland species (crownscale) would be affected under Alternative 4A. AMM11 would be implemented to avoid an adverse effect on the San Joaquin spearscale occurrence.

The primary effect of Alternative 4A on special-status alkali seasonal wetland plant species would be the loss of potential (i.e., modeled) habitat for San Joaquin spearscale and Delta button-celery. Approximately 1 acre of this habitat loss would be alkali seasonal wetlands. The actual effect on modeled habitat for alkali seasonal wetland species is expected to be somewhat less than the estimated impact because some of this habitat is composed of vernal pool complex, and the total loss of wetted vernal pool habitat is limited to 10 acres (approximately 67 acres of vernal pool complex) (AMM12). Loss of modeled habitat would be compensated for by restoring or creating vernal pool complex, alkali seasonal wetlands, and grasslands, in proportion to the amount of each habitat removed. At the proposed restoration ratios of 1:1 (prior to impact) and 1.5:1 (concurrent with impact), between 67 and 100.5 acres of vernal pool complex restoration would be required to compensate for the loss of modeled habitat composed of vernal pool complex. Loss of modeled habitat composed of grasslands would be compensated for by restoring grassland habitat on a 1:1 basis. These compensation levels would be consistent with typical NEPA and CEQA project-level mitigation ratios for impacts on vernal pools, alkali seasonal wetlands, and grasslands.

Alternative 4A would have a small beneficial effect on special-status alkali seasonal wetland plants by protecting a small amount of alkali seasonal wetland habitat. The environmental commitments also include protecting 2 occurrences of San Joaquin spearscale.

NEPA Effects: Under Alternative 4A, loss of modeled habitat for alkali seasonal wetland plant species would be offset through restoration of grassland, vernal pool, and alkali seasonal wetland habitat (Environmental Commitment 8, Environmental Commitment 9), and impacts on one occurrence of San Joaquin spearscale would be avoided through AMM11. With avoidance and habitat restoration, these effects would not be adverse. The loss of one occurrence of crownscale, a non-listed species, would result in a reduction in the range and numbers of this species and would be an adverse effect. Adverse effects on crownscale could be avoided or offset through implementation of Mitigation Measure BIO-170.

CEQA Conclusion: Because loss of modeled habitat for alkali seasonal wetland plant species would be offset through restoration, and because impacts on occurrences of special-status alkali seasonal wetland species would be avoided, impacts on alkali seasonal wetlands as a result of implementing Alternative 4A would not result in substantially reducing the number or restricting the range of seven special-status alkali seasonal wetland plant species. However, Environmental Commitments that benefit or protect listed species do not apply to nonlisted species, and loss of the crownscale population at Clifton Court Forebay would be a significant impact. Implementation of Mitigation Measure BIO-170 would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Special-Status Plant Species

DWR will evaluate all projects for their impacts on special-status plant species, avoid or minimize impacts on species that occur on project sites, and compensate for impacts on species. All impacts on diamond-petaled California poppyand caper-fruited tropidocarpum shall be avoided. Impacts on other special-status plant species shall be avoided to the extent feasible, and any unavoidable impacts shall be compensated for.

- DWR shall conduct surveys for special-status plant species within and adjacent to all project sites. Special-status plant surveys required for project-specific permit compliance will be conducted during the planning phase to allow design of the individual restoration projects to avoid adverse modification of habitat for specified plant species if feasible. The purpose of these surveys will be to verify that the locations of special-status species identified in previous record searches or surveys are extant, identify any new special-status plant species occurrences, and cover any portions of the project area not previously surveyed. The extent of mitigation of direct loss of or indirect effects on special-status plant species will be based on these survey results.
- All surveys shall be conducted by qualified biologists using the using *Guidelines for Conducting and Reporting Botanical Inventories for Federally Listed, Proposed and Candidate Plants* (U.S. Fish and Wildlife Service 1996) and *Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Natural Communities* (California Department of Fish and Game 2009) during the season that special-status plant species would be evident and identifiable, i.e., during their blooming season. Locations of special-status plant species in proposed construction areas will be recorded using a GPS unit and flagged.
- The construction monitoring plan for the protection of special-status fish, wildlife, and plant species, prepared by DWR before implementing an approved project, will provide for construction activity monitoring in areas identified during the planning stages and species/habitat surveys as having special-status plant species.
- Where surveys determine that a special-status plant species is present in or adjacent to a project site, direct and indirect impacts of the project on the species shall be avoided if feasable through the establishment of 250-foot activity exclusion zones surrounding the periphery of the occurrences, within which no ground-disturbing activities shall take place, including construction of new facilities, construction staging, or other temporary work areas. Activity exclusion zones for special-status plant species shall be according to a 250-foot buffer surrounding the periphery of each special-status plant species occurrence, the boundaries of which shall be clearly marked with standard orange plastic construction exclusion fencing or its equivalent. The establishment of activity exclusion zones shall not be required if no construction-related disturbances will occur within 250 feet of the occurrence periphery. The size of activity exclusion zones may be reduced through consultation with a qualified biologist and with concurrence from USFWS or CDFW based on project site-specific conditions.
- Where avoidance of impacts on a special-status plant species is infeasible, DWR will compensate for loss of individuals or occupied habitat of a special-status plant species through the acquisition, protection, and subsequent management in perpetuity of other existing occurrences at a 2:1 ratio (preservation: impact). DWR will provide detailed

information to USFWS and CDFW on the location of the preserved occurrences, quality of the preserved habitat, feasibility of protecting and managing the areas in-perpetuity, responsible parties, and other pertinent information. If suitable occurrences of a special-status plant species are not available for preservation, then the project shall be redesigned to remove features that would result in impacts on that species.

Grassland Species

Twelve special-status plant species occur in grasslands in the study area (Tables 12-2, 12-3, summarized in Table 12-4A-63). The only modeled plant species occurring in grassland is Carquinez goldenbush. Because this analysis relies on the data developed for the BDCP, models were only available for species covered under the BDCP. Habitat models were not developed for the six grassland species not proposed for coverage under the BDCP.

Carquinez goldenbush modeled habitat included hydrological features such as stream corridors on alluvium derived from the Montezuma Formation. Stream corridors (intermittent and perennial) that intersected these geologic units were selected and truncated at the point at which they encountered the upper elevation of intertidal marsh. The corridors were buffered 50 feet (15 meters) on either side in an effort to capture the estimated maximum extent of alluvium deposits in close proximity to the actual rivers/streams.

Of 78,047 acres of grasslands in the study area, Alternative 4A would adversely affect 678 acres under Alternative 4A. No known occurrences of special-status grassland plant species would be affected. Table 12-4A-63 summarizes the acreage of grassland habitat in the study area and the number of occurrences of each special-status grassland species in the study area.

Table 12-4A-63. Summary of Impacts on Grassland Plant Species under Alternative 4A

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Carquinez goldenbush modeled habitat	1,346	1	–	–	Potential habitat loss from tidal wetland restoration
Grassland	78,047	678	–	–	Habitat loss from construction of water conveyance facilities and tidal wetland restoration
Species					
Carquinez goldenbush	–	–	10	0	None
Big tarplant	–	–	5	0	None
Round-leaved filaree	–	–	2	0	None
Pappose tarplant	–	–	7	0	None
Parry's rough tarplant	–	–	5	0	None
Small-flowered morning-glory	–	–	0	0	None
Diamond-petaled poppy	–	–	1	0	None
Stinkbells	–	–	1	0	None
Fragrant fritillary	–	–	4	0	None
Gairdner's yampah	–	–	0	0	None
Streamside daisy[a]	–	–	1	0	None
Caper-fruited tropidocarpum	–	–	8	0	None

[a] This species actually occurs in upland woodland, a habitat that has not been mapped or quantified for analysis of Alternative 4A.

Impact BIO-171: Effects on Habitat and Populations of Grassland Plants

Alternative 4A would have no expected effects on known occurrences of special-status plant species that occur in grasslands. However, the loss of 678 acres of grassland would have the potential to affect undocumented populations of special-status grassland species.

No modeled habitat for Carquinez goldenbush and no known occurrences of the 12 special-status grassland plant species are within the proposed footprint for the Alternative 4A water conveyance facilities. About 647 acres of grassland habitat would be affected by construction of the water conveyance facilities. However, this grassland habitat consists of small patches of herbaceous ruderal vegetation along levees that do not provide habitat for special-status grassland species. Therefore, under Alternative 4A, construction and operation of the water conveyance facilities would not affect the 12 special-status grassland species.

- *Environmental Commitment 3 Natural Communities Protection and Restoration*: Alternative 4A would preserve 1,060 acres of grassland habitat. Protection of grassland habitat may also protect undiscovered occurrences of special-status plant species.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration is estimated to result in the loss of 26 acres of grassland habitat, including 1 acre of modeled

habitat for Carquinez goldenbush. However, under this environmental commitment, no tidal habitat restoration would be implemented in habitat for special-status plant species. No other occurrences of special-status grassland plants are within portions of the study area potentially suitable for tidal restoration. Therefore, tidal restoration would have no impacts on known occurrences of special-status grassland plants.

- *Environmental Commitment 6 Channel Margin Enhancement*: No known occurrences of special-status grassland plants are present within the general areas proposed for channel margin habitat enhancement. Areas mapped as grassland along levees that would be affected by channel margin habitat enhancement are small patches of ruderal vegetation along levees that do not provide habitat for special-status grassland species and are not modeled habitat for Carquinez goldenbush. Therefore, channel margin habitat enhancement would have no impacts on special-status grassland plants.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: No modeled habitat for Carquinez goldenbush or known occurrences of special-status grassland plants are present within the general areas (along levees and in cultivated lands) proposed for riparian habitat enhancement. Therefore, riparian habitat enhancement would have no impacts on special-status grassland plant species.
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: Vernal pool complex includes vernal pools as well as the surrounding grassland matrix. Because the habitat to be restored would consist of areas of former vernal pool complex that have been leveled for cultivation, special-status grassland plant species would not be present. Therefore, vernal pool complex restoration would not affect special-status grassland plant species.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid grassland habitat and would have no impacts on special-status grassland plant species.
- *Avoidance and Minimization Measures*: Potential effects on undiscovered populations of special-status grassland plants would be avoided or minimized though *AMM11 Covered Plant Species,* and *AMM2 Construction Best Management Practices and Monitoring*. Under AMM11, surveys for special-status plant species would be performed during the planning phase of projects, and any impacts on populations of special-status species would be avoided through project design or subsequently minimized through AMM2. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

NEPA Effects: Implementation of Alternative 4A would result in no adverse effects on federally listed grassland plant species.

CEQA Conclusion: Alternative 4A would have no impacts on special-status grassland species. No mitigation is required.

Valley/Foothill Riparian Species

Four special-status plant species occur in valley/foothill riparian habitat in the study area (Tables 12-2, 12-3, summarized in Table 12-4A-64). Habitat modeling was done for two species, Delta button celery and slough thistle. Because this analysis relies on the data developed for the BDCP, models were only available for species covered under the BDCP. Habitat models were not developed for the two valley/foothill species not proposed for coverage under the BDCP.

The valley/foothill riparian habitat model for Delta button-celery and slough thistle was mapped as all of the study area along the flood plain of the San Joaquin River between the levees from the Mossdale Bridge to Vernalis. Whether or not this modeled habitat is actually occupied by Delta button-celery and slough thistle is unknown; all known occurrences of these species within the area of modeled habitat are believed to be extirpated.

Of 17,966 acres of valley/foothill riparian habitat in the study area, Alternative 4A would affect73 acres, none of which is modeled habitat for Delta button-celery and slough thistle. Table 12-4A-64 summarizes the acreage of modeled habitat for Delta button-celery and slough thistle and the number of occurrences of each special-status riparian species in the study area.

Table 12-4A-64. Summary of Impacts on Valley/Foothill Riparian Plant Species under Alternative 4A

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Delta button-celery modeled habitat	3,361[a]	0	–	–	None
Slough thistle modeled habitat	1,834	0	–	–	None
Valley/foothill riparian habitat	17,966	73	–	–	Habitat loss from construction of water conveyance facilities
Species					
Delta button-celery	–	–	1[b]	0	None
Slough thistle	–	–	2	0	None
Northern California black walnut	–	–	1	0	None
Wright's trichocoronis	–	–	1	0	None

[a] A portion of this acreage consists of alkali seasonal wetland.
[b] A second occurrence is in alkali seasonal wetland.

Impact BIO-172: Effects on Habitat and Populations of Valley/Foothill Riparian Plants

No extant occurrences of Delta button-celery, slough thistle, Northern California black walnut, or Wright's trichocoronis are present in the study area. Therefore, no impacts on special-status valley/foothill riparian plant species are expected. Modeled habitat for Delta button-celery and slough thistle, which may support undocumented occurrences of these species, would not be affected by construction of the water conveyance facilities.

Construction of the water conveyance facilities would remove 73 acres of valley-foothill riparian habitat under Alternative 4A. However, no modeled habitat and no known occurrences of the four special-status valley/foothill riparian species are within the proposed footprint for the Alternative 4A water conveyance facilities. Therefore, under Alternative 4A, construction and operation of the water conveyance facilities would not affect special-status valley/foothill riparian species.

- *Environmental Commitment 3 Natural Communities Protection and Restoration*: Alternative 4A would protect up to 103 acres of existing valley/foothill riparian forest in CZ 7. This action would have no substantial effects on special-status valley/foothill plants because no extant occurrences of special-status valley/foothill plants are present in the study area.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration would inundate an estimated 5 acres of valley/foothill riparian habitat. However, no modeled habitat and no known occurrences of the four special-status valley/foothill riparian plants are within the portions of the study area potentially suitable for tidal restoration. Therefore, tidal restoration would not affect the special-status valley/foothill riparian plants.
- *Environmental Commitment 6 Channel Margin Habitat Enhancement*: No modeled habitat or occurrences of special-status valley/foothill riparian plants are present within the general areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on special-status valley/foothill riparian plant species.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: No extant occurrences of special-status valley/foothill riparian plant species are present within the general areas proposed for riparian habitat restoration. Therefore, riparian habitat restoration would have no impacts on special-status valley/foothill riparian plant species.
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: No occurrences of special-status valley/foothill riparian plant species are present within areas proposed for vernal pool and alkali seasonal wetland complex restoration. Therefore, vernal pool complex restoration would have no impacts on special-status valley/foothill riparian species.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid valley/foothill riparian habitat and would have no impacts on special-status valley/foothill riparian plant species.
- *Avoidance and Minimization Measures*: Effects on Delta button-celery and slough thistle would be avoided or minimized though *AMM11 Covered Plant Species* and *AMM2 Construction Best Management Practices and Monitoring*. Under AMM11, surveys for special-status plant species would be performed during the planning phase of projects, and any impacts on populations of special-status species would be avoided through project design or subsequently minimized though AMM2. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Because no extant occurrences of special-status valley/foothill riparian plants are known to occur in the study area, Alternative 4A is not expected to adversely affect any special-status valley/foothill riparian plants. Modeled habitat for both Delta button-celery and slough thistle would be affected. Under AMM11, surveys for special-status plants would be performed during the planning phase for floodplain restoration. If Delta button-celery or slough thistle were found to be present in the floodplain restoration area, then the project would be designed to avoid impacts on the populations. Therefore, Alternative 4A would not have an adverse effect on these species.

NEPA Effects: Implementation of Alternative 4A would not have an adverse effect on federally listed valley/foothill riparian plant species.

CEQA Conclusion: Alternative 4A would have no impact on special-status valley/foothill riparian plant species. No mitigation is required.

Tidal Wetland Species

Eight special-status plant species occur in tidal wetlands in the study area (Tables 12-2, 12-3, summarized in Table 12-4A-65). Five tidal wetland habitat models were developed for special-status plant species occurring in tidal wetland habitat. Because this analysis relies on the data developed for the BDCP, models were only available for species covered under the BDCP. Habitat models were not developed for the Bolander's water hemlock, which was not proposed for coverage under the BDCP.

Modeled habitat for Mason's lilaeopsis and Delta mudwort was mapped as areas within 10 feet (3 meters) on either side of the landward boundary of tidal perennial aquatic land cover type, which was obtained from the BDCP GIS vegetation data layer.

The side-flowering skullcap model mapped the distribution of suitable habitat in the study area according to the species' habitat association with woody riparian habitat. The model selected Delta riparian vegetation types providing the habitat characteristics that side-flowering skullcap seems to require, namely, woody substrate in freshwater tidal areas. The model included vegetation subunits of the BDCP Valley Riparian natural community characterized by California dogwood, white alder, and arroyo willow.

The modeled habitat for soft bird's-beak consisted of pickleweed- and saltgrass-dominated vegetation units located west of the Antioch Bridge. Modeled habitat for these two plant species was mapped as areas within 10 feet (3 meters) on either side of the landward boundary of tidal perennial aquatic land cover types. The model used all Tidal Brackish Emergent Wetland polygons that were limited by specific vegetation units that are known to be closely associated with soft bird's-beak habitat.

Habitat for Delta tule pea and Suisun Marsh aster was modeled separately based on the salinity of the water. For the tidal freshwater emergent wetland BDCP land cover type, modeled habitat was mapped as the area within 10 feet (3 meters) of the landward side of the landward boundary, exclusively where this land cover type is adjacent to grassland, vernal pool complex, valley/foothill riparian, or cultivated land habitats cover types. For brackish water areas in and near Suisun Marsh, the model used all tidal brackish emergent wetland polygons within an elevation range of 7 to 10 feet (2 to 3 meters) to capture elevations 1 foot (30 centimeters) below intertidal to 2 feet (60 centimeters) above intertidal.

The modeled habitat for Suisun thistle in and near Suisun Marsh consists of all tidal brackish emergent wetland polygons with the appropriate vegetation. This included vegetation units dominated by saltscale, saltgrass, pickleweed, and broad-leaved peppergrass.

Full implementation of Alternative 4A and compliance with Resource Restoration and Performance Principles TWS1 and TWS2 would include the following Environmental Commitments to minimize impacts on tidal wetland species.

- No net loss of Mason's lilaeopsis and delta mudwort occurrences within restoration sites (Resource Restoration and Performance Principle TWS1).
- No net loss of Delta tule pea and Suisun Marsh aster occurrences within restoration sites (Resource Restoration and Performance Principle TWS2).

Of 17,357 acres of tidal wetlands in the study area, Alternative 4A would affect 11 acres of tidal freshwater emergent wetland including areas that are modeled habitat for Mason's lilaeopsis, Delta mudwort, side-flowering skullcap, Delta tule pea, and Suisun Marsh aster. Known occurrences Mason's lilaeopsis, side-flowering skullcap, and Suisun Marsh aster would be affected. Table 12-4A-65 summarizes the acreage of modeled habitat for special-status tidal wetland species and the number of occurrences of each special-status tidal wetland plant species in the study area.

Table 12-4A-65. Summary of Impacts on Tidal Wetland Plant Species under Alternative 4A

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Delta mudwort/ Mason's lilaeopsis modeled habitat	6,081	37	–	–	Potential habitat loss from construction of water conveyance facilities
Side-flowering skullcap modeled habitat	2,497	7	–	–	Potential habitat loss from construction of water conveyance facilities
Soft bird's-beak modeled habitat	1,228	0	–	–	None
Delta tule pea/Suisun Marsh aster modeled habitat	5,853	2	–	–	Potential habitat loss from construction of water conveyance facilities
Suisun thistle modeled habitat	1,281	0	–	–	None
Tidal brackish emergent wetland	8,501	0	–	–	None
Tidal freshwater emergent wetland	8,856	11	–	–	Habitat loss from construction of water conveyance facilities
Species					
Delta mudwort	–	–	58	0	None
Delta tule pea	–	–	106	0	
Mason's lilaeopsis	–	–	181	8	Occurrences affected by construction of water conveyance facilities
Side-flowering skullcap	–	–	12	1	Occurrence affected by construction of water conveyance facilities
Soft bird's-beak	–	–	13	0	None
Suisun Marsh aster	–	–	164	3	Occurrences affected by construction of water conveyance facilities
Suisun thistle	–	–	4	0	None
Bolander's water hemlock	–	–	8	0	None

Impact BIO-173: Effects on Habitat and Populations of Tidal Wetland Plants

Alternative 4A would have adverse effects on tidal marsh special-status plant species.

The individual effects of each relevant Environmental Commitment are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

Water Facilities and Operations: Construction of the Alternative 4A water conveyance facilities would remove 37 acres of modeled habitat for delta mudwort and Mason's lilaeopsis, 7 acres of modeled habitat for side-flowering skullcap, and 2 acres of modeled habitat for Delta tule pea and Suisun Marsh aster. The extent to which modeled habitat is actually occupied by these species is not known; however, eight occurrences of Mason's lilaeopsis, three occurrences of Suisun Marsh aster, and one occurrence of side-flowering skullcap in the study area could be affected by construction impacts. No known occurrences of the other special-status tidal wetland species would be affected by construction of the water conveyance facilities.

- *Environmental Commitment 3 Natural Communities Protection and Restoration*: Alternative 4A does not specifically propose to protect any habitat or occurrences of tidal wetland plants nor does it propose active restoration of affected habitat or occurrences.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: As stated in this Environmental Commitment, no tidal habitat restoration would be implemented in habitat for special-status plant species. Therefore, tidal habitat restoration would not affect modeled habitat for Mason's lilaeopsis and Delta mudwort or any occurrences of tidal wetland special-status plant species.
- *Environmental Commitment 6 Channel Margin Enhancement*: Effects of channel margin enhancement were not analyzed. Channel margin enhancement could have adverse effects on tidal wetland plants through direct removal and habitat modification. However, it would compensate for effects on these species by improving the habitat functions of the channel margins as a result of riprap removal and creation of floodplain benches. Side-flowering skullcap would benefit from installation of large woody material, which it appears to colonize.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian habitat restoration is not expected to adversely affect special-status tidal wetland plants. Preparatory work that involves habitat disturbance would occur during implementation of Environmental Commitment 4. Riparian plantings carried out for Environmental Commitment 7 would be placed in floodplain areas, not in tidal wetlands.
- *Environmental Commitment 8 Grassland Natural Community Restoration*: No tidal wetlands or occurrences of special-status tidal wetland plants are present within areas proposed for grassland communities restoration. Therefore, grassland communities restoration would have no impacts on special-status tidal wetland plant species.
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: No tidal wetlands or occurrences of special-status tidal wetland plant species are present within areas proposed for vernal pool complex restoration. Therefore, vernal pool complex restoration would have no impacts on special-status tidal wetland plant species.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid tidal wetland habitat and would have no impacts on special-status tidal wetland plant species.

Avoidance and Minimization Measures: Effects on special-status tidal wetland plant species potentially resulting from construction of the water conveyance facilities would be avoided or minimized though *AMM11 Covered Plant Species, AMM2 Construction Best Management Practices and Monitoring,* and *AMM30 Transmission Line Design and Alignment Guidelines*. Under AMM11, surveys for special-status plant species would be performed during the planning phase of projects, and any impacts on populations of special-status species would be avoided through project design or subsequently minimized though AMM2. AMM30, which specifies that the alignment of proposed transmission lines will be designed to avoid sensitive terrestrial and aquatic habitats when siting poles and towers to the maximum extent feasible, would avoid some impacts on Mason's lilaeopsis and side-flowering skullcap. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

In summary, the GIS analysis indicates that Alternative 4A would result in the loss of modeled habitat for five special-status species and result in adverse effects on known occurrences of three of the special-status species occurring in tidal wetlands.

Delta mudwort could lose 37 acres of modeled habitat, but no known occurrences would be affected. Channel margin enhancement (Environmental Commitment 6) and riparian natural community restoration (Environmental Commitment 7) will consider the potential for creating habitat for Delta mudwort; creation of suitable habitat under these measures could also help offset this habitat loss. Although active restoration of this species is not proposed, natural expansion of populations into the restored habitat may take place

Mason's lilaeopsis could lose 37 acres of modeled habitat), including all or part of eight occurrences. Tidal habitat restoration activities (Environmental Commitment 4) would increase the extent of habitat available for colonization by Mason's lilaeopsis, which could offset this habitat loss. Although active restoration of this species is not proposed, the natural expansion of populations into the restored habitat may take place. The Environmental Commitments include post-implementation monitoring of affected occurrences and occurrences in conservation areas to confirm that no net loss of occurrences has been achieved.

Both of these species (Delta mudwort, Mason's lilaeopsis) are widespread in the study area with many occurrences. Habitat modification and loss are the primary stressors that are responsible for their decline and that currently limit their distribution and abundance. Therefore, restoring habitat and improving habitat functions for these species would provide a reasonable expectation that the distribution and abundance of these species would also improve. Because a relatively small amount of modeled habitat would be adversely affected, it is likely that the initial adverse effects of construction activities on these species would be offset and that the overall effect of Alternative 4A on these species would not be adverse.

Side-flowering skullcap could lose one occurrence. Under AMM11, this occurrence would be surveyed for, and because this is a tidal freshwater wetland species, avoidance of the habitat during project construction would be highly likely. No active restoration of this species is proposed, and no post-implementation monitoring of affected occurrences and occurrences in conservation areas would be done. Because impacts on occurrences of side-flowering skullcap would be avoided, the overall effect of Alternative 4A on this species would not be adverse.

***NEPA Effects*:** The loss of modeled and occupied habitat for special-status tidal wetland plants would be offset through tidal habitat restoration (Environmental Commitment 4). Therefore, implementation of Alternative 4A would result in no adverse effects on eight special-status tidal wetland plant species in the study area.

CEQA Conclusion: Because loss of occurrences and modeled habitat for special-status tidal habitat plant species would be offset through habitat restoration, impacts on special-status tidal wetland plants as a result of implementing Alternative 4A would not be significant.

Inland Dune Species

Five special-status plant species occur in inland dune habitat in the study area. No habitat models were prepared for inland dune habitat. Table 12-4A-66 summarizes the acreage of inland dune habitat in the study area and the number of occurrences for each special-status inland dune species in the study area.

Table 12-4A-66. Summary of Impacts on Inland Dune Plants under Alternative 4A

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Inland Dunes	19	0	–	–	None
Species					
Hoover's cryptantha	–	–	1	0	None
Antioch Dunes buckwheat	–	–	1	0	None
Mt. Diablo buckwheat	–	–	1	0	None
Contra Costa wallflower	–	–	3	0	None
Antioch Dunes evening-primrose	–	–	9	0	None

Impact BIO-174: Effects on Habitat and Populations of Inland Dune Plants

Alternative 4A would have no adverse effects on inland dune species (Table 12-4A-66). No construction activities would take place where the species occur. No specific actions to benefit inland dune species are proposed.

NEPA Effects: Implementation of Alternative 4A would not affect special-status inland dune species.

CEQA Conclusion: Implementation of Alternative 4A would have no impacts on inland dune species. No mitigation is required.

Nontidal Wetland Species

Six special-status plant species occur in nontidal wetlands in the study area. Table 12-4A-67 summarizes the acreage of nontidal wetland habitat in the study area and the number of occurrences of each special-status nontidal wetland species in the study area.

Table 12-4A-67. Summary of Impacts on Nontidal Wetland Plant Species under Alternative 4A

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Nontidal freshwater aquatic	5,567	2,339	–	–	Loss or disturbance of habitat from construction of water conveyance facilities and tidal habitat restoration
Nontidal freshwater perennial emergent wetland	1,509	6	–	–	Loss or disturbance of habitat from construction of water conveyance facilities and tidal habitat restoration
Species					
Watershield	–	–	3	1	Loss of habitat from construction of water conveyance facilities
Bristly sedge	–	–	18	3	Loss of occurrences from construction of water conveyance facilities
Woolly rose-mallow[a]	–	–	121	14	Loss of occurrences from construction of water conveyance facilities
Eel grass pondweed	–	–	1	0	None
Sanford's arrowhead	–	–	23	1	Loss of occurrences from construction of water conveyance facilities
Marsh skullcap[a]	–	–	1	0	None

[a] Also occurs in valley/foothill riparian habitat.

Impact BIO-175: Effects on Habitat and Populations of Nontidal Wetland Plants

Under Alternative 4A, known occurrences watershield, bristly sedge, woolly rose-mallow, and Sanford's arrowhead would be within the proposed footprint for the water conveyance facilities and could be adversely affected. Alternative 4A would have no adverse effects on eel-grass pondweed or marsh skullcap.

Construction of the Alternative 4A water conveyance facilities would adversely affect four special-status plant species occurring in nontidal wetlands. One of three watershield occurrences in CZ 5 on Bouldin Island could be affected by construction of the water conveyance facilities. This is a historical occurrence that has not been observed since 1893, and it may be extirpated (California Department of Fish and Wildlife 2013). Three occurrences of bristly sedge in CZ 4 and CZ 5, including approximately 1.54 acres of occupied habitat, would be affected by construction of the water conveyance facilities. Fourteen occurrences of woolly rose-mallow would be affected. Six occurrences in CZ 4 could be removed during construction of the intake facilities and disposal of RTM, and four occurrences in CZ 6 and four occurrences in CZ 8 could be affected by construction of other facilities and by geotechnical investigations. Construction of the water conveyance facilities could remove occupied habitat at one occurrence of Sanford's arrowhead in CZ 4. Under Alternative

4A, construction and operation of the water conveyance facilities could affect 77 acres of nontidal wetlands, which could have adverse effects on undiscovered occurrences of the six special-status nontidal wetland plant species.

- *Environmental Commitment 3 Natural Communities Protection and Restoration*: No specific natural communities protection is proposed for nontidal wetlands under Alternative 4A. Therefore, no occurrences of special-status nontidal plants are proposed for protection.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: No habitat or known occurrences of special-status nontidal wetland plants are present within the general areas proposed for tidal habitat restoration. Therefore, tidal habitat restoration would have no adverse effects on special-status nontidal wetland plants.
- *Environmental Commitment 6 Channel Margin Enhancement*: No known occurrences of special-status nontidal wetland plant species are present within the general areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on known occurrences of special-status nontidal wetland species.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: No known occurrences of special-status nontidal wetland plant species are present within the general areas proposed for riparian habitat restoration. Therefore, riparian habitat restoration would have no impacts on known occurrences of special-status nontidal wetland species.
- *Environmental Commitment 8 Grassland Natural Community Restoration*: No known occurrences of special-status nontidal wetland plant species are present within areas proposed for grassland communities restoration. Therefore, grassland communities restoration would have no impacts on special-status nontidal wetland species.
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: No known occurrences of special-status nontidal wetland plants are present within areas proposed for vernal pool complex restoration. Therefore, vernal pool complex restoration would have no impacts on special-status nontidal wetland plants.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid existing nontidal marsh and would have no adverse effects on special-status nontidal wetland plants. Alternative 4A may benefit nontidal wetland species by creating 832 acres of nontidal freshwater marsh, including components of nontidal perennial aquatic and nontidal freshwater perennial emergent wetland communities, and by maintaining and enhancing the habitat functions of protected and created nontidal wetland habitats for special-status and other native species. However, no specific actions to benefit special-status species are proposed.

Under Alternative 4A, 119 acres of nontidal marsh would be restored. However, these wetlands would be restored primarily as habitat for giant garter snake. These habitat restoration activities would be unlikely to expand the amount of habitat available to watershield, bristly sedge, woolly rose-mallow, and Sanford's arrowhead, and potential loss of habitat or occurrences resulting from construction activities would not be compensated for. Moreover, because special-status nontidal wetland plant species are not addressed by Environmental Commitments, the species protections afforded to listed species under the AMMs do not apply to these species, and the effects of Alternative 4A on these species would be adverse. Implementation of Mitigation Measure BIO-170, *Avoid, Minimize, or Compensate for Impacts on Special-Status Plant Species*, would reduce these effects.

NEPA Effects: Implementation of Alternative 4A could result in a reduction in the range and numbers of watershield, bristly sedge, woolly rose-mallow, and Sanford's arrowhead, four nontidal wetland species, which would be an adverse effect. Adverse effects on these species could be avoided or offset through implementation of Mitigation Measure BIO-170.

CEQA Conclusion: Under Alternative 4A, construction of the water conveyance facilities could result in a reduction in the range and numbers of watershield, bristly sedge, woolly rose-mallow, and Sanford's arrowhead. These impacts would be significant. Implementation of Mitigation Measure BIO-170 would reduce these impacts to a less-than-significant level.

Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Special-Status Plant Species

Please see Mitigation Measure BIO-170 under Impact BIO-170.

General Terrestrial Biology

Wetlands and Other Waters of the United States

Alternative 4A actions would both permanently and temporarily remove or convert wetlands and open water that are regulated by USACE under Section 404 of the CWA. The 404 regulations and relevant information on mitigating the effects of impact on wetlands and other waters of the United States are described in Section 12.2.1.1. The methods used to conduct these analyses are described in Section 12.3.2.4, *Methods Used to Assess Wetlands and Other Waters of the United States*. Waters of the United States data used for this analysis is based on a verified wetland delineation from the USACE that was completed in early 2015. The waters of the United States were mapped at a finer scale than that which was done for the natural community mapping for the BDCP and therefore the acreages of these two datasets differ when compared to each other. The waters of the United States mapping identified numerous agricultural ditches and seasonal wetlands occurring within and associated with cultivated lands, which explains the majority of the difference.

Impact BIO-176: Effects of Constructing Water Conveyance Facilities on Wetlands and Other Waters of the United States

Alternative 4A proposes the construction, maintenance, and operation of water conveyance facilities within, or requiring the unavoidable fill of, waters of the United States. The estimated fill of jurisdictional waters associated with this alternative is described in Table 12-4A-68 below. Based on the methodology used to conduct this analysis, the losses would occur at intake, tunnel, pipeline, canal, and RTM and borrow/spoil storage sites, transmission corridors, and multiple temporary work areas associated with the construction activity. The permanent waters of the United States losses would occur at various locations along the modified pipeline/tunnel alignment. The majority of the loss would result from the expansion of Clifton Court Forebay, new transmission lines, construction of Alternative 4A's three intake structures along the eastern bank of the Sacramento River between Clarksburg and Courtland in the north Delta, and at the RTM storage sites associated with tunnel construction at various locations between Lambert Road and Twin Cities Road, on Bouldin Island, and on Byron Tract, adjacent to Clifton Court Forebay.

The temporary effects on waters of the United States would also occur mainly at the three intake construction sites along the eastern bank of the Sacramento River, and at barge unloading facilities in the San Joaquin River, Snodgrass Slough, Potato Slough, Connection Slough, Old River, and West Canal. An additional temporary effect would result from dredging of Clifton Court Forebay.

Table 12-4A-68. Estimated Fill of Waters of the United States Associated with the Construction of Water Conveyance Facilities under Alternative 4A

Wetland/Water Type	Permanent Impact	Temporary Impacts Treated as Permanent[a]	Temporary Impact[b]	Total Impact[c]
Agricultural Ditch	42.2	13.2	0	55.4
Alkaline Wetland	10.4	0.1	0	10.5
Clifton Court Forebay	257.9	0	1,930.6	257.9
Conveyance Channel	7.1	2.9	0	10.0
Depression	29.3	6.2	0	35.5
Emergent Wetland	56.8	14.7	0	71.5
Forest	7.2	5.2	0	12.4
Lake	23.2	0	0	23.2
Scrub-Shrub	12.7	3.7	0	16.3
Seasonal Wetland	114.5	10.0	0	124.5
Tidal Channel	15.3	65.6	0	80.8
Vernal Pool	0.3	0	0	0.3
Total	**577**	**121**	**1,931**	**698**

[a] Temporary impacts treated as permanent are temporary impacts expected to last over one year. These impact sites will eventually be restored to pre-project conditions; however, due to the duration of effect, compensatory mitigation will be included for these areas.

[b] Temporary impacts are due to dredging Clifton Court Forebay.

[c] Total does not include temporary impacts on Clifton Court Forebay because these would just be temporary disturbance to open water, which typically do not require compensatory mitigation.

The majority of the impacts on wetlands and waters of United States would be on wetlands found within cultivated lands (mostly agricultural ditches and seasonal wetlands) and waters associated with Clifton Court Forebay. The impacted seasonal wetlands mapped within the Conveyance Planning Area, as described in Section 12.3.2.4, *Methods Used to Assess Wetlands and Other Waters of the United States*, all occur in the central Delta within plowed agricultural fields and would be mostly affected by the RTM storage sites and transmission line construction. The effects on Clifton Court Forebay would primarily result from the establishment of new embankments around and across the existing forebay. The forebay would be expanded to the south by an additional 450 acres of storage space resulting in a net gain of open water in the forebay.

Unavoidable impacts on waters of the United States would be offset such that the loss of acreage and functions due to construction activities are fully compensated. Wetland functions are defined as a process or series of processes that take place within a wetland. These include the storage of water, transformation of nutrients, growth of living matter, and diversity of wetland plants, and they have value for the wetland itself, for surrounding ecosystems, and for people. Functions can be grouped broadly as habitat, hydrologic/hydraulic, or water quality. Not all wetlands perform all functions nor do they perform all functions equally well. The location and size of a wetland may determine what functions it will perform. For example, the geographic location may determine its habitat functions, and the location of a wetland within a watershed may determine its hydrologic/hydraulic or water-quality functions. Many factors determine how well a wetland will perform these functions: climatic conditions, quantity and quality of water entering the wetland, and disturbances or alteration within the wetland or the surrounding ecosystem. Wetland disturbances may be the result of natural conditions, such as an extended drought, or human activities, such as land clearing, dredging, or the introduction of nonnative species. Wetlands are among the most productive habitats in the world, providing food, water, and shelter for fish, shellfish, birds, and mammals, and serving as a breeding ground and nursery for numerous species. Many endangered plant and animal species are dependent on wetland habitats for their survival. Hydrologic and hydraulic functions are those related to the quantity of water that enters, is stored in, or leaves a wetland. These functions include such factors as the reduction of flow velocity, the role of wetlands as ground-water recharge or discharge areas, and the influence of wetlands on atmospheric processes. Water-quality functions include the trapping of sediment, pollution control, and the biochemical processes that take place as water enters, is stored in, or leaves a wetland.

The functions of the waters of the United States that would be temporarily or permanently impacted by this alternative vary greatly depending primarily on existing land uses and historical levels of disturbance. Generally, agricultural ditches and conveyance channels, which are regularly maintained and often devoid of vegetation, support only minimal hydraulic function (water conveyance), with virtually no water quality or habitat function. With respect to Clifton Court Forebay, the facility is regularly maintained, but supports some hydrologic, hydraulic, and water quality functions (e.g., reduction of velocity, groundwater recharge, and trapping of sediment). Tidal channels affected by this alternative support functions in all three categories, but the level at which these functions perform vary depending on setting, size, and level of disturbance. The alkaline wetlands and vernal pools exist in non-native grasslands and have been subjected to some disturbance due to past land uses. Although these features likely support habitat, water quality, and hydrologic/hydraulic functions, the capacity of these features to perform such functions vary depending on the overall ecological setting and level of disturbance. Functions associated with emergent wetland, forest, and scrub-shrub, depend primarily on the location of these habitat types. Where they exist as in-stream (in-channel islands) or as the thick band of habitat adjacent to a waterway, these features are expected to function at a high level. However, where these habitats exist as thin bands, or where they are situated in agricultural fields, their habitat functions will be considerably lower. All of the wetlands classified as seasonal wetlands occur in agricultural fields. As such, their habitat functions have been greatly compromised, but they retain some water quality and hydrologic/hydraulic function. Like seasonal wetlands, most depressions occur within agricultural areas; however the depressions may support wetland vegetation at their edges. The areas mapped as lake are the dredged borrow ponds created during the construction of Interstate 5. Although relatively small, each lake is likely performing functions from all three categories.

A functional assessment of wetlands proposed for fill will be conducted during the development of the Conceptual Mitigation Plan as part of the Clean Water Act permitting process. The results of this assessment will be compared to the expected functions at the proposed mitigation site(s) such that it can be confirmed that the compensatory mitigation will in fact accomplish full functional replacement of impacted wetlands. All impacted wetlands will be replaced with fully functional compensatory wetland habitat demonstrating high levels of habitat, water quality, and hydrologic/hydraulic function. Since many impacted wetlands will be significantly less than high function, the compensatory mitigation will result in a net increase in wetland function.

The proposed project was designed to avoid waters of the United States to the maximum extent practicable. Each of the conveyance components has been located in upland areas where it was feasible to do so. Once construction begins, AMM2 and AMM6 would be implemented, as described in the AMMs set out in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to further avoid and minimize effects on waters of the United States as well as on special-status species. The AMMs would be implemented during all phases of a project, from siting through design, construction, and on to operations and maintenance. The AMMs that pertain specifically to waters of the United States are *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils*, *AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM12 Vernal Pool Crustaceans*, *AMM30 Transmission Line Design and Alignment Guidelines*, *AMM34 Construction Site Security*, and *AMM36 Notification of Activities in Waterways*.

The implementation of measures to avoid and minimize impacts on habitat for aquatic species and species which utilize aquatic habitats, such as California tiger salamander, giant garter snake, California red legged frog, western pond turtle, riparian woodrat, and riparian brush rabbit, will also result in further avoidance and minimization of effects to waters of the United States.

Aside from wetland habitats that would be created as a result of implementing Environmental Commitment 4–Environmental Commitment 10 described for Alternative 4A, some of which could serve the dual purpose of offsetting effects to species and mitigating impacts on waters of the United States, more specific mitigation is required to ensure that there is no net loss of wetland functions and values as a result of implementing Alternative 4A pursuant to USACE's and U.S. EPA's Mitigation Rule (see Section 12.2.1.1). Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the United States* would be available to address adverse impacts on waters of the United States.

NEPA Effects: The permanent and temporary loss of wetlands and waters of the United States as a result of constructing Alternative 4A water conveyance facilities would be a substantial effect if not compensated by wetland restoration and protection. This loss would represent a fill of water of the U.S. as defined by Section 404 of the CWA. The project proponents would implement AMM1–AMM7, AMM10, AMM12, AMM30, AMM34, and AMM36, which would avoid and minimize fill of wetlands and waters and any indirect effects on wetlands and waters. However, specific mitigation would be required to ensure that Alternative 4A does not result in a loss of functions and values of waters of the United States and thus that the affect is not adverse. Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the United States*, would be available to reduce these effects such that they are not adverse.

CEQA Conclusion: The permanent and temporary loss of wetlands and waters of the United States as a result of constructing Alternative 4A water conveyance facilities would be a significant impact. Specific mitigation would be required to ensure that Alternative 4A does not result in a loss of functions and values of waters of the United States. Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the United States*, would be available to reduce the impact to a less-than-significant level. Additionally, Alternative 4A would restore up to 1,134 acres of wetlands as part of the proposed project, which would include 295 acres of tidal marsh restoration (Environmental Commitment 4), 7 acres of vernal pool/alkali seasonal wetlands (Environmental Commitment 9; 48 acres of vernal pool complex assuming a wetland density of 15%), and 832 acres of nontidal marsh restoration (Environmental Commitment 10). In addition, Alternative 4A would restore up to 251 acres of riparian habitat (Environmental Commitment 7), some portion of which may also qualify as forested or scrub-shrub wetland. In addition, 4.6 miles of levees will have channel margin enhancement conducted on them (Environmental Commitment 6), which would include improving channel geometry and restoring riparian, marsh, and mudflat habitats on the water side of levees.

The success in implementing these Environmental Commitments would be assured through effectiveness monitoring, which includes success criteria, and adaptive management as outlined in the *Adaptive Management and Monitoring* sections of the BDCP for tidal marsh restoration (BDCP Chapter 3, *Conservation Strategy*, Section 3.4.4.4), channel margin enhancement (BDCP Section 3.4.6.4), valley/foothill riparian restoration (BDCP Section 3.4.7.4), vernal pool and alkali seasonal wetland complex restoration (BDCP Section 3.4.9.4), and nontidal marsh restoration (BDCP Section 3.4.10.3). All restored areas will be secured in fee-title or through conservation easements.

Alternative 4A would also protect and manage the following natural communities that contain wetlands: 103 acres of valley/foothill riparian, 188 acres of vernal pool/alkali seasonal wetland complex, and 119 of nontidal marsh. In addition, 1,060 acres of grasslands and 11,870 acres of cultivated lands will be protected and managed, which would likely include areas of seasonal wetlands, ponds, and agricultural ditches.

Alternative 4A also includes the following Resource Restoration and Performance Principles (see Table 3-12 in Chapter 3, *Description of Alternatives*) to further guide the Environmental Commitments that would also contribute to establishing and maintaining the functions and values of restored and protected waters of the United States.

- Restore or create vernal pool and alkali seasonal wetland complex to achieve no net loss of wetted acres (Resource Restoration and Performance Principle VP/AW2).
- Provide appropriate seasonal flooding characteristics for supporting and sustaining vernal pool and alkali seasonal wetland complex species (Resource Restoration and Performance Principle VP/AW4).
- In grasslands surrounding protected and created vernal pools and alkali seasonal wetlands complex, increase the extent, distribution, and density of native perennial grasses intermingled with other native species, including annual grasses, geophytes, and other forbs (Resource Restoration and Performance Principle VP/AW6).
- Increase the size and connectivity of protected vernal pool and alkali seasonal wetland complex in the greater Byron Hill area (Resource Restoration and Performance Principle VP/AW3).
- Protect up to six acres of stock ponds and other aquatic features within protected grasslands to provide aquatic breeding habitat for native amphibians and aquatic reptiles (Resource Restoration and Performance Principle G2).
- Maintain and enhance aquatic features in grasslands to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding for amphibian and aquatic reptile species (Resource Restoration and Performance Principle G7).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the conservation area, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Resource Restoration and Performance Principle CL1).

- Create and protect nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities, which will include suitable habitat characteristics for western pond turtle (Resource Restoration and Performance Principle WPT1).
- Create aquatic habitat for the giant garter snake will be connected to the protected rice land or equivalent-value habitat (Resource Restoration and Performance Principle GGS1).
- Protect, restore, and/or create rice land or equivalent-value habitat (e.g., perennial wetland) for the giant garter snake in Conservation Zones 4 and/or 5 (Resource Restoration and Performance Principle GGS3).
- Create at least 320 acres of managed wetlands (part of the nontidal wetland restoration acreage) in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6, with consideration of sea level rise and local seasonal flood events. The wetlands will be located within 2 miles of existing permanent roost sites and protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of 2:1 upland to wetland to provide buffers around the wetlands (Resource Restoration and Performance Principle GSC2).
- Create at least two 90-acre wetland complexes within the Stone Lakes NWR project boundary. The complexes will be no more than 2 miles apart and will help provide connectivity between the Stone Lakes and Cosumnes River Preserve greater sandhill crane populations. Each complex will consist of at least three wetlands totaling at least 90 acres of greater sandhill crane roosting habitat, and will be protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of at least 2:1 uplands to wetlands (i.e., two sites with at least 90 acres of wetlands each). One of the 90-acre wetland complexes may be replaced by 180 acres of cultivated lands (e.g., cornfields) that are flooded following harvest to support roosting cranes and provide highest-value foraging habitat, provided such substitution is consistent with the long-term conservation goals of Stone Lakes NWR for greater sandhill crane (Resource Restoration and Performance Principle GSC3).

The project proponents will also implement AMM1–AMM7, AMM10, AMM12, AMM30, AMM34, and AMM36, which would avoid and minimize fill of wetlands and waters and any indirect effects to wetlands and waters. As stated above, specific mitigation would be required to ensure that Alternative 4A does not result in a loss of functions and values of waters of the United States. Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the United States*, would be available to reduce the impact to a less-than-significant level.

Mitigation Measure BIO-176: Compensatory Mitigation for Fill of Waters of the United States

All mitigation proposed as compensatory mitigation would be subject to specific success criteria, success monitoring, long-term preservation, and long-term maintenance and monitoring pursuant to the requirements of the Mitigation Rule. All compensatory mitigation shall fully replace lost function through the mechanisms discussed below which will result in restoration and/or creation of habitat with at least as much function and value as those of the impacted habitat. In some cases, the mitigation habitat will afford significantly higher function and value than that of impacted habitat.

Compensation ratios are driven by type, condition, and location of replacement habitat as compared to type, condition and location of impacted habitat. Compensatory mitigation usually includes restoration, creation, or rehabilitation of aquatic habitat. The USACE does not typically accept preservation as the only form of mitigation; use of preservation as mitigation typically requires a very high ratio of replacement to impact. It is anticipated that ratios will be a minimum of 1:1, depending on the factors listed above.

Compensatory mitigation will consist of restoration, creation, and/or rehabilitation of aquatic habitat. Typically, impacted habitat will be replaced in-kind, although impacts on some habitat types such as agricultural ditches, conveyance channels, and Clifton Court Forebay, will be mitigated out-of-kind with higher functioning habitat types such as riparian wetland, marsh, and/or seasonal wetland. Compensatory mitigation shall be accomplished by one, or a combination of the following methods:

- Purchase credits for restored/created/rehabilitated habitat at an approved wetland mitigation bank;
- On-site (adjacent to the project footprint) restoration or rehabilitation of wetlands converted to uplands due to past land use activities (such as agriculture) or functionally degraded by such activities;
- On-site (adjacent to the project footprint) creation of aquatic habitat;
- Off-site (within the Delta) restoration or rehabilitation of wetlands converted to uplands due to past land use activities (such as agriculture) or functionally degraded by such activities;
- Off-site (within the Delta) creation of aquatic habitat; and/or
- Payment into the Corps' Fee-in-Lieu program.

Purchase of Credits or Payment into Fee-in-Lieu Program

It is envisioned that purchase of bank credits and/or payment into a fee-in-lieu program will be utilized for habitat types that would be difficult to restore or create within the Delta. Examples are vernal pool habitat, which requires an intact hardpan or other impervious layer and very specific soil types, and alkali seasonal wetland, which requires a specific set of chemical soil parameters. It is anticipated that only a small amount of compensatory mitigation will fall into these categories.

On-Site Restoration, Rehabilitation and/or Creation

Much of the Delta consists of degraded or converted habitat that is more or less functioning as upland. Opportunities will be sought where on-site restoration, rehabilitation, and/or creation could occur immediately adjacent to the project footprint. It is anticipated that some of the compensatory mitigation will fall into this category.

Off-Site Restoration, Rehabilitation and/or Creation

There exists, within the immediate vicinity of the project area, Delta land which has been subject to agricultural practices or other land uses which have degraded or even converted wetlands that existed historically. Sites within the Delta will be evaluated for their restoration, rehabilitation, and/or creation potential. It is anticipated that most of the compensatory mitigation will fall into this category.

Compensatory mitigation will result in no net loss of acreage of waters of the United States and will accomplish full functional replacement of impacted wetlands. All impacted wetlands will be replaced with fully functioning wetland habitat demonstrating high levels of habitat, water quality, and hydrologic/hydraulic function. Since many impacted wetlands are likely to function at significantly less than high levels, the compensatory mitigation will result in a significant net increase in wetland function.

Impact BIO-177: Effects of Implementing Environmental commitments (Environmental Commitment 4–Environmental Commitment 10) on Wetlands and Other Waters of the United States

The habitat protection and restoration activities associated with Alternative 4A's Environmental Commitments (Environmental Commitment 4–Environmental Commitment 10) could alter the acreages and functions and values of wetlands and waters of the United States in the study area. Because these Environmental Commitments have not been defined to the level of site-specific footprints, it is not possible to specifically delineate and quantify these effects on wetlands and waters; however the project would conduct tidal restoration (Environmental Commitment 4), riparian restoration (Environmental Commitment 7), grasslands restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10) in areas that would likely contain wetlands. Of the 2,448 acres of restoration proposed for the project, 2,344 acres (96%) are planned to take place in cultivated lands that likely contain agricultural ditches and seasonal wetlands (as was identified during the delineation for the Conveyance Planning Area). The proportion of cultivated areas that actually contain waters and wetlands is expected to be low; however for the purposes of this analysis a conservative estimate of 10% was applied to estimate the amount of wetlands and waters that may be affected within these areas, which would be 234 acres, plus the 49 acres of wetland natural communities estimated to be affected by tidal restoration brings the total estimate of wetland areas affected by restoration to 283 acres.

Alternative 4A would result in the restoration of approximately 1,175 acres of wetlands and waters (tidal natural communities, vernal pool complex, and nontidal marsh), as well the protection and management of 307 acres of wetland natural communities (vernal pool complex and nontidal marsh) and 13,033 acres of other natural communities that likely contain some degree of wetlands and waters (valley/foothill riparian, grasslands, and cultivated lands). As discussed above, Alternative 4A would also implement AMMs, Resource Restoration and Performance Principles, and adaptive management and monitoring together with these Environmental Commitments. The Environmental Commitments and associated measures could serve the dual purpose of offsetting effects to species and mitigation impacts on waters of the United State; however, more specific mitigation is required to ensure that there is no net loss of wetland functions and values as a result of implementing these Environmental Commitments under Alternative 4A pursuant to USACE's and U.S. EPA's Mitigation Rule. Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the United States*, would be available to address adverse impacts on waters of the United States.

NEPA Effects: The implementation of Environmental Commitment 4–Environmental Commitment 10 for Alternative 4A would potentially result in the conversion of wetlands and waters in cultivated lands and along the margins of Delta channels. These wetlands and waters would likely be converted to tidal and nontidal wetlands, including some open water, and possibly grasslands through implementation of Environmental Commitment 4, Environmental Commitment 8, and Environmental Commitment 10. Although, the increase in wetland acreage and wetland functions from these Environmental Commitments could offset the effects on waters of the United States occurring in these areas, implementation of Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the United States*, would be required to ensure that these effects are not adverse.

***CEQA Conclusion*:** The implementation of Environmental Commitment 4–Environmental Commitment 10 for Alternative 4A would potentially result in the conversion of wetlands and waters in cultivated lands and along the margins of Delta channels. These wetlands and waters would likely be converted to tidal and nontidal wetlands, including some open water, and possibly grasslands through implementation of Environmental Commitment 4, Environmental Commitment 8, and Environmental Commitment 10. Although, the increase in wetland acreage and wetland functions from these Environmental Commitments could offset the effects on waters of the United States occurring in these areas, implementation of Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the United States*, would be required to ensure that the impacts are reduced to a less-than-significant level.

Shorebirds and Waterfowl

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of the Environmental Commitments, on shorebirds and waterfowl. Managed wetlands, tidal and nontidal natural communities, grasslands, vernal pools, alkali seasonal wetlands, and cultivated lands (including grain and hay crops, pasture, field crops, rice, and idle lands) provide freshwater nesting, feeding, and resting habitat for a large number of Pacific flyway waterfowl and shorebirds.

Alternative 4A would result in both temporary and permanent losses of shorebird and waterfowl habitat. Full implementation of Alternative 4A would also include the following Environmental Commitments and associated Resource Restoration and Performance Principles that would benefit shorebirds and waterfowl through habitat restoration and protection.

- Restore or create up to 37 acres of tidal wetlands in the north Delta (Environmental Commitment 4).
- Restore or create up to 22 acres of *Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acres in the south Delta (Environmental Commitment 10 and Resource Restoration and Performance Principle CBR1).
- Protect up to 119 acres of nontidal wetlands and create up to 832 acres of nontidal wetlands (Environmental Commitment 3 and Environmental Commitment 10).
- Protect up to 1,060 acres of grassland and 11,870 acres of cultivated lands (Environmental Commitment 3).
- Restore up to 1,070 acres of grassland (Environmental Commitment 8).
- Restore vernal pool complex and alkali seasonal (Environmental Commitment 9).

Impact BIO-178: Loss or Conversion of Habitat for Waterfowl and Shorebirds as a Result of Water Conveyance Facilities Construction

Development of the water conveyance facilities would result in the permanent removal of approximately 22 acres of managed wetland, 3 acres of tidal wetlands, 61 acres of nontidal wetlands, 1 acre of alkali seasonal wetland, 19 acres of vernal pool complex, 467 acres of grasslands, and 3,768 acres of suitable cultivated lands (including grain and hay crops, pasture, field crops, rice, and idle lands). In addition, 29 acres of managed wetland, 15 acres of tidal wetlands, 15 acres of nontidal wetlands, 3 acres of vernal pool complex, 158 acres of grasslands, and 1,339 acres of suitable cultivated lands would be temporarily impacted. No rice would be impacted as a result of constructing the water conveyance facilities. These losses of habitat would occur within the first 10–14 years of Alternative 4A implementation in the Delta.

A total of 1,060 acres of grassland and 11,870 acres of cultivated lands would be protected and 1,070 acres of grassland would be restored through Alternative 4A. In addition, 295 acres of tidal freshwater emergent wetland would be restored or created and 119 acres of nontidal wetlands would be protected, and 832 acres of nontidal wetlands would be created in the Delta. The restored and protected acres described above would provide suitable nesting and/or foraging habitat for these species. These conservation actions would be associated with the aforementioned Environmental Commitments and would occur in the same timeframe as the construction losses. Construction activities could have an adverse effect on nesting shorebirds or waterfowl if they were present in or adjacent to work areas and could result in destruction of nests or disturbance of nesting and foraging behaviors. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on nesting birds.

NEPA Effects: Habitat loss from construction of the Alternative 4A water conveyance facilities would not result in an adverse effect on shorebirds and waterfowl because of the acres of natural communities and cultivated lands that would be restored and protected. If waterfowl were present in or adjacent to work areas, construction activities could result in destruction of nests or disturbance of nesting and foraging behaviors, which would be an adverse effect on nesting shorebirds and waterfowl. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on nesting birds.

CEQA Conclusion: Habitat loss from construction of the Alternative 4A water conveyance facilities would have a less-than-significant impact on shorebirds and waterfowl because of the acres of natural communities and cultivated lands that would be restored and protected. If waterfowl were present in or adjacent to work areas, construction activities could result in destruction of nests or disturbance of nesting and foraging behaviors, which would be a significant impact. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, which would identify birds prior to disturbance and would allow for avoidance measures, would reduce this impact on nesting birds to a less-than-significant level.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-179: Loss or Conversion of Habitat for Wintering Waterfowl as a Result of Implementation of Alternative 4A Environmental Commitments

The implementation of Environmental Commitments would result in the permanent loss or conversion of 2,295 acres of cultivated lands and natural communities suitable for wintering waterfowl.

- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 20 acres of managed wetlands, 1 acre of nontidal wetlands, 25 acres of vernal pool complex, 1 acre of alkali seasonal wetland, 40 acres of grassland, and 54 acres of cultivated lands.

- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 1 acre of grassland and 251 acres of cultivated lands.
- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would convert approximately 1,070 acres of cultivated lands into grasslands.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 832 acres of cultivated lands

A total of 1,060 acres of grassland and 11,870 acres of cultivated lands would be protected and 1,070 acres of grassland would be restored through Alternative 4A. In addition, 295 acres of tidal freshwater emergent wetland would be restored or created and 119 acres of nontidal wetlands would be protected, and 832 acres of nontidal wetlands would be created in the Delta. Some portion of these wetlands would be expected to provide suitable habitat for wintering waterfowl. The restored and protected acres described above would provide foraging habitat for wintering waterfowl and the acres of cultivated lands protected would provide adequate food sources and resting habitat for waterfowl species. Restoration and protection acres would be associated with Environmental Commitment 3, Environmental Commitment 4, Environmental Commitment 8, Environmental Commitment 9, and Environmental Commitment 10 and would occur in the same timeframe as the construction and early restoration losses. Environmental Commitment 11 would be implemented to guide management of cultivated lands and wetlands for shorebird and waterfowl species.

***NEPA Effects*:** The loss or conversion of 2,295 acres of cultivated lands and natural communities suitable for wintering waterfowl would not be adverse under NEPA because project proponents have committed to restoring and protecting an acreage that exceeds the typical mitigation ratios for cultivated lands (1:1 protection). This habitat protection and restoration would not be expected to substantially alter food productivity for wintering waterfowl in the Delta. Therefore the implementation of Alternative 4A would not represent an adverse effect on wintering waterfowl.

***CEQA Conclusion*:** The loss or conversion of 2,295 acres of cultivated lands and natural communities suitable for shorebirds and waterfowl would not represent a substantial impact because project proponents have committed to restoring and protecting an acreage that exceeds the typical mitigation ratios for cultivated lands (1:1 protection). This habitat protection and restoration would not be expected to substantially alter food productivity for wintering waterfowl in the Delta. Therefore the implementation of Alternative 4A would have a less-than-significant impact on wintering waterfowl.

Impact BIO-180: Loss or Conversion of Habitat for Breeding Waterfowl from Implementation of Alternative 4A Environmental Commitments

The implementation of Environmental Commitments would result in the permanent loss or conversion of 88 acres of natural communities suitable for breeding waterfowl.

- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 20 acres of managed wetlands, 1 acre of nontidal wetlands, 25 acres of vernal pool complex, 1 acre of alkali seasonal wetland, and 40 acres of grassland.

- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 1 acre of grassland.

Alternative 4A would protect up to 119 acres and create up to 832 acres of nontidal marsh. In addition, 295 acres of tidal freshwater wetlands would be restored in the Delta which would be expected to contain water during the breeding period (March through July). Up to 119 acres of nontidal wetlands would be protected and 832 acres of nontidal wetlands would be created in the Delta. Restoration and protection acres would be associated with Environmental Commitment 3, Environmental Commitment 4, and Environmental Commitment 8, Environmental Commitment 10 and would occur in the same timeframe as the construction and early restoration losses. Environmental Commitment 11 would be implemented to guide management of habitat for breeding waterfowl. Construction activities could have an adverse effect on nesting waterfowl if they were present in or adjacent to work areas and could result in destruction of nests or disturbance of nesting and foraging behaviors. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on nesting birds.

NEPA Effects: Habitat loss from the implementation of Environmental Commitments would not result in an adverse effect on breeding waterfowl because of the acres of natural communities and cultivated lands that would be restored and protected. If waterfowl were present in or adjacent to work areas, construction activities could result in destruction of nests or disturbance of nesting and foraging behaviors, which would be an adverse effect on nesting waterfowl. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on nesting birds.

CEQA Conclusion: Habitat loss from the implementation of Environmental Commitments would not result a significnat impact on breeding waterfowl because of the acres of natural communities and cultivated lands that would be restored and protected. If waterfowl were present in or adjacent to work areas, construction activities could result in destruction of nests or disturbance of nesting and foraging behaviors, which would be a significant impact. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, which would require identification of birds prior to disturbance and would allow for avoidance measures, would reduce this impact on nesting birds to a less-than-significant level.

Impact BIO-181: Loss or Conversion of Habitat for Shorebirds from the Implementation of Alternative 4A Environmental Commitments

Shorebird use of the study area varies by species and fluctuates both geographically and by habitat type throughout the year. Shallow flooded agricultural fields and wetlands support large numbers of wintering and migrating shorebirds (Shuford et al. 1998), particularly least and western sandpipers, dunlin, greater yellowlegs and long-billed dowitcher. Rice lands of the Sacramento Valley provide important breeding habitat for shorebirds such as American avocet, killdeer, and black-necked stilt (Shuford et al. 2004) and have been designated as a Western Hemisphere Shorebird Reserve Network Site of International Importance (Hickey et al. 2003). Managed wetlands provide suitable foraging and roosting habitat for shorebirds; black-necked stilts, avocets, and yellowlegs use this habitat type almost exclusively. Vernal pool complex and alkali seasonal wetland also provide nesting habitat for American avocet (Shuford et al. 2004). Water depth in all of these habitat types is an important habitat variable as the majority of shorebird species require water depths of approximately 10–20 cm for foraging (Isola et al. 2000, Hickey et al. 2003).

Managed Wetlands

According to Stralberg et al. 2011, the following species of shorebirds had a rank 1 designation for managed wetland habitat suitability (Table 1, ICF International 2013): black-necked stilt (*Himantopus mexicanus*), greater yellowlegs (*Tringa melanoleuca*), and long-billed dowitcher (*Limnodromus scolopaceus*). Dunlin (*Calidris alpine*), least sandpiper (*Calidris minutilla*), semipalmated plover (*Charadrius semipalmatus*), and western sandpiper (*Calidris mauri*), had a rank 2 for managed wetland habitat suitability. Black-bellied plover (*Pluvialis squatarola*) and whimbrel (*Numenius phaeopus*) both had rank 3 for managed wetland habitat suitability.

No managed wetlands would be converted or lost from the implementation of Environmental Commitment 4, Environmental Commitment 7, or Environmental Commitment 10. However, 832 acres of nontidal marsh would be created under Environmental Commitment 10.

Cultivated Lands

According to Stralberg et al. 2011, the following species of shorebirds had a rank 1 designation for cultivated lands habitat suitability (Table 1, ICF International 2013): killdeer (*Charadrius vociferous*), long-billed curlew, and whimbrel within pasture habitat. Long-billed dowitcher and killdeer both had a rank 2 for idle crop habitat suitability and black-bellied plover was ranked 2 for pasture habitat. Red-necked phalarope (*Phalaropus lobatus*) and Wilson's phalarope (*Phalaropus tricolor*) were both ranked 2 for grain and hay crops. Long-billed dowitcher, dunlin, least sandpiper, and long-billed curlew were all ranked 3 for rice habitat suitability and killdeer was ranked 3 for field crop habitat suitability.

Within the Delta, 54 acres of cultivated lands would be permanently converted to tidal wetlands as a result of tidal restoration (Environmental Commitment 4), 251 acres would be permanently lost as a result of riparian restoration (Environmental Commitment 7), 1,070 acres would be converted to grassland as a result of grassland restoration (Environmental Commitment 8), and 832 acres would be converted to nontidal wetlands as a result of nontidal marsh restoration (Environmental Commitment 10).

Tidal Wetlands

According to Stralberg et al. 2011, the following species of shorebirds had a rank 1 designation for tidal mudflat habitat suitability (Table 6, ICF International 2013): black-bellied plover, dunlin, least sandpiper, marbled godwit (*Limosa fedoa*), semipalmated plover, short-billed dowitcher (*Limnodromus griseus*), western sandpiper, and willet (*Tringa semipalmata*). Long-billed curlew (*Numenius americanus*) and whimbrel both had a rank 2 for tidal mudflat habitat suitability. American avocet (*Recurvirostra americana*) was ranked 3 for tidal mudflat habitat suitability. For tidal brackish emergent wetland/tidal freshwater emergent wetland, willet was ranked 2 and long-billed curlew and whimbrel were both ranked 3 for habitat suitability.

No tidal wetlands would be converted or lost from the implementation of Environmental Commitment 4, Environmental Commitment 7, Environmental Commitment 8, or Environmental Commitment 10. However, 295 acres of tidal wetlands would be created under Environmental Commitment 4.

Nontidal Wetlands

According to Stralberg et al. 2011, the following species of shorebirds had a rank 1 designation for nontidal wetland habitat suitability (Table 6, ICF International 2013): red-necked phalarope and Wilson's phalarope for nontidal freshwater perennial emergent wetland and American avocet for alkali seasonal wetland complex. Greater yellowlegs had a rank 2 for vernal pool complex habitat suitability. Red-necked phalarope and western sandpiper were both ranked 3 for alkali seasonal wetland habitat suitability and greater yellowlegs was ranked 3 for nontidal freshwater perennial emergent wetland habitat suitability.

No nontidal wetlands would be converted or lost from the implementation of Environmental Commitment 4, Environmental Commitment 7, or Environmental Commitment 10. However, 832 acres of nontidal wetlands would be created under Environmental Commitment 10.

The protection and restoration of natural communities would also include management and enhancement actions under *Environmental Commitment 11 Natural Communities Enhancement and Management.* The following management activities to benefit shorebirds would be considered for implementation under Environmental Commitment 11 in areas where they would not conflict with other species management.

- Managed wetlands and Nontidal Wetlands:
  - Managed wetlands can be potentially manipulated to provide the optimum water depths for foraging shorebirds and islands for nesting (Hickey et al. 2003).
  - During fall and spring, stagger the timing and location of draining and flooding to optimize the extent of shallow-water habitat; varying depths within the wetland unit helps to create temporal variation in foraging opportunities. During warm, dry springs when wetland units dry quickly, wetland units can be re-supplied with water to extend habitat availability for shorebirds.
  - Provide open, shallow water habitat adjacent to minimally vegetated, shallowly sloped edges for nesting shorebirds between April and July.
  - Provide islands with little to no vegetation to increase the likelihood of shorebird roosting and nesting.
  - Create low slopes on islands and levees; gradual angles (10–12:1) are better than steep angles.
  - Limit levee maintenance during the nesting season (April through July). However, mowing the center of levees is fine.
  - Potentially add material to levees or to islands to encourage nesting for some species.
- Cultivated Lands:
  - Maintaining a mosaic of dry and flooded crop types, and varying water depths will promote a diverse community of waterbirds, including shorebirds, during fall migration and winter (Shuford et al. 2013).
  - To provide wintering habitat for multiple waterbird guilds, including shorebirds, use a combination of flooding practices that include one-time water application and maintenance flooding while also providing unflooded habitat (Strum et al. *in review*).

- The post-harvest flooding of winter wheat and potato fields in early fall (July- September) can provide substantial benefits to shorebirds at a time of very limited shallow-water habitat on the landscape (Shuford et al. 2013).
- Stagger the drawdown of flooded rice and other winter-flooded agricultural fields to prolong the availability of flooded habitat (Iglecia et al. 2012). Be aware of soil type because this practice may not be as effective on soils that drain quickly.
- Remove as much stubble as possible in rice and other agricultural fields after harvest to increase the potential shorebird habitat on intentionally flooded or unflooded fields that may passively gather rain water (Iglecia et al. 2012).
- Shallowly flood available agricultural fields during July, August, and September to provide early fall migration habitat for shorebirds. Fields should be free of vegetation prior to flooding, have minimal micro-topography (e.g., no large clods), and should remain flooded for up to three week periods (after three weeks, vegetation encroachment reduces habitat value for shorebirds; ICF International 2013).
- Manage levee habitats to have minimal vegetation but do not spray herbicide directly or drive on levees during the nesting season (April–July, Iglecia et al. 2012).
- Maintain a minimum top-width of 30 inches for levees, based on increased avocet use of wider levees (Iglecia et al. 2012).
- When possible, flood fields with nesting habitat (modified levees and islands) in late April to provide nesting habitat for American avocets (Iglecia et al. 2012).
- Finer grained substrate (clods smaller than a fist) in rice and other agricultural fields may be more appealing for nesting shorebirds (Iglecia et al. 2012).
- Maintain gently sloping levees and island sides (10–12:1; Iglecia et al. 2012).
- Islands should be disked along with the rest of the field after harvest to help inhibit vegetation growth (Iglecia et al. 2012).

NEPA Effects: Alternative 4A implementation would result in the conversion of cultivated lands in the Delta to tidal and nontidal wetlands. The result would be a loss of the primary habitat of black-necked stilt, American avocet, greater yellowlegs, and long-billed dowitcher and a gain in the primary habitat of black-bellied plover, dunlin, least sandpiper, marbled godwit, semipalmated plover, short-billed dowitcher, western sandpiper, and willet. While losses of cultivated lands would be incurred, protection, enhancement, and management of 11,870 acres of cultivated lands would likely have substantial benefits for select species of wintering and breeding shorebirds. This is because impacts on crop types would be distributed across all crop types, while protection would focus primarily on pasture lands, grain and hay, corn, and rice types. While the protection, enhancement, and management of these crop types are being driven by Swainson's hawk, giant garter snake, and greater sandhill crane, they would also benefit shorebirds with the implementation of the management actions outlined in *Environmental Commitment 11 Natural Communities Enhancement and Management*. Habitat conversion would not be expected to result in an adverse effect on shorebird populations in the study area.

CEQA Conclusion: Alternative 4A implementation would result in the conversion of cultivated lands in the Delta to tidal and nontidal wetlands. The result would be a loss of the primary habitat of black-necked stilt, American avocet, greater yellowlegs, and long-billed dowitcher and a gain in the primary habitat of black-bellied plover, dunlin, least sandpiper, marbled godwit, semipalmated plover, short-billed dowitcher, western sandpiper, killdeer, and willet. While losses of cultivated lands would be incurred, protection, enhancement, and management of 11,870 acres of cultivated lands would likely have substantial benefits for select species of wintering and breeding shorebirds. This is because impacts on crop types would be distributed across all crop types, while protection would focus primarily on pasture lands, grain and hay, corn, and rice types. While the protection, enhancement, and management of these crop types are being driven by Swainson's hawk, giant garter snake, and greater sandhill crane, they would also benefit shorebirds with the implementation of the management actions outlined in *Environmental Commitment 11 Natural Communities Enhancement and Management*. Habitat conversion would not be expected to adversely affect shorebird populations in the study area. With the protection and restoration of acres in the Delta watershed, in addition to the implementation of the management actions outlined in *Environmental Commitment 11 Natural Communities Enhancement and Management*, habitat conversion would be expected to have a less-than-significant impact on shorebird populations in the study area.

Impact BIO-182: Effects on Shorebirds and Waterfowl Associated with Electrical Transmission Facilities

New transmission lines installed in the study area would increase the risk for bird-power line strikes, which could result in injury or mortality of shorebirds and waterfowl. The existing network of power lines in the study currently poses a risk for shorebirds and waterfowl in the Delta. New transmission lines would increase this risk and have an adverse effect on shorebird and waterfowl species in the absence of other avoidance and minimization measures. The implementation of *AMM20 Greater Sandhill Crane* would reduce potential effects through the installation of flight-diverters on new transmission lines and selected existing transmission lines in the study area.

NEPA Effects: New transmission lines would increase the risk for shorebird and waterfowl power line strikes which could have a substantial adverse effect as a result of direct mortality. This impact would be significant. With the implementation of *AMM20 Greater Sandhill Crane*, the potential effect of the construction of new transmission lines on shorebird and waterfowl would not be adverse.

CEQA Conclusion: New transmission lines would increase the risk for shorebird and waterfowl power line strikes which could have a substantial adverse effect as a result of direct mortality. This impact would be significant. The implementation of *AMM20 Greater Sandhill Crane* would reduce the potential impact of powerline strikes from the construction of new transmission lines on shorebirds and waterfowl to a less-than-significant level.

Impact BIO-183: Indirect Effects of Plan Implementation on Shorebirds and Waterfowl

Indirect Construction- and Operation-Related Effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect shorebird and waterfowl use of modeled habitat. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect shorebirds and waterfowl or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to shorebirds and waterfowl in the study area could also have a negative effect on these species. AMM1–AMM7 would ensure that measures were in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Project activities have the potential to exacerbate bioaccumulation of mercury in shorebird and waterfowl species. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Bioaccumulation of methylmercury varies by species as there are taxonomic differences in rates of detoxification within the liver (Eagles-Smith et al. 2009). Organisms feeding within pelagic-based (algal) foodwebs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic foodwebs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009). That is, the pelagic food chain tends to be longer than the benthic food chain, which allows for greater biomagnification of methylmercury in top predators. Also, there is less prey diversity at the top of the pelagic food chain than in the benthic food chain; pelagic top predators eat smaller fish and little else, while benthic top predators consume a variety of organisms, many of which are lower in the food chain than fishes and thus have less potential for methylmercury biomagnification. Shorebirds and waterfowl that forage on invertebrates and bivalves, may therefore have lower concentrations of methylmercury than diving ducks that forage on fish. A detailed review of the methylmercury issues associated with implementation of Alternative 4A are contained in Appendix 11F, *Substantive BDCP Revisions*,. The review includes an overview of the project-related mechanisms that could result in increased mercury in the foodweb, and how exposure of individual species to mercury may occur based on feeding habits and where species habitat overlaps with the areas where mercury bioavailability could increase.

Largemouth bass was used as a surrogate species for analysis and the modeled effects of mercury concentrations from changes in water operations under water conveyance facilities on largemouth bass did not differ substantially from existing conditions (see Appendix 11F, *Substantive BDCP Revisions*); therefore, results also indicate that shorebird and waterfowl mercury tissue concentrations would not measurably increase as a result of water conveyance facilities implementation.

Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, Alternative 4A restoration activities that create newly inundated areas (Environmental Commitment 4) could increase bioavailability of mercury. In general, the highest methylation rates are associated with high tidal marshes that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury. Given that some species have elevated mercury tissue levels without the project, these low level increases could result in some level of effects. Restoration in Suisun Marsh would convert managed wetlands to tidal wetlands, which would be expected to result in an overall reduction in mercury methylation.

Due to the complex and very site-specific factors that will determine if mercury becomes mobilized into the foodweb, Environmental Commitment 12, is included to provide for site-specific evaluation for each restoration project. On a project-specific basis, where high potential for methylmercury production is identified that restoration design and adaptive management cannot fully address while also meeting restoration objectives, alternate restoration areas will be considered. Environmental Commitment 12 will be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This Environmental Commitment will include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and project activities have the potential to exacerbate bioaccumulation of selenium in avian species, including shorebird and waterfowl species. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of selenium (see Chapter 3, *Conservation Strategy*, of the BDCP for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with Environmental Commitment 4 would lead to adverse effects on shorebirds and waterfowl species.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on shorebirds and waterfowl from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management,* which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats, (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Noise and visual disturbances from the construction of Alternative 4A water conveyance facilities could reduce shorebird and waterfowl use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect shorebird and waterfowl use of the surrounding habitat. AMM1–AMM7 would minimize these effects, and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting individuals.

Tidal habitat restoration could result in increased exposure of shorebirds and waterfowl to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Therefore, the indirect effects associated with noise and visual disturbances, and increased exposure to selenium from Alternative 4A implementation would not have an adverse effect on shorebirds and waterfowl.

Changes in water operations under water conveyance facilities would not be expected to result in increased mercury bioavailability or exposures to Delta foodwebs. Tidal habitat restoration could result in increased exposure of California least tern to methylmercury. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the concentrations of methylmercury that are harmful varies by species, and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on shorebirds and waterfowl.

CEQA Conclusion: Indirect effects that include noise and visual disturbance, potential hazardous spills, increased dust and sedimentation, and increased methylmercury and selenium exposure as a result of Alternative 4A water conveyance facilities construction and operation and maintenance would represent an adverse effect as a result of habitat modification and potential for direct mortality of shorebirds and waterfowl in the absence of the environmental commitments and AMMs. This would be a significant impact.

AMM1–AMM7, and implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce potential adverse effects of noise, visual disturbance and potential for spills, dust, and sedimentation.

Tidal habitat restoration could result in increased exposure of shorebirds and waterfowl to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Changes in water operations under water conveyance facilities would not be expected to result in increased mercury bioavailability or exposures to Delta foodwebs. Tidal habitat restoration could result in increased exposure of California least tern to methylmercury. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. This could result in a significant impact. However, the concentrations of methylmercury that are harmful varies by species, and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on shorebirds and waterfowl.

Therefore, with AMM1–AMM7, AMM27, and Environmental Commitment 12 in place, in addition to the implementation of Mitigation Measure BIO-75, the indirect effects of Alternative 4A implementation would not result in a substantial adverse effect through habitat modification or potential mortality. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on shorebirds and waterfowl.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Common Wildlife and Plants

Common wildlife and plants are widespread, often abundant, species that are not all covered under laws or regulations that address conservation or protection of individual species. Common wildlife do have some level of protection under California Fish and Game Code and most bird species have protections under the Migratory Bird Treaty Act. Examples of common wildlife and plants occurring in the study area are provided within the discussion for each natural community type in Section 12.1.2.2, *Special-Status and Other Natural Communities*. Impacts on common wildlife and plants would occur through the same mechanisms discussed for natural communities and special-status wildlife and plants for each alternative.

Impact BIO-184: Effects on Habitat and Populations of Common Wildlife and Plants

Effects on habitat of common wildlife and plants, including habitat removal and conversion, are discussed in the analysis of Alternative 4A effects on natural communities (Impacts BIO-1 through BIO-21). In general, effects on habitat of common wildlife and plants would not be adverse. Through the course of implementing the project over a 15-year time period, several natural communities and land cover types would be reduced in size, primarily from construction of the water conveyance facility, but also from restoration of other natural communities. Grassland, managed wetland and cultivated lands would be reduced in acreage, so the common species that occupy these habitats would be affected. However, the losses in acreage and value of these habitats would be offset by protection, restoration, enhancement, and management actions under Alternative 4A, including *Environmental Commitment 3 Natural Communities Protection and Restoration*, *Environmental Commitment 4 Tidal Natural Communities Restoration*, *Environmental Commitment 6 Channel Margin Enhancement*, *Environmental Commitment 7 Riparian Natural Community Restoration*, *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *Environmental Commitment 10 Nontidal Marsh Restoration*, and *Environmental Commitment 11 Natural Communities Enhancement and Management*. In addition, the AMMs contained in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, would be in place to reduce or eliminate the potential to adversely affect both special-status and common wildlife and plants.

Direct effects on common wildlife and plants from constructing water conveyance facilities and implementing Environmental Commitments would include construction or inundation-related disturbances that result in injury or mortality of wildlife or plants and the immediate displacement of wildlife, including increased traffic on local roads from construction vehicles that could increase wildlife mortality and impede wildlife movement. Effects of construction traffic on wildlife moving in the vicinity of Stone Lakes NWR would be minimized by *AMM20 Greater Sandhill Crane*, which includes a measure for the installation of a vegetation screen or other noise and visual barrier along Hood Franklin Road for the benefit of cranes, which would be a minimum of 5 feet high (above the adjacent elevated road, if applicable) and which would provide a continuous surface impenetrable by light. This measure would potentially direct wildlife wishing to cross Hood Franklin toward the overcrossing of the canal that links the Stone Lakes properties just east of the town of Hood. The overcrossing includes strips of terrestrial habitat on either side of the canal.

Indirect effects include project-related disturbances to nearby wildlife and plants during construction (e.g., disruption of breeding and foraging behaviors from noise and human activity, habitat degradation from fugitive dust and runoff) and effects occurring later in time (e.g., collisions of birds with transmission lines, habitat fragmentation, vegetation management). Indirect effects could result both from construction and from operations and maintenance (e.g., ground disturbances could result in the spread and establishment of invasive plants).

***NEPA Effects*:** The direct and indirect effects associated with implementing the Environmental Commitments of Alternative 4A would not be adverse because the Environmental Commitments and AMMs also expand and protect natural communities, avoid or minimize effects on special-status species, prevent the introduction and spread of invasive species, and enhance natural communities. These actions would result in avoiding and minimizing effects on common wildlife and plants as well.

***CEQA Conclusion*:** Construction and operation of the water conveyance facilities and habitat restoration activities would have impacts on common wildlife and plants in the study area through habitat loss and through direct or indirect loss or injury of individuals. The loss of habitat would not be substantial, because habitat restoration would increase the amount and extent of habitat available for use by most common wildlife and plant species. Environmental commitments to avoid or minimize effects on special-status species, and to enhance natural communities also would result in avoiding and minimizing effects on common wildlife and plants. Consequently, implementation of Alternative 4A is not expected to cause any populations of common wildlife or plants to drop below self-sustaining levels, and this impact would be less than significant. No mitigation would be required.

Wildlife Corridors

Essential Connectivity Areas (ECAs) are lands likely to be important to wildlife movement between large, mostly natural areas at the state wide level. The ECAs form a functional network of wildlands that are considered important to the continued support of California's diverse natural communities. Four general areas were identified within the study area that contain ECAs (Figure 12-2). The BDCP also identified important landscape linkages in the Plan Area to guide reserve design, which can also be seen on Figure 12-2.

Impact BIO-185: Effects of Alternative 4A on Wildlife Corridors

Alternative 4A water conveyance facilities would cross two of the ECAs identified during the analysis, the Stone Lake-Yolo Bypass ECA and the Mandeville Island-Staten Island ECA.

The construction of Intakes 2 and 3, temporary tunnel work areas, and RTM areas would occur within the Stone Lake-Yolo Bypass ECA. These activities would result in the permanent loss of narrow strips of riparian vegetation along the Sacramento River and the permanent and temporary loss of cultivated lands. Alternative 4A would not substantially increase impediments to movement of any nonavian wildlife that could move from Stone Lakes to Yolo Bypass because the Sacramento River and Sacramento River Deep Water Ship Channel already create a barrier to dispersal for nonavian species. However, the conversion of riparian and cultivated lands and the presence of the intakes would locally constrict the north-south movement of nonavian terrestrial species in the area between the Sacramento River and the Southern Pacific Dredger Cut west of Stone Lakes, as well as the east-west movement between Stone Lakes and the east bank of the Sacramento River. No records of wildlife species were identified within these construction footprints, though there are several records for Swainson's hawk in the vicinity. Though there would be losses in Swainson's hawk foraging habitat and potential nesting habitat in these areas, these loses would not substantially impede the movements of Swainson's hawks in the area. The loss in habitat is addressed in the Swainson's hawk effects analysis.

The addition of temporary transmission lines within the Stone Lake-Yolo Bypass ECA, which would be in place for approximately 7 years, could adversely affect birds during periods of low visibility. Sandhill cranes that are known to roost at Stones Lakes could particularly be adversely affected by the addition of the north-south running transmission line to the west of Stone Lakes and by the east-west transmission line between Stone Lakes and the Cosumnes Preserve; however, this line would generally parallel an existing transmission line. Because the proposed east-west transmission line parallels an existing line and would only be in place for approximately 7 years it would not likely create a barrier to the future movement of cranes in this area (see impact discussions for greater and lesser sandhill cranes).

The Alternative 4A conveyance facilities would also pass through the Mandeville Island-Staten Island ECA, which also has several know roost locations for greater sandhill crane. Within this ECA, Alternative 4A would result in the construction of a large RTM disposal area on Bouldin Island, permanent access roads on Bouldin and Mandeville Islands, and temporary transmission lines across most of the ECA. As discussed above, the temporary transmission lines could adversely affect the movement of cranes and other bird species during periods of low visibility. The RTM disposal area may create a physical barrier to movement for some species and could make this area unusable as wildlife habitat for close to 10 years during the tunnel construction. The access roads are mostly located on existing dirt and paved roads and would therefore not create any new physical barriers but could temporarily increase road mortality during periods of construction. The conveyance alignment at this location would be within the tunnel and thus not create a barrier to wildlife movement.

Alternative 4A conveyance facilities would create some localized disruption in wildlife movement and the temporary and permanent transmission lines would create additional barriers to movement for avian species during periods of low visibility. However, overall the Alternative 4A alignment would not create substantial barriers to movement between ECAs because the majority of the alignment consists of a tunnel that would be beneath riparian corridors, which are the most likely dispersal routes for terrestrial animals in the majority of the study area, and because the large surface impacts (the intakes) are in areas that already have barriers to movement for nonavian terrestrial species (Sacramento River and Sacramento River Deep Water Ship Channel).

Restoration activities may occur in some of the ECAs. These activities would generally improve the movement of wildlife within and outside of the study area. In addition, the preservation of restored lands (Environmental Commitment 3) and the enhancement and management of these areas (Environmental Commitment 11) would improve and maintain wildlife corridors within the study area.

NEPA Effects: Alternative 4A conveyance facilities would create local barriers to dispersal but overall the restoration activities would improve opportunities for wildlife dispersal within the study area and between areas outside of the study area and therefore overall Alternative 4A would not adversely affect wildlife corridors.

CEQA Conclusion: Alternative 4A conveyance facilities would create local barriers to dispersal and create barriers to safe movement of avian species during periods of low visibility but overall the restoration activities would improve opportunities for wildlife dispersal within the study area and between areas outside of the study area and therefore overall Alternative 4A would result in less-than-significant impacts on wildlife corridors.

Invasive Plant Species

The invasive plant species that primarily affect each natural community in the study area, which include water hyacinth, perennial pepperweed, giant reed, and Brazilian waterweed, are discussed in Section 12.1.4, *Invasive and Noxious Plant Species*. Invasive species compete with native species for resources and can alter natural communities by altering fire regimes, hydrology (e.g., sedimentation and erosion), light availability, nutrient cycling, and soil chemistry but also have the potential to harm human health and the economy by adversely affecting natural ecosystems, water delivery, flood protection systems, recreation, agricultural lands, and developed areas (Randall and Hoshovsky 2000). The construction and restoration activities associated with Alternative 4A could result in the introduction or spread of invasive plant species by creating temporary ground disturbance that provides opportunities for colonization by invasive plants in the study area.

The primary mechanisms for the introduction of invasive plants as the result of implementation of Alternative 4A are listed here.

- Grading, excavation, grubbing, and placement of fill material.
- Breaching, modification, or removal of existing levees and construction of new levees.

- Modification, demolition, and removal of existing infrastructure (e.g., buildings, roads, fences, electric transmission and gas lines, irrigation infrastructure).
- Maintenance of infrastructure.
- Removal of existing vegetation and planting/seeding of vegetation.
- Maintaining vegetation and vegetation structure (e.g., grazing, mowing, burning, trimming).
- Dredging waterways.

Clearing operations and the movement of vehicles, equipment, and construction materials in the study area would facilitate the introduction and spread of invasive plants by bringing in or moving seeds and other propagules. These effects would result from four activities.

- Spreading chipped vegetative material from clearing operations over topsoil after earthwork operations are complete.
- Importing, distributing, storing, or disposing of fill, RTM, borrow, spoil, or dredge material.
- Traffic from construction vehicles (e.g., water and cement trucks) and personal vehicles of construction staff.
- Transport of construction materials and equipment within the study area and to/from the study area.

Table 12-4A-69 lists the acreages of temporary disturbance in each natural community in the study area that would result from implementation of Alternative 4A.

Table 12-4A-69. Summary of Temporary Disturbance in Natural Communities under Alternative 4A

Natural Community	Temporary Impacts (acres)
Tidal perennial aquatic	2,098
Tidal brackish emergent wetland	0
Tidal freshwater emergent wetland	15
Valley foothill riparian	31
Grassland	151
Inland dune scrub	0
Alkali seasonal wetland complex	0
Vernal pool complex	3
Other natural seasonal wetland	0
Nontidal freshwater perennial emergent wetland	6
Nontidal perennial aquatic	10
Managed wetlands	29
Cultivated lands	1,309
Total	**3,652**

Impact BIO-186: Adverse Effects on Natural Communities Resulting from the Introduction and Spread of Invasive Plant Species

Alternative 4A would have adverse effects on natural communities as a result of the introduction and spread of invasive plant species through implementation of water conveyance facilities, Environmental Commitment 3, Environmental Commitment 4, Environmental Commitment 6, Environmental Commitment 7, Environmental Commitment 9, Environmental Commitment 10 and AMM6. No adverse effects are expected from implementation of other project-related Environmental Commitments.

- *Water Facilities and Operations*: Construction of the Alternative 4A water conveyance facilities would result in the temporary disturbance of 3,652 acres that would provide opportunities for colonization by invasive plant species.
- *Environmental Commitment 3 Natural Communities Protection and Restoration*: The restoration activities in the natural communities located in planned conservation areas would result in the temporary disturbance of restoration areas that would provide opportunities for colonization by invasive plant species.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: The activities associated with the restoration of tidal perennial aquatic, tidal mudflat, tidal freshwater emergent wetland, and tidal brackish emergent wetland in ROAs would result in the temporary disturbance of tidal areas that would provide opportunities for colonization by invasive plant species. These adverse effects would be reduced by designing restoration projects to minimize the establishment of nonnative submerged aquatic vegetation, and early restoration projects would be monitored to assess the response of nonnative species to restoration designs and local environmental conditions. If indicated by monitoring results, the project proponents would implement invasive plant control measures in restored natural communities to help ensure the establishment of native marsh plain plant species. Additionally, the project proponents would actively remove submerged and floating aquatic vegetation in subtidal portions of tidal natural community restoration sites.
- *Environmental Commitment 6 Channel Margin Enhancement*: The temporary effects of channel margin enhancement were not estimated because specific locations for this activity and their areal extent have not been developed. Channel margin enhancement (Sacramento River between Freeport and Walnut Grove, San Joaquin River between Vernalis and Mossdale, Steamboat and Sutter Sloughs, and salmonid migration channels in the interior Delta) would result in the temporary disturbance of channel areas that would provide opportunities for colonization by invasive plant species.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: The restoration of valley/foothill riparian habitat would result in the temporary disturbance of riparian areas that would provide opportunities for colonization by invasive plant species.
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: The restoration of vernal pool and alkali seasonal wetland complexes, primarily in CZ 8, would result in the temporary disturbance of grassland areas that would provide opportunities for colonization by invasive plant species.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration, which would take place through conversion of agricultural lands primarily in CZ 4, would result in the temporary disturbance of fallow agricultural areas that would provide opportunities for

colonization by invasive plant species. These adverse effects would be reduced by monitoring the development of marsh vegetation to determine if nonnative vegetation needs to be controlled to facilitate the establishment of native marsh vegetation or if restoration success could be improved with supplemental plantings of native species. If indicated by monitoring, nonnative vegetation control measures and supplemental plantings would be implemented.

- *Avoidance and Minimization Measures*: *AMM6 Disposal and Reuse of Spoils* would have adverse effects if spoils, RTM, dredged material, or chipped vegetative materials containing viable invasive plant propagules are used as topsoil in uninfested areas.

The adverse effects that would result from the introduction and spread of invasive plants through colonization of temporarily disturbed areas would be minimized by implementation of Environmental Commitment 11, AMM4, AMM10, and AMM11.

Environmental Commitment 11 Natural Communities Enhancement and Management would reduce these adverse effects by implementing invasive plant control within the Alternative 4A restoration areas to reduce competition on native species, thereby improving conditions for special-status species, ecosystem function, and native biodiversity. The invasive plant control efforts would target new infestations that are relatively easy to control or the most ecologically damaging nonnative plants for which effective suppression techniques are available. In aquatic and emergent wetland communities, Brazilian waterweed, perennial pepperweed, barbgrass, and rabbitsfoot grass would be controlled (and tidal mudflats would be maintained). In riparian areas, invasive plant control would focus on reducing or eliminating species such as Himalayan blackberry, giant reed, and perennial pepperweed. In grassland areas, techniques such as grazing and prescribed burning may be used to decrease the cover of invasive plant species.

Implementation of AMM4, AMM10, and AMM11 would also reduce the adverse effects that could result from construction activities. The AMMs provide methods to minimize ground disturbance, guidance for developing restoration and monitoring plans for temporary construction effects, and measures to minimize the introduction and spread of invasive plants. AMM4 would involve the preparation and implementation of an erosion and sediment control plan that would control erosion and sedimentation and restore soils and vegetation in affected areas. The restoration and monitoring plans for implementation of AMM10 would involve methods for stockpiling, storing, and restoring topsoil, revegetating disturbed areas, monitoring and maintenance schedules, adaptive management strategies, reporting requirements, and success criteria. AMM10 would also include planting native species appropriate for the natural community being restored, with the exception of some borrow sites in cultivated lands that would be restored as grasslands.

AMM11 specifies that the project proponent would retain a qualified botanist or weed scientist prior to clearing operations to determine if affected areas contain invasive plants. If areas to be cleared do contain invasive plants, then chipped vegetation material from those areas would not be used for erosion control but would be disposed ~~of~~ to minimize the spread of invasive plant propagules (e.g., burning, composting). During construction of the water conveyance facilities and construction activities associated with the Environmental Commitments, construction vehicles and construction machinery would be cleaned prior to entering construction sites that are in or adjacent natural communities other than cultivated lands and prior to entering any Alternative 4A restoration sites or conservation lands other than cultivated lands. Vehicles working in or travelling off paved roads through areas with infestations of invasive plant species would be cleaned before travelling to other parts of the study area. Cleaning stations would be established at the perimeter of Alternative 4A activities along construction routes as well as at the entrance to conservation area lands. Biological monitoring would include locating and mapping locations of invasive plant species within the construction areas during the construction phase and the restoration phase. Infestations of invasive plant species would be targeted for control or eradication as part of the restoration and revegetation of temporarily disturbed construction areas.

NEPA Effects: The implementation of AMM4, AMM10, and AMM11, and Environmental Commitment 11 would reduce the potential for the introduction and spread of invasive plants and avoid or minimize the potential effects on natural communities and special-status species; therefore, these effects would not be adverse.

CEQA Conclusion: Under Alternative 4A, impacts on natural communities from the introduction or spread of invasive plants as a result of implementing Alternative 4A would not result in the long-term degradation of a sensitive natural community due to substantial alteration of site conditions and would, therefore, be considered less than significant. No mitigation would be required.

Compatibility with Plans and Policies

Impact BIO-187: Compatibility of the Proposed Water Conveyance Facilities and Other Environmental Commitments with Federal, State, or Local Laws, Plans, Policies, or Executive Orders Addressing Terrestrial Biological Resources in the Study Area

Constructing the water conveyance facilities and implementing associated Environmental Commitments for Alternative 4A have the potential for being incompatible with plans and policies related to managing and protecting terrestrial biological resources of the study area. A number of laws, plans, policies, programs, and executive orders that are relevant to actions in the study area provide guidance for terrestrial biological resource issues as overviewed in Section 12.2, *Regulatory Setting*. This overview of plan and policy compatibility evaluates whether Alternative 4A would be compatible or incompatible with such enactments, rather than whether impacts would be adverse or not adverse, or significant or less than significant. If the incompatibility relates to an applicable plan, policy, or executive order adopted to avoid or mitigate terrestrial biological resource effects, then an incompatibility might be indicative of a related significant or adverse effect under CEQA and NEPA, respectively. Such physical effects of Alternative 4A on terrestrial biological resources are addressed in the impacts on natural communities and species. The following is a summary of compatibility evaluations related to terrestrial biological resources for laws, plans, policies, and executive orders relevant to the project.

Federal and State Legislation

- The federal Clean Water Act, Endangered Species Act, Fish and Wildlife Coordination Act, Migratory Bird Treaty Act, Rivers and Harbors Act and Marine Mammal Protection Act all contain legal guidance that either directly or indirectly promotes or stipulates the protection and conservation of terrestrial biological resources in the process of undertaking activities that involve federal decisionmaking. The goals and objectives contained in Alternative 4A that provide the major guidance for implementing the various project elements of Alternative 4A are all designed to promote the long-term viability of the natural communities, special-status species, and common species that inhabit the study area. While some of the Environmental Commitments of the alternative involve permanent and temporary loss of natural communities and associated habitats during facilities construction and expansion of certain natural communities, the long-term implementation of the project would provide for the long-term viability and expansion of the habitats and special-status species populations in the study area.

Alternative 4A Environmental Commitments would be compatible with the policies and directives for terrestrial biological resources contained in these federal laws.

- The California Endangered Species Act, California Native Plant Protection Act, Porter-Cologne Water Quality Control Act, and Natural Communities Conservation Planning Act are state laws that have relevance to the management and protection of terrestrial biological resources in the study area. Each of these laws promotes consideration of wildlife and native vegetation either through comprehensive planning or through regulation of activities that may have an adverse effect on the terrestrial and aquatic natural resources of the state. Alternative 4A contains goals and objectives that have been developed to promote the species protection and natural resource conservation that are directed by these state laws. Alternative 4A Environmental Commitments would be compatible with the policies and directives contained in these laws.

- The *Johnston-Baker-Andal-Boatwright Delta Protection Act of 1992* (*Delta Protection Act*) and the *Sacramento-San Joaquin Delta Reform Act*, which updated the Delta Protection Act, promote the maintenance and protection of natural resources and the protection of agricultural land uses in the Delta's primary zone through the goals and policies contained in the 2009 updated Land Use and Resources Management Plan (LURMP). While nothing in the LURMP is binding on state agencies that are project proponents, the LURMP does promote restoration and enhancement of habitats for the terrestrial and aquatic species of the Delta on public land. The project's goals and objectives would be compatible with these LURMP goals (Delta Protection Commission 2010).

- The *Suisun Marsh Preservation Act* of 1974 was designed to protect the Suisun Marsh for long-term use as wildlife habitat, with a goal of preserving and enhancing the quality and diversity of the Marsh's aquatic and wildlife habitats. Alternative 4A would not affect Suisun Marsh; therefore, it would be compatible with the intent of the Suisun Marsh Preservation Act.

Plans, Programs, and Policies

- *The Delta Plan*, which was developed by the Delta Stewardship Council in compliance with the 2009 Sacramento-San Joaquin Delta Reform Act, is mandated to achieve two co-equal goals: provide for a more reliable water supply for California and protect, restore, and enhance the Delta ecosystem. The co-equal goals are to be achieved in a manner that protects and enhances the unique cultural, recreational, natural resource, and agricultural values of the Delta as an evolving place. The project is intended to contain water management and Environmental Commitments consistent with the Delta Plan. The Delta Stewardship Council will determine whether the project is compatible with the goals and objectives of the Delta Plan prior to its approval. The compatibility of the project with the Delta Plan is considered in detail in Section 13.2.2.2, *The Delta Plan*.

- *California Wetlands Conservation Policy*, which was adopted by Executive Order in 1993, promotes a long-term gain in the quantity, quality and permanence of wetlands acreages and values in California. The project's Environmental Commitments that provide for an expansion of wetland acreage and quality in the Delta are compatible with the intent of the California Wetlands Conservation Policy.

- *The North American Waterfowl Management Plan* (*NAWMP*) and *Central Valley Joint Venture* (*CVJV*) strive to maintain and expand wetlands and uplands for waterfowl and shorebirds in the major basins of California's Central Valley. The NAWMP is a management plan jointly approved by the United States and Canada in 1986. It contains general guidance from the principal wildlife management agencies of the two countries for sustaining abundant waterfowl populations by conserving landscapes through self-directed partnerships (joint ventures) that are guided by sound science. The CVJV is the joint venture established for overseeing NAWMP implementation in the Central Valley. The CVJV is made up of 21 conservation organizations, state and federal government agencies, and one corporation that have formed a partnership to improve the habitat conditions for breeding and nonbreeding waterfowl, breeding and nonbreeding shorebirds, waterbirds, and riparian-dependent songbirds in the Central Valley. The CVJV's 2006 Implementation Plan (Central Valley Joint Venture 2006) establishes conservation objectives and priorities for these bird groups within the basins of the Central Valley. The project study area includes all or portions of three Implementation Plan basins— the Delta, Yolo and Suisun basins. The 2006 Implementation Plan contains basin-specific objectives for wetland restoration, protection of existing wetland habitats, wetland enhancement, adequate power and water supplies for wetland management, agricultural land enhancement, farmland easements that maintain waterfowl food resources on agricultural land, and farmland easements that buffer existing wetlands from urban and residential growth.

Implementation of the Alternative 4A Environmental Commitments would result in reductions in cultivated land and managed wetland acreage in the Delta only; however, increases in tidal and nontidal wetlands in this basin would be another result. The project also contains a significant commitment to long-term protection of agricultural land (over 9,000 acres) for waterfowl, shorebirds and other sensitive wildlife species. The sum of these actions would be consistent with the objectives of the Implementation Plan.

- *Stone Lakes National Wildlife Refuge Comprehensive Conservation Plan*, *Cosumnes River Preserve Management Plan*, *Brannan Island and Franks Tract State Recreation Areas General Plan*, and the *Lower Sherman Island Wildlife Area Land Management Plan* are primarily designed to preserve and enhance the natural resource and recreation qualities of these areas. Implementing Alternative 4A, especially construction of water conveyance facilities, and land modification associated with Environmental Commitment 4 restoration activities, could create temporary disruptions to the terrestrial biological resource management activities in these management areas. The proposed intermediate forebay and the RTM area on Zacharias Island fall within the Stone Lakes Cooperative Wildlife Management Area identified in the Stone Lakes Wildlife Refuge CCP. The primary objective of the Cooperative Wildlife Management Area is to maintain lands in private ownership and continue agricultural production but also allow USFWS to pursue a number of approaches to conserve and manage lands, depending on the preferences of willing landowners. The location of the intermediate forebay is an area that is entirely planted in vineyard, which has very little to no habitat value for wildlife species. The RTM area is used for hay or grain production, which does have high value for wildlife species. Project activities in these areas would conflict with the CCP.

  The ultimate goals of aquatic and terrestrial habitat enhancement and restoration contained in the project would be compatible with the overall long-term management goals of these areas. Proposed restoration areas in the Delta would be designed to be compatible with and to complement the current management direction for these areas and would be required to adapt restoration proposals to meet current policy established for managing these areas.

- *Suisun Marsh Preservation Agreement* and *Suisun Marsh Plan* are the most recent efforts by the state and federal agencies responsible for Suisun Marsh to maintain its long-term viability as managed wetlands and wildlife habitat, consistent with the Suisun Marsh Preservation Act.

Alternative 4A would not directly or indirectly affect the Suisun Marsh and its natural habitats; therefore, it would be consistent with the Plan's management goals.

- *California Aquatic Invasive Species Management Plan* does not address terrestrial invasive species. Implementation of the project's habitat management objectives affect terrestrial species that utilize study area aquatic habitats. These effects are positive in that the project's objectives are to control and remove invasive aquatic species that are detrimental to native aquatic and terrestrial species. Implementation of project's Environmental Commitments would be undertaken with the goal of avoiding any further spread of aquatic invasive species. Alternative 4A would, therefore, be compatible with the objectives of the California Aquatic Invasive Species Management Plan.

- *Habitat Conservation Plans and Natural Community Conservation Plans* are the subject of a detailed analysis in Section 12.3.6, *Effects on Other Conservation Plans*. The analysis considers the compatibility of the alternatives with all HCPs and NCCPs that share planning area with the study area. The Alternative 4A study area overlaps geographically with six conservation plans. The water conveyance facilities construction actions would still overlap with the South Sacramento, San Joaquin, East Contra Costa and East Alameda County planning areas, but there would be little effect on implementation of the HCP/NCCPs for these areas. The Environmental Commitments associated with Alternative 4A would remove relatively small acreages of primarily cultivated land in all six of the overlapping plan areas (Yolo, Solano, South Sacramento, East Contra Costa, East Alameda and San Joaquin County HCP/NCCPs). The consistency analysis below indicates that the degree to which the competition for conservation lands would impact the conservation goals of other plans is limited. Alternative 4A would have much less risk from competition for conservation lands. In most cases, because of the flexibility for acquisition targets incorporated into Alternative 4A and other plans, the potential conflict would be manageable, and significant conflicts with the implementation of overlapping plans could be avoided. In certain cases, especially pertaining to similar restoration objectives, perceived conflicts may also represent opportunities for collaboration to jointly achieve similar conservation goals. Because implementing Alternative 4A would not result in a conflict with the provisions of an adopted HCP, NCCP or other approved local, regional or state habitat conservation plan, there would be a less-than-significant impact.

Executive Orders

- *Executive Order 11990: Protection of Wetlands* requires all federal agencies to consider wetland protection in their policies and actions. The project proposes to protect, enhance and expand the wetlands of the study area, and, therefore, would be compatible with Executive Order 11990.

- *Executive Order 13112: Invasive Species* directs federal agencies to prevent and control the introduction and spread of invasive species in a cost-effective and environmentally sound manner. Alternative 4A construction and restoration actions have the potential to both introduce and spread invasive species in the study area. Implementation of AMM11, described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, could make Alternative 4A implementation compatible with Executive Order 13112.

- *Executive Order 113443: Facilitation of Hunting Heritage and Wildlife Conservation* directs federal agencies whose activities affect public land management, outdoor recreation, and wildlife management to facilitate the expansion and enhancement of hunting opportunities, and the management of game species and their habitat. Alternative 4A Environmental Commitments that involve conversion of cultivated land and managed wetland to tidal and nontidal wetlands and other natural communities would conflict with the hunting expansion and enhancement aspects of this executive order. Refer to Chapter 15, *Recreation*, for a detailed analysis of the effects of alternatives on hunting opportunities. The habitat protection and expansion Environmental Commitments of Alternative 4A would be compatible with the executive order's goal of facilitating the management of habitats for some game species.

***NEPA Effects*:** The potential plan and policy incompatibilities of implementing Alternative 4A identified in the analysis above indicate the potential for a physical consequence to the environment. The primary physical consequence of concern is the conversion of cultivated land and managed wetland to natural wetland and riparian habitat in the study area. The physical effects are discussed in the *Shorebirds and Waterfowl* analysis above, and no additional NEPA effects determination is required related to the compatibility of the alternative with relevant plans and polices. The reader is referred to Chapter 13, Section 13.2, *Regulatory Setting*, for a further discussion of the responsibilities of state and federal agencies to comply with local regulations, and a discussion of the relationship between plan and policy consistency and physical consequences to the environment.

***CEQA Conclusion*:** The potential plan and policy incompatibilities of implementing Alternative 4A identified in the analysis above indicate the potential for a physical consequence to the environment. The primary physical consequence of concern is the conversion of cultivated land and managed wetland to natural wetland and riparian habitat in the study area. The physical effects are discussed in the *Shorebirds and Waterfowl* analysis above, and no additional CEQA conclusion is required related to the compatibility of the alternative with relevant plans and polices. The reader is referred to Chapter 13, Section 13.2, *Regulatory Setting*, for a further discussion of the responsibilities of state and federal agencies to comply with local regulations, and a discussion of the relationship between plan and policy consistency and physical consequences to the environment.

12.3.4.3 Alternative 2D—Dual Conveyance with Modified Pipeline/Tunnel and Intakes 1, 2, 3, 4, and 5 (15,000 cfs; Operational Scenario B)

Alternative 2D is generally similar to Alternative 4A except that Alternative 2D includes two additional intakes (Intakes 1 and 4) along the Sacramento River and operates under a different operational scenario. Like Alternative 4A, this alternative would not serve as an NCCP/HCP and thus the analysis below only considers construction and operation of the conveyance facilities and only includes the Environmental Commitments necessary to fully mitigate the project's impacts under CEQA and NEPA. Other than the increased impacts from the intakes and associated restoration actions, the effects from Alternative 2D would be relatively the same as those under Alternative 4A; therefore, Alternative 2D is considered here in a summary fashion. The reader is referred to the discussion of Alternative 4A for a detailed analysis of impacts that would be associated with implementing Alternative 2D. The impacts associated with Alternatives 2D and 4A were derived by comparing the alternative with the No Action Alternative for NEPA purposes, and with Existing Conditions for CEQA purposes.

Operations under Alternative 2D would be similar, but not identical, to those described under Operational Scenario B (see Chapter 3, Section 3.6.4.2, *North Delta and South Delta Water Conveyance Operational Criteria*). These operations would include both new and existing water conveyance facilities once the new north Delta facilities are completed and become operational, thereby enabling joint management of north and south Delta diversions. Operations included in this alternative for south Delta export facilities would replace the south Delta operations currently implemented in compliance with the USFWS (2008) and NMFS (2009) BiOps. The north Delta intakes and the head of Old River barrier would be new facilities for the SWP and CVP and would be operated as described in Chapter 3, Section 3.6.4.2. Alternative 2D operations include a preference for south Delta pumping in July through September to provide limited flushing for improving general water quality conditions and reduced residence times. The operational scenario under Alternative 2D would have a greater operational capacity than the Alternative 4A operational scenario would have (15,000 cfs compared with 9,000 cfs).

Comparative Differences in Effects for Alternatives 2D and 4A

The principal differences in effects between these two alternatives are related to the differing construction footprints of the water conveyance facilities and the differences in proposed restoration efforts. The Alternative 2D water conveyance facilities would entail construction of two additional north Delta intakes (Intakes 1 and 4). Intake 1 would be located northeast of Clarksburg on the east side of the river, and Intake 4 would be located just south of Hood, also on the east side of the river. There also would be a large RTM disposal area and a new permanent transmission line between Intakes 1 and 2. The operational scenario for Alternative 2D (Scenario B) is also different from Alternative 4A (Scenario H3–H4), but the difference in water operations would not significantly change the operational effects on terrestrial biological resources in the study area. Under Alternative 4A, geotechnical exploration within conveyance construction areas would cause temporary impacts. Alternative 2D would not cause geotechnical exploration impacts.

As a result of the greater impacts from Alternative 2D, additional restoration and protection acreages would be required under the Environmental Commitments to achieve the applicable regulatory standards under ESA Section 7 and CESA Section 2081(b). The restoration actions would themselves result in effects on natural communities where they are likely to occur. Specific locations for implementing many of the restoration commitments have not been identified at this time. Therefore, the analysis considers typical activities that would be undertaken for implementation of the habitat restoration and provides an estimate of what acreages of natural communities would be lost or converted by these activities. These activities under Alternative 2D would generally be the same as those under Alternative 4A but would result in additional impacts on grassland and cultivated lands natural communities. The effects from these activities are summarized below in Table 12-2D-1. The temporary impacts from geotechnical exploration under Alternative 4A were not included for the comparison of temporary impacts for Alternative 2D to Alternative 4A in Table 12-2D-1.

Due to the addition of the two intakes and their associated pumps and pipelines, the additional RTM disposal area, and the additional restoration under the Environmental Commitments, Alternative 2D would create differences in the permanent and temporary loss of natural communities and cultivated lands when compared with Alternative 4A (Table 12-2D-1). Alternative 2D would permanently remove 8 more acres of valley/foothill riparian habitat along the Sacramento River, 8 acres more of grassland, 74 acres more of managed wetlands, 5 more acres of tidal perennial aquatic habitat, and 919 acres more of cultivated land when compared with Alternative 4A.

During the water conveyance facilities construction process, Alternative 2D would result in 10 fewer acres of temporary loss of natural communities when compared with Alternative 4A because Intake 4 under Alternative 2D would be placed within the large intake work area under Alternative 4A that is located just south of the town of Hood (see Figure 3-2). The difference is due to decreased temporary impacts on cultivated lands (32 fewer acres); however, Alternative 2D would also result in greater impacts on tidal perennial aquatic (14 acres more), valley foothill riparian (4 acres more), and grassland (3 acres more) natural communities as a result of two more intakes along the Sacramento River. No temporary impacts from restoration actions are anticipated because all restoration activities would take place within in the footprint of the proposed restoration site.

These differences in permanent loss of habitat associated with water conveyance construction and habitat restoration would create some differences in effects on wildlife, primarily birds that utilize croplands for foraging and some species that utilize managed wetlands in the north Delta. The increase in permanent loss of cultivated land associated with Alternative 2D would result in a larger loss of habitat for species such as tricolored blackbird, greater sandhill crane, Swainson's hawk, white-tailed kite, western burrowing owl, short-eared owl, loggerhead shrike, northern harrier, and California horned lark. The increase in impacts on managed wetland would result in increased impacts on, white-tailed kite, northern harrier, yellow-head blackbird, and short-eared owl but the particular area of managed wetland that would be affected is not identified as suitable for greater sandhill crane (i.e., is not included as part of the species' modeled habitat). Alternative 2D would also result in an increase in the loss of riparian habitat along the Sacramento River, which would affect nesting habitat for Swainson's hawk, white-tailed kite, cormorants, herons, egrets, and migratory habitat for birds moving along the Sacramento River corridor. Alternative 2D would also result in greater impacts on giant garter snake aquatic and upland habitats.

Overall, the temporary losses of habitat for species would be less under Alternative 2D than under Alternative 4A, except for species restricted primarily to riparian habitats such as valley elderberry longhorn beetle, least Bell's vireo, and yellow-breasted chat, and species restricted to tidal perennial aquatic habitat, such as California least tern, where impacts would increase. Species with relative decreases in temporary habitat losses include greater sandhill crane, Swainson's hawk, tricolored blackbird, western burrowing owl, and white-tailed kite. Overall, when combining permanent and temporary impacts, Alternative 2D would result in greater impacts on species than Alternative 4A.

. Alternative 2D would also affect 35 more acres of jurisdictional wetlands and waters as regulated by Section 404 of the CWA, when compared with Alternative 4A (Table 12-2D-2). Refer to Table 12-4A-68 for a summary of Alternative 4A jurisdictional waters and wetlands impacts. The majority of this difference is due to impacts on tidal channel and scrub-shrub wetlands (as mapped for the wetland delineation) as a result of construction of the intakes along the Sacramento River.

The Environmental Commitments described in Chapter 3, *Description of Alternatives*, Section 3.6.3 and the acreages of these commitments presented in Table 3-10, in Chapter 3, would provide for protection, enhancement, and restoration of habitats affected under Alternative 2D. In addition, the Resource Restoration and Performance Principles in Table 3-12 in Chapter 3, *Description of Alternatives*, would further guide the environmental commitments in mitigating the effects on terrestrial biological resources. AMM1–AMM7, AMM10, AMM12–AMM15, AMM18, AMM20–AMM25, AMM27, AMM30, AMM38, and AMM39, described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, would be available to further avoid and minimize impacts, and preparation of an adaptive management and monitoring program as would likely be required during the ESA Section 7 and CESA Section 2081(b) process would further avoid, minimize, and mitigate the effects of Alternative 2D.

Table 12-2D-1. Alternative 2D Effects on Natural Communities Relative to Alternative 4A (acres)

	Permanent Impacts from Alternative 2D

Table 12-2D-2. Alternative 2D Effects on Jurisdictional Wetlands and Waters Relative to Alternative 4A (acres)

	Alternative 2D Impacts on Jurisdictional Wetlands and Waters				
Wetland/Water Type	Permanent Impact	Temporary Impacts Treated as Permanent[a]	Temporary Impact[b]	Total Impact[c]	Difference from 4A[d]
Agricultural Ditch	45.3	13.5	0	58.8	3.4
Alkaline Wetland	10.4	0.1	0	10.5	0
Clifton Court Forebay	257.9	0	1,930.6	257.9	0
Conveyance Channel	7.1	2.9	0	10.0	0
Depression	29.3	6.2	0	35.5	0
Emergent Wetland	56.8	14.7	0	71.5	0
Forest	7.3	5.3	0	12.6	0.2
Lake	23.2	0	0	23.2	0
Scrub-Shrub	25.2	4.1	0	29.3	13.0
Seasonal Wetland	114.5	10.0	0	124.5	0
Tidal Channel	19.4	80.2	0	99.6	18.8
Vernal Pool	0.3	0	0	0.3	0
Total	**597**	**137**	**1,931**	**734**	**35.4**

[a] Temporary impacts treated as permanent are temporary impacts expected to last more than 1 year. These impact sites would eventually be restored to pre-project conditions; however, because of the duration of effect, compensatory mitigation would be included for these areas.

[b] Temporary impacts would result from dredging Clifton Court Forebay.

[c] Total does not include temporary impacts on Clifton Court Forebay because these would be temporary disturbance to open water, which typically does not require compensatory mitigation.

[d] Difference in total impacts between Alternatves 2D and 4A.

NEPA Effects: Alternative 2D would not have adverse effects on the terrestrial natural communities, special-status species, and common species that occupy the study area. As with Alternative 4A, this alternative also would not substantially disrupt wildlife movement corridors, significantly increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 4A, Alternative 2D would result in existing habitat converted by water conveyance facilities construction and restoration actions but to a slightly larger degree than under Alternative 4A. The temporarily affected habitat would be restored to its pre-project condition and the restoration under Environmental Commitments 4, 6–8, 10, and11 would permanently replace primarily cultivated land with tidal and nontidal marsh, grassland, and riparian vegetation. The Environmental Commitments would result in the protection of up to 15,012 acres and restoration of up to 3,085 acres of natural communities to offset effects. Where Environmental Commitments would not fully offset effects, AMM1–AMM7, AMM10, AMM12–AMM15, AMM18, AMM20–AMM25, AMM27, AMM30, AMM38, and –AMM39, and in some cases specific mitigation measures have been developed to avoid and minimize adverse effects. Alternative 2D would not require mitigation measures beyond what is proposed for Alternative 4A to offset effects.

CEQA Conclusion: Alternative 2D would not have significant and unavoidable impacts on the terrestrial natural communities, special-status species, and common species that occupy the study area. As with Alternative 4A, this alternative also would not significantly disrupt wildlife movement corridors, significantly increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 4A, existing habitat would be converted during construction of water conveyance facilities and the associated restoration to offset these impacts. The temporarily affected habitat would be restored to its pre-project condition and the restoration measures (Environmental Commitments 4, 6–8, 10, and11) would permanently replace primarily cultivated land with tidal and nontidal marsh, grassland, and riparian vegetation. The Environmental Commitments would result in the protection of up to 15,012 acres and restoration of up to 3,805 acres of natural communities and, together with AMM1–AMM7, AMM10, AMM12–AMM15, AMM18, AMM20–AMM25, AMM27, AMM30,AMM38, and AMM39, and in some cases specific mitigation measures would mitigate the projects impacts to a less-than significant-level. Alternative 2D would not require mitigation measures beyond what is proposed for Alternative 4A to offset effects.

As with Alternative 4A, Alternative 2D would require several mitigation measures to be adopted to reduce all effects on terrestrial biological resources to less-than-significant levels. These mitigation measures would be needed beyond the Environmental Commitments and AMMs provided by Alternative 2D. The relevant mitigation measures, which are included in detail in the analysis of Alternative 4A, are as follows:

- Mitigation Measure BIO-42: Avoid Impacts on Delta Green Ground Beetle and its Habitat
- Mitigation Measure BIO-43: Avoid and Minimize Loss of Callippe Silverspot Butterfly Habitat
- Mitigation Measure BIO-55: Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs
- Mitigation Measure BIO-66: California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized
- Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds
- Mitigation Measure BIO-117: Avoid Impacts on Rookeries
- Mitigation Measure BIO-146: Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized
- Mitigation Measure BIO-147: Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area
- Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger
- Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures
- Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Special-Status Plant Species
- Mitigation Measure BIO-176: Compensatory Mitigation for Fill of Waters of the United States

12.3.4.4 Alternative 5A—Dual Conveyance with Modified Pipeline/Tunnel and Intake 2 (3,000 cfs; Operational Scenario C)

Alternative 5A is generally similar to Alternative 4A except that it has only one intake (Intake 2) along the Sacramento River compared with the three under Alternative 4 A (Intakes 2, 3, and 5) and operates under a different operational scenario. Like Alternative 4A, this alternative would not serve as an NCCP/HCP and thus the analysis below only considers construction and operation of the conveyance facilities and only includes the Environmental Commitments necessary to fully mitigate the projects impacts under CEQA and NEPA. Other than the decreased impacts from the intakes and associated restoration actions, the effects from Alternative 5A would be relatively the same as those under Alternative 4A; therefore, Alternative 5A is considered here in a summary fashion. The reader is referred to the discussion of Alternative 4A for a detailed analysis of impacts that would be associated with implementing Alternative 5A. The impacts associated with Alternatives 5A and 4A were derived by comparing the alternative with the No Action Alternative for NEPA purposes, and with Existing Conditions for CEQA purposes.

Operational components of the water conveyance facilities under Alternative 5A would be similar, but not identical, to those described under Scenario C in Chapter 3, Section 3.6.4.2, *North Delta and South Delta Water Conveyance Operational Criteria*. These operations would include both new and existing water conveyance facilities once the new north Delta facilities are completed and become operational, thereby enabling joint management of north and south Delta diversions. Alternative 5A operations include a preference for south Delta pumping in July through September to provide limited flushing for improving general water quality conditions and reduced residence times. The operational scenario under Alternative 5A would have less operational capacity than the Alternative 4A operational scenario would have (3,000 cfs compared with 9,000 cfs).

Comparative Differences in Effects for Alternatives 5A and 4A

The principal differences in effects between these two alternatives would be related to the differing construction footprints of the water conveyance facilities and the differences in proposed restoration efforts. The Alternative 5A water conveyance facilities would entail construction of one north Delta intake (Intake 2). Intake 2 would be located southeast of Clarksburg on the east side of the river, which is the same location of Intake 2 under Alternative 4A. The operational scenario for Alternative 5A (Scenario C) is also different from Alternative 4A (Scenario H3–H4), but the difference in water operations would not significantly change the operational effects on terrestrial biological resources in the study area.

As a result of fewer impacts from Alternative 5A, less habitat restoration and protection would be required under the Environmental Commitments to achieve the applicable regulatory standards under ESA Section 7 and CESA Section 2081(b). These restoration actions would themselves result in affects on natural communities where they are likely to occur. Specific locations for implementing many of the restoration commitments have not been identified at this time. Therefore, the analysis considers typical activities that would be undertaken for implementation of the habitat restoration and provides an estimate of what acreages of natural communities would be lost or converted by these activities. These activities under Alternative 5A would generally be the same as those under Alternative 4A but would result in fewer impacts on valley foothill riparian, grasslands, tidal perennial aquatic, and cultivated lands natural communities. The effects from these activities are summarized below in Table 12-5A-1.

Due to having fewer intakes and associated infrastructure and the decreased restoration under the Environmental Commitments, Alternative 5A would have fewer permanent and temporary losses of natural communities and cultivated lands when compared with Alternative 4A (Table 12-5A-1). Alternative 5A would permanently remove 5 fewer acres of valley/foothill riparian habitat along the Sacramento River, 13 fewer acres of grassland, 3 fewer acres of tidal perennial aquatic, and 226 acres fewer of cultivated land when compared with Alternative 4A.

During the water conveyance facilities construction process, Alternative 5A would involve less temporary loss of habitat when compared with Alternative 4A. The differences would consist of fewer impacts on cultivated lands east of the river (100 acres less), grassland along the river levee (3 acres less), tidal perennial aquatic within the river channel (18 acres less), and valley/foothill riparian along the river levee (5 acres less). No temporary impacts from restoration actions are anticipated because all restoration activities would take place within in the footprint of the proposed restoration site.

These differences in permanent loss of habitat associated with water conveyance construction and habitat restoration would create relatively minor differences in effects on wildlife. The decrease in permanent loss of cultivated lands creates the largest difference between the two alternatives' impacts on wildlife. Alternative 5A would result in less loss of habitat for sandhill cranes, tricolored blackbird, western burrowing owl, Swainson's hawk, white-tailed kite, short-eared owl, loggerhead shrike, northern harrier, and California horned lark. The reduction in impacts on valley/foothill riparian habitat would result fewer impacts on breeding habitat for raptors, herons and egrets, Swainson's hawk, Cooper's hawk, and white-tailed kite, and migratory habitat for species that use the river corridor, such as western yellow-billed cuckoo. Alternative 5A would also result in fewer impacts on giant garter snake.

Alternative 5A would also cause slightly fewer temporary losses of cultivated land, grassland and valley/foothill riparian natural communities and thus decrease the impacts on the species that use these areas relative to Alternative 4A. There would be fewer acres of foraging habitat temporarily lost for sandhill cranes, tricolored blackbird, Swainson's hawk, white-tailed kite, short-eared owl, loggerhead shrike, northern harrier, and California horned lark.

Alternative 5A would also permanently affect 25 fewer acres of jurisdictional wetlands and waters as regulated by Section 404 of the CWA, when compared with Alternative 4A (Table 12-5A-2). Refer to Table 12-4A-68 for a summary of Alternative 4A permanent and temporary jurisdictional waters and wetlands impacts. The majority of this difference is due to fewer impacts on tidal channel (21 fewer acres) with a small difference in impacts on scrub-shrub wetlands (3 fewer acres) as a result of fewer intakes along the Sacramento River.

The Environmental Commitments described in Chapter 3, *Description of Alternatives*, Section 3.6.3,3 and the acreages of these commitments presented in Table 3-11, in Chapter 3, would provide for protection, enhancement, and restoration of habitats affected under Alternative 5A. In addition, the Resource Restoration and Performance Principles in Table 3-12, in Chapter 3, would further guide the Environmental Commitments in mitigating the effects on terrestrial biological resources. AMM 1–AMM7, AMM10, AMM12–AMM15, AMM18, AMM20–AMM25, AMM27, AMM30, AMM38, and AMM39, described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, would be available to further avoid and minimize impacts, and preparation of an adaptive management and monitoring program as would likely be required during the ESA Section 7 and CESA Section 2081(b) process would further avoid, minimize, and mitigate the effects of Alternative 5A.

Table 12-5A-1. Alternative 5A Effects on Natural Communities Relative to Alternative 4A (acres)

[a] Temporary impacts treated as permanent are temporary impacts expected to last more than 1 year. These impact sites would eventually be restored to pre-project conditions; however, because of the duration of effect, compensatory mitigation would be included for these areas.
[b] Temporary impacts would result from dredging Clifton Court Forebay.
[c] Total does not include temporary impacts on Clifton Court Forebay because these would be temporary disturbance to open water, which typically does not require compensatory mitigation.
[d] Difference in total impacts between Alternatives 5A and 4A.

NEPA Effects: Alternative 5A would not have adverse effects on the terrestrial natural communities, special-status species and common species that occupy the study area. As with Alternative 4A, this alternative also would not substantially disrupt wildlife movement corridors, significantly increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 4A, Alternative 5A would result in existing habitat converted by water conveyance facility construction and habitat restoration actions but to a slightly smaller degree. The temporarily affected habitat would be restored to its pre-project condition and the restoration under Environmental Commitments 4, 6–8, 10, and11 would permanently replace primarily cultivated land with tidal and nontidal marsh, grassland, and riparian vegetation. The Environmental Commitments would result in the protection of up to 12,728 acres and restoration of up to 2,428 acres of natural communities to offset effects. Where Environmental Commitments would not fully offset effects, AMM1–AMM7, AMM10, AMM12–AMM15, AMM18, AMM20–AMM25, AMM27, AMM30, AMM38, andAMM39, and in some cases specific mitigation measures have been developed to avoid and minimize adverse effects. Alternative 5A would not require mitigation measures beyond what is proposed for Alternative 4A to offset effects.

CEQA Conclusion: Alternative 5A would not have significant and unavoidable impacts on the terrestrial natural communities, special-status species and common species that occupy the study area. As with Alternative 4A, this alternative also would not significantly disrupt wildlife movement corridors, significantly increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 4A, existing habitat would be converted construction of water conveyance facilities and the associated restoration to offset these impacts. The temporarily-affected habitat would be restored to its pre-project condition and the restoration measures (Environmental Commitments 4, 6–8, 10, and11) would permanently replace primarily cultivated land a with tidal and nontidal marsh, grassland, and riparian vegetation. The Environmental Commitments would result in the protection of up to 12,728 acres and restoration of up to 2,428 acres of natural communities and, together with AMM1–AMM7, AMM10, AMM12–AMM15, AMM18, AMM20–AMM25, AMM27, AMM30, AMM38, and AMM39, and some cases specific mitigation measures would mitigate the projects impacts to a less-than-significant level. Alternative 5A would not require mitigation measures beyond what is proposed for Alternative 4A to offset effects.

As with Alternative 4A, Alternative 5A would require several mitigation measures to be adopted to reduce all effects on terrestrial biological resources to less-than-significant levels. These mitigation measures would be needed beyond the Environmental Commitments and AMMs provided by Alternative 5A. The relevant mitigation measures, which are included in detail in the analysis of Alternative 4A, are as follows:

- Mitigation Measure BIO-42: Avoid Impacts on Delta Green Ground Beetle and its Habitat
- Mitigation Measure BIO-43: Avoid and Minimize Loss of Callippe Silverspot Butterfly Habitat
- Mitigation Measure BIO-55: Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs
- Mitigation Measure BIO-66: California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized
- Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds
- Mitigation Measure BIO-117: Avoid Impacts on Rookeries
- Mitigation Measure BIO-146: Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized
- Mitigation Measure BIO-147: Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area
- Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger
- Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures
- Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant Species
- Mitigation Measure BIO-176: Compensatory Mitigation for Fill of Waters of the United States

12.3.5 Cumulative Effects

12.3.5.1 Assessment Methodology

The cumulative effects analysis for terrestrial biological resources addresses the potential for the project alternatives to act in combination with other past, present, and reasonably foreseeable future projects, programs or conditions to create a cumulatively significant adverse impact. The analysis also considers whether any incremental effect of the alternative is cumulatively considerable. Chapter 4, Section 4.2, *Resource Chapter Organization*, provides the regulatory and statutory basis for the cumulative analyses found in this document.

The geographic scope of the analysis for natural communities is the terrestrial biology study area (the BDCP Plan Area and the two transmission corridors that extend beyond the Plan Area) and lands immediately adjacent to this study area where past, present or reasonably foreseeable activities might indirectly affect the natural communities in the study area. While the natural communities extend beyond these boundaries, the focus of the actions that might affect these resources is the Delta and other lands involved in project conservation efforts. The geographic scope of the cumulative analysis for each of the covered and noncovered species varies, depending on the potential for other projects or programs to influence individuals that rely on the study area for some stage of their life history. For some wildlife species, such as migratory birds, this area includes their entire range within California. For other species whose individuals do not range beyond the study area and its immediate surroundings, the geographic range of the cumulative analysis has been limited to this smaller area. The geographic scope for cumulative effects from spread of invasive species is the study area.

The projects and programs that have been considered as part of the cumulative analysis have been drawn primarily from a list developed for this EIR/EIS and contained in Appendix 3D, *Defining Existing Conditions, No Action Alternative, No Project Alternative, and Cumulative Impact Conditions*. This list was compiled in part by reviewing the projects addressed in the cumulative impacts analysis for the Delta Land Use and Resource Management Plan (Delta Protection Commission 2010). The list was augmented by reviewing the Appendix 3A, *Identification of Water Conveyance Alternatives, Conservation Measure 1*, and other recent environmental documents for Delta-area projects, and by coordinating with local, state, and federal agencies that are sponsoring activities in the Delta area or on other lands within the relevant range of individual species. The list of past, present and reasonably foreseeable future projects and programs has been evaluated to determine which of these activities may have effects on terrestrial habitats and terrestrial species that are known to occur within the study area. The list of projects and programs relevant to terrestrial biological resources is contained in Table 12-8. Most of these projects and programs are also a part of the NAA that is addressed in Section 12.3.3.1, *No Action Alternative,* and in Section 12.3.4.1, *Impacts of No Action Alternative Early Long-Term*.

In addition, the effects of global climate change have been considered in addressing the cumulative effects of alternatives on terrestrial biological resources. Changes that might occur within the study area related to climate change are considered reasonably foreseeable and part of the cumulative condition that might combine with the effects of the implementation of project alternatives. Climate change is also considered an element of the No Action Alternatives (see Section 12.3.3.1 and Section 12.3.4.1). Chapter 29, *Climate Change*, provides background and assumptions associated with climate change in the Plan Area, and also addresses general effects on terrestrial habitat and species.

To assess whether implementation of the alternatives would contribute to an adverse cumulative effect on the terrestrial biological resources of the study area, a judgment must first be made regarding potential adverse effects of the alternatives. Where adverse effects are anticipated, a determination must be made as to whether these effects would contribute to a cumulative adverse effect on a terrestrial biological resource. If there is a contribution to a cumulative adverse effect, a final judgment must be made as to whether the effect of the alternative represents a considerable contribution to the cumulative effect.

Table 12-8. Effects on Terrestrial Biological Resources from Plans, Policies and ProgramsConsidered for Cumulative Analysis

Agency	Program/Project	Status	Description of Program/Project	Effects on Terrestrial Biological Resources
Alameda County	East Alameda County Conservation Strategy	Approved in 2011.	There is less than a 2% overlap with BDCP (4,643 acres) and this overlap only occurs in one conservation zone. The conservation strategy addresses the conservation needs of 19 species, including eight species that overlap with the BDCP. Currently no planned conservation activity in the overlap area, so the conservation strategy would not affect BDCP species in the Plan Area.	The East Alameda strategy has beneficial effects on eight of the BDCP covered species.
California Department of Fish and Wildlife	Calhoun Cut/Lindsey Slough Restoration		Increase intertidal marsh habitat and adjacent riparian habitat on 927 acres in Cache Slough ROA.	
California Department of Fish and Wildlife	Ecosystem Restoration Program Conservation Strategy	Ongoing implementation.	Created in 2000. Ongoing program to preserve, restore, and enhance terrestrial natural communities and ecosystems in the San Francisco Bay and Sacramento-San Joaquin Delta. Protected and restored more than 150,000 acres of habitat, including 3,900 acres and 59 miles of riparian and riverine aquatic habitat (as of 2010) after 7 of the planned 30 years of the project.	The conservation strategy creates beneficial impacts on the natural communities and special-status species discussed in this EIR/EIS.
California Department of Fish and Wildlife	Fremont Landing Conservation Bank	Ongoing implementation.	Enhances 40 acres of riparian habitat and restores 60 acres of riparian woodlands and sloughs.	This bank provides benefits for many riparian bird, reptile, and mammal species that occupy the Delta.

Agency	Program/Project	Status	Description of Program/Project	Effects on Terrestrial Biological Resources
California Department of Fish and Wildlife	Grizzly Island Wildlife Area Land Management Plan		Estuarine marsh that contains about 15,300 acres of wildlife habitat. Will continue to be managed for wildlife, with an emphasis on waterfowl, threatened and endangered species, and the resident tule elk herd.	Actions at this wildlife area will maintain and enhance managed wetland as some of the private wetland is converted to tidal marsh.
California Department of Fish and Wildlife	Lower Sherman Island Wildlife Area Land Management Plan	Ongoing implemen-tation.	Directs habitat and species management on 3,100 acres of marsh and open water. The plan's goals are to restore and improve marsh and upland habitats for threatened and endangered species, control invasive species and allow for hunting and fishing recreation activities.	The plan has a positive effect on species of concern in the BDCP.
California Department of Fish and Wildlife	Private Lands Incentive Program		Includes 29,000 acres of habitat in Tulare Basin, Grasslands, Suisun Marsh, and Sacramento Valley. Encourages development and enhancement of habitat for shorebirds and waterfowl on private lands, and encourages wildlife-friendly farming practices.	This program has beneficial effects on waterfowl and shorebird species in the Plan Area.
California Department of Fish and Wildlife	Restoring Ecosystem Integrity in the Northwest Delta	Ongoing program.	Focused on habitat restoration. Currently concentrating acquisition efforts on 3 specific properties consisting of about 150 acres and baseline monitoring. The project centers on Calhoun Cut and Lindsay Slough in the Cache Slough ROA. The plan is designed to create a restored, protected corridor extending from Jepson Prairie to Prospect Island, doubling the overall acreage of marsh and riparian habitats, doubling the protected acres of vernal pool/perennial grasslands and increasing the abundance and local distribution of at risk and other native plant and animal species.	The program is consistent with BDCP goals for habitat restoration in the Cache Slough ROA.

Agency	Program/Project	Status	Description of Program/Project	Effects on Terrestrial Biological Resources
California Department of Fish and Wildlife	Staten Island Wildlife-Friendly Farming Demonstration	Ongoing program.	Objective is ecosystem restoration; 2,500–5,000 acres of corn will be flooded to increase habitat availability and to improve wildlife-friendly agriculture to foster recovery of at-risk species and to investigate effects of agriculture on water quality.	This program is focused on improving agricultural land as seasonal habitat for greater and lesser sandhill cranes, a target species of the BDCP.
California Department of Fish and Wildlife	Yolo Bypass Wildlife Area Land Management Plan	Ongoing program.	Provides for multiple use management of 16,000 acres of mixed agricultural, grassland and managed wetland habitats. This wildlife area is managed to support wintering waterfowl populations, shorebird migration, waterfowl hunting, and active wildlife observation, especially bird watching. This is accomplished by actively managing wetland habitats and providing for wildlife-friendly farming.	
Department of Water Resources	California Water Action Plan	Initiated in January 2014.	This plan lays out a roadmap for the next 5 years for actions that would fulfill 10 key themes. In addition, the plan describes certain specific actions and projects that call for improved water management throughout the state.	
California Department of Water Resources	Central Valley Flood Protection Plan		Proposes significant expansion of flood protection features in the study area, including expansion of the Yolo Bypass.	Plan implementation could conflict with the BDCP's effort to improve giant garter snake habitat just outside of the current floodway, and to improve fish passage through Yolo Bypass waterways.
California Department of Water Resources	Delta Levees Flood Protection Program	Ongoing program.	Includes modification to Delta levees within the Sacramento-San Joaquin Delta and portions of the Suisun Marsh, with a focus on western Delta island levees. The project works with 60 reclamation districts and strives to complete levee rehabilitation projects with no net loss of habitat in the Delta.	The program has some potential to remove grassland, emergent marsh, and riparian habitats in the short-term. Habitat losses would have to be offset with protection or restoration actions.

Agency	Program/Project	Status	Description of Program/Project	Effects on Terrestrial Biological Resources
California Department of Water Resources	FloodSAFE California		Promotes public safety through integrated flood management while protecting environmental resources; emphasizes action in the Delta. This program is very broad, but is designed to improve flood safety throughout the state while encouraging sound conservation actions that benefit California's native fish and wildlife and promote wildlife-friendly agricultural practices.	The program is not intended to reduce habitat values in the Delta.
California Department of Water Resources	Levee Repair-Levee Evaluation Program	Ongoing program.	Upgrading levees along the Sacramento and San Joaquin Rivers and Delta; 1,600 miles of levees included in Central Valley.	Most of the program efforts are geotechnical, bathymetric, and geomorphic evaluations that have little to no effect on terrestrial wildlife in the study area.
California Department of Water Resources and MOA Partners	Lower Yolo Restoration Project		In Cache Slough ROA, reintroduce tidal action to half of 3,408-acre Yolo Ranch. This project would eliminate existing agricultural land used primarily for grazing, and create tidal marsh for the benefit of special-status Delta anadromous and resident fish species.	The project is expected to be part of the BDCP's early implementation program. It will adversely affect some grassland species in favor of tidal marsh and riparian species.
California Department of Water Resources	Dutch Slough Tidal Marsh Restoration Project	Implementation began in 2012.	Converts 240–840 acres from agricultural uses and grazing to wetland, riparian, and upland habitats. The project also includes development of a recreation center at one end of the property.	The restoration will benefit tidal marsh and riparian habitats and species in the western Delta on lands with considerable topographic diversity and little to no land subsidence.
California Department of Water Resources, Bureau of Reclamation, Contra Costa Water District	Los Vaqueros Reservoir Expansion	Completed in 2012.	Project enlarged Los Vaqueros Reservoir to develop water supplies for environmental water management that supports fish protection, habitat management, and other environmental needs in the Delta.	

Agency	Program/Project	Status	Description of Program/Project	Effects on Terrestrial Biological Resources
California High Speed Rail Authority	Sacramento to Merced Section of High Speed Rail System		One possible alignment for the section from Sacramento to Merced would includes major infrastructure construction along the I-5 corridor between French Camp and Lathrop, which would pass through the portion of the study area around the I-5 and Hwy. 120 junction. The potential alignment from the Bay Area to Stockton would cross the study area from the west near Tracy and head east to Lathrop. These alignments are within or parallel existing rail corridors.	The project has the potential to remove grassland and cultivated lands along existing rights-of-way in the study area.
California Partners in Flight	Riparian Habitat Joint Venture	Ongoing program.	Promotes and supports riparian conservation and enhancement, contributes to flood control and maximizes habitat available to wildlife. Protects and restores riparian areas with intact adjacent upland habitats.	The program has a positive influence on the value of riparian habitat.
Central Valley Joint Venture	Central Valley Joint Venture Program	Ongoing program.	Strives to protect, restore, and enhance wetlands. Contributes to habitat conservation on a total of 714,000 acres in California.	This program has the potential to convert agricultural land to managed wetland or natural wetlands.
Contra Costa County and East Contra Costa County Habitat Conservancy	East Contra Costa County HCP/NCCP	Approved in 2007. Ongoing implemen-tation.	Encompasses about 175,000 acres and contains 30,000 acres of preserved land. Purpose is to purchase, restore, and permanently protect large, interconnected and biologically rich blocks of habitat. A 63,073 acre overlap with the BDCP boundary.	This HCP/NCCP will result in restoration of native grassland, vernal pools, and oak woodland on the southwestern edge of the BDCP Plan Area.
Contra Costa Water District	Contra Costa Canal Fish Screen Project	Completed in 2011.	Designed to restore Delta ecosystems.	Minor terrestrial biological impact at fish screen sites.
Contra Costa Water District, Bureau of Reclamation, and California Department of Water Resources	Contra Costa Water District Middle River Intake and Pump Station (Alternative Intake Project)	Completed in 2010.	Resulted in permanent conversion of 6–8 acres of rural agricultural land. Features about 12,000 feet of pipe across Victoria Island and under Old River.	Permanent conversion of rural agricultural land.

Agency	Program/Project	Status	Description of Program/Project	Effects on Terrestrial Biological Resources
Delta Conservancy	California EcoRestore	Initiated in 2015,	This program will accelerate and implement a suite of Delta restoration actions for up to 30,000 acres of fish and wildlife habitat by 2020.	
Delta Protection Commission	Land Use and Resource Management Plan		Outlines long-term land use requirements for the Sacramento-San Joaquin Delta. This plan directs the long-term protection of agricultural, recreational, and open space uses of the Delta and restricts urban and other types of development that would reduce the value of these uses.	The Plan supports protection and restoration of riparian and aquatic habitats in the Delta, and improvement in water quality in Delta channels.
National Marine Fisheries Service, Bureau of Reclamation, and Department of Water Resources	Biological Opinion on the Long-Term Operations of the Central Valley Project and State Water Project	Ongoing program.	Action area consists of the Oroville Reservoir, Feather River downstream of Oroville, Sacramento River downstream of Feather River, Sacramento-San Joaquin Delta, and adjacent habitats that are dependent on or influenced by waterways. Designed to conserve freshwater, estuarine, nearshore, and offshore aquatic habitats, for the benefit of federally protected fish species.	The project includes 8,000-acre tidal wetland restoration requirement, which will result in conversion of agricultural land and managed wetland in the Delta and Suisun Marsh.
Reclamation District 2093	Liberty Island Conservation Bank	Ongoing implement ation.	Permits and approvals acquired in 2009. Project site is on northern tip of Liberty Island. Over 160 acres in the project site with about 50 acres proposed to be converted to open water channels, emergent marsh wetland, and riparian habitat.	Conseervation bank focuses on Delta fish habitat but will restore 2.7 acres of riparian habitat.
Placer County Water Agency and Bureau of Reclamation	Sacramento River Water Supply Study	Study has begun.	Feasibility study under way to assess options for providing water supply to future growth in Sacramento-Placer Counties region. Includes potential new surface diversion from the Sacramento River upstream of the Delta.	

Agency	Program/Project	Status	Description of Program/Project	Effects on Terrestrial Biological Resources
Sacramento Area Flood Control Agency, Central Valley Flood Protection Board, and U.S. Army Corps of Engineers	Central Valley Flood Management Program	Ongoing program.	Supports flood management planning in Sacramento and San Joaquin Valleys. To be updated every 5 years with first update to be completed in 2017. Combined total of about 2.2 million acres of land within the Central Valley. The program supports improvements in flood management structures, including levees and bypasses.	Facilities improvements could result in removal of vegetation in the study area as flood control facilities are improved and expanded.
San Joaquin Council of Governments	San Joaquin County Multi-Species Habitat Conservation and Open Space Plan	Approved in 2011. Ongoing implemen-tation.	Includes most of San Joaquin County. Assumes 100,000 acres of open land conversion and provides about 100,000 acres of preserves. About 35% of this plan overlaps with BDCP so competition for restoration sites and land acquisition would exist. There are 39 covered species in common and very similar land acquisition targets, such as riparian forests and grasslands.	The plan is likely to result in conversion of agricultural land to native vegetation, including riparian and grassland areas in the south and east Delta.
Semi Tropic Water Storage District	Delta Wetlands	Draft EIR issued in 2010 and a Final EIR certified in 2012.	Flood storage and habitat conservation project on four Delta islands. This project could convert four large Delta islands into 11,000 acres of freshwater storage and 9,000 acres of managed agricultural lands, wetlands, riparian areas and other types of wildlife habitat.	A significant amount of agricultural land could be removed from production.
Solano County	Solano County Multispecies Habitat Conservation Plan		Establishes habitat conservation goals for Solano County, including approximately 205,000 acres of the study area. This conservation plan focuses on protection and restoration of 13,000-15,000 acres of valley floor grassland and vernal pool habitat for a range of special-status species. Many of the target species are common with the BDCP, including fairy shrimp, Swainson's hawk, western burrowing owl, giant garter snake, California red-legged frog, and Mason's lilaeopsis.	

Agency	Program/Project	Status	Description of Program/Project	Effects on Terrestrial Biological Resources
U.S. Army Corps of Engineers	CALFED Levee Stability Program		Includes maintaining and improving levee stability in the Delta. Long-term strategy will include ecosystem restoration. Partially funds McCormack-Williamson Tract Restoration in Cosumnes-Mokelumne ROA. 1	The program's 500 acres of tidal and floodplain habitat restoration would expand habitats also targeted by the BDCP.
Bureau of Reclamation	Delta-Mendota Canal/California Aqueduct Intertie	Completed in April 2012.	Included construction of a pump and 500-foot pipeline between the two canals near the Jones Pumping Plant.	The majority of the habitat disturbed was nonnative annual grassland. No special-status plant community was affected.
Bureau of Reclamation, U.S. Fish and Wildlife Service, National Marine Fisheries Service, Department of Water Resources, and Department of Fish and Wildlife	San Joaquin River Restoration Program	Ongoing program initiated in 2006.	150 miles of the river is planned for restoration, with an emphasis on improving fish passage and riparian habitats within and adjacent to the river's floodplain.	This program does not include lands within the BDCP Plan Area, but would provide habitat connections along the San Joaquin River upstream of the Plan Area.
Bureau of Reclamation and San Luis & Delta Mendota Water Authority	Agricultural Drainage Selenium Management Program	Under develop-ment.	San Joaquin Valley agricultural drainage control program designed to reduce agricultural-related discharges of selenium into the San Joaquin River and south Delta.	
U.S. Fish and Wildlife Service, Bureau of Reclamation, and California Department of Fish and Wildlife	San Joaquin Basin Action Plan		Includes a habitat acquisition and wetland enhancement project on 23,500 acres in northern San Joaquin River basin, outside of the BDCP Plan Area. This program is focused on supplying adequate water to state and federal refuges and managed wetlands in the San Joaquin Valley for the benefit of migratory waterfowl and other species that are supported by these managed wetlands. These habitats are elements of the larger Central Valley flyway that includes wetlands in the BDCP Plan Area	The plan benefits migratory waterfowl and other species supported by managed wetlands

Agency	Program/Project	Status	Description of Program/Project	Effects on Terrestrial Biological Resources
U.S. Fish and Wildlife Service and Sacramento County	South Sacramento Habitat Conservation Plan		Establishes conservation goals for south Sacramento County, including approximately 43,000 acres of the study area. This plan targets habitat restoration and preservation for 16 species that are common to the BDCP. Habitat improvements are sought for grassland, wetland, agricultural land and riparian areas. There is overlap in the demand for land acquisition sites between the BDCP and the South Sacramento Plan. The Plan also provides for an urban expansion area within the BDCP Plan Area.	Collaborative planning for the plan and the BDCP could improve the opportunities to create a continuous band of preserved land from giant garter snake populations in the White Slough area to Stone Lakes NWR and Cosumnes River Preserve.
U.S. Fish and Wildlife Service	Recovery Plan for Sacramento-San Joaquin Delta Native Fishes	Ongoing implementation.	Released in 1995, the recovery plan includes developing additional shallow water habitat, riparian vegetation zones and tidal marsh to restore wetland habitats for the benefit of 8 native species throughout the Bay-Delta ecosystem. The objective of the plan is to establish self-sustaining populations of the species included in the plan. The goals for chinook salmon, green sturgeon, and splittail include providing for a limited harvest that can be sustained. The estuary is to be managed so that it is better habitat for aquatic life in general and for the fish species of concern in particular. This plan complements the goals of the BDCP, for both terrestrial and aquatic species in the Delta.	

Agency	Program/Project	Status	Description of Program/Project	Effects on Terrestrial Biological Resources
U.S. Fish and Wildlife Service	Stone Lakes National Wildlife Refuge Comprehensive Conservation Plan	Ongoing implemen-tation.	Directs habitat and species management on approximately 17,600 acres of grassland, agricultural land, managed wetland and riparian habitat. The managed lands of the refuge are a major conservation feature on the eastern boundary of the BDCP Plan Area. Lands within the refuge are owned in fee title or cooperatively managed with landowners through easements. The goals of the refuge are to conserve, restore and manage wetland, grassland, and riparian habitat for the benefit of fish, wildlife and plants, and special-status species; conserve enhance, and restore high quality migrating, wintering and breeding habitat for migrating birds; provide visitors with wildlife-dependent recreation, education and interpretation opportunities; and identify and protect cultural resources. The refuge represents an opportunity for cooperative habitat conservation between the USFWS and BDCP implementing entities.	
U.S. Fish and Wildlife Service, Bureau of Reclamation, and California Department of Water Resources	Biological Opinion on the Long-Term Operations of the Central Valley Project and State Water Project (delta smelt)	Ongoing program.	The opinion directs reasonable and prudent actions associated with the ongoing operation of the CVP and SWR, as they relate to the long-term survival of delta smelt. It directs actions associated with reducing entrainment of adult, juvenile and larval smelt in the south Delta pumps; improving habitat for smelt within the Delta by regulating river outflow, restoring or creating at least 8,000 acres of intertidal and related subtidal habitat for delta smelt in the Delta and Suisun Marsh; and initiating a monitoring and reporting program.	This program is a principal element in controlling west Delta and Suisun Marsh salinity levels that might affect terrestrial species and habitats.

Agency	Program/Project	Status	Description of Program/Project	Effects on Terrestrial Biological Resources
Yolo County	Yolo Natural Heritage Program Plan	First administrative draft plan released in June 2013.	Establishes habitat conservation goals for Yolo County (653,818 acres), including 111,383 acres of the BDCP study area. The principal areas of overlap are in the Yolo plan's Planning Units 17 and 18, northern and southern Yolo Bypass. This corresponds primarily with BDCP CZ 2. Thirty-two species are being considered for ESA and NCCPA coverage, including Swainson's hawk and giant garter snake. The Yolo plan proposes to restore or protect over 76,000 acres of valley oak woodland, valley foothill riparian, fresh emergent wetland, shrubland, agricultural land and grassland.	The plan provides the potential to work toward common habitat protection, restoration, and enhancement with the BDCP in the Yolo Bypass area.
Zone 7 Water Agency and Department of Water Resources	South Bay Aqueduct Improvement and Enlargement Project	Completed in 2012.	More than 40 miles of pipelines, a 500 acre-foot reservoir, and new pumping facilities.	Located outside of the BDCP Plan Area, the project removed grassland, riparian, and related habitats in the hills west of the Plan Area.

12.3.5.2 Cumulative Effects of the No Action Alternative

Effects of Past, Present and Reasonably Foreseeable Projects and Programs

The current conditions of study area biological resources are the byproduct of past and ongoing human activity and natural processes. The present geographic range and condition of natural communities, special-status and common plants and wildlife, and invasive species are described in Section 12.1, *Environmental Setting/Affected Environment*. A brief synopsis of general environmental conditions and their evolution in the study area is presented in Section 12.1.1, *Historical Trends in Biodiversity of the Plan Area*. This discussion provides a context of gradually declining acreages of natural habitat due to agricultural, urban development, flood control and water management activities.

The various projects and programs listed in Table 12-8 will have cumulative effects on the existing biological resources of the study area through the early long-term (year 15) and over the next 50 years. The most relevant elements of these projects and programs are their ability to modify land use patterns, modify land management practices, and change the patterns of hydrology and vegetation in the study area. Most of the local, state and federal land use and land management programs that are affecting or will affect the Delta are designed to preserve open space and agricultural lands, and to manage the resources of the area for multiple uses, including agriculture, recreation, fish and wildlife habitat, flood protection and water management. The restoration programs will increase primarily wetland and riparian natural communities by converting agricultural land or managed wetland. The special-status and common plants and wildlife that rely on wetland and riparian habitats for some stage of their life will benefit from these changes over time. Other species that rely on agricultural land and managed wetland, but do not benefit from wetland and riparian expansion, may decline in the study area. On the upland fringes of the Delta, plans exist for small expansions of urban development that would remove primarily agricultural land uses. The management of state- and federally owned wildlife areas, including Grizzly Island, Sherman Island and Yolo Bypass State Wildlife Areas and Stone Lakes NWR, will continue to focus on multiple uses, including wildlife habitat improvement, public access for wildlife viewing, wildlife-friendly agricultural production, and hunting opportunities. Natural habitat will be improved and expanded. The principal changes that are likely to result from the various habitat conservation plans that overlap with the study area would be expected to include the restoration and protection of the habitats that support the same special-status species being addressed in the BDCP (see *Effects of Other BDCP Conservation Measures on Overlapping Conservation Plans*, below). These changes would be expected to result in increases of wetland, grassland and riparian habitats, and a decrease in agricultural lands, and possibly managed wetlands in the study area.

Implementation of the water management strategies associated with the programs listed in Table 12-8 would not significantly modify the principal natural communities in the study area. These management strategies are designed, in part, to improve aquatic habitat conditions in the Delta for the benefit of special-status fish species. Periodic levee and channel maintenance activities associated with the flood management programs in Table 12-8 would result in localized disturbances to valley/foothill riparian, grassland, and tidal perennial aquatic natural communities, and to a lesser extent to tidal brackish and tidal freshwater emergent wetlands. To the extent that ongoing levee repair and replacement involves use of reinforcing rock and discouragement of replanting streamside vegetation, there could be a gradual decline in the extent and value of valley/foothill riparian habitat and grassland along minor and major waterways. Several of the water management and transportation projects listed in Table 12-8 require localized removal of natural communities and agricultural land for expanding infrastructure. Most of these activities are on the periphery or just outside of the study area, including the Contra Costa Water District fish screen and diversion structure modifications, the Delta Mendota Canal/California Aqueduct intertie project, the South Bay Aqueduct improvement project, and California High Speed Rail.

Even though the ELT period is significantly reduced from the No Action Alternative (LLT) time period, the overall direction of these existing and ongoing programs and policies that influence land conversion and land management in the study area would continue to be toward maintaining the mix of agricultural, recreational, water management, and wildlife uses in the Delta, Yolo Bypass, and Suisun Marsh. Some actions that will occur under the No Action Alternative (ELT) will expand natural and manmade terrestrial and wetland habitats that will benefit the special-status and common plants and wildlife with expanded and enhanced habitat in the study area. The potential will remain, however, for long-term trends in levee deterioration, global climate change, and seismic activity that could damage levees and result in significant changes in natural communities and cultivated lands.

Effects of Global Climate Change

As discussed in Chapter 29, *Climate Change*, global climate change is expected to result in many physical changes to the BDCP Plan Area. From a terrestrial biology perspective, the most significant changes would include a gradual rise in sea level, increasing water and air temperatures, more frequent drought and extreme rainfall events, and changes in the hydrologic patterns of the rivers and the Delta channels that influence the terrestrial and aquatic habitats used by terrestrial plants and wildlife. The BDCP climate change analysis included in Chapter 29 considers sea level increases at various levels, including 18–55 inches during the Plan period (see Chapter 29, Section 29.3.1). Air temperatures are projected to rise by 2–5 degrees F by 2050 and water temperatures are projected to increase as some proportion (2–3 degrees F) of the air temperature rise (see Appendix 29C, Section 29C.2.1). The changed frequency of drought and extreme rainfall events has not been predicted, but these events are expected to be part of future California conditions with global climate change. Hydrologic conditions in the rivers and Delta channels are expected to be altered by changes in precipitation patterns, with a portion of precipitation shifting from snow to rainfall in the winter months. This would increase river flows in winter and early spring, and decrease flows in the remainder of the year as snowmelt runoff decreases. The changes in river flows would generate subsequent changes in west Delta and Suisun Marsh salinity levels.

The physical changes in conditions in the study area related to the climate change described above, especially the sea level rise, could change the distribution and value of study area habitats. The sea level rise is expected to gradually inundate existing habitats on the periphery of the Delta, in the lower Yolo Bypass, and the northern and southern edges of Suisun Marsh. This pattern of inundation, which assumes a 55-inch sea level rise, is shown in Figure 29-1. Projected sea level rise by around the early long term (2025) would range between 1.7 and 11.7 inches (see Table 29-2 in Chapter 29, *Climate Change*). Tidal brackish and freshwater marsh could be gradually inundated and converted to more subtidal habitat. In areas where there is no upland barrier (e.g., levees, roads, residential development, agricultural fields), some portion of the tidal marsh may re-establish upslope with the higher water levels if there is sufficient sediment available to provide an appropriate substrate. However, decreases in sediment availability that have occurred in the Delta and Suisun Marsh over time and that may continue may not keep pace if the higher estimated rates of sea level rise occur (Barnard et al. 2013). The result could be a gradual loss of these tidal marshes. Where barriers exist upslope of existing marsh, the tidal marsh habitat could be gradually inundated and subtidal areas would remain. Subtidal habitat is less valuable to the special-status and common terrestrial plants and wildlife of the study area. Low-lying upland grassland and riparian areas that border the study area waterways could also be gradually converted to tidal marsh, but would be expected to re-establish upslope where open ground exists and there are no physical barriers. Where these deeper water incursions bisect existing wildlife corridors, the ability of certain species to move and interact with adjacent populations would decrease. Population numbers of riparian, grassland, and tidal marsh species would be likely to decrease and population distribution would be altered. The habitats adjacent to study area waterways would also be exposed to more frequent inundation and desiccation as precipitation levels show greater fluctuation.

Land subsidence, sea level rise, gradual or catastrophic levee failure, or a combination of these conditions, should they occur, would result in flooding and inundation that could significantly damage existing facilities and infrastructure, uproot and kill vegetation to an unknown extent, permanently flood Delta islands, and drastically alter the salinity of Delta waterways and wetlands. Depending on the extent and duration of flooding, significant short- and long-term changes could occur in the availability of shallow tidal wetlands, riparian and grassland habitats and managed lands useful to certain special-status and common species (e.g., cultivated lands, managed wetland). Depending on the amount of human intervention to drain islands and rebuild levees, there may be a gradual succession of habitats less valuable to the plant and animal species currently relying on the Delta for growth and seed production, cover, breeding, nesting, resting, movement corridors and foraging. Refer to Appendix 3E, *Potential Seismic and Climate Change Risks to SWP/CVP Water*

Supplies, for a further discussion of seismic and climate change effects that might occur in the study area under the no action condition. While similar risks would occur under implementation of the action alternatives, these risks may be reduced by BDCP-related levee improvements, along with implementation of those projects identified for the purposes of flood protection in Table 12-8.

The negative elements of global climate change described above would be a contributing factor to any cumulative effects of implementing the projects and programs that are part of the No Action scenario (Table 12-8). Any negative effects on terrestrial biological resources associated with the action alternatives (see below), when considered with all of the above effects of the No Action Alternative, could create adverse cumulative effects to these terrestrial biological resources.

12.3.5.3 Concurrent Project Effects

The terrestrial biological resources impact analyses for the BDCP alternatives contains separate sections for effects on 12 different natural communities, on cultivated land, and on 149 special-status wildlife and plant species. For each of these resources, the first impact discussion presented (e.g., *Impact BIO-44: Loss or Conversion of Habitat for and Direct Mortality of California Red-Legged Frog*) is structured to provide a concurrent analysis of the effects of CM1 and CM2–CM11, and CM18 during the near-term time frame (the period in which CM1 would be constructed) and provides NEPA and CEQA conclusions for the near-term as well as the late long-term time periods of the Plan. The near-term analysis includes individual discussions of each Conservation Measure's contribution to the effect. For many of the natural communities and associated habitats for the special-status species, the near-term construction of CM1 and the conversion of lands for restoration would jointly reduce the acreages of essential habitat at locations scattered throughout the Plan Area. To avoid a substantial short-term loss of essential habitat during the near-term period, many of the habitat protection and restoration actions (CM3, CM4, CM6, CM7, CM8, CM9, CM10, and CM11) would include early implementation schedules to allow habitat protection and habitat creation to keep pace with the gradual losses that would occur. The goal would be to avoid and minimize temporal losses in habitat acreage and value that could limit the range or reduce the long-term viability of the Plan Area's sensitive biological resources.

Each of the BDCP alternatives would provide sufficient habitat protection and restoration acreage in the near-term to keep pace with habitat losses by including CMs and AMMs to avoid significant impacts, with small exceptions. The impacts on vernal pool habitat and its associated special-status vernal pool crustaceans generated by construction of CM1 for Alternatives 1C, 2C, and 6C (the western canal alignment) would require mitigation in the form of increasing the amount of vernal pool complex habitat to avoid significant impacts. Also, the construction of the extensive, linear CM1 canals for Alternatives 1B, 1C, 2B, 2C, 6B, and 6C would contribute to a significant and unavoidable cumulative effect on wildlife movement corridors across the Sacramento-San Joaquin Delta. CM1 construction for Alternatives 1B, 2B, and 6B would also create a significant and unavoidable cumulative impact by creating barriers to the movement and population connectivity of giant garter snakes in the western portion of the Plan Area.

The analyses for Alternatives 4A, 2D, and 5A address both the effects of constructing the water conveyance facilities and implementing the Environmental Commitments concurrently (restoration, enhancement, and protection), and the NEPA and CEQA conclusions are based on the overall effects of both the water facilities and the Environmental Commitments.

12.3.5.4 Cumulative Effects of the Action Alternatives

This cumulative analysis discusses both the BDCP alternatives (1A, 1B, 1C, 2A, 2B, 2C, 3, 4, 5, 6A, 6B, 6C, 7, 8, and 9) and the non-HCP Alternatives (4A, 2D, and 5A).

BDCP Alternatives

Based on the analyses presented in earlier parts of this chapter, the alternatives would have little or no negative effect on nearly all of the terrestrial biological resources of concern in the study area. For the BDCP alternatives, this is consistent with the goal of HCP/NCCP programs, which is to improve the long-term viability of special-status species and their habitats. The positive effects of implementing the BDCP are similar in all of the project alternatives other than the No Action Alternative. There are relatively small variations in the acres affected by construction of the alternative water conveyance facilities (CM1), but the restoration, protection, enhancement and stressor reduction elements of the alternatives are the same for Alternatives 1A, 1B, 1C, 2A, 2B, 2C, 3, 4, 6A, 6B, 6C, 8 and 9. These elements of the BDCP have the greatest potential to modify natural communities and affect special-status plants and wildlife. There are reductions in tidal marsh restoration (CM4) associated with Alternative 5, and expansion of channel margin habitat enhancement (CM6) and floodplain restoration (CM5) associated with Alternative 7 that create significant variances from the rest of the alternatives. Where relevant, these differences are addressed in the impact analysis that follows.

While construction and restoration activities in the near-term period of the alternatives would temporarily or permanently remove natural communities and modeled habitat for special-status plant and wildlife species, the near-, mid- and long-term conservation actions would replace, enhance and in most cases expand habitat acres and value for these species. The positive effects the alternatives would have on special-status species would also provide benefits to common terrestrial wildlife and plants.

The potential adverse effects of implementing all of the BDCP alternatives include potential disturbance of nesting colonies of bank swallows, should they be present adjacent to construction activity at the north end of the Yolo Bypass, and the potential that BDCP-related changes in river stage upstream of the study area on the Sacramento and Feather Rivers could adversely affect bank swallow colonies. Though the alternatives using the east (Alternatives 1B, 2B, and 6B) and west (Alternatives 1C, 2C, and 6C) alignments would provide the same conservation benefits as the other alternatives, the construction of the canal portions of the conveyance facilities would create substantial barriers to wildlife movement within and through the study area. Also, the canal associated with the east alignment alternatives (1B, 2B, and 6B) would adversely affect movement and connectivity between subpopulations of giant garter snake in the vicinity of White Slough in the eastern Delta.

Because these are the only potential adverse effects that could combine with the projects and programs in Table 12-8 and with global climate change to create a cumulatively considerable effect, the discussion that follows is limited to these issues.

Non-HCP Alternatives

For Alternatives 4A, 2D, and 5A, the Environmental Commitments, resource guidelines, AMMs, and mitigation measures presented are sufficient to avoid significant cumulative effects from the combined losses due to water conveyance construction and restoration except for upstream effects on bank swallows (see Impact BIO-189: *Cumulative Upstream Effects of Reservoir and Water Conveyance Facilities Operations on Bank Swallow*).

Impact BIO-188: Cumulative Indirect Effects of the Construction of Conservation Components on Bank Swallow

Noise and visual disturbances during restoration activities for all action alternatives could result in temporary disturbances that cause bank swallow to abandon active nest burrows adjacent to construction areas, and construction-related disturbances could result in an adverse effect on individuals. The noise and visual disturbance could result from implementing *CM2 Yolo Bypass Fisheries Enhancement*, and *CM4 Tidal Natural Communities Restoration* including operation of earthmoving equipment and human activities at work sites. Bank swallow colonies with occupied burrows have been recorded in CZ 2 and CZ 5. Various activities related to *CM11 Natural Communities Enhancement and Management* could also have indirect impacts on bank swallow. Alternatives 4A, 2D, and 5A would not include the CM2 (Yolo Bypass) restoration activities, so they would not create the potential noise and visual disturbances that could affect bank swallow in CZ 2.

Other projects and programs listed in Table 12-8 also have the potential to directly or indirectly affect bank swallow in the study area and in areas upstream of the study area along the Sacramento and Feather Rivers.

- DWR Central Valley Flood Protection Plan (Yolo Bypass widening).
- DWR Delta Levees Flood Protection Program.
- DWR FloodSAFE California.
- Sacramento Area Flood Control Agency, Central Valley Flood Protection Board, and USACE Central Valley Flood Management Program.
- UUSACE CALFED Levee Stability Program.
- Reclamation and Placer County Water Agency Sacramento River Water Supply Study

All of the flood control and levee protection programs and plans listed above could involve modification and armoring of levees within the range of known bank swallow colonies adjacent to and north of the study area. Additional bank protection could further reduce the availability of bank swallow nesting sites and could involve indirect disturbance of active nesting colonies. The action alternatives, in combination with the other projects and programs listed above, could result in adverse effects on bank swallow nesting colonies that are individually limited but cumulatively considerable.

***NEPA Effects*:** The indirect disturbance to bank swallow nesting colonies caused by implementing any action alternative, in combination with the potential direct and indirect effects on these colonies caused by other past, present, or reasonably foreseeable projects and programs, would create an adverse cumulative effect on this species adjacent to and north of the study area. The disturbances could result in take of a state-listed threatened species. Although the potential effect of the alternatives is restricted to few colonies, the state recognizes this species as both imperiled and vulnerable because of its restricted range and low populations. Therefore, the effect of the alternatives represents an adverse cumulative effect. Implementation of Mitigation Measure BIO-146, *Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized*, would be available to address this effect.

***CEQA Conclusion*:** The indirect disturbance to bank swallow nesting colonies caused by implementing any action alternative, in combination with the potential direct and indirect effects on these colonies caused by other past, present or reasonably foreseeable projects and programs, would create a significant cumulative impact on this species adjacent to and north of the study area. The disturbances could result in take of a state-listed threatened species. Although the potential cumulative effect is restricted to a single colony, the state recognizes this species as both imperiled and vulnerable because of its restricted range and low populations. The contribution of action alternatives to this cumulative impact is considered cumulatively considerable because construction of these alternatives related to the Yolo Bypass could indirectly affect this species. Implementation of Mitigation Measure BIO-146, *Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized*, would reduce this impact less than cumulatively considerable.

Mitigation Measure BIO-146: Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized

To the extent practicable, project proponents will not conduct restoration activities during the bank swallow nesting season (April 1 through August 31). If construction activities cannot be avoided during nesting season, a qualified biologist will conduct preconstruction surveys to determine if active bank swallow nesting colonies are present within 500 feet of work areas. If no active nesting colonies are present, no further mitigation is required. Reusable tunnel material areas are not expected to be colonized by nesting bank swallows, as it is unlikely that the substrate would provide suitable nesting habitat for the species. However, reusable tunnel material sites could become suitable for swallows over time. Surveys of reusable tunnel material areas that have been present for at least 1 year, allowing the substrate to stabilize, will be conducted prior to the removal of reusable tunnel material.

If active colonies are detected, project proponents will establish a nondisturbance buffer (determined in coordination with CDFW and the Bank Swallow Technical Advisory Committee) around the colony during the breeding season. In addition, a qualified biologist will monitor any active colony within 500 feet of construction to ensure that construction activities do not affect nest success.

Impact BIO-189: Cumulative Upstream Effects of Reservoir and Water Conveyance Facilities Operations on Bank Swallow

One the primary threats to bank swallows is loss of nesting habitat from the placement of rock revetment for levee stabilization. Because of this limited available habitat, and the reduction of natural river process, the species is highly sensitive to 1) reductions in winter flows which are necessary to erode banks for habitat creation, and 2) high flows during the breading season. The potential impacts of changes in upstream flows during the breeding season on bank swallows are the flooding of active burrows and destruction of burrows from increased bank sloughing. Bank swallows arrive in California and begin to excavate their burrows in March, and the peak egg-laying occurs between April and May (Bank Swallow Technical Advisory Committee 2013). Therefore, increases in flows after the March when the swallows have nested and laid eggs in the burrows could result in the loss of nests. On the Sacramento River, breeding season flows between 14,000 and 30,000 cfs have been associated with localized bank collapses which resulted in partial or complete colony failure (Stillwater Sciences 2007).

The CALSIM II modeling results of mean monthly flow were analyzed for three flow gauge stations on the Sacramento (Sacramento River at Keswick, Sacramento River upstream of Red Bluff, Sacramento River at Verona) and two flow gauge stations on the Feather River (Feather River high-flow channel Thermalito Dam, and Feather River at the Confluence with the Sacramento River). Flows were estimated for wet years, above normal years, below normal years, dry years, critical years, and an average (see Chapter 5, Section 5.3.1, *Methods for Analysis*, for a description of the model).

On the Sacramento River, at the Keswick and Red Bluff gauges, mean monthly flows under the action alternatives 1–9 and potentially other cumulative projects would increase between April and August in some water years which could lead to inundation of active colonies. However, the flows under Existing Conditions and the predicted flows in the late long-term without the project also show increases in flows during the breeding season (April–August) in these water year types. Similar trends occur for the Feather River. In addition, under the action alternatives flows are predicted to be greater than 14,000 cfs during the breeding season (April–August,) during certain water years which could lead to bank collapse. However, flows of this height are recorded under Existing Conditions at this flow gauge and are also predicted for the late long-term time without the project (the No Action Alternative).

NEPA Effects: High spring flows on the Sacramento and Feather Rivers may already be impacting bank swallow colonies during the breeding season, and predicted flows under the action alternatives would not be substantially greater than under the No Action Alternative. However, because of the complexity of variables that dictate suitable habitat for the species, there is uncertainty regarding the potential for and magnitude of impacts on bank swallow from changes in upstream operations. Soil type, high winter flows, and low spring flows all contribute to successful nesting of bank swallow, and even moderate changes in seasonal flows could have an adverse effect on breeding success for the species. Mitigation Measure BIO-147, *Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area*, would be available to address the uncertainty of potential adverse effects of upstream operations on bank swallow. Because the state recognizes this species as both imperiled and vulnerable due to its restricted range and low populations, any negative effect of the alternatives would represent a cumulatively considerable contribution to an adverse cumulative effect.

CEQA Conclusion: High spring flows on the Sacramento and Feather Rivers may already be impacting bank swallow colonies during the breeding season, and predicted flows under the action alternatives would not be substantially greater than under the No Action Alternative. However, because of the complexity of variables that dictate suitable habitat for the species, there is uncertainty regarding the potential for and magnitude of upstream impacts on bank swallow from changes in operations. There are many variables that dictate suitable habitat for the species that cannot be clearly quantified, and seasonal changes in flow could increase or decrease suitable habitat for bank swallow depending on soil type and location of current colonies. Mitigation Measure BIO-147, *Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area* would address this significant impact and further determine if additional mitigation is required for bank swallow. Because the state recognizes this species as both imperiled and vulnerable due to its restricted range and low populations, any adverse impact of the alternatives would represent a cumulatively considerable contribution to a significant cumulative impact.

Mitigation Measure BIO-147: Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area

To address the uncertainty of the impact of upstream spring flows on existing bank swallow habitat, DWR will monitor existing colonies upstream of the study area and collect habitat suitability data including soil type, number of active burrows per colony, and height of average burrows. DWR will quantify the magnitude of spring flows that would result in potential mortality of active colonies. In addition, to determine the degree to which reduced winter flows are contributing to habitat loss, DWR will quantify the winter flows required for river meander to create suitable habitat through lateral channel migration and bank resurfacing. If impacts of upstream flows on bank swallow are identified, replacement habitat will be established at a minimum of 2:1 for the length of bank habitat affected. Replacement habitat will consist of removing bank revetment to create habitat for bank swallow at a location subject to CDFW approval (Bank Swallow Technical Advisory Committee 2013).

Impact BIO-190: Cumulative Effect of Constructing Conveyance Facilities on Giant Garter Snake Movements and Connectivity between Subpopulations

The construction of the conveyance facilities under the alternatives using the eastern alignments (Alternatives 1B, 2B, and 6B) would adversely affect movement and connectivity for the Coldani Marsh/White Slough subpopulation of giant garter in the study area. The facilities would eliminate Coldani Marsh/White Slough subpopulation connectivity with areas containing current or previous occurrences of giant garter snake, specifically in the vicinity of Stone Lakes NWR to the north and in the Delta to the southwest (Figure 12-15B). An unknown number of small agricultural ditches and drains between Disappointment Slough and Stone Lakes would be lost, rerouted, or directed into culverts and affect species' movements and connectivity. Siphons would be constructed underneath sloughs (Disappointment Slough, White Slough, Sycamore Slough, Hog Slough, and Beaver Slough) and Stone Lakes Drain, and a tunnel would be constructed under the Lost Slough/Mokelumne River area that connects with Snodgrass Slough. These sloughs and drains would still provide some aquatic habitat and opportunities for movement and connectivity between giant garter snakes in the vicinity of Stone Lakes NWR and the Coldani Marsh/White Slough subpopulation.

Other factors, projects, or programs also have the potential to directly or indirectly affect giant garter snake movements and connectivity in the study area.

- Urbanization continues to be one of the greatest threats to the giant garter snake throughout much of its extant range. Environmental impacts associated with urbanization are loss of habitat, introduction of nonnative species with a resulting loss of biodiversity, fragmentation of habitat due to road construction, and degradation of habitat due to pollutants. Within the current range of the giant garter snake, cities that are rapidly expanding and, in some instances, intruding upon or otherwise impacting giant garter snake habitat include, Chico, Woodland, Yuba City, Marysville, Sacramento, Galt, Stockton, Gustine, Los Banos, Merced, and Fresno. Urbanization increasingly threatens the viability of giant garter snake populations as urban landscapes encroach on ever-diminishing habitat for this listed species, including eliminating rice agriculture that serves as an alternative habitat for the giant garter snake.
- A number of HCPs have been issued by USFWS for projects anticipated to impact the giant garter snake, which include the San Joaquin County multi-species HCP, the East Contra Costa County HCP, and the PG&E San Joaquin Valley HCP. In addition, eight other HCPs that include areas within the range of the giant garter snake are currently being developed: Butte County, South

Sacramento, Solano County, Yolo County, Yuba/Sutter County, Placer County, PG&E Statewide Operations and Maintenance, and PG&E Bay Area.

- Giant garter snakes found in rice fields or agricultural canals are threatened by conversion of rice crops to non-agricultural land uses and other crops such as grape-producing vineyards, fruit or nut producing orchards, or annual row crops (e.g., cotton). Unlike flood irrigated rice fields, other agricultural cropping systems do not hold sufficient water for long enough time periods to create artificial, temporary wetlands.

- The White Slough Wildlife Area (WSWA) is owned by DWR and managed by CDFW. WSWA consists of 880 acres of man-made ditches, canals, and freshwater marshes with associated grassland/upland habitats used for hunting and fishing. From 1974 to 1978, 13 rectangular borrow pits were excavated from 1 to 5 miles west of I-5 to provide fill for freeway construction. The pits are fed by groundwater and periodic runoff from precipitation, irrigation, and high canal flows, creating a series of ponds characterized by vegetated sloping or vertical banks and open water with adjacent uplands and high ground. As a management area, WSWA comprises a discontinuous series of properties encompassing ponds 5–13, which occur along a roughly 11-mile stretch between Thornton and Stockton. WSWA supports the preponderance of the Coldani Marsh/ White Slough giant garter snake population, one of 13 giant garter snake populations described in the USFWS 1999 *Draft Recovery Plan for the Giant Garter Snake*. In the 1970s, CDFW stocked large-mouth bass, channel catfish, and red-eared sunfish in at least two of the ponds: each of these species probably prey on giant garter snakes and compete with them for smaller prey (58 FR 54053).

- DWR Central Valley Flood Protection Plan (Yolo Bypass widening) proposes expansion of flood protection features in the study, including expansion of the Yolo Bypass. This flood protection improvement project would potentially conflict with BDCP's effort to improve giant garter snake habitat just outside of the current floodway.

- The NMFS, Reclamation and DWR BiOp on the long-term pperations of the CVP and SWP includes the Sacramento River downstream of Feather River, Sacramento-San Joaquin Delta, and adjacent habitats that are dependent on or influenced by waterways. The BiOp includes landscape designs to conserve freshwater, estuarine, nearshore, and offshore aquatic habitats, for the benefit of federally protected fish species. Including 8,000-acre tidal wetland restoration requirement, which would result in conversion of agricultural land and managed wetland in the Delta and Suisun Marsh, which could negatively affect giant garter snake connectivity and movement in the study area.

- Sacramento Area Flood Control Agency, Central Valley Flood Protection Board, and USACE Central Valley Flood Management Program is an ongoing program that supports flood management planning in Sacramento and San Joaquin Valleys. The program supports improvements in flood management structures, including levees and bypasses. Facilities improvements could result in local removal of vegetation in the study area as flood control facilities are improved and expanded which could include effects on giant garter snakes in the study area.

Past development within the study area, including urbanization and the construction of irrigation canals, levees, local roads, highways, agricultural development, and the development of wildlife management areas, has already affected the ability for giant garter snake to move within and through the study area.

NEPA Effects: The construction of the water conveyance facilities under Alternatives 1B, 2B, and 6B, in combination with past, present or reasonably foreseeable projects would create an adverse cumulative effect on giant garter snake movement and connectivity within and in the vicinity of the study area. The alternatives' effects represent a cumulatively considerable contribution to an adverse cumulative effect. The only ways to reduce the effects these alternatives would have on giant garter snake movement would be to eliminate the canals from these alternatives, which cannot be done because the canals are essential components of these alternatives, or to create numerous overpass structures along the canals, which would substantially increase the costs and would not fully address the habitat connectivity and movement needs of giant garter snake. For these reasons, there is no feasible mitigation to address this effect.

CEQA Conclusion: The construction of the water conveyance facilities under Alternatives 1B, 2B, and 6B, in combination with past, present or reasonably foreseeable projects would create a significant cumulative impact on giant garter snake movement and connectivity within and in the vicinity of the study area. The alternatives' impact would represent a cumulatively considerable contribution to a significant cumulative impact. This impact would be significant and unavoidable. The only ways to reduce the effects these alternatives would have on giant garter snake would be to eliminate the canals from these alternatives, which cannot be done because the canals are essential components of these alternatives, or to create numerous overpass structures along the canals, which would substantially increase the costs and would not fully address the habitat connectivity and movement needs of giant garter snake. For these reasons there is no feasible mitigation to reduce this impact to a less-than-significant level.

Impact BIO-191: Cumulative Effect of Constructing Conveyance Facilities on Wildlife Corridors

The construction of the water conveyance facilities (CM1) under the alternatives using the eastern alignment (Alternatives 1B, 2B, and 6B) and western alignment (Alternatives 1C, 2C, and 6C) would adversely affect wildlife corridors within and through the study area. The intakes, forebays, and canal portions of these alternatives would create barriers to the movement of nonavian wildlife within and through the study area. Nonavian wildlife in large portions of the study area would be restricted to moving across the canals via roads and bridges that would likely act as deterrents to wildlife movement and would be a source of wildlife mortality. The canal for the eastern alignment would act as a major barrier to the movement of nonavian wildlife within the eastern portion of the Delta. The canals for the western alignment would create a substantial barrier to the east-west movement of nonavian wildlife from Clifton Court Forebay north to around the community of Knightsen, and to the north-south movement of wildlife from the town of Hood west to the Sacramento Deep Water Ship Channel. Avian species would also be subject to increased mortality where new transmission lines are installed; however, these lines would not serve as major barriers to avian species' ability to disperse within and through the study area.

One project listed in Table 12-8, the California High-Speed Rail, would also have the potential to adversely affect wildlife corridors in the study area and region. One of the proposed alignments for the Sacramento-to-Merced section of the California High Speed Rail would pass through the study area between French Camp and Lathrop, generally following the I-5 corridor and eventually heading east along State Route 120. A proposed option for the Bay Area-to-Central Valley alignment passes through the study area from just west of Tracy east to around Lathrop, a route that generally follows the existing Union Pacific Rail Road corridor. Both of these areas already have barriers to species dispersal, but increased rail traffic and the speed of the trains could serve as deterrents and sources of mortality to wildlife trying to cross these areas.

Past development within the study area, including the construction of irrigation canals, levees, local roads, highways, and agricultural development, has already affected the ability for wildlife to move within and through the study area.

NEPA Effects: The construction of the water conveyance facilities under Alternatives 1B, 1C, 2B, 2C, 6B, and 6C, in combination with past, present or reasonably foreseeable projects, would create an adverse cumulative effect on wildlife corridors within and in the vicinity of the study area. The alternatives' effects represent a cumulatively considerable contribution to an adverse cumulative effect. The only ways to reduce the effects these alternatives would have on wildlife corridors would be to eliminate the canals from these alternatives, which cannot be done because the canals are essential components of these alternatives, or to create numerous overpass structures along the canals, which would substantially increase the costs and would not fully address all of the movement needs of the wildlife being considered (e.g., giant garter snake). For these reasons, there is no feasible mitigation to address this effect.

CEQA Conclusion: The construction of the water conveyance facilities under Alternatives 1B, 1C, 2B, 2C, 6B, and 6C, in combination with past, present or reasonably foreseeable projects, would create a significant cumulative impact on wildlife corridors within and in the vicinity of the study area. The alternatives' impact would represent a cumulatively considerable contribution to a significant cumulative impact. This impact would be significant and unavoidable. The only ways to reduce the effects these alternatives would have on wildlife corridors would be to eliminate the canals from these alternatives, which cannot be done because the canals are essential components of these alternatives, or to create numerous overpass structures along the canals, which would substantially increase the costs and would not fully address all of the movement needs of the wildlife being considered (e.g., giant garter snake). For these reasons, there is no feasible mitigation to reduce this impact to a less-than-significant level

12.3.6 Effects on Other Conservation Plans

Impact BIO-192: Potential for Conflicts between Implementation of the BDCP and Other Conservation Plans

To comply with CEQA, potential conflicts with the provisions of an adopted HCP, NCCP, or other approved local, regional, or state habitat conservation plan must be analyzed. Within or near the study area, numerous HCPs, NCCPs, and other regional conservation plans have been permitted or are in process, including those listed below.

- Placer County Conservation Plan (TRA Environmental Services 2011)
- Yuba-Sutter HCP/NCCP (Yuba County et al. 2011)
- Natomas Basin HCP (City of Sacramento et al. 2003)
- Yolo Natural Heritage Program (YNHP) (Yolo County Habitat/Natural Community Conservation Plan Joint Powers Authority 2013)
- South Sacramento HCP (Sacramento County 2010)
- Solano County Multispecies HCP (Solano County MSHCP) (Solano County Water Agency 2009)

- East Contra Costa County HCP/NCCP (ECCCHCP/NCCP) (East Contra Costa Habitat Conservation Plan Association 2006)
- San Joaquin County Multi-Species HCP and Open Space Plan (SJCMSHCP) (Jones & Stokes 2000)
- East Alameda County Conservation Strategy (EACCS) (East Alameda County Conservation Strategy Steering Committee 2010)

Of these, the first three plans have little (less than 1%) or no physical overlap with the study area boundary and, thus, no potential for conflict with BDCP actions (Figure 12-3). The Placer County Conservation Plan is found in western Placer County and does not overlap with BDCP. The Yuba-Sutter HCP/NCCP covers Yuba and Sutter Counties and overlaps with less than 200 acres of the study area at the northern end of the Yolo Bypass (Table 12-9). The Natomas Basin HCP is found in northwestern Sacramento and southern Sutter Counties. This plan is adjacent to the study area but does not overlap with it. Because of the lack of overlap and the location of these plans upstream of BDCP, they are not discussed further in this section.

The remaining six plans overlap with the study area to varying extents (Table 12-9). Each of these six plans includes a conservation strategy that implements land restoration, enhancement and/or acquisition within or near their respective boundaries. The following discussion addresses whether the implementation of BDCP covered activities and conservation actions have the potential to conflict with these plans and their conservation strategies.

Table 12-9. Summary Table of Conservation Plans that Overlap with BDCP

Conservation Plan	Plan Status	Plan Area (ac)	Boundary Overlap with BDCP (ac)	Overlap Relative to Other Plans	Overlap relative to BDCP
East Contra Costa County HCP/NCCP	Approved in 2007	174,116	63,073	36.2%	7.3%
San Joaquin County MSHCP and Open Space Plan	Approved in 2001	912,386	317,355	34.8%	37.0%
East Alameda County Conservation Strategy	Approved in 2011	271,486	4,643	1.7%	0.5%
Solano County MSHCP	In Process	581,874	198,149	34.1 %	22.9%
South Sacramento HCP	In Process	374,733	41,130	11.0%	4.8%
Yolo Natural Heritage Program	In Process	653,818	111,383	17.1%	12.9%

Table 12-10 lists the amount of conservation remaining in each of the three approved plans based on summary reports released in 2011. Because EACCS was just approved in 2011, no land has been acquired to date for its reserve system. The acreage provided in Table 12-10 is the estimated amount needed for the entire plan area under each plan, and is not limited to the overlap area.

Table 12-10. Conservation Status of Approved Plans (acres)

Plan	Target Reserve System Size	Current Reserve System Size	Amount Remaining to Acquire
East Contra Costa County HCP/NCCP*	30,300	4,589	25,711
San Joaquin County MSHCP**	100,841	8,942	91,899
East Alameda County Conservation Strategy***	N/A	0	N/A

Sources: ICF International 2011; San Joaquin Council of Governments 2010.

* Reserve System Size based on Maximum Development Scenario

** Based on estimated acreage of take according to mitigation ratios. Actual amount remaining likely to be much less.

*** Conservation Strategy is implemented project-by-project according to established mitigation ratios. Because the strategy is not dependent on a certain amount of development occurring, there is no target reserve system size.

Effects of Water Conveyance Facilities Construction on Other Conservation Plans

The BDCP conservation measures, or Environmental Commitments under the non-HCP alternatives, that have the potential to affect overlapping conservation plans include the construction and operation of new water conveyance facilities associated with the SWP and CVP, and the implementation of restoration and acquisition actions and other conservation activities. The effects of restoration, acquisition, and other conservation activities are discussed in the next section. To quantify the potential effects of the construction of the water conveyance facilities on overlapping plans, the permanent surface impacts of the construction of Alternatives 1A, 1B, 1C, 2A, 2B, 2C, 2D, 3, 4, 4A, 5, 5A, 6A, 6B, 6C, 7, 8, and 9 were identified.

Construction of the water conveyance facilities would result in permanent surface disturbance within the Plan Area. Depending upon the alternative, a portion of these impacts would occur outside of the plan area boundaries for the six overlapping plans (Figure 12-4). The remaining impacts would be small relative to the size of the overlapping plan areas, varying from less than 0.01% of total plan areas, to a maximum of 2.7% of the East Contra Costa County HCP/NCCP area under Alternatives 1C, 2C, and 6C (4,755 acres of impacts within a 174,115-acre plan area). Construction of the water conveyance facilities would reduce the amount of available cultivated land for acquisition by overlapping conservation plans by as little as 5 acres in the East Alameda County Conservation Strategy (Alternatives 2D, 4, 4A, and 5A) and as much as 14,050 acres in the San Joaquin County HCP (Alternatives 1B, 2B, 6B).

The construction of the water conveyance facilities would avoid all existing reserve lands of the East Contra Costa County HCP/NCCP because these lands are outside of the study area (Figure 12-4). Similarly, construction of the water conveyance facilities using the west alignment, Modified Pipeline/Tunnel Alignment, or Pipeline/Tunnel Alignment would avoid all existing reserve lands of the San Joaquin County HCP (Figure 12-4). Construction of the east canal has the potential to temporarily affect existing preserve lands of the San Joaquin County HCP near Sycamore Slough and Walnut Grove. See the section below on this plan for details of these potential impacts and mitigation measures.

Table 12-11. Impacts from Construction of Water Conveyance Facilities under the Alternatives Relative to Total Area of Overlapping Conservation Plans

Effects of BDCP Acquisition and Restoration on Other Conservation Plans

Like the BDCP, each of the six overlapping conservation plans contains a conservation strategy composed of a variety of actions or measures. Approved conservation plans (ECCCHCP/NCCP, SJCMSHCP, EACCS) are required to implement those actions in order to meet their permit conditions. Proposed plans (YNHP, South Sacramento HCP, and Solano County MSHCP) are not yet permitted but are far enough along in their development process to predict the nature and general location of likely conservation actions. In all overlapping conservation plans (approved or in process), the primary conservation actions are a combination of land preservation through acquisition in fee title or conservation easement and restoration of natural communities. All of the overlapping plans focus primarily on terrestrial species (see Table 1-4 in Chapter 1 of the BDCP for the overlap of covered species) and, consequently, on the preservation and restoration of terrestrial natural communities and adjacent wetland and stream systems.

This regional focus on land protection and conservation to benefit endangered species creates opportunities for coordination, partnerships, and achieving common conservation goals. However, the need to fulfill acquisition and restoration targets in geographically overlapping areas also creates the potential for conflicts. For example, in certain areas, sites available for acquisition and restoration with rare natural communities or physical conditions may be limited. This limitation may cause plans to compete for conservation lands, particularly to meet HCP obligations that are driven by mitigation-to-impact ratios.

Conservation components under Alternatives 1B, 1C, 2A, 2B, 2C, 3, 4, 6A, 6B, 6C, 8 and 9 would be the same as those under Alternative 1A. Conservation components under Alternative 5 would be the same as those under Alternative 1A, except that 25,000 acres, rather than 65,000 acres, of tidal habitat would be restored. Conservation components under Alternative 7 would be similar to those under Alternative 1A, but 40 linear miles, rather than 20 linear miles, of channel margin habitat would be enhanced, and 20,000 acres, rather than 10,000 acres, of seasonally inundated floodplain would be restored to further improve fish and wildlife habitat, particularly along the San Joaquin River.

Alternatives 4A, 2D, and 5A would not be implemented as HCP/NCCPs and would require substantially less conservation relative to the other alternatives. Tidal habitat restoration would range between 292 and 300 acres, nontidal marsh restoration would range between 832 and 1,356 acres, channel margin enhancement would range between 3.1 and 5.5 levee miles, and there would be no seasonally inundated floodplain restoration. The cultivated lands needed for protection under the non-HCP alternatives ranges between 11,301 and 13,432 acres, which is substantially less than the 48,625 acres of cultivated lands proposed for protection under the BDCP alternatives. Alternatives 4A, 2D, and 5A generally would result in the same or fewer impacts than the water conveyance facilities for the BDCP alternatives and would require substantially less restoration and protection; therefore, the analysis presented below focuses only on the BDCP alternatives, which have a greater potential for conflict with the six overlapping plans.

This analysis addresses the potential for conflict by analyzing the conservation needs of the BDCP and each of the six plans with substantial (more than 1%) overlap with the BDCP (Table 12-11).

12.3.6.1 Methodology

To understand the conservation issues of all plans relative to the overlap areas, several analyses were conducted. First, a crosswalk table was developed for all natural community types with restoration or acquisition targets in the BDCP. Because each plan uses a different land-cover dataset, a crosswalk was created that broadly assimilates these land-cover types into six categories relevant for conservation: wetlands, tidal, riparian, grassland, agriculture, and streams (Table 12-12). The BDCP dataset contains both tidal and nontidal wetlands. Tidal wetlands were assigned to the "tidal" community, while nontidal wetlands were assigned to the "wetland" community. Note that land cover types without restoration or acquisition targets in the BDCP (e.g., chaparral, urban, conifer) were not crosswalked because the analysis is limited to understanding how the implementation of BDCP restoration and acquisition targets might affect other plans.

1 **Table 12-12. Crosswalk of BDCP Natural Communities with those of Overlapping Conservation Plans**

BDCP Natural Communities		ECCC HCP/NCCP	SJCMSHCP	EACCS	Solano MSHCP	South Sacramento HCP	YNHP
Wetlands	Vernal pool complex	Perennial Wetland	Vernal Pool Grassland	Alkali Wetland	Vernal Pools	Vernal Impoundment	(riparian and wetlands)

Grassland	Grassland	Alkali Grassland	Grassland	Alkali Meadow and Scalds	Valley Floor Grasslands	Valley Grassland	Grasslands
		Annual Grasslands		California Annual Grassland			
Dune Scrub	Inland dune scrub						
Streams	Nontidal perennial aquatic (lakes, ponds, streams)	Perennial Streams	Submerged Aquatic Vegetation	Streams			

Notes: All natural communities are crosswalked to column B NOT to each other.
Crosswalk based on aggregated Preserve Types from 2000 SJC MSCP and Open Space Plan Table 5.4.2. Each preserve includes multiple vegetation types resulting in overlaps between the preserves and the major natural community types created by the crosswalking exercise.

The six natural community categories were analyzed for each of the six plans with respect to both acquisition and restoration. Tables 12-13 through 12-17 summarize the acquisition targets for each plan, if available. In order to roughly approximate potential acquisition needs of each plan in the overlap areas, the acquisition targets from each plan for each natural community type were multiplied by the proportion of each community type in the overlap area relative to each plan as a whole. This method assumes that acquisition will be evenly distributed throughout each plan area and roughly approximates potential acquisition in the overlapping zones. In cases where acquisition was focused geographically (i.e., did not fit this assumption), a "correction factor" was applied to account for underestimates or overestimates based on plan requirements and ICF's familiarity with each overlapping plan. We used the U.S. Forest Service's California Vegetation (CALVEG) and BDCP vegetation datasets to calculate the proportion of each natural community type in the overlap areas. Because the draft conservation strategy for the YCHP has not been released, acquisition targets were not provided, only the overlap acres (Table 12-17).

Table 12-13. Estimated Overlap in Acquisition Activities by Major Natural Community Type for ECCCHCP/NCCP

	East Contra Costa County HCP/NCCP				
	Overlap with BDCP	Plan-Wide Target (acres)	Correction Factor	Estimated Acquisition Needs in BDCP Plan Area (acres)	Notes
Agriculture	96%	400	1.04	400	All agriculture acquisition will occur in BDCP overlap area.
Grassland	11%	17,750	0.5	957	Most grassland will be protected outside of the BDCP overlap area; includes alkali grassland.
Riparian	60%	70	1	42	
Wetlands	94%	336	0.4	127	Most wetlands will be preserved in foothills, not agricultural areas.

Wetlands	11,501	10,932	95%

Effects of BDCP Acquisition of Cultivated Land on Other Conservation Plans

By far the BDCP's largest land acquisition need is for cultivated land, which the BDCP calls "cultivated lands." BDCP would acquire cultivated lands for three primary purposes. First, cultivated land would be acquired to build the water conveyance facilities, as describe above and quantified in Tables 12-18 through 12-21. Second, cultivated land would be acquired by BDCP for preservation as foraging habitat for three covered species (Swainson's hawk, sandhill crane, and tricolored blackbird). Finally, cultivated land would be acquired for restoration to tidal wetland, floodplains, riparian woodland, or nontidal marsh.

This acquisition and preservation has the greatest potential for conflict with overlapping conservation plans that have substantial needs for acquisition of cultivated lands to satisfy their own conservation requirements. Acquisition by BDCP of cultivated land reduces the amount of such land available for overlapping plans. The assessment of this potential conflict compares the amount of cultivated land not already protected (i.e., that available for acquisition) with the need for cultivated land by BDCP and each plan in the overlap area. The analysis also takes into account that BDCP and each plan would remove cultivated lands through their own covered activities, further reducing the available cultivated land for preservation. This assessment assumes all covered activities in each plan are implemented and, therefore, all mitigation or conservation needs for cultivated lands are realized in each plan. In reality, some plans may not have the development assumed by the plan and, therefore, would not have the full need assumed by the plan for mitigation or conservation (which is proportional to the development that occurs).

The cultivated preservation needs of BDCP and the other conservation plan are deemed to be without conflict if the available cultivated land with full buildout is at least double the sum of the needs of the two plans in the overlap area. This assumption is based on the need to have more cultivated land for preservation than required to ensure that enough willing sellers are available for each plan.

One limitation of this analysis is that it is a snapshot at the end of the permit terms of each plan. In reality, each plan will be gradually preserving cultivated land in the overlap area at the same time. BDCP and overlapping plans would also be coordinating and cooperating in their land acquisition activities. For example, BDCP Chapter 3, Section 3.4.1.3.1, *Land Protection*, describes a process for coordination among BDCP, South Sacramento HCP, and San Joaquin Multiple Species Conservation Plan to ensure that sufficient lands are available in the overlap area for each plan to meet its conservation obligations. Additionally, for NCCPs in development that have planning agreements, discretionary projects within the plan area that are subject to CEQA are subject to review by the CDFW to ensure that they do not conflict with the preliminary conservation objectives of an NCCP under development (Fish and Game Code Section 2810(b)(8)). Both the gradual preservation in the overlap area over time and ongoing coordination would help to minimize any conflicts that might arise with individual acquisitions or with a gradual shortage that might arise near the end of the last permit.

Tables 12-22 through 12-25 summarize the restoration targets for each plan and estimate the overlap with BDCP. The restoration targets are multiplied by the percentage of overlap between each plan area and the BDCP to approximate the potential for competition over land cover for restoration. Like the analysis for Table 12-22, a correction factor was applied to targets and plans where additional information regarding the location of restoration was available. Because the draft conservation strategy for the YNHP has not been released, a restoration table was not developed. The acres of each natural community type relative the YNHP plan area and the overlap area are provided in Table 12-17.

Table 12-22. Estimated Overlap in Restoration Activities by Major Natural Community Type for ECCCHCP/NCCP

East Contra Costa County Habitat Conservation Plan				
	Plan-Wide Target (acres)	Overlap	Correction Factor[a]	Estimated Overlap (acres)
Wetlands	315	36%	0.4	45
Riparian	55	36%	1	20

[a] Wetlands are less likely to be restored within the BDCP Plan Area because of the location of existing preserves outside of the BDCP Plan Area (wetland restoration must occur on the preserves).

Table 12-23. Estimated Overlap in Restoration Activities by Major Natural Community Type for San Joaquin County MSHCP and Open Space Plan

San Joaquin County MSHCP and Open Space Plan[a]				
	Plan-Wide Target (acres)	Overlap	Correction Factor	Estimated Overlap (acres)
Wetlands	350	35%	1	123
Riparian	751	45%	1	338

[a] Table based on remaining acres for restoration from 2011 San Joaquin County MSHCP and Open Space Plan Annual Report. Vegetation management and enhancement in other natural community types (e.g., riparian) occurring in SJC MSHCP preserves acquired under the plan. However, specific targets for this restoration is not associated with the acreages provided for plan mitigation. Riparian includes: Great Valley Riparian Forest (R), Great Valley Oak Riparian Forest (R2), Arroyo Willow Thicket (R4), Great Valley Mixed Riparian Forest (R5), Riparian Scrub (RS2), and Great Valley Riparian Scrub(S)

Table 12-24. Estimated Overlap in Restoration Activities by Major Natural Community Type for Solano County MSHCP

	Solano County MSHCP			
	Plan-Wide Target (acres)	Overlap	Correction Factor	Estimated Overlap (acres)
Wetlands	270–400	34%	1	62–92
Tidal	75–100	34%	2.94[a]	75–100
Riparian	50	34%	1	17

[a] All tidal wetland restoration is expected to occur in the overlap area.

Table 12-25. Estimated Overlap in Restoration Activities by Major Natural Community Type for South Sacramento HCP

	South Sacramento HCP			
	Plan-Wide Target (acres)	Overlap	Correction Factor	Estimated Overlap (acres)
Wetlands	722	11%	1	79
Riparian	315	11%	1	35

Note that for Tables 12-13 through 12-25, if a plan did not set an acquisition or restoration target for a given natural community type, that community type was not included in the table.

Plan-Specific Analysis

East Contra Costa County

The ECCCHCP/NCCP was adopted in 2006 by Contra Costa County and the cities of Brentwood, Clayton, Pittsburg, and Oakley. Permits were issued in 2007 by USFWS and CDFW for a 30-year term. A joint powers authority of the agencies receiving the permits and the East Bay Regional Park District formed the East Contra Costa County Habitat Conservancy to implement the plan.

The HCP/NCCP provides regional conservation while improving and streamlining the permit process for endangered species. In 2012, the Corps issued a Regional General Permit to the East Contra Costa County Habitat Conservancy to provide additional streamlining for wetland regulations. Within the 174,115-acre plan area, the HCP/NCCP covers 8,670–11,853 acres of development and 1,126 acres of rural infrastructure projects. The HCP/NCCP requires creation of a preserve system of 23,800–30,300 acres that will be managed for the benefit of 28 covered species and their associated natural communities. The range of impacts and conservation requirements varies depending on whether the current urban limit lines of the participating cities are expanded.

The BDCP overlaps with the ECCCHCP/NCCP in the central western portion of the study area (Figure 12-3). The two plans have 15 covered species in common, including San Joaquin kit fox, western burrowing owl, and Swainson's hawk (BDCP Chapter 1, Table 1-4). While approximately 36% of the ECCC plan area overlaps with that of the BDCP (Table 12-9), the overlap area is largely cultivated land outside of the urban limit lines of the county and participating cities.

The proposed preserve system for the ECCCHCP/NCCP occurs almost entirely outside of the BDCP boundary. Construction of the water conveyance facilities would have impacts in the ECCCHCP/NCCP plan area (e.g., new forebay adjacent to Clifton Court), but not on any existing preserves. Some riparian acquisition and restoration may occur in the overlap area, particularly in the lower reaches of Marsh Creek or Kellogg Creek. Preservation and acquisition of riparian woodland and streams in the overlap area would not be likely to result in conflicts because each plan has many options for riparian restoration both inside and outside of the overlap area. These needs present an opportunity for coordination of East Contra Costa County Habitat Conservancy efforts with proposed tidal marsh restoration for the BDCP (see discussion below).

While acquisition and restoration needs of the ECCCHCP/NCCP for wetlands, grasslands, and riparian land cover are relatively low within the overlap area, all acquisition of cultivated lands will occur there (Table 12-13). Because the ECCCHCP/NCCP acquisition target for agriculture is only 400 acres, and there are more than 30,000 acres of cultivated lands within the overlap area, implementation of the BDCP is not anticipated to conflict with the ability of ECCCHCP/NCCP to meet its conservation obligations. Each plan is expected to be able to meet its conservation requirements for cultivated lands easily; together, both plans would need less than 11% of the cultivated land available at the end of the permit term of both plans once covered activities "consumption" of cultivated land is taken into account.

Below is a description of specific BDCP actions and a brief discussion of how they might affect implementation of the ECCCHCP/NCCP Conservation Strategy.

- **Permanent Surface Disturbance.** The water conveyance facilities (CM1) would be located within the ECCCHCP/NCCP area (Subzone 6d), resulting in permanent surface impacts that may remove lands available for conservation. Under all BDCP alternatives, this represents less than 3% of the total acreage within the ECCCHCP/NCCP area (Table 12-11), and land in this area is designated as having a "lower" level of acquisition effort by the ECCCHCP/NCCP, with the exception of "higher" priority acquisition lands near Byron Airport–an area where BDCP actions are not projected to occur.
- **Grasslands and Vernal Pools Restoration**. The northwest portion of CZ 8 of the BDCP overlaps with the southeast corner of the ECCCHCP/NCCP Acquisition Analysis Zone 6 (Figure 12-3). Implementation of CM3 would secure and protect at least 1,000 acres of grassland and 1,000 acres of wetlands (i.e., vernal pools and alkali seasonal wetland) within CZ 8. Within Acquisition Analysis Zone 6, ECCCHCP/NCCP intends to acquire 250–400 acres of agriculture, 100–300 acres of grassland (i.e., alkali grasslands) and 20–40 acres of wetlands (i.e., alkali wetlands). Because more than half of BDCP CZ 8 lies outside of the ECCCHCP/NCCP, implementation of the BDCP conservation strategy is not likely to preclude any grassland or wetland acquisition and restoration for the ECCCHCP/NCP. Grassland restoration is also targeted in BDCP CM8. Some of this restoration could take place in the southeast portion of the ECCCHCP/NCCP around Byron Airport. The ECCCHCP/NCCP does not target a specific acreage of grassland restoration, but does target lands surrounding Byron Airport for preservation. However, the BDCP area overlaps with a relatively small proportion of the total amount of grassland in ECCCHCP/NCCP area (Table 12-13).
- **Restoration of Dutch Slough**. BDCP CM4 identifies Dutch Slough, located with the ECCCHCP/NCCP area, as an area suitable for restoration, as does the ECCCHCP/NCCP. However, the BDCP targets tidal areas for restoration or acquisition while the ECCCHCP/NCCP targets riparian and stream communities, creating an opportunity for restoration synergies in streams, riparian, and tidal areas, including in Dutch Slough.

- **Riparian Habitat Restoration**. BDCP CM7 proposes 5,000 acres of riparian forest and scrub protection, a portion of which may occur in CZs 6 and 8, which overlap with the ECCCHCP/NCCP area (Figure 12-4). Table 12-13 indicates a moderate amount of overlap in riparian land cover targeted for preservation, but little relative to the amount existing in the ECCCHCP/NCCP area (less than 10%). Based on the proportion of overlap between the two plans, Table 12-22 indicates a relatively small area of potential overlap for riparian restoration priorities.

San Joaquin County Multi-Species Habitat Conservation and Open Space Plan

The SJCMSHCP was permitted in 2000 and is administered by the San Joaquin Council of Governments. This 50-year plan addresses 97 special-status plant, fish and wildlife species (47 of which are on the federal permit) throughout most of San Joaquin County (more than 900,000 acres), including a substantial portion of the eastern Delta. The plan participants include the County of San Joaquin and the cities of Stockton, Lodi, Manteca, Tracy, Ripon, Escalon and Lathrop. Activities covered under the plan include urban development, mining, expansion of existing urban boundaries, nonagricultural activities occurring outside of urban boundaries, levee maintenance undertaken by the San Joaquin Area Flood Control Agency, transportation projects, school expansions, nonfederal flood control projects, new parks and trails, maintenance of existing facilities for non-federal irrigation district projects, utility installation, maintenance activities, managing preserves, and similar public agency projects.

The study area overlaps a substantial portion (almost 35%) of the SJCMSHCP (Figure 12-3), which itself overlaps approximately half of the legal Delta. The plans have 39 covered species in common, including San Joaquin kit fox, western burrowing owl, giant garter snake, and Swainson's hawk (BDCP Table 1-4). Within the overlapping area, the SJCMSHCP targets for acquisition include flooded fields, grasslands, riparian woodland, row and field crops, and wetlands. The potential exists for competition for restoration sites and land acquisition in these land cover types. BDCP proposes to acquire and restore freshwater tidal, seasonal floodplains, riparian forest, grassland, and nontidal marsh in portions of the overlapping area. However, because the acquisition and restoration requirements of the SJCMSHCP are based upon mitigation ratios applicable to the natural community types where impacts occur, and the plan operates on a "pay-as-you-go" basis, the acquisition targets depend on the amount and location of impacts occurring within the county. In the 11 years of plan implementation, the vast majority of impacts and, consequently, preservation and creation efforts have occurred on cultivated land. The mitigation needs for other community types, including wetlands and riparian areas, have been minimal (Tables 12-26 and 12-27). There have been almost no impacts to wetlands in the SJCMSHCP since its inception. Most of the impacts with San Joaquin County occur on cultivated land; therefore, this land cover type has the greatest potential for competition with BDCP. A more detailed assessment is provided below for each natural community type.

Table 12-26. SJCMSHCP Preserve Acreages by SJCMSHCP Zone with Overlap of BDCP

Habitat Type	Central	Delta	Vernal Pool	Total
Wetlands	–	–	6.00	6.00
Agricultural	2,036.70	1,837.20	–	3,873.90
Agricultural and Grassland	360.00	–	–	360.00
Natural[a]	27.00	–	–	27.00
Total	**2,423.70**	**1,837.20**	**6.00**	**4,260.90**

[a] This table includes preserves in the entirety of all SJCMSHCP Zones, regardless of the proportion of each Zone that overlaps with BDCP. The SJCMSHCP 2010 Annual Report does not identify specific habitat types within preserves. Natural Habitat Lands are lands which "retain natural vegetation and are not irrigated or cultivated agricultural lands."

Table 12-27. SJCMSHCP Mitigation (acres) Owed from Existing Impacts by Habitat Type as of 2010

Habitat Type	Central	Central/Southwest	Delta	Vernal Pool	Total
Wetlands	–	15.27	–	–	15.27
Tidal	0.07	–	–	–	0.07
Riparian	–	–	–	–	0.00
Agriculture	1,948.28	1,087.33[a]	9.44	–	1,957.72
Grassland	17.21	–	–	0.85	18.06
Streams	66.13	50.46	–	–	116.59
Total	**2,031.69**	**65.73**	**9.44**	**0.85**	**2,107.71**

[a] The SJCMSHCP was partially through the easement acquisition process for a large grassland preserve of approximately 1,095 acres to close in 2011 which would negate the row and field crop mitigation acreage required in the Central/Southwest Zone.

Below is a description of specific BDCP actions and a discussion of their effects on implementation of the SJCMSHCP.

- **Permanent Surface Disturbance and Connectivity.** Under CM1, construction of water conveyance facilities located in the SJCMSHCP area would result in permanent surface impact that would remove between 6 acres and 14,050 acres of land available for conservation (Table 12-11). However, under all BDCP alternatives, this land represents less than 1.6 % of the total SJCMSHCP area (Table 12-11). Above-ground conveyance would permanently impact habitat connectivity for less mobile species. Although the eastern alignment (Alternative 1B) would not affect known occurrences of giant garter snake in San Joaquin County, it would adversely affect the giant garter snake population in the vicinity of White Slough in San Joaquin County by impairing habitat connectivity in this area: this could affect the ability for SJCMSHCP to achieve its conservation goals for giant garter snake.
- **Cultivated Lands Preservation.** The southern portion of the BDCP, including almost all of CZ 7, the eastern portions of CZs 5, 6, and 8, and the southern portion of CZ 4, overlaps the SJCMSHCP area (Figure 12-4). There is an estimated 218,370 acres of cultivated land in the overlap area that is not protected (Tables 12-18 through 12-21). Of this total, approximately 16,770 acres would be lost to covered activities planned by the SJCMSHCP and 32,580 acres expected under Alternatives 1A, 2A and 6A. BDCP effects on cultivated lands would result primarily from

construction of the water facilities and restoration of tidal wetlands and floodplains in the South Delta and Cosumnes-Mokelumne ROAs. The SJCMSHCP needs approximately 14,487–36,382 acres of cultivated land acquisition to mitigate for the remaining impacts under that plan, or 9%–22% of the total remaining. BDCP would need between 7,400–12,987 acres of acquisition in the overlap area (4%–8% of the total), depending on the habitat values of the cultivated land lost to covered activities. At the end of the permit terms, there would be an estimated 169,000 acres of cultivated land available for preservation. The combined preservation needs of the SJCMSHCP and the BDCP in the overlap area is between 21,887 and 49,369 acres, or 13%–30% of the total cultivated lands available for preservation. The Delta Wetlands Project (Delta Wetlands Project 2010), a water supply and habitat restoration project that is independent of SJMSHCP and BDCP, will require an additional estimated 20,000 acres of cultivated lands (11,000 acres for water storage and 9,000 acres of conservation easements to offset the loss of cultivated lands) within the overlap area: this would reduce the amount of lands available for preservation to 149,000. With implementation of the Delta Wetlands project, the preservation needs in the overlap area for the SJCMSHCP and the BDCP would still constitute only 15%-33% of the total cultivated lands available for preservation. This analysis demonstrates that enough cultivated lands would remain to meet the conservation and mitigation needs of both plans, even after full implementation of covered activities. In reality, preservation would occur gradually over time, prior to full implementation of all covered activities. Nonetheless, this analysis provides a conservative assessment of the potential for conflict between BDCP and the SJCMSHCP with respect to conservation and mitigation of cultivated lands. The east alignment (Alternatives 1B, 2B, and 6B) of the proposed water conveyance system poses potential impacts to the 783-acre East and West Nuss cultivated land preserves in the SJCMSHCP. However, these impacts would be temporal in nature because the impacted area would be restored to pre-existing baseline conditions following the construction of the water conveyance facilities. Loss of cultivated lands habitat from the construction of the water conveyance facilities would have a less-than-significant impact on agriculturally-dependent species, such as Swainson's hawk, because the enhancement and management of 8,000 acres of cultivated lands as foraging habitat for Swainson's hawk distributed throughout Conservation Zones 1, 2, 3, 4, and 7 of the BDCP would provide ample foraging habitat for these species in the long term. Additionally, if the East Alignment alternative is chosen as the preferred alternative, the BDCP Implementation Office would pursue a temporary conservation easement over the affected preserve that would extend for the duration of the construction and restoration activities.

Each plan is expected to be able to meet its conservation requirements for cultivated lands easily; together, both plans would need less than 30% of the cultivated land available at the end of the permit term of both plans once covered activities "consumption" of cultivated land is taken into account.

- **Tidal Wetland Restoration.** There is a large amount of overlap between the SJCMSHCP and BDCP in tidal areas (Table 12-14). The SJCMSHCP does not include any requirements for tidal wetland preservation or restoration, so there would be no direct conflicts with BDCP on these targets. However, BDCP proposes to convert an estimated 2,200 acres of cultivated land to tidal wetlands. Under Alternative 5, tidal habitat restoration would be reduced from 65,000 acres to 25,000 acres, which would not meet the BDCP restoration target for this natural community type. As a result, the extent to which the BDCP would support the recovery and long-term survival of the covered species that depend on these habitats would be substantially reduced compared with other BDCP alternatives.

The tidal restoration proposed in the South Delta ROA (CZ 7) has the potential to conflict with the existing 300-acre Ishizuka Preserve in the SJCMSHCP. In addition, tidal restoration proposed in the Cosumnes/Mokelumne ROA (CZ 4) has potential to conflict with the existing 350-acre Wing Levee Road preserve in the SJCMSHCP. These preserves provides protection for cultivated lands which the BDCP may convert to tidal natural communities. If tidal restoration occurs on one of these sites (or any other owned by the SJCMSHCP), the BDCP Implementation Office would provide compensation to property owners for the conversion of existing land use and the associated economic losses. Additionally, the BDCP Implementation Office would coordinate with SJMSHCP to identify and acquire lands of equal or greater biological value to replace the conservation needs for SJCMSHCP, as described in BDCP Chapter 3, Section 3.4.3, *Conservation Measure 3*. Mitigation Measure AG-1 requires the BDCP Implementation Office to develop an Agricultural Lands Stewardship Plan (ALSP) to preserve agricultural productivity of Important Farmland and land subject to Williamson Act contracts and to compensate off-site. In addition to Mitigation Measure AG-1, as discussed above in the cultivated land preservation section, the enhancement and management of 8,000 acres of cultivated lands as foraging habitat for Swainson's hawk distributed throughout Conservation Zones 1, 2, 3, 4, and 7 of the BDCP would provide ample foraging habitat for these species in the long term. Additional tidal restoration is targeted in the South Delta ROA (at least 5,000 acres) and the Cosumnes-Mokelumne ROA (up to 1,500 acres). All of the South Delta ROA and approximately half of the Cosumnes-Mokelumne ROA are within the SJCMSHCP plan area.

- **Riparian Preservation and Restoration.** BDCP proposes to acquire 750 acres of riparian natural community in CZ 7 under CM7. In addition, BDCP would restore at least 5,000 acres of riparian woodland and forest in the Plan Area. Approximately 40–50% of the acquisition and restoration of riparian woodland and forest is expected to occur in the overlap area of San Joaquin County (i.e., up to 375 acres of preservation and 2,500 acres of restoration). The majority of the restoration would occur on cultivated lands.

  The SJCMSHCP has an estimated need of 992 acres of riparian woodland preservation in the overlap area (Table 12-14) and 25 acres of riparian restoration if all impacts to this community occur. The SJCMSHCP permits allow removal of up to 750 acres of riparian woodland in San Joaquin County, most of which would occur in the study area (Table 12-23). There are an estimated 17,930 acres of riparian woodland and forest in the study area and approximately 8,070 acres in the overlap area. This amount is enough to meet the riparian preservation and impact needs of both plans.

- **Floodplain Restoration.** The SJCMSHCP does not require restoration of floodplains so would not conflict with BDCP in this restoration action. In BDCP, CM5 calls for restoration of 10,000 acres of seasonally inundated floodplains. Under Alternative 7, seasonally inundated floodplain restoration would be increased from 10,000 acres to 20,000 acres, which would increase costs and reduce the practicability of the conservation strategy, but would increase benefits to some covered species. Floodplains would be created by breaching and/or setting back existing levees and seasonally flooding cultivated lands, similar to what is done now in the Yolo Bypass. In this situation, cultivated lands continue to produce food but the periodic flooding limits the suitable crop types and the duration of the growing season. CM5 identifies the most promising opportunities for large-scale floodplain restoration as being in the south Delta along the San Joaquin, Old, and Middle Rivers all of which are located within the SJCMSHCP area. Therefore, this action would cause the loss or degradation of cultivated lands within the restored floodplains. The amount of cultivated land affected is estimated at 7,750–9,100 acres. This represents less than 2% of the total cultivated lands available for preservation within the SJCMSHCP area.

- **Channel Margin Enhancement.** Channel margin enhancement (CM6) would be performed along the Sacramento River between Freeport and Walnut Grove, and along the San Joaquin River between Vernalis and Mossdale, which lies within the SJCMSHCP area. Under Alternative 7, channel margin enhancement would be increased from 20 linear miles to 40 linear miles. This alternative would increase costs and reduce the practicability of the conservation strategy, but would increase benefits to some covered species. However, channel margin enhancements are not likely to conflict with SJCMSHCP conservation requirements. These actions are not likely to convert a substantial amount of agricultural land, and the SJCMSHCP is unlikely to need large amounts of riparian or channel margin habitat to meet its mitigation requirements because of the limited impacts to this land cover type in the county.

- **Grassland Preservation and Restoration.** The BDCP target of 8,000 acres of grassland preservation would occur in CZ 1 and 8, outside of the SJCMSHCP area. The SJCMSHCP plan also has substantial grassland preservation needs but these would be met largely in the inner Coast Range in southwestern San Joaquin County, outside of the study area (San Joaquin Council of Governments 2010).

  lThe BDCP may restore a portion of its target of 2,000 acres of grassland (CM8) in the western portion of the SJCMSHCP area, primarily from existing degraded grasslands. The SJCMSHCP does not specifically target grassland for restoration. However, based on the limited proportion of grassland overlap between the plans (Table 12-14), potential conflicts in acquisition or restoration targets are minimal.

- **Nontidal Marsh Restoration.** CM10 of the BDCP targets 400 acres of nontidal marsh for restoration, a portion of which could occur adjacent to habitat occupied by the Coldani Marsh/White Slough giant garter snake population in CZ 4 within the SJCMSHCP area. However, the proposed restoration would be designed to meet the conservation goals of each plan for giant garter snake and Swainson's hawk. This conservation measure is likely to provide a mutual benefit to both plans, as the SJCMSHCP specifies avoidance for known giant garter snake habitat.

East Alameda County Conservation Strategy

EACCS provides a mechanism for endangered species permitting under CESA and ESA within 271,485 acres of eastern Alameda County. The Conservation Strategy does not directly result in permits for any participating local agency but provides a framework for endangered species permitting of projects in the study area. The strategy was completed in early 2011 and is currently being utilized by local jurisdictions. The plan was prepared by Alameda County; the cities of Dublin, Livermore, and Pleasanton; Alameda County Waste Management Authority; the Alameda County Congestion Management Agency; East Bay Regional Parks District; the Alameda County Resource Conservation Service; the Natural Resource Conservation Service and in consultation with the USFWS, CDFW, and the San Francisco Regional Water Quality Control Board. The conservation strategy addresses the conservation needs of 19 species, including eight species that overlap with the BDCP (BDCP Table 1-4). In June 2012, USFWS issued a programmatic Section 7 Biological Opinion with the USACE that can be used for Clean Water Act Section 404 compliance using the framework of the conservation strategy for federally-listed species.

Only a small portion of the northeastern corner of the EACCS study area overlaps with the study area (less than 2%) and the overlap occurs in one conservation zone only (zone 7 of the EACCS). There is little anticipated urban development in that area that would be permitted using the strategy guidelines, due in part to Alameda County Measure D, which does not allow for growth outside of the existing urban limit line for the county. However, several large commercial solar energy facilities have been proposed in the overlap area. Despite this, it is unlikely that BDCP implementation would negatively affect any of the provisions associated with EACCS or vice-versa.

Below is a description of specific BDCP activities and a brief discussion of the overlap with EACCS:

- **Permanent Surface Impacts.** A small portion of the water conveyance facilities may be located in the EACCS area, resulting in permanent surface impacts of up to 4,755 acres that would remove lands available for conservation (Table 12-11). However, under all BDCP alternatives, this land only represents 2.73% of the total EACCS area.
- **Restoration and Acquisition Overall.** CZ 8 of the BDCP intersects with Conservation Zone 7 of the EACCS. Within BDCP CZ 8 (Figure 12-3), BDCP would acquire or protect riparian forest and scrub, grassland, and vernal pool communities (CM7, CM8, and CM9, respectively). However, based on the relatively small amount of overlap between the two plans (Table 12-9), the potential for conflict is minimal.

Solano County Multi-Species Habitat Conservation Plan

The Solano County Water Agency is developing the Solano County MSHCP to support the issuance of an incidental take permit under the ESA for a period of 30 years. The plan covers activities within the Solano County Water Agency's contract service area, including the cities of Fairfield, Vacaville, Vallejo, Suisun City, the Solano Irrigation District, and the Maine Prairie Water District. The plan area also covers all of unincorporated Solano County and a small portion of Yolo County.

Primary conservation actions include preservation (primarily through avoidance), restoration, invasive species control, and improvement of water quality. The plan area covers 580,000 acres, which includes 12,000 acres of proposed development and the creation of reserve system to protect natural communities and habitat for covered species[2].

- 10, 500 to 11,500 acres of valley floor grassland and vernal pools.
- 5,700 acres of cultivated lands, 1,000 of nesting and associated foraging habitat, and 1,000 of grassland/oak savanna for Swainson's hawk and burrowing owls.
- 3,300 acres of upland habitat for the California red-legged frog and callippe silverspot butterfly.
- 50 acres of riparian woodland.
- 36 acres of freshwater marsh, pond, and seasonal wetlands.

The two plans share 29 covered species (BDCP Table 1-4), including Swainson's hawk, California clapper rail, and salt marsh harvest mouse.

The Solano County MSHCP overlaps substantially with the study area in Suisun Marsh and Cache Slough (Figure 12-2) including the entirety of BDCP CZs 1 and 11, the southern portions of CZs 2 and 3, and a small, western portion of CZ 5. Most of the overlap area occurs within the Suisun Marsh and

[2] Conservation targets for the Solano HCP are based on a June 2011 working draft plan and are therefore preliminary.

Cache Slough, which the BDCP identifies as restoration opportunity areas. The Solano County MSHCP identifies providing additional funding for management and restoration of Suisun Marsh and the Delta as one of its main objectives. The areas of overlap, therefore, are likely to represent opportunities for collaboration, based upon like objectives between BDCP and Solano County MSHCP. Below is a description of specific BDCP action and a discussion of how they might affect the Solano County MSHCP.

- **Floodplain Restoration.** The BDCP proposes to increase the frequency, duration, and magnitude of floodplain inundation in the Yolo Bypass (CM2). This would restore habitat in the Suisun Marsh and Cache Slough and bays downstream of the bypass that overlap with the Solano County MSHCP area. Restoration targets for wetlands and tidal communities would be designed to benefit covered species in common with both plans such as the giant garter snake.
- **Wetlands and Vernal Pools Restoration.** Within CZs 1 and 11, the BDCP intends to protect a portion of the 600 acres of existing vernal pool complex in the Jepson-Prairie core vernal pool recovery area (U.S. Fish and Wildlife Service 2005), a portion of the 400 acres of existing alkali seasonal wetland complex, and at least 1,000 acres of existing grassland, which may include vernal pool complex and several occurrences of covered plant species (see Table 12-15 for summary of wetland acquisition). The BDCP proposes no net loss of vernal pool acreage, and a portion of proposed restoration and acquisition which would occur in CZ 1 and/or CZ 11, both of which overlap with the Solano County MSHCP plan area. The Solano County MSHCP does identify acreage targets for wetlands restoration (Table 12-15), including vernal pools. However, all of the vernal pool acquisition and restoration needs of the Solano County MSHCP will be acquired from existing commercial mitigation banks that have adequate capacity to meet the requirements of the Plan. Therefore, BDCP wetland preservation and restoration is not expected to conflict with the Solano County MSHCP.
- **Cultivated Lands Preservation.** The cultivated land acquisition target for the Solano County MSHCP is 5,700 acres of agricultural foraging habitat for Swainson's hawk and burrowing owl. Most of the cultivated land preservation will take place in the northern or northeastern portion of the county (near Dixon Ridge), which is outside of the study area. These areas have been selected for preservation because they are cultivated with crops such as alfalfa, which is preferred by Swainson's hawk as foraging habitat for. The BDCP may also maintain a portion of non-rice agriculture as foraging habitat for Swainson's Hawk in CZs 1, 2, and 3, all three of which overlap with the Solano County MSHCP (Figure 12-3). However, based on emphasis of the Solano County MSHCP to preserve cultivated lands in the northern portion of the county, outside of the areas where the Plans overlap, there is limited potential for conflicting acquisition and restoration priorities.
- **Tidal Habitat Restoration.** The BDCP identifies the Cache Slough ROA as a substantial area of land with elevations suitable for freshwater tidal natural community restoration (CM4). Almost all of the Cache Slough ROA occurs in Solano County. This would result in the conversion of approximately 5,000 to 7,000 cultivated lands to tidal natural communities. As described above, neither the loss of cultivated land or the creation of tidal natural communities is expected to conflict with the Solano County MSHCP conservation strategy, because the Cache Slough area is only targeted for conservation by BDCP. The Solano County MSHCP targets 75–100 acres of tidal habitat (coastal marsh habitat) for restoration (Table 12-15), with more than 50,000 acres available in the overlap area. Consequently, there is minimal potential for conflicting acquisition and restoration priorities.

South Sacramento Habitat Conservation Plan

The proposed South Sacramento HCP would address issues related to species conservation, agricultural protection, and urban development in 341,000 acres of south Sacramento County. The plan is being prepared by Sacramento County; the cities of Sacramento, Elk Grove, Galt, and Rancho Cordova; Sacramento Regional County Sanitation District; and the Capital Southeast Connector Joint Powers Authority. The HCP would cover 30 species of plants and wildlife, including 10 that are state- or federally listed as threatened or endangered. The western extent of the South Sacramento HCP plan area, approximately 11%, overlaps the study area Conservation Zone 4 (Figure 12-3). Included in the overlap is a portion of the South Sacramento HCP's Urban Development Area. Sixteen species are covered by both plans, including greater sandhill crane, Swainson's hawk, and giant garter snake (BDCP Table 1-4).

The South Sacramento HCP, over its permit term, intends to conserve at least 41,923 acres, most of which would be agricultural and grassland land cover types with limited overlap with the BDCP (Table 12-9). The South Sacramento HCP also intends to restore 1,786 acres, most of which would be wetland and riparian land cover types. Most of the preservation and restoration would be directed towards Primary Conservation Zones identified by the plan. Small portions of the Primary Conservations Zones for valley elderberry longhorn beetle, California tiger salamander, giant garter snake, and western burrowing owl, and most of the Primary Conservation Zone for Swainson's hawk overlap with BDCP. In these areas, the potential for conflict in acquisition efforts between the plans would be greatest, but so would the potential for restoration collaboration, especially in regards to freshwater marsh and giant garter snake habitat.

The South Sacramento HCP aims to preserve mostly grassland, by a ratio of more than 2:1 relative to other land cover types, and the BDCP does not target grassland preservation in CZ 4, thereby limiting the amount of potential conflict between the two plans overall. Approximately 41% (20,041 of 48,832 acres) of CZ 4 consists of existing protected lands, so there are ample opportunities in this zone to link the reserve system with existing open space. Stone Lakes National Refuge Wildlife Refuge and Cosumnes Preserve occupy a majority of the land in the northern half of CZ 4, which signifies less private land ownership and potential conflicts in meeting the preservation targets of both plans. The BDCP Implementing Office would protect a corridor that would be composed of contiguous patches of agricultural, restored tidal, and nontidal wetlands, grassland, vernal pool complex, and other seasonal wetlands. This corridor would extend from the Caldoni Marsh/White Slough giant garter snake subpopulation area north to Stone Lakes National Wildlife Refuge, and to the extent possible would also connect to the Cosumnes River Preserve. The corridor would be configured to provide a giant garter snake movement habitat along this north-south corridor. Tables 12-16, 12-18 through 12-21 and 12-25 summarize potential overlap in acquisition and restoration targets, respectively.

- **Permanent Surface Disturbance**. The construction of the water conveyance facilities poses the greatest permanent surface impacts to the South Sacramento HCP area (up to 3,988 acres under the eastern alignment). However, because of the limited geographic overlap between the two plans, and the Sacramento HCP's emphasis on acquisition of grassland, which is ample in the South Sacramento HCP overall area (more than 175,000 acres available), there is limited potential for conflicting acquisition priorities. Under CM1, construction of the water conveyance facilities located in the South Sacramento HCP would result in permanent surface impacts that would remove between 150 acres and 3,998 acres of land available for conservation (Table 12-

11). However, under all BDCP alternatives this represents less than 1.1 % of the total South Sacramento HCP area (Table 12-11).

- **Cultivated Lands Preservation.** The northeastern portion of the BDCP, including over half of CZ 4 and the northern portion of CZ 5 (Figure 12-3). There is an estimated 17,583 acres of cultivated land in the overlap area that is not protected (Tables 12-18 through 12-21). Of this total, approximately 1,900 acres would be lost to covered activities planned by the South Sacramento HCP and 3,556 acres expected under the BDCP. The water conveyance facilities footprint impacts are the among the largest in the South Sacramento HCP area. BDCP impacts to cultivated lands would occur primarily from construction of the water facilities and restoration of tidal wetlands and floodplains in the Cosumnes-Mokelumne ROA. After subtracting all the remaining impacts assumed from both plans, there would be an estimated 13,181 acres available for preservation. The combined preservation needs of the South Sacramento HCP and the BDCP in the overlap area is between 3,341 and 13,090 acres, or 25–99% of the total cultivated lands available for preservation. If all the preservation needs of both plans were to be acquired in the overlap area, there is potential for conflict in meeting the acquisition targets of both plans. Alternative 1B poses the greatest impacts to the South Sacramento HCP overlap area (4,024 acres), and could present conflicts in achieving cultivated land preservation targets for both plans in the overlap area (Table 12-19). However, as discussed above, there is an estimated 60,000 acres of cultivated land remaining for preservation in the South Sacramento HCP area that does not overlap with the BDCP study area, so both plans would easily be able to achieve their cultivated land preservation targets. As described in BDCP Section 3.4.3, *Conservation Measure 3*, if during the permit terms of the overlapping plans, the South Sacramento HCP is unable to meet its mitigation requirements due to a lack of willing sellers and due in part to acquisition by BDCP in the overlap area, a credit swap of easement(s) would be initiated. Determination that this criterion has been met would be made jointly by CDFW, USFWS, the BDCP Implementation Office, and the South Sacramento HCP implementing entity. Land owned by the BDCP Authorized Entities or Supporting Partners in the overlap area in fee title or conservation easements would be identified for their applicability to the South Sacramento HCP conservation strategy. The South Sacramento HCP would acquire conservation easements or fee title on land outside of the overlap area with equivalent or greater conservation value to BDCP as the land identified in the criteria above. This land acquired would be within the BDCP Plan Area but could be outside Sacramento County. As an alternative, the BDCP Authorized Entities or Supporting Partners could acquire the additional lands with funds from the South Sacramento HCP. Once the additional land is acquired outside of the overlap area, the BDCP land within the overlap area would be transferred in fee title or conservation easement holder to the South Sacramento HCP. The land acquired by the South Sacramento HCP outside of the plan area with equivalent or greater conservation value to BDCP would be transferred to a BDCP Authorized Entity or Supporting Partner. Once the transfers are complete, the credit assigned to each plan for the conserved land would also be transferred. BDCP would ultimately acquire no more than 3,000 acres in the overlap area with South Sacramento HCP.

- **Tidal Habitat Restoration.** Approximately half of the proposed 3,072 acre Cosumnes Mokelumne ROA overlaps with the South Sacramento HCP, resulting in an estimated 1,535 acres of cultivated land converted into tidal natural communities. However, as discussed above, both plans would easily achieve their cultivated lands preservation targets through the implementation of MM AG-1 and the preservation of cultivated lands in the South Sacramento HCP area that does not overlap with the BDCP study area.

- **Nontidal Marsh Restoration.** The South Sacramento HCP proposes to restore 600 acres of nontidal wetland habitat in Caldoni Marsh/ White Slough, which overlaps with the CZ 4 of the BDCP. The BDCP proposes 200 acres of nontidal restoration in CZ 4. In total, the two plans propose to convert 800 acres of the approximately 1,700 available acres of cultivated land in the overlap area to nontidal wetland natural communities. This represents less than half of the total cultivated land available in the overlap area and as such both plans would be able to meet their restoration targets in this area. CZ 4 of the BDCP contains the Caldoni Marsh/White Slough subpopulation of giant garter snake, providing opportunities for joint preservation of agricultural land and restoration of nontidal and riparian habitats to protect and expand this subpopulation and create habitat connectivity with the giant garter snakes in the Stone Lakes area.
- **Wetlands and Vernal Pools Restoration.** The BDCP proposes to protect 600 acres of existing vernal pool habitat and 400 acres of existing alkalai seasonal wetland complex, with the majority of the preservation occurring in CZ 1, 8, and 11. The South Sacramento HCP proposes to preserve a total of 1,048 acres of vernal pool, or vernal impoundment and 170 acres of vernal swale in a matrix of valley grassland, and restore a total of 363 acres of vernal pool or vernal impoundment in a matrix of valley grassland. The total preservation and restoration of vernal pools and alkalai seasonal wetlands proposed by the South Sacramento HCP is approximately 1,800 acres, or 24%, of an estimated 7,500 acres available in the South Sacramento HCP area. The BDCP does not have specific requirements for vernal pools or alkalai seasonal wetland preservation in CZ 4, so there is minimal potential for conflict in achieving the preservation targets of the South Sacramento HCP in the overlap area.

Yolo Natural Heritage Program

The Yolo County NCCP/HCP Joint Powers Authority, consisting of five local public agencies, launched the YNHP in March 2007. Member agencies are Yolo County and the cities of Davis, Woodland, West Sacramento, and Winters. In addition, a representative of University of California, Davis, serves as an ex-officio member of the Joint Powers Authority board. The YNHP covers a 653,818-acre planning area, 17% of which overlaps with the BDCP. The YNHP documents are in development. The proposed list of covered species contains 32 sensitive species in five principal natural communities. The YNHP overlaps with the BDCP in the Yolo Bypass area (CZs 2 and 3) (Figure 12-3) and has 20 species in common with the BDCP (BDCP Table 1-4). Within the overlapping area, the YNHP targets for acquisition include annual grasslands, riparian, and cultivated lands. BDCP proposes to acquire cultivated lands, acquire or restore grasslands, and restore nontidal marsh in portions of the overlapping area, primarily to benefit giant garter snake. Additionally, BDCP proposes tidal restoration in the Cache Slough ROA, which partly overlaps with the YNHP plan area. The potential exists for competition for restoration sites and land acquisition, but the overlap also creates opportunities for coordination, partnerships, and achieving common conservation goals.

Based on a simple analysis of the major natural community types for the intersecting area of the two plans (Table 12-17), there is significant overlap between tidal and wetland land cover types. In other words, most conservation targets for these land cover types in the YNHP would need to be addressed within the overlap area. However, the overlap area has more than 10,000 acres of mapped wetland available for acquisition or restoration and almost 5,000 acres of tidal land cover type. BDCP CM4 would restore or create at least 24,000 acres of tidal freshwater emergent wetland, a portion of which would be located in CZ 2 (within the overlap area). The BDCP targets 600 acres of nontidal marsh restoration (crosswalked to “wetlands” in this analysis), 200 acres of grassland protection or restoration, and 700 acres of cultivated lands protection within or adjacent to habitat occupied by the giant garter snake Yolo/Willow Slough subpopulation in CZ 2, entirely within Yolo County. The YNHP also has conservation targets for giant garter snakes in this subpopulation, but it is focused in the YNHP Willow Slough Basin Planning Unit, only a small portion of which overlaps with the BDCP Plan Area. The two plans could work together to jointly achieve conservation for giant garter snake in the Yolo/Willow Slough subpopulation.

Below is a description of specific BDCP actions and a brief discussion of the overlap with YNHP.

- **Permanent Surface Disturbance.** Under CM1, water conveyance facilities located in the YNHP area would result in permanent surface impacts of up to 5,834 acres under Alternative 1C that may remove lands available for conservation (Table 12-11). There would be no permanent surface impacts of the water conveyance facilities from the other BDCP alternatives.
- **Cultivated Lands Preservation.** Within CZs 2 and 3, BDCP may protect a portion of the total conservation goal of 1,000 acres of cultivated lands as foraging habitat for Swainson's hawk (CM3), thus removing it from conservation under the YNHP. There is an approximately 17,500 acres of cultivated land in the area where the BDCP overlaps with the YNHP. An estimated 6,158 acres of cultivated would be lost under CM1 in the overlap area, approximately 35% of the cultivated land available for preservation. BDCP CM4 would restore or create at least 24,000 acres of tidal freshwater emergent wetland, a portion of which would occur in CZ 2, within the overlap area.
- **Riparian Restoration.** CM7 would restore 5,000 acres of riparian forest and scrub in the BDCP Plan Area in association with restoration of tidal wetlands and floodplains. A portion of this restoration would occur in CZ 2, although most is expected to occur in CZ 7, outside the overlap area. The YNHP also has conservation targets for riparian but most of it is targeted for YNHP planning units outside the overlap area.
- **Floodplain Restoration.** Implementation of BDCP CM2 would increase the annual average inundation of the Yolo floodplain within the overlap area of the two plans. This measure would help to restore habitat in Cache Slough (a portion of which is within the YNHP area) for delta smelt, longfin smelt, and other BDCP covered fish species. The YNHP conservation strategy does not include any conservation measures within the Yolo Bypass, so an increase in inundation frequency and duration as a result of BDCP is not expected to affect the YNHP. BDCP will mitigate for any significant impacts on terrestrial species that would result from inundation.
- **Wetlands Restoration.** CM10 would restore 600 acres of nontidal marsh within or adjacent to habitat occupied by the giant garter snake Yolo/Willow Slough subpopulation in CZ 2. Approximately 58% of CZ 2 consists of protected land, and there remain ample opportunities to protect cultivated lands and associated natural communities in large blocks connected to open space. Yolo Bypass Wildlife Area and other open space lands owned by CDFW are present in the central and northern portions of CZ 2, while Liberty Island, owned by the Trust for Public Lands, and other land owners by the U.S. Army Corps of Engineers and the Bureau of Reclamation are present in the southern portion. Based on the amount of overlap between YNHP and BDCP areas (Table 12-9), there may be limited potential for conflict and possibilities for joint collaboration in restoration efforts.

Effects of Other BDCP Conservation Measures on Overlapping Conservation Plans

The BDCP contains management-based conservation measures designed to meet or contribute to the biological goals and objectives identified in BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*. Many of these conservation measures are designed to address "other stressors" of the BDCP covered fish. While many of these conservation measure are expected to occur within the overlapping conservation plans (Table 12-28), most would occur within the aquatic environment of the Delta, resulting in minimal overlap with the other conservation plans (which focus primarily on upland and terrestrial areas). Potential areas for overlap are identified in this section and are considered to be manageable and/or avoidable.

- *CM11 Natural Communities Enhancement and Management* outlines a suite of management techniques to be applied across the BDCP reserve system and for each natural community. CM11 would overlap all other conservation plans and be applied wherever BDCP acquires land for the reserve system. The management techniques described in CM11 are similar or the same as those of the other conservation plans, so management is expected to be highly compatible where conservation lands of overlapping plans occur adjacent or near to each other.
- *CM13 Invasive Aquatic Vegetation Control* would be applied in aquatic systems throughout the BDCP Plan Area, with concentrated activities expected within the five ROAs. Therefore, this conservation measure is likely to overlap with most of the other conservation plans (Table 12-28). Invasive aquatic vegetation is a serious problem identified in several other conservation plans, so this BDCP conservation measure is expected to be consistent with the other overlapping plans.
- *CM14 Stockton Deep Water Ship Channel Dissolved Oxygen Levels* would only be applied in the Stockton Deep Water Ship Channel in San Joaquin County. This measure is compatible with the goals of the SJCMSHCP, which also covers green sturgeon. This species is expected to be benefit from this conservation measure.
- *CM15 Localized Reduction of Predatory Fishes* would be applied in select locations throughout the Plan Area. The conservation measure is likely to be applied in the overlap areas of the SJCMSHCP, Yolo HCP, and South Sacramento HCP, and may be applied in the Solano HCP and ECCC HCP/NCCP. Predator control measures would not conflict with existing or planned conservation plans because they would be applied in aquatic systems only, which does not overlap with most plans. Of these plans, only the SJCMSHCP and Solano HCP cover fish also covered by BDCP.
- *CM18 Conservation Hatcheries* requires the establishment of new hatcheries, and the expansion of existing conservation propagation programs for delta and longfin smelt. CM18 would be implemented near Rio Vista in Solano County. A small amount of land would need to be acquired to build the longfin smelt hatchery. Because the planned site is already disturbed, this acquisition would not conflict with the Solano HCP.
- *CM19 Urban Stormwater Treatment*, *CM20 Recreational Users Invasive Species Program*, and *CM21 Nonproject Diversions*, would be implemented throughout the BDCP Plan Area and are likely to overlap with almost all of the other conservation plans. The exact locations of their implementation are not known because CM19 and CM21 rely on willing participants that have not been identified yet. Despite this uncertainty, these conservation measures are likely to be compatible with or at least not conflict with the other conservation plans because they are restricted to aquatic areas that are largely not addressed by the other conservation plans.

Table 12-28. Potential Occurrence of Other BDCP Conservation Measures in Overlapping Conservation Plans

BDCP Conservation Measure	ECCC HCP/NCCP	San Joaquin	EACCS	Solano MSHCP	South Sacramento HCP	YNHP

12.3.6.2 CEQA Conclusion

The BDCP overlaps geographically with six conservation plans. Impacts from construction and implementation of BDCP alternatives are not anticipated to affect implementation of the overlapping plans. Understanding whether BDCP acquisition and restoration goals would preclude the implementation of other conservation plans is more challenging. The analysis above indicates that the degree to which this competition would impact the conservation goals of other plans is limited. In most cases, because of the flexibility for acquisition targets incorporated into the BDCP and other plans, the potential conflict would be manageable, and significant conflicts with the implementation of overlapping plans could be avoided. Because the conservation strategy for the YNHP and South Sacramento HCP are not available, further analysis may be required at a later date. In certain cases, especially pertaining to similar restoration objectives, perceived conflicts may also represent opportunities for collaboration to jointly achieve similar conservation goals. Because implementing the BDCP would not result in a conflict with the provisions of an adopted HCP, NCCP or other approved local, regional or state habitat conservation plan, there would be a less-than-significant impact.
