The invasive plant species that primarily affect each natural community in the study area, which include water hyacinth, perennial pepperweed, giant reed, and Brazilian waterweed, are discussed in Section 12.1.4. Invasive species compete with native species for resources and can alter natural communities by altering fire regimes, hydrology (e.g., sedimentation and erosion), light availability, nutrient cycling, and soil chemistry but also have the potential to harm human health and the economy by adversely affecting natural ecosystems, water delivery, flood protection systems, recreation, agricultural lands, and developed areas (Randall and Hoshovsky 2000). The construction and restoration activities covered under the BDCP could result in the introduction or spread of invasive plant species by creating temporary ground disturbance that provides opportunities for colonization by invasive plants in the study area.

The primary mechanisms for the introduction of invasive plants as the result of implementation of the BDCP are listed here.

- Grading, excavation, grubbing, and placement of fill material.
- Breaching, modification, or removal of existing levees and construction of new levees.
- Modification, demolition, and removal of existing infrastructure (e.g., buildings, roads, fences, electric transmission and gas lines, irrigation infrastructure).
- Maintenance of infrastructure.
- Removal of existing vegetation and planting/seeding of vegetation.
- Maintaining vegetation and vegetation structure (e.g., grazing, mowing, burning, trimming).
- Dredging waterways.

Clearing operations and the movement of vehicles, equipment, and construction materials in the study area would facilitate the introduction and spread of invasive plants by bringing in or moving seeds and other propagules. These effects would result from four activities.

- Spreading chipped vegetative material from clearing operations over topsoil after earthwork operations are complete.
- Importing, distributing, storing, or disposing of fill, reusable tunnel material, borrow, spoil, or dredge material.
- Traffic from construction vehicles (e.g., water and cement trucks) and personal vehicles of construction staff.
- Transport of construction materials and equipment within the study area and to/from the study area.

Table 12-4-70 lists the acreages of temporary disturbance in each natural community in the study area that would result from implementation of Alternative 4.

Table 12-4-70. Summary of Temporary Disturbance in Natural Communities under Alternative 4

Natural Community	Temporary Impacts (acres)
Tidal perennial aquatic	2,114
Tidal brackish emergent wetland	0
Tidal freshwater emergent wetland	16
Valley foothill riparian	154
Grassland	424
Inland dune scrub	0
Alkali seasonal wetland complex	0
Vernal pool complex	3
Other natural seasonal wetland	0
Nontidal freshwater perennial emergent wetland	7
Nontidal perennial aquatic	38
Managed wetlands	73
Cultivated lands	2,896
Total	**5,649**

Impact BIO-186: Adverse Effects on Natural Communities Resulting from the Introduction and Spread of Invasive Plant Species

Under Alternative 4, the BDCP would have adverse effects on natural communities as a result of the introduction and spread of invasive plant species through implementation of CM1–CM10 and AMM6. No adverse effects are expected from implementation of CM11–CM21.

- *CM1 Water Facilities and Operations*: Construction of the Alternative 4 water conveyance facilities would result in the temporary disturbance of 3,531 acres that would provide opportunities for colonization by invasive plant species.
- *CM2 Yolo Bypass Fisheries Enhancements*: Construction of the Yolo Bypass fisheries enhancements would result in the temporary disturbance of 758 acres that would provide opportunities for colonization by invasive plant species. Vegetation maintenance activities for the Fremont Weir and Yolo Bypass improvements may include the removal of giant reed; however, the clearing of linear areas to facilitate water flow may also result in increased

opportunities for invasion. Sediment removal, transportation, and application as a source material for restoration or levee projects as part of Fremont Weir and Yolo Bypass maintenance activities could also result in the spread of invasives if the sediment contains viable invasive plant propagules.

- *CM3 Natural Communities Protection and Restoration*: The restoration activities in the natural communities located in the eleven CZs would result in the temporary disturbance of restoration areas that would provide opportunities for colonization by invasive plant species.
- *CM4 Tidal Natural Communities Restoration*: The activities associated with the restoration of tidal perennial aquatic, tidal mudflat, tidal freshwater emergent wetland, and tidal brackish emergent wetland in ROAs would result in the temporary disturbance of tidal areas that would provide opportunities for colonization by invasive plant species. These adverse effects would be reduced by designing restoration projects to minimize the establishment of nonnative submerged aquatic vegetation, and early restoration projects would be monitored to assess the response of nonnative species to restoration designs and local environmental conditions. If indicated by monitoring results, the BDCP Implementation Office would implement invasive plant control measures in restored natural communities to help ensure the establishment of native marsh plain plant species. Additionally, the BDCP Implementation Office would actively remove submerged and floating aquatic vegetation in subtidal portions of tidal natural community restoration sites.
- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration levee construction would result in the temporary disturbance of 1,285 acres along channels in the north, east, and south Delta (San Joaquin, Old, and Middle Rivers) that would provide opportunities for colonization by invasive plant species.
- *CM6 Channel Margin Enhancement*: The temporary effects of channel margin enhancement were not estimated because specific locations for this activity and their areal extent have not been developed. Channel margin enhancement (Sacramento River between Freeport and Walnut Grove, San Joaquin River between Vernalis and Mossdale, Steamboat and Sutter Sloughs, and salmonid migration channels in the interior Delta) would result in the temporary disturbance of channel areas that would provide opportunities for colonization by invasive plant species.
- *CM7 Riparian Natural Community Restoration*: The restoration of valley/foothill riparian habitat would result in the temporary disturbance of riparian areas that would provide opportunities for colonization by invasive plant species.
- *CM8 Grassland Natural Community Restoration*: The restoration of grassland habitat in CZs 1, 8, and/or 11 would result in the temporary disturbance of degraded grassland or cultivated land that would provide opportunities for colonization by invasive plant species.
- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: The restoration of vernal pool and alkali seasonal wetland complexes in CZs 1, 8, or 11 would result in the temporary disturbance of grassland areas that would provide opportunities for colonization by invasive plant species.
- *CM10 Nontidal Marsh Restoration*: Nontidal marsh restoration, which would take place through conversion of agricultural lands in CZs 2 and 4, would result in the temporary disturbance of fallow agricultural areas that would provide opportunities for colonization by invasive plant species. These adverse effects would be reduced by monitoring the development of marsh vegetation to determine if nonnative vegetation needs to be controlled to facilitate the

establishment of native marsh vegetation or if restoration success could be improved with supplemental plantings of native species. If indicated by monitoring, nonnative vegetation control measures and supplemental plantings would be implemented.

- *Avoidance and Minimization Measures*: *AMM6 Disposal and Reuse of Spoils* would have adverse effects if spoils, RTM, dredged material, or chipped vegetative materials containing viable invasive plant propagules are used as topsoil in uninfested areas.

The adverse effects that would result from the introduction and spread of invasive plants through colonization of temporarily disturbed areas would be minimized by implementation of CM11, AMM4, AMM10, and AMM11.

CM11 Natural Communities Enhancement and Management would reduce these adverse effects by implementing invasive plant control within the BDCP reserve system to reduce competition on native species, thereby improving conditions for covered species, ecosystem function, and native biodiversity. The invasive plant control efforts would target new infestations that are relatively easy to control or the most ecologically damaging nonnative plants for which effective suppression techniques are available. In aquatic and emergent wetland communities, Brazilian waterweed, perennial pepperweed, barbgrass, and rabbitsfoot grass would be controlled (and tidal mudflats would be maintained). In riparian areas, invasive plant control would focus on reducing or eliminating species such as Himalayan blackberry, giant reed, and perennial pepperweed. In grassland areas, techniques such as grazing and prescribed burning may be used to decrease the cover of invasive plant species.

Implementation of AMM4, AMM10, and AMM11 would also reduce the adverse effects that could result from construction activities. The AMMs provide methods to minimize ground disturbance, guidance for developing restoration and monitoring plans for temporary construction effects, and measures to minimize the introduction and spread of invasive plants. AMM4 would involve the preparation and implementation of an erosion and sediment control plan that would control erosion and sedimentation and restore soils and vegetation in affected areas. The restoration and monitoring plans for implementation of AMM10 would involve methods for stockpiling, storing, and restoring topsoil, revegetating disturbed areas, monitoring and maintenance schedules, adaptive management strategies, reporting requirements, and success criteria. AMM10 would also include planting native species appropriate for the natural community being restored, with the exception of some borrow sites in cultivated lands that would be restored as grasslands.

AMM11 specifies that the BDCP Implementation Office would retain a qualified botanist or weed scientist prior to clearing operations to determine if affected areas contain invasive plants. If areas to be cleared do contain invasive plants, then chipped vegetation material from those areas would not be used for erosion control but would be disposed ~~of~~ to minimize the spread of invasive plant propagules (e.g., burning, composting). During construction of the water conveyance facilities and construction activities associated with the other CMs, construction vehicles and construction machinery would be cleaned prior to entering construction sites that are in or adjacent natural communities other than cultivated lands and prior to entering any BDCP restoration sites or conservation lands other than cultivated lands. Vehicles working in or travelling off paved roads through areas with infestations of invasive plant species would be cleaned before travelling to other parts of the Plan Area. Cleaning stations would be established at the perimeter of BDCP covered activities along construction routes as well as at the entrance to reserve system lands. Biological monitoring would include locating and mapping locations of invasive plant species within the construction areas during the construction phase and the restoration phase. Infestations of invasive plant species would be targeted for control or eradication as part of the restoration and revegetation of temporarily disturbed construction areas.

NEPA Effects: The implementation of AMM4, AMM10, and AMM11, and CM11 would reduce the potential for the introduction and spread of invasive plants and avoid or minimize the potential effects on natural communities and special-status species; therefore, these effects would not be adverse.

CEQA Conclusion: Under Alternative 4, impacts on natural communities from the introduction or spread of invasive plants as a result of implementing the BDCP would not result in the long-term degradation of a sensitive natural community. With implementation of AMM4, AMM10, AMM11 and CM11, the temporary disturbance of land associated with the alternative would be offset and would not result in substantial alteration of site conditions. Therefore, the impact would be considered less than significant. No mitigation would be required.

Compatibility with Plans and Policies

Impact BIO-187: Compatibility of the Proposed Water Conveyance Facilities and Other Conservation Measures with Federal, State, or Local Laws, Plans, Policies, or Executive Orders Addressing Terrestrial Biological Resources in the Study Area

Constructing the water conveyance facilities (CM1) and implementing CM2–CM21 for Alternative 4 have the potential for being incompatible with plans and policies related to managing and protecting terrestrial biological resources of the study area. A number of laws, plans, policies, programs, and executive orders that are relevant to actions in the study area provide guidance for terrestrial biological resource issues as overviewed in Section 12.2, *Regulatory Setting*. This overview of plan and policy compatibility evaluates whether Alternative 4 would be compatible or incompatible with such enactments, rather than whether impacts would be adverse or not adverse, or significant or less than significant. If the incompatibility relates to an applicable plan, policy, or executive order adopted to avoid or mitigate terrestrial biological resource effects, then an incompatibility might be indicative of a related significant or adverse effect under CEQA and NEPA, respectively. Such physical effects of Alternative 4 on terrestrial biological resources are addressed in the impacts on natural communities and species. The following is a summary of compatibility evaluations related to terrestrial biological resources for laws, plans, policies, and executive orders relevant to the BDCP.

Federal and State Legislation

- The federal *Clean Water Act*, *Endangered Species Act*, *Fish and Wildlife Coordination Act*, *Migratory Bird Treaty Act*, *Rivers and Harbors Act* and *Marine Mammal Protection Act* all contain legal guidance that either directly or indirectly promotes or stipulates the protection and conservation of terrestrial biological resources in the process of undertaking activities that involve federal decisionmaking. The biological goals and objectives contained in the BDCP that provide the major guidance for implementing the various conservation elements of Alternative 4 are all designed to promote the long-term viability of the natural communities, special-status species, and common species that inhabit the Plan Area. While some of the conservation measures of the alternative involve permanent and temporary loss of natural communities and associated habitats during facilities construction and expansion of certain natural communities, the long-term guidance in the Plan would provide for the long-term viability and expansion of the habitats and special-status species populations in the Plan Area. Alternative 4 conservation actions would be compatible with the policies and directives for terrestrial biological resources contained in these federal laws.

- The *California Endangered Species Act*, *California Native Plant Protection Act*, *Porter-Cologne Water Quality Control Act*, and *Natural Communities Conservation Planning Act* are state laws that have relevance to the management and protection of terrestrial biological resources in the study area. Each of these laws promotes consideration of wildlife and native vegetation either through comprehensive planning or through regulation of activities that may have an adverse effect on the terrestrial and aquatic natural resources of the state. The BDCP, which is the basis for Alternative 4, contains biological goals and objectives that have been developed to promote the species protection and natural resource conservation that are directed by these state laws. Alternative 4 conservation actions would be compatible with the policies and directives contained in these laws.
- The *Johnston-Baker-Andal-Boatwright Delta Protection Act of 1992* (*Delta Protection Act*) and the *Sacramento-San Joaquin Delta Reform Act*, which updated the Delta Protection Act, promote the maintenance and protection of natural resources and the protection of agricultural land uses in the Delta's primary zone through the goals and policies contained in the 2009 updated Land Use and Resources Management Plan (LURMP). While nothing in the LURMP is binding on state agencies that are BDCP proponents, the LURMP does promote restoration and enhancement of habitats for the terrestrial and aquatic species of the Delta on public land. The BDCP biological goals and objectives would be compatible with these LURMP goals (Delta Protection Commission 2010).
- The *Suisun Marsh Preservation Act* of 1974 was designed to protect the Suisun Marsh for long-term use as wildlife habitat, with a goal of preserving and enhancing the quality and diversity of the Marsh's aquatic and wildlife habitats. The BDCP and its plans for protection and restoration of tidal marsh habitats in Suisun Marsh would be compatible with the intent of the Suisun Marsh Preservation Act.

Plans, Programs, and Policies

- *The Delta Plan*, which was developed by the Delta Stewardship Council in compliance with the 2009 Sacramento-San Joaquin Delta Reform Act, is mandated to achieve two co-equal goals: provide for a more reliable water supply for California and protect, restore, and enhance the Delta ecosystem. The co-equal goals are to be achieved in a manner that protects and enhances the unique cultural, recreational, natural resource, and agricultural values of the Delta as an evolving place. The BDCP is intended to become a component of the Delta Plan. The Delta Stewardship Council will determine whether the BDCP is compatible with the goals and objectives of the Delta Plan prior to its incorporation into the Plan. The compatibility of the BDCP with the Delta Plan is considered in detail in Chapter 13, Section 13.2.2.2, *The Delta Plan*.
- *California Wetlands Conservation Policy*, which was adopted by Executive Order in 1993, promotes a long-term gain in the quantity, quality and permanence of wetlands acreages and values in California. The BDCP conservation measures that provide for a significant expansion of wetland acreage and quality in the Delta and Suisun Marsh are compatible with the intent of the California Wetlands Conservation Policy.
- *The North American Waterfowl Management Plan* (*NAWMP*) and *Central Valley Joint Venture* (*CVJV*) strive to maintain and expand wetlands and uplands for waterfowl and shorebirds in the major basins of California's Central Valley. The NAWMP is a management plan jointly approved

by the United States and Canada in 1986. It contains general guidance from the principal wildlife management agencies of the two countries for sustaining abundant waterfowl populations by conserving landscapes through self-directed partnerships (joint ventures) that are guided by sound science. The CVJV is the joint venture established for overseeing NAWMP implementation in the Central Valley. The CVJV is made up of 21 conservation organizations, state and federal government agencies, and one corporation that have formed a partnership to improve the habitat conditions for breeding and nonbreeding waterfowl, breeding and nonbreeding shorebirds, waterbirds, and riparian-dependent songbirds in the Central Valley. The CVJV's 2006 Implementation Plan (Central Valley Joint Venture 2006) establishes conservation objectives and priorities for these bird groups within the basins of the Central Valley. The BDCP Plan Area includes all or portions of three Implementation Plan basins—the Delta, Yolo and Suisun basins. The 2006 Implementation Plan contains basin-specific objectives for wetland restoration, protection of existing wetland habitats, wetland enhancement, adequate power and water supplies for wetland management, agricultural land enhancement, farmland easements that maintain waterfowl food resources on agricultural land, and farmland easements that buffer existing wetlands from urban and residential growth.

Implementation of the Alternative 4 conservation measures would result in significant reductions in cultivated land and managed wetland acreage in the Delta, Yolo and Suisun basins; however, significant increases in tidal and nontidal wetlands in these basins would be another result. Because of the large conversion of managed wetland in the Suisun basin, the BDCP has included a large managed wetland conservation and enhancement goal for this area. For the Suisun basin conversions to be compatible with the 2006 Implementation Plan goals, this EIR/EIS has added mitigation that would require food production studies and adaptive management to ensure that the Suisun basin would continue to provide the waterfowl and shorebird habitat envisioned in the Implementation Plan.

- *Stone Lakes National Wildlife Refuge Comprehensive Conservation Plan*, *Cosumnes River Preserve Management Plan*, *Brannan Island and Franks Tract State Recreation Areas General Plan*, *Yolo Bypass Wildlife Area Land Management Plan*, *Grizzly Island Wildlife Area Management Plan*, and the *Lower Sherman Island Wildlife Area Land Management Plan* are primarily designed to preserve and enhance the natural resource and recreation qualities of these areas. Implementing Alternative 4, especially construction of CM1 and CM2 facilities, and land modification associated with CM4 restoration activities, could create temporary disruptions to the terrestrial biological resource management activities in these management areas. The proposed locations of the intermediate forebay and the RTM area on Zacharias Island fall within the Stone Lakes Cooperative Wildlife Management Area identified in the Stone Lakes Wildlife Refuge Comprehensive Conservation Plan (CCP). The primary objective of the Cooperative Wildlife Management Area is to maintain lands in private ownership and continue agricultural production but also allow USFWS to pursue a number of approaches to conserve and manage lands, depending on the preferences of willing landowners. The location of the intermediate forebay is an area that is entirely planted in vineyard, which has very little to no habitat value for wildlife species. The RTM area is used for hay or grain production, which does have high value for wildlife species. The placement of these project activities in these areas would be in conflict with the CCP.

  The ultimate goals of aquatic and terrestrial habitat enhancement and restoration contained in the BDCP would be compatible with the long-term management goals of these areas. Proposed restoration areas in the Yolo Bypass, on Sherman Island, and in Suisun Marsh would be designed to be compatible with and to complement the current management direction for these areas and would be required to adapt restoration proposals to meet current policy established for managing these areas.

- *Suisun Marsh Preservation Agreement* and *Suisun Marsh Plan* are the most recent efforts by the state and federal agencies responsible for Suisun Marsh (the Marsh) to maintain its long-term viability as managed wetlands and wildlife habitat, consistent with the Suisun Marsh Preservation Act. The SMPA was signed in 1987 and modified in 2005 by DWR, CDFW, Reclamation and the Suisun Resource Conservation District to establish the mitigation approach in the Marsh for effects of operating the SWP and CVP. The primary concerns were the effects of CVP and SWP Delta diversions on salinity in the Marsh. The SMPA focused on ways to ensure adequate water quality and quantity for the managed wetlands and wildlife habitats in the Marsh to assure equal waterfowl values in the Marsh. The Suisun Marsh Plan, for which a Final EIS/EIR was released in 2010 by these agencies, provides for restoration of tidal marsh habitat and enhancement of managed wetland in the Marsh, maintenance of waterfowl hunting and recreational opportunities in the Marsh, maintenance and improvement of the Marsh levee system, and protection and enhancement of water quality for beneficial uses of the Marsh. An integral component of the Suisun Marsh Plan is balancing continued managed wetland operation with new tidal wetland restoration to provide improved and greater habitat for fish and wildlife species. The Suisun Marsh Plan is a programmatic, long-term plan and does not include specific projects, project proponents, or funding mechanisms. However, the Suisun Marsh Plan relies on tidal restoration to allow for managed wetland operations to continue. The BDCP would provide a funding mechanism and increased management potential relative to existing and restored habitats, assisting the Suisun Marsh Plan in meeting its broader ecological goals, consistent with long-term operation of the SWP and CVP water conveyance facilities. The conservation actions contained in the BDCP, which are designed to ensure the long-term protection and recovery of special-status fish and wildlife species dependent on the Marsh, would be compatible with the water quality and habitat restoration goals of the SMPA and Suisun Marsh Plan.

- *California Aquatic Invasive Species Management Plan* does not address terrestrial invasive species. Implementation of the Plan's long-term control and management objectives affect terrestrial species that utilize study area aquatic habitats. These effects are positive in that Plan objectives are to control and remove invasive aquatic species that are detrimental to native aquatic and terrestrial species. Implementation of BDCP's conservation actions would be undertaken with the goal of avoiding any further spread of aquatic invasive species. Alternative 4 would, therefore, be compatible with the objectives of the California Aquatic Invasive Species Management Plan.

- *Habitat Conservation Plans and Natural Community Conservation Plans* are the subject of a detailed analysis at the end of this chapter. The analysis considers the compatibility of the BDCP with all HCPs and NCCPs that share planning area with the BDCP Plan Area.

Executive Orders

- *Executive Order 11990: Protection of Wetlands* requires all federal agencies to consider wetland protection in their policies and actions. The BDCP proposes to protect, enhance and expand the wetlands of the Plan Area, and, therefore, would be compatible with Executive Order 11990.

- *Executive Order 13112: Invasive Species* directs federal agencies to prevent and control the introduction and spread of invasive species in a cost-effective and environmentally sound manner. Alternative 4 construction and restoration actions have the potential to both introduce and spread invasive species in the study area. Implementation of mitigation measures described in this chapter would be capable of making Alternative 4 implementation compatible with Executive Order 13112.
- *Executive Order 113443: Facilitation of Hunting Heritage and Wildlife Conservation* directs federal agencies whose activities affect public land management, outdoor recreation, and wildlife management to facilitate the expansion and enhancement of hunting opportunities, and the management of game species and their habitat. Alternative 4 conservation measures that involve conversion of cultivated land and managed wetland to tidal and nontidal wetlands and other natural communities would conflict with the hunting expansion and enhancement aspects of this executive order. Refer to Chapter 15, *Recreation*, for a detailed analysis of the effects of alternatives on hunting opportunities. The habitat protection and expansion conservation measures of Alternative 4 would be compatible with the executive order's goal of facilitating the management of habitats for some game species.

***NEPA Effects*:** The potential plan and policy incompatibilities of implementing Alternative 4 identified in the analysis above indicate the potential for a physical consequence to the environment. The primary physical consequence of concern is the conversion of cultivated land and managed wetland to natural wetland and riparian habitat in the study area. The physical effects are discussed in the *Shorebirds and Waterfowl* analysis above, and no additional NEPA effects determination is required related to the compatibility of the alternative with relevant plans and polices. The reader is referred to Chapter 13, Section 13.2, *Regulatory Setting*, for a further discussion of the responsibilities of state and federal agencies to comply with local regulations, and a discussion of the relationship between plan and policy consistency and physical consequences to the environment.

***CEQA Conclusion*:** The potential plan and policy incompatibilities of implementing Alternative 4 identified in the analysis above indicate the potential for a physical consequence to the environment. The primary physical consequence of concern is the conversion of large acreages of cultivated land and managed wetland to natural wetland and riparian habitat in the study area. The physical effects are discussed in the Shorebirds and Waterfowl analysis above, and no additional CEQA conclusion is required related to the compatibility of the alternative with relevant plans and polices. The reader is referred to Chapter 13, Section 13.2.3, *Local and Regional Plans, Policies, and Regulations*, for a further discussion of the responsibilities of state and federal agencies to comply with local regulations, and a discussion of the relationship between plan and policy consistency and physical consequences to the environment.

12.3.3.10 Alternative 5—Dual Conveyance with Pipeline/Tunnel and Intake 1 (3,000 cfs; Operational Scenario C)

Alternative 5 proposes construction of only one Sacramento River intake in the north Delta (see Section 3.5.10 in Chapter 3, *Description of Alternatives*, for a complete description of this alternative). Intake 1 would be constructed just across the river and upstream of Clarksburg. A tunnel would be constructed to connect this lone intake and pump station to the forebay located immediately east of Courtland (see Figure 3-2 in Chapter 3). The remainder of the construction associated with Alternative 5 would be the same as Alternatives 1A, 2A, 3, 6A, 7, and 8 that rely on a western tunnel alignment under Andrus and Tyler Islands to transport Sacramento River water across the Delta to the south Delta canals (see Table 12-5-1). For this reason, Alternative 5 is considered here in a summary fashion; the reader is referred to Alternative 1A for a detailed description of impacts that would be associated with implementing Alternative 5. The impacts associated with Alternatives 1A and 5 were derived by comparing the alternatives to the No Action Alternative for NEPA purposes, and to Existing Conditions for CEQA purposes.

Alternative 5 would be operated under Operational Scenario C, which involves north Delta operations as proposed for Alternative 1A and south Delta operations directed by existing biological opinions from USFWS and NMFS. Scenario C includes the additional Delta outflow requirements associated with Scenarios B, D, E, F, and G. These requirements result in larger Delta outflows during September through November of certain water years.

Alternative 5 proposes a significant deviation in the re-establishment of tidal marsh as compared with all of the other BDCP alternatives. Tidal marsh restoration (CM4) would be limited to 25,000 acres for Alternative 5 as opposed to the 65,000 acres proposed for all other BDCP alternatives. The restoration activities would be limited to what is proposed during the first 15 years for the other options. The 40,000-acre reduction would have significant implications for cultivated lands and managed wetland conversion (see Table 12-5-2).

Note that the acres of habitat affected by CM1, as listed in Table 12-5-1, would be acres affected in the near-term timeframe, or the first 10 years of Plan implementation. The acres represented in Table 12-5-3 and Table 12-5-4 for the late long-term timeframe are acres that would be affected cumulatively over the entire 50-year period of the Plan. Table 3-4 in Chapter 3, *Description of Alternatives*, describes the schedule for implementation of natural community restoration and protection conservation measures.

Comparative Differences in CM1 Construction Effects for Alternatives 5 and 1A

With only one intake and pump station located in the north Delta, Alternative 5 would create significant differences in the permanent and temporary loss of natural communities and cultivated lands during water conveyance facilities construction when compared with alternatives having five intakes along the Sacramento River (Alternatives 1A, 1B, 1C, 2A, 2B, 2C, 6A, 6B, and 6C). The relative differences in direct loss of habitat between Alternative 5 and Alternative 1A are included in Table 12-5-1. All of these differences would occur during the near-term timeframe associated with water conveyance facilities construction along and just east of the Sacramento River between Clarksburg and Courtland. Alternative 5 would permanently remove 13 fewer acres of tidal perennial aquatic habitat in the Sacramento River, 12 fewer acres of valley/foothill riparian habitat along the eastern bank of the Sacramento River, 21 fewer acres of grassland along and behind the levees of the river, and 166 fewer acres of cultivated land immediately east of the river (Table 12-5-1). Alternative 5 would also permanently affect a smaller acreage of jurisdictional waters (including wetlands) as regulated by Section 404 of the CWA, when compared to Alternative 1A (14 acres fewer; see Table 12-5-2). Refer to Table 12-1A-69 for a summary of Alternative 1A permanent and temporary impacts on jurisdictional waters and wetlands.

Alternative 5 also would result in significantly fewer temporary losses of natural communities, including reduced losses of tidal perennial aquatic (49 acres less), valley/foothill riparian (11 acres less), grassland (27 acres less), tidal freshwater emergent wetland (3 acres less), and cultivated lands (461 acres less) when compared with Alternative 1A (Table 12-5-1). Alternative 5 would temporarily affect a smaller acreage of jurisdictional waters (including wetlands) as regulated by Section 404 of the CWA, when compared to Alternative 1A (57 acres fewer; see Table 12-5-2). Refer to Table 12-1A-69 for a summary of Alternative 1A permanent and temporary jurisdictional waters and wetlands impacts.

These differences in loss of natural communities associated with CM1 construction would create differences in effects on covered and noncovered wildlife species. The reduced level of valley/foothill riparian habitat loss would be a positive influence on valley elderberry longhorn beetle, breeding habitat for raptors, herons and egrets (great egret, snowy egret, great blue heron, Swainson's hawk, Cooper's hawk, white-tailed kite, and black-crowned night heron), and migratory habitat for species that use the river corridor, such as western yellow-billed cuckoo. Species that would benefit from smaller permanent losses of grassland and cultivated land would include foraging raptors (Swainson's hawk, short-eared owl, northern harrier, merlin and white-tailed kite), greater sandhill crane, mountain plover, California horned lark, tricolored blackbird and several species of bats. Alternative 5 would result in a smaller permanent loss (116 acres less) of crane foraging habitat compared to Alternative 1A. The significantly smaller temporary habitat conversions associated with Alternative 5 would have comparable benefits to these species during the construction period. There would be 323 fewer acres of foraging habitat temporarily lost under Alternative 5 for greater sandhill crane than under Alternative 1A because of the lower acreage of cultivated land loss.

The differences in effects that construction of the water conveyance facilities associated with Alternatives 1A and 5 could have on special-status plant species are extremely minor. Habitat modeling indicates that Alternative 5 would result in smaller permanent losses of habitat associated with side-flowering skullcap (1 acre less), Mason's lilaeopsis (5 acres less) and delta mudwort (5 acres less), when compared with Alternative 1A. Similar small differences would result from temporary construction effects (6 acres less effect on Mason's lilaeopsis and delta mudwort habitat with Alternative 5).

The near-term conservation activities described in Appendix 12D, *Feasibility Assessment of Conservation Measures Offsetting Water Conveyance Facilities Construction Impacts on Terrestrial Biological Resources*, would provide for conservation, enhancement and replacement of habitats affected by the early water conveyance facility construction activities. This conservation activity, which is part of the early implementation of the BDCP, would offset water conveyance facilities construction effects on both covered and noncovered special-status species in the study area.

Table 12-5-1. Alternative 5 Near-Term Effects of Water Conveyance Facilities (CM1) on Natural Communities (acres)

		Conveyance Option		Conveyance Option	
Natural Community	Total Existing Habitat in Study Area	Alternative 5 Removed Habitat (Permanent)[b]	Difference from Alternative 1A	Alternative 5 Removed Habitat (Temporary)[c]	Difference from Alternative 1A
Tidal perennial aquatic[a]	86,263	35	-13	84	-49
Tidal brackish emergent wetland	8,501	0	0	0	0
Tidal freshwater emergent wetland	8,856	6	0	3	-3
Valley/foothill riparian	17,966	47	-11	17	-11
Nontidal perennial aquatic	5,567	12	0	9	0
Nontidal freshwater perennial emergent wetland	1,509	1	0	1	0
Alkali seasonal wetland complex	3,723	0	0	0	0
Vernal pool complex	12,133	3	0	0	0
Managed wetland	70,798	3	0	83	0
Other natural seasonal wetland	842	0	0	0	0
Grassland	78,047	294	-21	235	-27
Inland dune scrub	19	0	0	0	0
Cultivated lands	487,106	3,657	-179	1,730	-461

[a] Tidal mudflat has been included in the tidal perennial aquatic natural community.

[b] Features in this category include the following conveyance-related facilities: Forebay, Afterbay, Intake Facilities, Pump Stations, Permanent Access Roads, Shaft Locations, and Reusable Tunnel Material Storage Areas.

[c] Features in this category include the following conveyance features: Canal Work Area, Barge Unloading Facility, Control Structure Work Area, Intake Road Work Area, Intake Work Area, Pipeline, Pipeline Work Area, Road Work Area, Safe Haven Work Area, Temporary Access Road Work Area, Tunnel Work Area, and Borrow/Spoil Areas.

Table 12-5-2 Alternative 5 Effects on Jurisdictional Wetlands and Waters Relative to Alternative 1A (acres)

	Alternative 5 Impacts on Jurisdictional Wetlands and Waters			
Wetland/Water Type	Permanent Impact	Difference from Alternative 1A	Temporary Impact	Difference from Alternative 1A
Agricultural Ditch	64.8	-0.1	20.7	-2.7
Alkaline Wetland	0.1	0	0	0
Clifton Court Forebay	1.0	0	0	0
Conveyance Channel	12.7	0	1.1	0

Effects of Restoration-Related Conservation Actions of Alternative 5

The natural communities and managed land conversions associated with the major restoration-related conservation measures under Alternative 5 (CM2, CM4, and CM5, CM7, CM8, CM10, and CM18) present the greatest potential to affect both covered and noncovered plants and wildlife in the study area. Most of these restoration-related conservation measures (CM2, CM7, CM8, and CM10) would be identical to the other BDCP alternatives. However, for *CM4 Tidal Natural Communities Restoration*, Alternative 5 would result in a much smaller conversion of natural habitats, managed wetlands and cultivated lands. Table 12-5-3 lists the permanent and temporary natural community and managed land conversions associated with CM2, CM4, and CM5 for Alternative 5. These losses would be a significant reduction in the acreage of managed wetland (6,445 acres fewer) and cultivated lands (28,142 acres fewer) that would be converted through tidal marsh (tidal perennial aquatic, tidal brackish emergent wetland, tidal freshwater emergent wetland) habitat restoration when compared with the other BDCP alternatives. There would be less dramatic reductions in the conversion of tidal (42 acres fewer) and nontidal (169 acres fewer) aquatic and wetland habitats, grassland (390 acres fewer) and valley/foothill riparian habitat (49 acres fewer). Table 12-5-4 presents permanent and temporary natural community effects under other conservation measures. These measures would restore large areas of grassland (CM8), valley/foothill riparian (CM7), and nontidal marsh (CM10) habitats to compensate for the conversions associated with tidal marsh and floodplain restoration, but these other measures would be implemented through the course of the BDCP restoration program. None of these measures includes subsequent expansions of cultivated lands.

Table 12-5-3. Alternative 5 Late Long-Term Effects of Restoration Activities (CM2, CM4, CM5) that Affect Most Natural Communities (acres)

	Conservation Measure					
	CM2[b]		CM4[c]		CM5[d]

Nontidal freshwater perennial emergent wetland	25	1	51	0	0	0
Alkali seasonal wetland complex	45	0	13	0	0	0
Vernal pool complex	0	0	269	0	0	0
Managed wetland	24	44	7,301	0	0	0
Other natural seasonal wetland	0	0	0	0	0	0
Grassland	338	239	732	0	51	34
Inland dune scrub	0	0	0	0	0	0
Cultivated lands	629	363	11,423	0	2,087	1,194

[a] Tidal mudflat has been included in the tidal perennial aquatic natural community.

[b] Yolo Bypass Fisheries Enhancement.

[c] Tidal Natural Communities Restoration.

[d] Seasonally Inundated Floodplain Restoration.

[e] Features in this category include the following: construction of fish passage structures and infrastructure in the Yolo Bypass, construction of permanent structures and infrastructure associated with restoration, and loss of habitat associated with removal and replacement by other habitats.

[f] Features in this category include the following: temporary work areas associated with construction of permanent restoration features, and temporary grading/vegetation removal associated with restoration activities.

Table 12-5-4. Alternative 5 Late Long-Term Effects of Restoration Activities (CM7, CM8, CM10, CM18) that Affect Only Grassland and Cultivated Lands (acres)

Natural Community	Conservation Measure							
	CM7[a]		CM8[b]		CM10[c]		CM18[d]	
	Perm[e]	Temp[f]	Perm[e]	Temp[f]	Perm[e]	Temp[f]	Perm[e]	Temp[f]
Grassland	410	0	0	0	0	0	35	0
Cultivated lands	4,553	0	2,000	0	1,950	0	0	0

[a] Riparian Natural Community Restoration.
[b] Grassland Natural Community Restoration.
[c] Nontidal Marsh Restoration.
[d] Conservation Hatcheries.
[e] Features in this category include the following: construction of permanent structures and infrastructure associated with restoration, recreation facilities and hatcheries; and loss of habitat associated with removal and replacement by other habitats.
[f] Features in this category include the following: temporary work areas associated with construction of permanent restoration features, recreation facilities and hatcheries; and temporary grading/vegetation removal associated with restoration activities.
Perm = Permanent.
Temp = Temporary.

The 25,000-acre expansion of tidal wetland habitats would occur during the course of the BDCP restoration program. The conversions indicated in Table 12-5-3 include a permanent conversion of 16 acres of tidal perennial aquatic, 1 acre of tidal freshwater emergent wetland, 403 acres of valley/foothill riparian, 732 acres of grassland, 13 acres of alkali seasonal wetland complex, 269 acres of vernal pool complex, and 68 acres of nontidal perennial aquatic natural communities. Larger acreages of managed wetland (7,301 acres) and cultivated land of various types (11,423 acres) would be converted. These conversions would occur in multiple conservation zones, but would be focused in CZs 1, 2, 4, 5 and 11 (see Figure 12-1). Suisun Marsh (CZ 11) would undergo significant conversion of managed wetland while the Cosumnes-Mokelumne area (CZ 4) would have mostly cultivated lands converted. Riparian habitat losses would occur in multiple conservation zones, while grassland conversion would occur primarily in the Yolo Bypass (CZ 2) and the west Delta (CZ 5). Vernal pool inundation would occur in the Cache Slough (CZ 1) and Suisun Marsh (CZ 11) areas.

This removed habitat supports various life stages of many covered and noncovered species that are found in the study area (see Tables 12-2 and 12-3 in Section 12.1.3, *Special-Status Species*). The loss of managed wetland in the Suisun Marsh area would affect some common waterfowl that prefer freshwater wetlands and prefer the water depths associated with lands that are managed to attract waterfowl. Other species that occupy Suisun Marsh managed wetlands would also be able to occupy the tidal marsh habitats developed as part of CM4. The conversion of valley/foothill riparian habitat would influence special-status species such as valley elderberry longhorn beetle, breeding habitat for raptors, herons and egrets (great egret, snowy egret, great blue heron, Swainson's hawk, Coopers hawk, and black-crowned night heron), and migratory habitat for species that use the riparian corridors, such as western yellow-billed cuckoo. The potential for loss of vernal pool complex through tidal inundation would affect numerous special status fairy shrimp and potentially western spadefoot and California tiger salamander. Grassland conversion would affect foraging for raptors and some passerines, such as loggerhead shrike, tricolored blackbird and grasshopper sparrow. The large acres of converted cultivated land in Cosumnes-Mokelumne area, the west Delta and the Yolo Bypass would affect a variety of species, including raptors, greater sandhill crane, tricolored blackbird, and potentially giant garter snake and western pond turtle.

The reader is referred to the Alternative 1A impact analysis above for the broader discussion of overall terrestrial biological resources effects that would result from implementation of Alternative 5, beyond only the effects of tidal marsh restoration. The principal effects of concern associated with both Alternative 1A and 5 are related to the conversion of large acreages of cultivated lands and managed wetland to tidal marsh and other habitat types during restoration activities. All of the permanent habitat loss associated with Alternative 5 would take place through the course of implementing the BDCP. The BDCP conservation components are designed to eventually replace and expand habitats that would have a positive influence on plant and animal species covered in the Plan. These conservation components would also have a positive effect on noncovered and common species that occupy the study area.

NEPA Effects**:** Alternative 5 would not have adverse effects on the terrestrial natural communities, special-status species and common species that occupy the study area. The alternative also would not disrupt wildlife movement corridors, significantly increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 1A, there would be large acreages of existing habitat converted by the Plan's conservation actions, including the construction of water conveyance tunnels from the north Delta to Clifton Court Forebay in the south Delta. The temporarily affected habitat would be restored to its pre-project condition and the restoration conservation measures (CM2–CM10) would permanently replace primarily cultivated land and managed wetland with tidal and nontidal marsh, riparian vegetation, and grassland. The increases in acreage and value of the sensitive natural communities in the study area would have beneficial effects on covered and noncovered species. Where conservation actions would not fully offset effects, the Plan has developed AMMs and this document has included additional mitigation measures to avoid adverse effects. Alternative 5 would not require mitigation measures beyond what is proposed for Alternative 1A to offset effects.

CEQA Conclusion**:** Alternative 5 would not have significant and unavoidable impacts on the terrestrial natural communities, special-status species and common species that occupy the study area. The alternative also would not disrupt wildlife movement corridors, significantly increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 1A, there would be large acreages of existing habitat converted by the Plan's conservation actions, including the construction of water conveyance tunnels from the north Delta to Clifton Court Forebay in the south Delta. The temporarily affected habitat would be restored to its pre-project condition and the restoration conservation measures (CM2–CM10) would permanently replace primarily cultivated land and managed wetland with tidal and nontidal marsh, riparian vegetation, and grassland. The increases in acreage and value of the sensitive natural communities in the study area would have beneficial effects on covered, noncovered, and common species. Where conservation actions would not fully offset impacts, the Plan has developed AMMs and this document has included additional mitigation measures to avoid significant impacts. Alternative 5 would not require mitigation measures beyond what is proposed for Alternative 1A to offset effects.

As with Alternative 1A, Alternative 5 would require several mitigation measures to be adopted to reduce all effects on terrestrial biological resources to less-than-significant levels. These mitigation measures would be needed beyond the impact offsets provided by Alternative 5 AMMs and CM2–CM21 conservation actions. The relevant mitigation measures, which are included in detail in the analysis of Alternative 1A, are as follows:

- Mitigation Measure BIO-42: Avoid Impacts on Delta Green Ground Beetle and its Habitat
- Mitigation Measure BIO-43: Avoid and Minimize Loss of Callippe Silverspot Butterfly Habitat
- Mitigation Measure BIO-55: Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs
- Mitigation Measure BIO-66: California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized
- Mitigation Measure BIO-69a: Compensate for the Loss of Medium to Very High-Value Greater Sandhill Crane Foraging Habitat
- Mitigation Measure BIO-72: Compensate for the Loss of Medium- to Very High-Value Lesser Sandhill Crane Foraging Habitat
- Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds
- Mitigation Measure BIO-91: Compensate for Near-Term Loss of High-Value Western Burrowing Owl Habitat
- Mitigation Measure BIO-113: Compensate for the Near-Term Loss of Golden Eagle and Feruginous Hawk Foraging Habitat
- Mitigation Measure BIO-117: Avoid Impacts on Rookeries
- Mitigation Measure BIO-125: Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat
- Mitigation Measure BIO-129a: Compensate for Loss of Black Tern Nesting Habitat
- Mitigation Measure BIO-130: Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat
- Mitigation Measure BIO-138: Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat
- Mitigation Measure BIO-146: Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized
- Mitigation Measure BIO-147: Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area
- Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger
- Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures
- Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant Species
- Mitigation Measure BIO-176: Compensatory Mitigation for Fill of Waters of the United States

- Mitigation Measure BIO-179a: Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh
- Mitigation Measure BIO-179b: Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins
- Mitigation Measure BIO-180: Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh

12.3.3.11 Alternative 6A—Isolated Conveyance with Pipeline/Tunnel and Intakes 1–5 (15,000 cfs; Operational Scenario D)

Alternative 6A would affect terrestrial biological resources in the same manner as Alternative 1A. Alternative 6A, which is fully described in Section 3.5.11 of Chapter 3, *Description of Alternatives*, and depicted in Figure 3-2 in Chapter 3, would employ the same construction footprint and include the same suite of conservation components as Alternative 1A. For this reason, Alternative 6A is considered here in a summary fashion; the reader is referred to Alternative 1A for a detailed description of impacts that would be associated with implementing Alternative 6A. The impacts associated with Alternatives 1A and 6A were derived by comparing the alternatives to the No Action Alternative for NEPA purposes, and to Existing Conditions for CEQA purposes.

The only difference between the two alternatives is the operational scenario that is proposed. Alternative 6A would use Operational Scenario D rather than Operational Scenario A. Scenario D calls for the pipeline and tunnel to act as an isolated conveyance facility. All water destined for the CVP and SWP canals in the south Delta would be diverted in the north Delta and transported south through the pipeline and tunnel. The pumping of water directly from south Delta channels would no longer occur. Operational Scenario D also provides for an increased Delta outflow during September and October of some water years. These water operations would have no significant effect on terrestrial biological resources in the study area.

The reader is referred to the Alternative 1A impact analysis for the broader discussion of overall terrestrial biological resources effects that would result from implementation of Alternative 6A. The Alternative 6A water conveyance facilities construction effects on natural communities are included in Table 12-6A-1. The principal effects of concern associated with both Alternative 1A and 6A are related to the conversion of large acreages of cultivated lands and managed wetland to water conveyance facilities (CM1; Table 12-6A-1), and to tidal marsh and other habitat types (CM2, CM4, and CM5—Table 12-6A-2; CM7, CM8, CM10, and CM18—Table 12-6A-3). Refer to Table 12-1A-69 for a summary of Alternative 1A permanent and temporary jurisdictional waters and wetlands impacts.

Note that the acres of habitat affected by CM1, as listed in Table 12-6A-1, would be acres affected in the near-term timeframe, or the first 10 years of Plan implementation. The acres represented in Table 12-6A-2 and Table 12-6A-3 for the late long-term timeframe are acres that would be affected cumulatively over the entire 50-year period of the Plan. Table 3-4 in Chapter 3, *Description of Alternatives*, describes the schedule for implementation of natural community restoration and protection conservation measures.

These effects accrue to special-status species and common wildlife species that rely on cultivated lands and managed wetlands during some life stage. Foraging raptors and passerines and some waterbirds are regular inhabitants of the Delta's cultivated lands. The Delta's managed wetlands provide freshwater nesting, feeding and resting habitat for a large number of Pacific flyway waterfowl and shorebirds, as well as nesting passerines, such as tricolored blackbird. Special-status plant species that occupy the tidal fringe in Suisun Marsh and parts of the Delta would be subject to losses associated with physical construction activities (levee breaching and reconstruction) and changes in water depth and salinity in their current habitat as a result of tidal marsh restoration.

Table 12-6A-1. Alternative 6A Near-Term Effects of Water Conveyance Facilities (CM1) on Natural Communities (acres)

		Conveyance Option		Conveyance Option	
Natural Community	Total Existing Habitat in Study Area	Alternative 6A Removed Habitat (Permanent)[b]	Difference from Alternative 1A	Alternative 6A Removed Habitat (Temporary)[c]	Difference from Alternative 1A

Cultivated lands	629	363	39,565	0	2,087	1,194

[a] Tidal mudflat has been included in the tidal perennial aquatic natural community.
[b] Yolo Bypass Fisheries Enhancement.
[c] Tidal Natural Communities Restoration.
[d] Seasonally Inundated Floodplain Restoration.
[e] Features in this category include the following: construction of fish passage structures and infrastructure in the Yolo Bypass, construction of permanent structures and infrastructure associated with restoration, and loss of habitat associated with removal and replacement by other habitats.
[f] Features in this category include the following: temporary work areas associated with construction of permanent restoration features, and temporary grading/vegetation removal associated with restoration activities.

3

Table 12-6A-3. Alternative 6A Late Long-Term Effects of Restoration Activities (CM7, CM8, CM10, CM18) that Affect Only Grassland and Cultivated Lands (acres)

Natural Community	Conservation Measure							
	CM7[a]		CM8[b]		CM10[c]		CM18[d]	
	Perm[e]	Temp[f]	Perm[e]	Temp[f]	Perm[e]	Temp[f]	Perm[e]	Temp[f]
Grassland	410	0	0	0	0	0	35	0
Cultivated lands	4,553	0	2,000	0	1,950	0	0	0

[a] Riparian Natural Community Restoration.
[b] Grassland Natural Community Restoration.
[c] Nontidal Marsh Restoration.
[d] Conservation Hatcheries.
[e] Features in this category include the following: construction of permanent structures and infrastructure associated with restoration, recreation facilities and hatcheries; and loss of habitat associated with removal and replacement by other habitats.
[f] Features in this category include the following: temporary work areas associated with construction of permanent restoration features, recreation facilities and hatcheries; and temporary grading/vegetation removal associated with restoration activities.
Perm = Permanent.
Temp = Temporary.

Some of the permanent habitat loss associated with these alternatives would occur during the early, construction-related stage of the BDCP. Other losses would occur over time as some habitats (cultivated lands, managed wetland, valley/foothill riparian and grassland) are converted to tidal marsh (tidal perennial aquatic, tidal brackish emergent wetland, tidal freshwater emergent wetland) and other natural communities. The BDCP conservation components are designed to eventually replace and expand habitats that would have a positive influence on plant and animal species covered in the Plan. These conservation components would also have a positive effect on noncovered and common species that occupy the study area.

NEPA Effects: Alternative 6A would not have adverse effects on the terrestrial natural communities, special-status species and common species that occupy the study area. The alternative also would not disrupt wildlife movement corridors, significantly increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 1A, there would be large acreages of existing habitat converted by the Plan's conservation actions, including the construction of water conveyance tunnels from the north Delta to Clifton Court Forebay in the south Delta. The temporarily affected habitat would be restored to its pre-project condition and the restoration conservation measures (CM2–CM10) would permanently replace primarily cultivated land and managed wetland with tidal and nontidal marsh, riparian vegetation, and grassland. The increases in acreage and value of the sensitive natural communities in the study area would have beneficial effects on covered and noncovered species. Where conservation actions would not fully offset effects, the Plan has developed AMMs and this document has included additional mitigation measures to avoid adverse effects. Alternative 6A would not require mitigation measures beyond what is proposed for Alternative 1A to offset effects because the affects to terrestrial resources are exactly the same.

CEQA Conclusion: Alternative 6A would not have significant and unavoidable impacts on the terrestrial natural communities, special-status species and common species that occupy the study area. The alternative also would not disrupt wildlife movement corridors, significantly increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 1A, there would be large acreages of existing habitat converted by the Plan's conservation actions, including the construction of water conveyance tunnels from the north Delta to Clifton Court Forebay in the south Delta. The temporarily affected habitat would be restored to its pre-project condition and the restoration conservation measures (CM2–CM10) would permanently replace primarily cultivated land and managed wetland with tidal and nontidal marsh, riparian vegetation, and grassland. The increases in acreage and value of the sensitive natural communities in the study area would have beneficial effects on covered, noncovered, and common species. Where conservation actions would not fully offset impacts, the Plan has developed AMMs and this document has included additional mitigation measures to avoid significant impacts. Alternative 6A would not require mitigation measures beyond what is proposed for Alternative 1A to offset effects because the affects to terrestrial resources are exactly the same.

As with Alternative 1A, Alternative 6A would require several mitigation measures to be adopted to reduce all effects on terrestrial biological resources to less-than-significant levels. These mitigation measures would be needed beyond the impact offsets provided by Alternative 6A AMMs and CM2–CM21 conservation actions. The relevant mitigation measures, which are included in detail in the analysis of Alternative 1A, are as follows:

- Mitigation Measure BIO-42: Avoid Impacts on Delta Green Ground Beetle and its Habitat
- Mitigation Measure BIO-43: Avoid and Minimize Loss of Callippe Silverspot Butterfly Habitat
- Mitigation Measure BIO-55: Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs
- Mitigation Measure BIO-66: California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized
- Mitigation Measure BIO-69a: Compensate for the Loss of Medium to Very High-Value Greater Sandhill Crane Foraging Habitat
- Mitigation Measure BIO-72: Compensate for the Loss of Medium- to Very High-Value Lesser Sandhill Crane Foraging Habitat
- Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds
- Mitigation Measure BIO-91: Compensate for Near-Term Loss of High-Value Western Burrowing Owl Habitat
- Mitigation Measure BIO-113: Compensate for the Near-Term Loss of Golden Eagle and Feruginous Hawk Foraging Habitat
- Mitigation Measure BIO-117: Avoid Impacts on Rookeries
- Mitigation Measure BIO-125: Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat
- Mitigation Measure BIO-129a: Compensate for Loss of Black Tern Nesting Habitat

- Mitigation Measure BIO-130: Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat
- Mitigation Measure BIO-138: Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat
- Mitigation Measure BIO-146: Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized
- Mitigation Measure BIO-147: Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area
- Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger
- Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures
- Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant Species
- Mitigation Measure BIO-176: Compensatory Mitigation for Fill of Waters of the United States
- Mitigation Measure BIO-179a: Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh
- Mitigation Measure BIO-179b: Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins
- Mitigation Measure BIO-180: Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh

12.3.3.12 Alternative 6B—Isolated Conveyance with East Alignment and Intakes 1–5 (15,000 cfs; Operational Scenario D)

Alternative 6B would affect terrestrial biological resources in the same manner as Alternative 1B. Alternative 6B, which is described fully in Section 3.5.12 of Chapter 3, *Description of Alternatives*, and depicted in Figure 3-4 in Chapter 3, would employ the same construction footprint and contain the same suite of conservation components as Alternative 1B. For this reason, Alternative 6B is considered here in a summary fashion; the reader is referred to Alternative 1B for a detailed description of impacts that would be associated with implementing Alternative 6B. The impacts associated with Alternatives 1B and 6B were derived by comparing the alternatives with the No Action Alternative for NEPA purposes, and to Existing Conditions for CEQA purposes.

The only difference between the two alternatives is the operational scenario that is proposed. Alternative 6B would use Operational Scenario D rather than Operational Scenario A. Scenario D calls for the eastern canal to act as an isolated conveyance facility. All water destined for the CVP and SWP canals in the south Delta would be diverted in the north Delta and transported south through the eastern canal. The pumping of water directly from south Delta channels would no longer occur. Operational Scenario D also provides for an increased Delta outflow during September and October of some water years. These water operations would have no significant effect on terrestrial biological resources in the study area.

The Alternative 6B water conveyance facilities construction effects on natural communities are included in Table 12-6B-1. The principal effects of concern associated with both Alternative 1B and 6B are related to the conversion of large acreages of cultivated lands and managed wetland to water conveyance facilities(Table 12-6B-1), tidal marsh and other habitat types (Table 12-6B-2 and Table 12-6B-3). Refer to Table 12-1B-68 for a summary of Alternative 1B permanent and temporary jurisdictional waters and wetlands impacts.

Note that the acres of habitat affected by CM1, as listed in Table 12-6B-1, would be acres affected in the near-term timeframe, or the first 10 years of Plan implementation. The acres represented in Table 12-6B-2 and Table 12-6B-3 for the late long-term timeframe are acres affected cumulatively over the entire 50-year period of the Plan. Table 3-4 in Chapter 3, *Description of Alternatives*, describes the schedule for implementation of natural community restoration and protection conservation measures.

The major habitat conversions associated with Alternatives 1B and 6B accrue to special-status species and common wildlife species that rely on cultivated lands and managed wetlands during some life stage. Foraging raptors and passerines and some waterbirds are regular inhabitants of the Delta's cultivated lands. The Delta's managed wetlands provide freshwater nesting, feeding and resting habitat for a large number of Pacific flyway waterfowl and shorebirds, as well as nesting passerines, such as tricolored blackbird. Special-status plant species that occupy the tidal fringe in Suisun Marsh and parts of the Delta would be subject to losses associated with physical construction activities (levee breaching and reconstruction) and changes in water depth and salinity in their current habitat as a result of tidal marsh restoration.

Cultivated land	487,106	7,886	0	12,551	0

[a] Tidal mudflat has been included in the tidal perennial aquatic natural community.

[b] Features in this category include the following conveyance-related facilities: Canal, Forebay, Afterbay, Intake Facilities, Pump Stations, Permanent Access Roads, Shaft Locations, and Reusable Tunnel Material Storage Areas.

[c] Features in this category include the following conveyance features: Canal Work Area, Barge Unloading Facility, Control Structure Work Area, Intake Road Work Area, Intake Work Area, Pipeline, Pipeline Work Area, Road Work Area, Safe Haven Work Area, Temporary Access Road Work Area, Tunnel Work Area, and Borrow/Spoil Areas.

Some of the permanent habitat loss associated with these alternatives would occur during the early, construction-related stage of the BDCP. Other losses would occur over time as some habitats (cultivated lands, managed wetland, valley/foothill riparian and grassland) are converted to tidal marsh (tidal perennial aquatic, tidal brackish emergent wetland, tidal freshwater emergent wetland; CM4) and other natural communities (CM2 and CM5, Table 12-6B-2; CM7, CM8, CM10, and CM18, Table 12-6B-3). The BDCP conservation components are designed to eventually replace and expand habitats that would have a positive influence on plant and animal species covered in the Plan. These conservation components would also have a positive effect on noncovered and common species that occupy the study area.

Cultivated lands	629	363	39,565	0	2,087	1,194

[a] Tidal mudflat has been included in the tidal perennial aquatic natural community.
[b] Yolo Bypass Fisheries Enhancement.
[c] Tidal Natural Communities Restoration
[d] Seasonally Inundated Floodplain Restoration
[e] Features in this category include the following: construction of fish passage structures and infrastructure in the Yolo Bypass, construction of permanent structures and infrastructure associated with restoration, and loss of habitat associated with removal and replacement by other habitats.
[f] Features in this category include the following: temporary work areas associated with construction of permanent restoration features, and temporary grading/vegetation removal associated with restoration activities.

Table 12-6B-3. Alternative 6B Late Long-Term Effects of Restoration Activities (CM7, CM8, CM10, CM18) that Affect Only Grassland and Cultivated Lands (acres)

Natural Community	Conservation Measure							
	CM7[a]		CM8[b]		CM10[c]		CM18[d]	
	Perm[e]	Temp[f]	Perm[e]	Temp[f]	Perm[e]	Temp[f]	Perm[e]	Temp[f]

[a] Riparian Natural Community Restoration.
[b] Grassland Natural Community Restoration.
[c] Nontidal Marsh Restoration.
[d] Conservation Hatcheries.
[e] Features in this category include the following: construction of permanent structures and infrastructure associated with restoration, recreation facilities and hatcheries; and loss of habitat associated with removal and replacement by other habitats.
[f] Features in this category include the following: temporary work areas associated with construction of permanent restoration features, recreation facilities and hatcheries; and temporary grading/vegetation removal associated with restoration activities.
Perm = Permanent.
Temp = Temporary.

NEPA Effects**:** Alternative 6B would not have adverse effects on the terrestrial natural communities, special-status species and common species that occupy the study area except for an adverse effect on giant garter snake population connectivity and on wildlife movement corridors in general. The construction of the canal would substantially inhibit the movement of giant garter snakes and other wildlife from moving within and outside of the Delta. This alternative would not significantly increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 1B, there would be large acreages of existing habitat converted by the Plan's conservation actions, including the construction of the water conveyance canal from the north Delta to Clifton Court Forebay in the south Delta. The temporarily affected habitat would be restored to its pre-project condition and the restoration conservation measures (CM2–CM10) would permanently replace primarily cultivated land and managed wetland with tidal and nontidal marsh, riparian vegetation, and grassland. The increases in acreage and value of the sensitive natural communities in the study area would have beneficial effects on covered and noncovered species. Where conservation actions would not fully offset effects, the Plan has developed AMMs and this document has included additional mitigation measures to avoid and minimize adverse effects to the maximum extent practicable. Alternative 6B would not require mitigation measures beyond what is proposed for Alternative 1B to offset effects.

CEQA Conclusion**:** Alternative 6B would not have significant and unavoidable impacts on the terrestrial natural communities, special-status species and common species that occupy the study area except for giant garter snake habitat connectivity, or to wildlife movement corridors in general. The construction of the canal would substantially inhibit the movement of giant garter snakes and other wildlife from moving within and outside of the Delta. The alternative would not increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 1B, there would be large acreages of existing habitat converted by the Plan's conservation actions, including the construction of water conveyance tunnels from the north Delta to Clifton Court Forebay in the south Delta. The temporarily affected habitat would be restored to its pre-project condition and the restoration conservation measures (CM2–CM10) would permanently replace primarily cultivated land and managed wetland with tidal and nontidal marsh, riparian vegetation, and grassland. The increases in acreage and value of the sensitive natural communities in the study area would have beneficial effects on covered, noncovered, and common species. Where conservation actions would not fully offset impacts, the Plan has developed AMMs and this document has included additional mitigation measures to avoid and minimize significant impacts. Alternative 6B would not require mitigation measures beyond what is proposed for Alternative 1B to offset effects. Despite these measures, there would remain significant and unavoidable impacts on giant garter snake population connectivity and wildlife movement corridors from Alternative 6B.

As with Alternative 1B, Alternative 6B would require several mitigation measures to be adopted to reduce effects on terrestrial biological resources to less-than-significant levels when possible. These mitigation measures would be needed beyond the impact offsets provided by Alternative 6B AMMs and CM2–CM21 conservation actions. The relevant mitigation measures, which are included in detail in the analysis of Alternative 1B, are as follows:

- Mitigation Measure BIO-42: Avoid Impacts on Delta Green Ground Beetle and its Habitat
- Mitigation Measure BIO-43: Avoid and Minimize Loss of Callippe Silverspot Butterfly Habitat
- Mitigation Measure BIO-50a: Provide Connectivity between Coldani Marsh/White Slough Population and the Giant Garter Snake's Historical Range
- Mitigation Measure BIO-55: Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs
- Mitigation Measure BIO-66: California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized
- Mitigation Measure BIO-69a: Compensate for the Loss of Medium to Very High-Value Greater Sandhill Crane Foraging Habitat
- Mitigation Measure BIO-69b: BDCP-Related Construction Will Not Result in A Net Decrease in Crane Use Days on Bract Tract
- Mitigation Measure BIO-72: Compensate for the Loss of Medium- to Very High-Value Lesser Sandhill Crane Foraging Habitat
- Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds
- Mitigation Measure BIO-91: Compensate for Near-Term Loss of High-Value Western Burrowing Owl Habitat
- Mitigation Measure BIO-113: Compensate for the Near-Term Loss of Golden Eagle and Feruginous Hawk Foraging Habitat
- Mitigation Measure BIO-117: Avoid Impacts on Rookeries
- Mitigation Measure BIO-121: Compensate for Loss of Short-Eared Owl and Northern Harrier Nesting Habitat
- Mitigation Measure BIO-125: Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat

- Mitigation Measure BIO-129a: Compensate for Loss of Black Tern Nesting Habitat
- Mitigation Measure BIO-130: Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat
- Mitigation Measure BIO-138: Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat
- Mitigation Measure BIO-146: Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized
- Mitigation Measure BIO-147: Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area
- Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger
- Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures
- Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant Species
- Mitigation Measure BIO-176: Compensatory Mitigation for Fill of Waters of the United States
- Mitigation Measure BIO-179a: Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh
- Mitigation Measure BIO-179b: Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins
- Mitigation Measure BIO-180: Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh

12.3.3.13 Alternative 6C—Isolated Conveyance with West Alignment and Intakes W1–W5 (15,000 cfs; Operational Scenario D)

Alternative 6C would affect terrestrial biological resources in the same manner as Alternative 1C. Alternative 6C, which is described fully in Section 3.5.13 of Chapter 3, *Description of Alternatives*, and depicted in Figure 3-6 in Chapter 3, would employ the same construction footprint and include the same suite of conservation components as Alternative 1C. For this reason, Alternative 6C is considered here in a summary fashion; the reader is referred to Alternative 1C for a detailed description of impacts that would be associated with implementing Alternative 6C. The impacts associated with Alternatives 1C and 6C were derived by comparing the alternatives with the No Action Alternative for NEPA purposes, and to Existing Conditions for CEQA purposes.

The only difference between the two alternatives is the operational scenario that is proposed. Alternative 6C would use Operational Scenario D rather than Operational Scenario A. Scenario D calls for the western canal and tunnel to act as an isolated conveyance facility. All water destined for the CVP and SWP canals in the south Delta would be diverted in the north Delta and transported south through the western canal and tunnel. The direct pumping of water from south Delta waterways would no longer occur. Operational Scenario D also provides for an increased Delta outflow during September and October of some water years. These water operations would have no significant effect on terrestrial biological resources in the study area.

CM1 Construction Effects for Alternative 6C

The Alternative 6C water conveyance facilities construction effects on natural communities are included in Table 12-6C-1. The principal effects of concern associated with both Alternative 1C and 6C are related to the conversion of large acreages of cultivated lands, managed wetland, grassland, vernal pool complex and alkali seasonal wetland complex to water conveyance facilities (Table 12-6C-1). Refer to Table 12-1C-68 for a summary of Alternative 1C permanent and temporary jurisdictional waters and wetlands impacts.

Note that the acres of habitat affected by CM1, as listed in Table 12-6C-1, would be acres affected in the near-term timeframe, or the first 10 years of Plan implementation. The acres represented in Table 12-6C-2 and Table 12-6C-3 for the late long-term timeframe are acres that would be affected cumulatively over the entire 50-year period of the Plan. Table 3-4 in Chapter 3, *Description of Alternatives*, describes the schedule for implementation of natural community restoration and protection conservation measures.

Construction of the Alternative 6C canal and tunnel in the western Delta and west and northwest of Clifton Court Forebay would have significant impacts on cultivated lands, and grassland, vernal pool and alkali seasonal wetland natural communities. The large acreages of vernal pool and alkali seasonal wetland impacted near Clifton Court Forebay would exceed the offsetting restoration and protection included in the BDCP, so additional mitigation would be required. These effects accrue to special-status species and common wildlife species that rely on cultivated land, grassland, vernal pool complex and alkali seasonal wetland complex during some life stage. Foraging raptors and passerines and some waterbirds are regular inhabitants of the Delta's cultivated lands. Grassland habitats also provide foraging for raptors and passerines, and upland habitat for some mammals and amphibians. Vernal pools provide habitat to special-status crustaceans, California tiger salamander, numerous common waterbirds, and a suite of special-status plants. Alkali seasonal wetland complex provides habitat to California tiger salamander, numerous common waterbirds, foraging raptors and its own suite of special-status, salt tolerant plants.

The near-term conservation activities described in Appendix 12D, *Feasibility Assessment of Conservation Measures Offsetting Water Conveyance Facilities Construction Impacts on Terrestrial Biological Resources*, and the mitigation measures proposed in the Alternative 1C analysis would provide for conservation, enhancement and replacement of habitats affected by the early water conveyance facility construction activities of Alternative 6C. This conservation activity, which is part of the early implementation of the BDCP, would offset most water conveyance facilities construction effects on both covered and noncovered special-status species in the study area. As indicated above, additional mitigation would be required for species reliant on vernal pool complex and alkali seasonal wetland complex natural communities.

Table 12-6C-1. Alternative 6C Near-Term Effects of Water Conveyance Facilities (CM1) on Natural Communities (acres)

Natural Community	Total Existing Habitat in Study Area	Conveyance Option: Alternative 6C Removed Habitat (Permanent)[b]	Conveyance Option: Difference from Alternative 1C	Conveyance Option: Alternative 6C Removed Habitat (Temporary)[c]	Conveyance Option: Difference from Alternative 1C

[f] Features in this category include the following: temporary work areas associated with construction of permanent restoration features, recreation facilities and hatcheries; and temporary grading/vegetation removal associated with restoration activities.
Perm = Permanent.
Temp = Temporary.

Effects of Restoration-Related Actions of Alternative 6C

Some of the permanent habitat loss associated with Alternative 6C would occur during the early, construction-related stage of the BDCP. Other losses would occur over time as some natural communities (cultivated lands, managed wetland, alkali seasonal wetland complex, grassland and valley/foothill riparian) are converted to tidal marsh (tidal perennial aquatic, tidal brackish emergent wetland, tidal freshwater emergent wetland) and other natural communities as part of restoration actions (CM2, CM4, and CM5; Table 12-6C-2; CM7, CM8, CM10, and CM18; Table 12-6C-3). The large acreages of cultivated land and managed wetland converted during marsh, grassland and riparian habitat restoration would affect species similar to those described above for losses associated with CM1, only on a larger scale. The BDCP restoration-related conservation components are designed to eventually replace and expand habitats that would have a positive influence on plant and animal species covered in the Plan. These conservation components would also have a positive effect on noncovered and common species that occupy the study area.

***NEPA Effects*:** Alternative 6C would not have adverse effects on the terrestrial natural communities, special-status species and common species that occupy the study. The construction of the canal and associated infrastructure would substantially inhibit the movement of wildlife from moving within and outside of the Delta resulting in an adverse effect. This alternative would not significantly increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 1C, there would be large acreages of existing habitat converted by the Plan's conservation actions, including the construction of the water conveyance canal from the north Delta to Clifton Court Forebay in the south Delta. The temporarily affected habitat would be restored to its pre-project condition and the restoration conservation measures (CM2–CM10) would permanently replace primarily cultivated land and managed wetland with tidal and nontidal marsh, riparian vegetation, and grassland. The increases in acreage and value of the sensitive natural communities in the study area would have beneficial effects on covered and noncovered species. Where conservation actions would not fully offset effects, the Plan has developed AMMs and this document has included additional mitigation measures to avoid and minimize adverse effects to the maximum extent practicable. Alternative 6C would not require mitigation measures beyond what is proposed for Alternative 1C to offset effects.

CEQA Conclusion: Alternative 6C would not have significant and unavoidable impacts on the terrestrial natural communities, special-status species and common species that occupy the study. The construction of the canal and associated infrastructure would substantially inhibit the movement of wildlife from moving within and outside of the Delta resulting in an adverse effect. The alternative would not increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 1C, there would be large acreages of existing habitat converted by the Plan's conservation actions, including the construction of water conveyance tunnels from the north Delta to Clifton Court Forebay in the south Delta. The temporarily affected habitat would be restored to its pre-project condition and the restoration conservation measures (CM2–CM10) would permanently replace primarily cultivated land and managed wetland with tidal and nontidal marsh, riparian vegetation, and grassland. The increases in acreage and value of the sensitive natural communities in the study area would have beneficial effects on covered, noncovered, and common species. Where conservation actions would not fully offset impacts, the Plan has developed AMMs and this document has included additional mitigation measures to avoid and minimize significant impacts. Alternative 6C would not require mitigation measures beyond what is proposed for Alternative 1C to offset effects. Despite these measures, there would remain a significant and unavoidable impact on wildlife movement corridors from Alternative 6C.

As with Alternative 1C, Alternative 6C would require several mitigation measures to be adopted to reduce effects on terrestrial biological resources to less-than-significant levels when possible. These mitigation measures would be needed beyond the impact offsets provided by Alternative 6C AMMs and CM2–CM21 conservation actions. The relevant mitigation measures, which are included in detail in the analysis of Alternative 1C, are as follows:

- Mitigation Measure BIO-18: Compensate for Loss of Alkali Seasonal Wetland Complex
- Mitigation Measure BIO-27: Compensate for Loss of Other Natural Seasonal Wetland
- Mitigation Measure BIO-32: Restore and Protect Vernal Pool Crustacean Habitat
- Mitigation Measure BIO-42: Avoid Impacts on Delta Green Ground Beetle and its Habitat
- Mitigation Measure BIO-43: Avoid and Minimize Loss of Callippe Silverspot Butterfly Habitat
- Mitigation Measure BIO-55: Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs
- Mitigation Measure BIO-66: California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized
- Mitigation Measure BIO-69a: Compensate for the Loss of Medium to Very High-Value Greater Sandhill Crane Foraging Habitat
- Mitigation Measure BIO-72: Compensate for the Loss of Medium- to Very High-Value Lesser Sandhill Crane Foraging Habitat

- Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds
- Mitigation Measure BIO-91: Compensate for Near-Term Loss of High-Value Western Burrowing Owl Habitat
- Mitigation Measure BIO-91a, Compensate for Permanent Loss of Low-Value Western Burrowing Owl Habitat
- Mitigation Measure BIO-113: Compensate for the Near-Term Loss of Golden Eagle and Feruginous Hawk Foraging Habitat
- Mitigation Measure BIO-117: Avoid Impacts on Rookeries
- Mitigation Measure BIO-121: Compensate for Loss of Short-Eared Owl and Northern Harrier Nesting Habitat
- Mitigation Measure BIO-125: Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat
- Mitigation Measure BIO-129a: Compensate for Loss of Black Tern Nesting Habitat
- Mitigation Measure BIO-130: Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat
- Mitigation Measure BIO-138: Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat
- Mitigation Measure BIO-146: Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized
- Mitigation Measure BIO-147: Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area
- Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger
- Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures
- Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant Species
- Mitigation Measure BIO-176: Compensatory Mitigation for Fill of Waters of the United States
- Mitigation Measure BIO-179a: Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh
- Mitigation Measure BIO-179b: Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins
- Mitigation Measure BIO-180: Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh

12.3.3.14 Alternative 7—Dual Conveyance with Pipeline/Tunnel, Intakes 2, 3, and 5, and Enhanced Aquatic Conservation (9,000 cfs; Operational Scenario E)

The water conveyance facilities construction elements (CM1) of Alternative 7 would affect terrestrial biological resources in a nearly identical fashion to Alternative 1A. The principal differences between Alternative 7, which is described fully in Section 3.5.14 of Chapter 3, *Description of Alternatives*, and depicted in Figure 3-2 in Chapter 3, and Alternative 1A are related to the differing construction footprints. For this reason, Alternative 7 is considered here in a summary fashion; the reader is referred to Alternative 1A for a detailed description of impacts that would be associated with implementing Alternative 7. The impacts associated with Alternatives 1A and 7 were derived by comparing the alternatives with the No Action Alternative for NEPA purposes, and to Existing Conditions for CEQA purposes.

The Alternative 7 water conveyance facilities would entail construction at north Delta Intakes 2, 3, and 5 rather than 1–5. The locations of these intakes are depicted in Figure 3-2 in Chapter 3. Eliminating Intakes 1 and 4 would reduce the construction footprint along the eastern bank of the Sacramento River just north of Clarksburg and immediately south of Hood. The operational scenario for Alternative 7 (Scenario E) is also different from Alternative 1A (Operational Scenario A), but this change would not significantly alter terrestrial biological resources effects. Alternative 7 operations would extract water from the river at the three intakes and would require additional pumping at the south Delta pumps. Also, Operational Scenario E would involve greater Delta freshwater outflows during September, October and November of some water years when compared with Operational Scenario A.

Alternative 7 would include the same conservation activities as Alternative 1A beyond CM1 with two exceptions. *CM6 Channel Margin Enhancement* would include restoration and enhancement activities along 40 miles of river channel in the Delta rather than the 20 miles proposed for all other BDCP alternatives. Also, *CM5 Seasonally Inundated Floodplain Restoration* would expand from 10,000 acres to 20,000 acres under Alternative 7. These expansions would have major positive impacts on valley/foothill riparian natural community along major Delta waterways; at the same time, other natural communities and cultivated land would experience reductions as riparian habitats are enhanced and expanded.

Comparative Differences in CM1 Construction Effects for Alternatives 7 and 1A

Because of the elimination of Intakes 1 and 4 and their associated pumps and pipelines, Alternative 7 would create relatively small differences in the permanent and temporary loss of natural communities and cultivated lands during water conveyance facilities construction when compared with Alternative 1A (Table 12-7-1). All of these differences would occur during the near-term timeframe associated with water conveyance facilities construction. Alternative 7 would permanently remove 7 fewer acres of tidal perennial aquatic habitat in the Sacramento River, 10 fewer acres of valley/foothill riparian habitat along the eastern bank of the Sacramento River, and 5 fewer acres of grassland along the river levees. These reductions would occur as a result of not constructing Intakes 1 and 4 on the east bank of the Sacramento River. There would also be a reduction in loss of cultivated lands (95 fewer acres) east of the river near these intake sites. Alternative 7 would also permanently affect a smaller acreage of jurisdictional waters (including wetlands) as regulated by Section 404 of the CWA, when compared to Alternative 1A (7 acres fewer;

see Table 12-7-2). Refer to Table 12-1A-69 for a summary of Alternative 1A permanent and temporary jurisdictional waters and wetlands impacts.

Table 12-7-1. Alternative 7 Near-Term Effects of Water Conveyance Facilities (CM1) on Natural Communities (acres)

		Conveyance Option		Conveyance Option

Total	**209**	**-6.8**	**181**	**-29.8**

During the water conveyance facilities construction process, Alternative 7 would also involve less temporary loss of habitat when compared with Alternative 1A. The difference would be reflected in reduced losses of tidal perennial aquatic (25 acres less), valley/foothill riparian (3 acres less), grassland (7 acres less), and cultivated land (214 acres less) when compared with Alternative 1A (Table 12-7-1). Alternative 7 would also temporarily affect a smaller acreage of jurisdictional waters (including wetlands) as regulated by Section 404 of the CWA, when compared to Alternative 1A (30 acres fewer; see Table 12-7-2). Refer to Table 12-1A-69 for a summary of Alternative 1A permanent and temporary jurisdictional waters and wetlands impacts.

These differences in permanent loss of habitat from constructing the water conveyance facility would create differences in effects on covered and noncovered wildlife. The reduced level of valley/foothill riparian habitat loss would be a positive influence on valley elderberry longhorn beetle, breeding habitat for raptors, herons and egrets (great egret, snowy egret, great blue heron, Swainson's hawk, Cooper’s hawk, white-tailed kite, and black-crowned night heron), and migratory habitat for species that use the river corridor, such as western yellow-billed cuckoo. Species that would benefit from smaller permanent losses of grassland and cultivated land would include foraging raptors (Swainson’s hawk, short-eared owl, northern harrier, merlin and white-tailed kite), greater sandhill crane, mountain plover, California horned lark, tricolored blackbird and several species of bats. Alternative 7 would permanently remove 85 fewer acres of greater sandhill crane foraging habitat when compared to Alternative 1A. The smaller temporary habitat conversions associated with Alternative 7 would have comparable benefits to these species.

The differences in effect that Alternatives 1A and 7 could have on special-status plant species are extremely minor. Habitat modeling indicates that Alternative 7 would create 5 fewer acres of habitat loss for Mason’s lilaeopsis and delta mudwort when compared with Alternative 1A.

The near-term conservation activities described in Appendix 12D, *Feasibility Assessment of Conservation Measures Offsetting Water Conveyance Facilities Construction Impacts on Terrestrial Biological Resources*, and the mitigation measures proposed in the Alternative 1A analysis would provide for protection, enhancement and restoration of habitats affected by the early water conveyance facility construction activities associated with Alternative 7. This conservation activity, which is part of the early implementation of the BDCP, would offset water conveyance facilities construction effects on both covered and noncovered special-status species in the study area.

Effects of Restoration-Related Actions of Alternative 7

The natural communities and managed land conversions associated with the restoration-related conservation measures of Alternative 7 present the greatest potential to affect both covered and noncovered plants and wildlife in the study area (CM2, CM4, and CM5—Table 12-7-3; CM7, CM8, CM10, and CM18—Table 12-7-4). Most of Alternative 7's other conservation measures (CM2, CM4, CM7, CM8, CM10, and CM18) are identical to the other BDCP alternatives described above. However, the seasonally inundated floodplain restoration (CM5) and channel margin enhancement (CM6) for Alternative 7 would be expanded compared with the other BDCP alternatives. The seasonally inundated floodplain restoration would be expanded by 10,000 acres and the channel margin habitat enhancement would be extended for another 20 linear miles. Both of these activities would extend valley/foothill riparian habitat adjacent to some of the Delta's major waterways, including the Sacramento, San Joaquin and Mokelumne Rivers, and Sutter and Steamboat Sloughs. The floodplain expansion would also allow for the introduction of wildlife-compatible cultivated land in the newly created floodplains.

The expansion of floodplain habitat would be accomplished through the course of the BDCP restoration program. During that period, setback of levees and other activities associated with the conservation components would permanently remove acreages from some natural communities. The permanent and temporary conversions for Alternative 7 are shown in Table 12-7-3 and Table 12-7-4. Table 3-4 in Chapter 3, *Description of Alternatives*, describes the schedule for implementation of natural community restoration and protection conservation measures. The principal permanent losses would be in nontidal perennial aquatic, managed wetland, grassland and cultivated lands natural communities. These losses would affect plant and wildlife species associated with the habitats. Grassland and cultivated lands losses along the Delta waterways mentioned above would reduce foraging habitat for some special-status raptors (short-eared owl, Swainson's hawk, white-tailed kite, northern harrier, merlin, western burrowing owl), greater sandhill crane and tricolored blackbird; upland habitat for giant garter snake and riparian brush rabbit; and dispersal and upland nesting habitat for western pond turtle. The permanent loss of nontidal perennial aquatic habitat would affect aquatic habitat for giant garter snake and western pond turtle. The temporary removal of existing riparian habitat to move levees and prepare stream channels for replanting of riparian species would have a short-term effect on multiple species, including riparian woodrat, riparian brush rabbit, nesting raptors, valley elderberry longhorn beetle, yellow-breasted chat, western yellow-billed cuckoo, and western pond turtle.

Table 12-7-3. Alternative 7 Late Long-Term Effects of Restoration Activities (CM2, CM4, CM5) that Affect Most Natural Communities (acres)

	Conservation Measure					
	CM2[b]		CM4[c]		CM5[d]	
Natural Community	Permanent[e]	Temporary[f]	Permanent[e]	Temporary[f]	Permanent[e]	Temporary[f]

Cultivated lands	629	363	39,565	0	4,174	2,388

[a] Tidal mudflat has been included in the tidal perennial aquatic natural community.

[b] Yolo Bypass Fisheries Enhancement.

[c] Tidal Natural Communities Restoration.

[d] Seasonally Inundated Floodplain Restoration; the acreages included for CM5 in this table were estimated by doubling the acreages calculated for CM5 for other BDCP alternatives. The CM5 acres for other BDCP alternatives were estimated based on a hypothetical footprint for the restoration action, but no similar footprint was developed for Alternative 7.

[e] Features in this category include the following: construction of fish passage structures and infrastructure in the Yolo Bypass, construction of permanent structures and infrastructure associated with restoration, and loss of habitat associated with removal and replacement by other habitats.

[f] Features in this category include the following: temporary work areas associated with construction of permanent restoration features, and temporary grading/vegetation removal associated with restoration activities.

Table 12-7-4. Alternative 7 Late Long-Term Effects of Restoration Activities (CM7, CM8, CM10, CM18) that Affect Only Grassland and Cultivated Lands (acres)

	Conservation Measure							
	CM7[a]		CM8[b]		CM10[c]		CM18[d]	
Natural Community	Perm[e]	Temp[f]	Perm[e]	Temp[f]	Perm[e]	Temp[f]	Perm[e]	Temp[f]

Cultivated lands	4,553	0	2,000	0	1,950	0	0	0

[a] Riparian Natural Community Restoration.
[b] Grassland Natural Community Restoration.
[c] Nontidal Marsh Restoration.
[d] Conservation Hatcheries.
[e] Features in this category include the following: construction of permanent structures and infrastructure associated with restoration, recreation facilities and hatcheries; and loss of habitat associated with removal and replacement by other habitats.
[f] Features in this category include the following: temporary work areas associated with construction of permanent restoration features, recreation facilities and hatcheries; and temporary grading/vegetation removal associated with restoration activities.
Perm = Permanent.
Temp = Temporary.

A number of special-status plant species would have modeled habitat affected by the extension of seasonally inundated floodplain for Alternative 7. There would be permanent and temporary effects on this habitat. The habitat lost permanently includes 10 acres for slough thistle, 13 acres for delta button celery, 2 acres each for San Joaquin spearscale and side-flowering skullcap and 1 acre each for Mason's lilaeopsis and delta mudwort. Slightly larger acreages of habitat for these same species would be affected temporarily.

For a broader view of the overall effects of Alternative 7 beyond its unique effects associated with CM5 and CM6, the reader is referred to the Alternative 1A impact analysis earlier in this chapter. The principal effects of concern associated with both Alternative 1A and 7 are related to the conversion of large acreages of cultivated lands and managed wetland to tidal marsh and other habitat types. These effects accrue to special-status species and common wildlife species that rely on cultivated lands and managed wetlands during some life stage. Foraging raptors and some waterbirds are regular inhabitants of the Delta's cultivated lands. The Delta's managed wetlands provide freshwater nesting, feeding and resting habitat for a large number of Pacific flyway waterfowl and shorebirds, as well as nesting passerines, such as tricolored blackbird. Special-status plant species that occupy the tidal fringe in Suisun Marsh and parts of the Delta would be subject to losses associated with physical construction activities (levee breaching and reconstruction) and changes in water depth and salinity in their current habitat as a result of tidal marsh restoration.

Some of the permanent habitat loss associated with these alternatives would take place during the early, construction-related stage of the BDCP. Other losses would occur over time as some habitats (cultivated lands, managed wetland, valley/foothill riparian and grassland) are converted to tidal marsh (tidal perennial aquatic, tidal brackish emergent wetland, tidal freshwater emergent wetland) and other natural communities. The BDCP conservation components are designed to eventually replace and expand habitats that would have a positive influence on plant and animal species covered in the Plan. These conservation components would also have a positive effect on noncovered and common species that occupy the study area.

***NEPA Effects*:** Alternative 7 would not have adverse effects on the terrestrial natural communities, special-status species and common species that occupy the study area. The alternative also would not disrupt wildlife movement corridors, significantly increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 1A, there would be large acreages of existing habitat converted by the Plan's conservation actions, including the construction of water conveyance tunnels from the north Delta to Clifton Court Forebay in the south Delta. The temporarily affected habitat would be restored to its pre-project condition and the restoration conservation measures (CM2–CM10) would permanently replace primarily cultivated land and managed wetland with tidal and nontidal marsh, riparian vegetation, and grassland. The increases in acreage and value of the sensitive natural communities in the study area would have beneficial effects on covered and noncovered species. Where conservation actions would not fully offset effects, the Plan has developed AMMs and this document has included additional mitigation measures to avoid adverse effects. Alternative 7 would not require mitigation measures beyond what is proposed for Alternative 1A to offset effects.

***CEQA Conclusion*:** Alternative 7 would not have significant and unavoidable impacts on the terrestrial natural communities, special-status species and common species that occupy the study area. The alternative also would not disrupt wildlife movement corridors, significantly increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 1A, there would be large acreages of existing habitat converted by the Plan's conservation actions, including the construction of water conveyance tunnels from the north Delta to Clifton Court Forebay in the south Delta. The temporarily affected habitat would be restored to its pre-project condition and the restoration conservation measures (CM2–CM10) would permanently replace primarily cultivated land and managed wetland with tidal and nontidal marsh, riparian vegetation, and grassland. The increases in acreage and value of the sensitive natural communities in the study area would have beneficial effects on covered, noncovered, and common species. Where conservation actions would not fully offset impacts, the Plan has developed AMMs and this document has included additional mitigation measures to avoid significant impacts. Alternative 7 would not require mitigation measures beyond what is proposed for Alternative 1A to offset effects.

As with Alternative 1A, Alternative 7 would require several mitigation measures to be adopted to reduce all effects on terrestrial biological resources to less-than-significant levels. These mitigation measures would be needed beyond the impact offsets provided by Alternative 7 AMMs and CM2–CM21 conservation actions. The relevant mitigation measures, which are included in detail in the analysis of Alternative 1A, are as follows:

- Mitigation Measure BIO-42: Avoid Impacts on Delta Green Ground Beetle and its Habitat
- Mitigation Measure BIO-43: Avoid and Minimize Loss of Callippe Silverspot Butterfly Habitat
- Mitigation Measure BIO-55: Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs
- Mitigation Measure BIO-66: California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized

- Mitigation Measure BIO-69a: Compensate for the Loss of Medium to Very High-Value Greater Sandhill Crane Foraging Habitat
- Mitigation Measure BIO-72: Compensate for the Loss of Medium- to Very High-Value Lesser Sandhill Crane Foraging Habitat
- Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds
- Mitigation Measure BIO-91: Compensate for Near-Term Loss of High-Value Western Burrowing Owl Habitat
- Mitigation Measure BIO-113: Compensate for the Near-Term Loss of Golden Eagle and Feruginous Hawk Foraging Habitat
- Mitigation Measure BIO-117: Avoid Impacts on Rookeries
- Mitigation Measure BIO-125: Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat
- Mitigation Measure BIO-129a: Compensate for Loss of Black Tern Nesting Habitat
- Mitigation Measure BIO-130: Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat
- Mitigation Measure BIO-138: Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat
- Mitigation Measure BIO-146: Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized
- Mitigation Measure BIO-147: Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area
- Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger
- Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures
- Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant Species
- Mitigation Measure BIO-176: Compensatory Mitigation for Fill of Waters of the United States
- Mitigation Measure BIO-179a: Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh
- Mitigation Measure BIO-179b: Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins
- Mitigation Measure BIO-180: Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh

12.3.3.15 Alternative 8—Dual Conveyance with Pipeline/Tunnel, Intakes 2, 3, and 5, and Increased Delta Outflow (9,000 cfs; Operational Scenario F)

Alternative 8, which is described fully in Section 3.5.15 of Chapter 3, *Description of Alternatives*, and depicted in Figure 3-2 in Chapter 3, would affect terrestrial biological resources in a nearly identical fashion to Alternative 1A. For this reason, Alternative 8 is considered here in a summary fashion; the reader is referred to Alternative 1A for a detailed description of impacts that would be associated with implementing Alternative 8. The impacts associated with Alternatives 1A and 8 were derived by comparing the alternatives with the No Action Alternative for NEPA purposes, and to Existing Conditions for CEQA purposes.

The principal differences between these two alternatives would be related to the differing construction footprints of the water conveyance facilities (CM1). The Alternative 8 water conveyance facilities would entail construction at north Delta Intakes 2, 3, and 5 rather than Intakes 1–5. The locations of these intakes are depicted in Figure 3-2 in Chapter 3, *Description of Alternatives*. Eliminating Intakes 1 and 4 would reduce the construction footprint along the eastern bank of the Sacramento River just north of Clarksburg and immediately south of Hood. The operational scenario for Alternative 8 (Scenario F) is also different from Alternative 1A (Scenario A), but this change would not significantly alter terrestrial biological resources effects. Alternative 8 operations would extract water from the river at the three intakes and would require additional pumping at the south Delta pumps. Also, Operational Scenario F would involve greater Delta freshwater outflows during September and October of some water years when compared with Operational Scenario A. All of the conservation measures other than CM1 would be the same as Alternative 1A.

Comparative Differences in CM1 Construction Effects for Alternatives 8 and 1A

Because of the elimination of Intakes 1 and 4 and their associated pumps and pipelines, Alternative 8 would create relatively small differences in the permanent and temporary loss of natural communities and cultivated land during water conveyance facilities construction when compared with Alternative 1A (Table 12-8-1). All of these differences would take place during the near-term timeframe associated with water conveyance facilities construction. Alternative 8 would permanently remove 7 fewer acres of tidal perennial aquatic habitat, 10 fewer acres of valley/foothill riparian habitat, and 5 fewer acres of grassland along the east bank of the Sacramento River. Alternative 8 would also remove 95 fewer acres of cultivated land east of the Sacramento River. Alternative 8 would also permanently affect a smaller acreage of jurisdictional waters (including wetlands) as regulated by Section 404 of the CWA, when compared to Alternative 1A (7 acres fewer; see Table 12-8-2). Refer to Table 12-1A-69 for a summary of Alternative 1A permanent and temporary jurisdictional waters and wetlands impacts.

During the water conveyance facilities construction process, Alternative 8 would involve less temporary loss of habitat when compared with Alternative 1A. There would be reduced losses of tidal perennial aquatic (25 acres less), tidal freshwater emergent wetland (1 acre less), valley/foothill riparian (3 acres less), grassland (7 acres less) and cultivated land (214 acres less) when compared with Alternative 1A (Table 12-8-1). Alternative 8 would also temporarily affect a smaller acreage of jurisdictional waters (including wetlands) as regulated by Section 404 of the CWA, when compared to Alternative 1A (30 acres fewer, see Table 12-8-2). Refer to Table 12-1A-69

1 for a summary of Alternative 1A permanent and temporary jurisdictional waters and wetlands
2 impacts.

3 **Table 12-8-1. Alternative 8 Near-Term Effects of Water Conveyance Facilities (CM1) on Natural**
4 **Communities (acres)**

Natural Community	Total Existing Habitat in Study Area	Conveyance Option: Alternative 8 Removed Habitat (Permanent)[b]	Conveyance Option: Difference from Alternative 1A	Conveyance Option: Alternative 8 Removed Habitat (Temporary)[c]	Conveyance Option: Difference from Alternative 1A

[a] Tidal mudflat has been included in the tidal perennial aquatic natural community.

[b] Features in this category include the following conveyance-related facilities: Forebay, Afterbay, Intake Facilities, Pump Stations, Permanent Access Roads, Shaft Locations, and Reusable Tunnel Material Storage Areas.

[c] Features in this category include the following conveyance features: Barge Unloading Facility, Control Structure Work Area, Intake Road Work Area, Intake Work Area, Pipeline, Pipeline Work Area, Road Work Area, Safe Haven Work Area, Temporary Access Road Work Area, Tunnel Work Area, and Borrow/Spoil Areas.

5

Table 12-8-2 Alternative 8 Effects on Jurisdictional Wetlands and Waters Relative to Alternative 1A (acres)

	Alternative 8 Impacts on Jurisdictional Wetlands and Waters			
Wetland/Water Type	Permanent Impact	Difference from Alternative 1A	Temporary Impact	Difference from Alternative 1A
Agricultural Ditch	64.6	-0.3	21.9	-1.6
Alkaline Wetland	0.1	0	0	0
Clifton Court Forebay	1.0	0	0	0
Conveyance Channel	12.7	0	1.1	0
Depression	1.9	0	0.4	-1.3
Emergent Wetland	46.8	0	6.7	-0.6
Forest	5.6	-0.1	10.8	-1.1
Lake	0	0	0.3	0
Scrub-Shrub	20.3	-0.3	3.3	-1.0
Seasonal Wetland	18.7	0	26.6	0
Tidal Channel	36.9	-6.1	109.6	-24.2
Vernal Pool	0		0	0
Total	**209**	**-6.8**	**181**	**-29.8**

These differences in loss of habitat from constructing the water conveyance facilities would create differences in effects on covered and noncovered wildlife. The reduced level of valley/foothill riparian habitat loss would be a positive influence on valley elderberry longhorn beetle, breeding habitat for raptors, herons and egrets (great egret, snowy egret, great blue heron, Swainson's hawk, Cooper's hawk, white-tailed kite and black-crowned night heron), and migratory habitat for species that use the river corridor, such as western yellow-billed cuckoo. Species that would benefit from smaller permanent losses of grassland and cultivated land would include foraging raptors (Swainson's hawk, short-eared owl, northern harrier, merlin and white-tailed kite), greater sandhill crane, mountain plover, California horned lark, tricolored blackbird and several species of bats. Alternative 8 would permanently remove 85 fewer acres of greater sandhill crane foraging habitat when compared to Alternative 1A The smaller temporary habitat conversions associated with Alternative 8 would have comparable benefits to these species.

The differences in effect that Alternatives 1A and 8 could have on special-status plant species are extremely minor. Habitat modeling indicates that Alternative 8 would cause 3 fewer acres of permanent and 2 fewer acres of temporary habitat loss for Mason's lilaeopsis and delta mudwort when compared with Alternative 1A.

The near-term conservation activities described in Appendix 12D, *Feasibility Assessment of Conservation Measures Offsetting Water Conveyance Facilities Construction Impacts on Terrestrial Biological Resources*, would provide for conservation, enhancement and replacement of habitats affected by the early water conveyance facility construction activities. This conservation activity, which is part of the early implementation of the BDCP, and the mitigation measures included in the Alternative 1A analysis would offset water conveyance facilities construction effects of Alternative 8 on both covered and noncovered special-status species in the study area.

Effects of Restoration-Related Actions of Alternative 8

Natural community changes associated with the other major restoration activities in Alternative 8 (CM2, CM4, and CM5— Table 12-8-3; CM7, CM8, CM10, and CM18—Table 12-8-4) would be identical to those described for Alternative 1A. Table 3-4 in Chapter 3, *Description of Alternatives*, describes the schedule for implementation of natural community restoration and protection conservation measures.

Table 12-8-3. Alternative 8 Late Long-Term Effects of Restoration Activities (CM2, CM4, CM5) that Affect Most Natural Communities (acres)

[f] Features in this category include the following: temporary work areas associated with construction of permanent restoration features, recreation facilities and hatcheries; and temporary grading/vegetation removal associated with restoration activities.
Perm = Permanent
Temp = Temporary

The reader is referred to the Alternative 1A impact analysis earlier in this chapter for the broader discussion of overall terrestrial biological resources effects that would result from implementation of Alternative 8 restoration-related conservation actions. The principal effects of concern associated with both Alternative 1A and 8 are related to the conversion of large acreages of cultivated lands, managed wetland, grassland and valley/foothill riparian habitat to tidal marsh and other habitat types during restoration activities. These effects accrue to special-status species and common wildlife species, especially to those that rely on cultivated lands and managed wetland during some life stage. Foraging raptors and some waterbirds are regular inhabitants of the Delta's cultivated lands. The Delta's managed wetlands provide freshwater nesting, feeding and resting habitat for a large number of Pacific flyway waterfowl and shorebirds, as well as nesting passerines, such as tricolored blackbird. Special-status plant species that occupy the tidal fringe in Suisun Marsh and parts of the Delta would be subject to losses associated with physical construction activity (levee breaching and reconstruction) and changes in water depth and salinity in their current habitat as a result of tidal marsh restoration.

Some of the permanent habitat loss associated with the restoration components of Alternative 8 would occur during the early, construction-related stage of the BDCP. Other losses would occur over time as some habitats (cultivated lands, managed wetland, valley/foothill riparian and grassland) are converted to tidal marsh (tidal perennial aquatic, tidal brackish emergent wetland, tidal freshwater emergent wetland) and other natural communities. The BDCP conservation components, including the restoration components (CM2–CM10), are designed to eventually replace and expand habitats that would have a positive influence on plant and animal species covered in the Plan, including those that rely on managed wetland and cultivated land. These conservation components would also have a positive effect on noncovered and common species that occupy the study area.

NEPA Effects: Alternative 8 would not have adverse effects on the terrestrial natural communities, special-status species and common species that occupy the study area. The alternative also would not disrupt wildlife movement corridors, significantly increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 1A, there would be large acreages of existing habitat converted by the Plan's conservation actions, including the construction of water conveyance tunnels from the north Delta to Clifton Court Forebay in the south Delta. The temporarily affected habitat would be restored to its pre-project condition and the restoration conservation measures (CM2–CM10) would permanently replace primarily cultivated land and managed wetland with tidal and nontidal marsh, riparian vegetation, and grassland. The increases in acreage and value of the sensitive natural communities in the study area would have beneficial effects on covered and noncovered species. Where conservation actions would not fully offset effects, the Plan has developed AMMs and this document has included additional mitigation measures to avoid adverse effects. Alternative 8 would not require mitigation measures beyond what is proposed for Alternative 1A to offset effects.

CEQA Conclusion: Alternative 8 would not have significant and unavoidable impacts on the terrestrial natural communities, special-status species and common species that occupy the study area. The alternative also would not disrupt wildlife movement corridors, significantly increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 1A, there would be large acreages of existing habitat converted by the Plan's conservation actions, including the construction of water conveyance tunnels from the north Delta to Clifton Court Forebay in the south Delta. The temporarily affected habitat would be restored to its pre-project condition and the restoration conservation measures (CM2–CM10) would permanently replace primarily cultivated land and managed wetland with tidal and nontidal marsh, riparian vegetation, and grassland. The increases in acreage and value of the sensitive natural communities in the study area would have beneficial effects on covered, noncovered, and common species. Where conservation actions would not fully offset impacts, the Plan has developed AMMs and this document has included additional mitigation measures to avoid significant impacts. Alternative 8 would not require mitigation measures beyond what is proposed for Alternative 1A to offset effects.

As with Alternative 1A, Alternative 8 would require several mitigation measures to be adopted to reduce all effects on terrestrial biological resources to less-than-significant levels. These mitigation measures would be needed beyond the impact offsets provided by Alternative 8 AMMs and CM2–CM21 conservation actions. The relevant mitigation measures, which are included in detail in the analysis of Alternative 1A, are as follows:

- Mitigation Measure BIO-42: Avoid Impacts on Delta Green Ground Beetle and its Habitat
- Mitigation Measure BIO-43: Avoid and Minimize Loss of Callippe Silverspot Butterfly Habitat

12.3.3.16 Alternative 9—Through Delta/Separate Corridors (15,000 cfs; Operational Scenario G)

Section 3.5.16 of Chapter 3, *Description of Alternatives*, describes Alternative 9 in detail, and Figure 3-16 depicts the alternative.

Natural Communities

Tidal Perennial Aquatic

Construction, operation, maintenance and management associated with the conservation components of Alternative 9 would have no long-term adverse effects on the habitats associated with the tidal perennial aquatic natural community. Initial development and construction of CM1, CM2, CM4, CM5, and CM6 would result in both permanent and temporary removal or modification of this community (see Table 12-9-1). Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit the tidal perennial aquatic natural community (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore and protect 65,000 acres of tidal natural communities and transitional uplands to accommodate sea level rise (Objective L1.3, associated with CM4).
- Within the restored and protected tidal natural communities and transitional uplands, restore or create tidal perennial aquatic natural community as necessary when creating tidal emergent wetland (Objective TPANC1.1, associated with CM4).
- Control invasive aquatic vegetation that adversely affects native fish habitat (Objective TPANC2.1, associated with CM13).

There is a variety of other, less specific conservation goals and objectives that would improve the value of tidal perennial aquatic natural community for terrestrial species. As explained below, with the restoration and enhancement of these amounts of habitat, in addition to AMMs, impacts on tidal aquatic natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Note that two time periods are represented in Table 12-9-1 and the other tables contained in the analysis of Alternative 9. The near-term (NT) acreage effects listed in the table would occur over the first 10 years of Plan implementation. The late long-term (LLT) effects contained in these tables represent the cumulative effects of all activities over the entire 50-year term of the Plan. This table and all impact tables in the chapter include reference to only those CMs that would eliminate natural community acreage either through construction or restoration activities, or would result in periodic inundation of the community. Table 3-4 in Chapter 3, *Description of Alternatives*, describes the schedule for implementation of natural community protection and restoration conservation measures.

Table 12-9-1. Changes in Tidal Perennial Aquatic Natural Community Associated with Alternative 9 (acres)[a]

	Permanent		Temporary		Periodic[d]	
Conservation Measure[b]	NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	675	675	345	345	0	0
CM2	8	8	11	11	9–36	0
CM4	11	18	0	0	0	0
CM5		2	0	5	0	39
CM6	Unk.	Unk.	Unk.	Unk.	0	0
TOTAL IMPACTS	**694**	**703**	**356**	**361**	**9–36**	**39**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
Unk. = unknown

Impact BIO-1: Changes in Tidal Perennial Aquatic Natural Community as a Result of Implementing BDCP Conservation Measures

Construction, channel dredging and land grading activities that would accompany the implementation of CM1, CM2, CM4, CM5, and CM6 would permanently affect an estimated 703 acres and temporarily remove 361 acres of tidal perennial aquatic natural community in the study area. These modifications would affect approximately 1% of the 86,263 acres of the community that is mapped in the study area. The majority of the permanent and temporary effects would occur during the first 10 years of Alternative 9 implementation, as water conveyance facilities are constructed and habitat restoration is initiated. Natural communities restoration would add 8,300 acres of tidal wetlands, including an estimated 3,400 acres of tidal perennial aquatic natural community during the same period, which would expand the area of that habitat and offset the losses. The 3,400-acre increase is estimated, based on modeling reported in BDCP Appendix 3.B, Table 5, by comparing existing Plan Area subtidal habitat to near-term subtidal habitat with the Plan. The BDCP beneficial effects analysis for Alternative 4 (BDCP Chapter 5, Section 5.4.1.2) indicates that, while there would be no minimum restoration requirement for the tidal perennial aquatic natural community, an estimated approximately 27,000 acres of tidal perennial aquatic natural community would be restored based on tidal restoration modeling. This estimate is based on Table 5 in BDCP Appendix 3.B, subtracting late long-term without project acreage from late long-term with project acreage. The same conservation actions would be implemented for Alternative 9.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of in-water features and dredging of existing Delta waterways as part of Alternative 9's water conveyance facilities would permanently remove 675 acres and temporarily remove 345 acres of tidal perennial aquatic community. The permanent effects would occur at channel dredging sites, operable barrier construction sites and channel widening sites throughout the study area. These construction and dredging activities would not permanently remove the waterways, but would permanently modify the channel bottoms and eliminate any associated aquatic vegetation. The affected areas and type of activity are listed below (refer to the Terrestrial Biology Mapbook for details of these locations).
  - Dredging for channel enlargement in Victoria Canal from Middle River to Old River.
  - Dredging for channel enlargement in Middle River from Victoria Canal to Mildred Island.
  - Canal construction in Old River south of Grant Line Canal.
  - Canal construction across Old River and West Canal at Coney Island.
  - Operable barrier construction in San Joaquin River just north of junction with Old River, near Lathrop.
  - Operable barrier construction in Middle River just south of Victoria Canal.
  - Operable barrier construction in Victoria Canal at its junction with Old River.
  - Operable barrier construction in North Victoria Canal/Woodward Canal just west of Middle River.
  - Operable barrier construction in Railroad Cut at the south end of Bacon Island.
  - Operable barrier construction in Connection Slough just west of Middle River.
  - Operable barrier construction at the west end of Three Mile Slough at its junction with the Sacramento River.
  - Operable barrier construction at the north end of Fishermans Cut at its junction with the San Joaquin River.
  - Operable barrier construction in Old River at its junction with the San Joaquin River north of Franks Tract.
  - Operable barrier construction at the north end of Georgianna Slough at the Sacramento River.
  - Operable barrier construction at the west end of Delta Cross Channel at the Sacramento River.
  - Operable barrier construction in Snodgrass Slough just north of its junction with Delta Cross Channel.
  - Channel enlargement and operable barrier construction in Mokelumne River at Lost Slough.
  - Channel enlargement and connection in the Meadows Slough at its junction with the Sacramento River.
  - Channel enlargement and connection within the Meadows Slough east of the Sacramento River.
  - Fish screen construction in the Sacramento River at Georgianna Slough and Delta Cross Channel.

The temporary effects to tidal perennial aquatic natural community would occur primarily along the channels of the Middle River and Victoria Canal, where temporary work areas would be needed to support channel dredging operations described above. Several smaller temporary impact areas would occur where barge operations areas would be developed at these sites.

- o North Victoria Canal at Middle River.
- o Railroad Cut at Middle River at south end of Bacon Island.
- o Middle River at southeastern edge of Bacon Island.
- o Middle River at Upper Jones Tract,
- o Fishermans Cut at its junction with the San Joaquin River.
- o Old River at the San Joaquin River north of Franks Tract.

All of these temporary and permanent effects on tidal perennial aquatic natural community from CM1 would occur during the near-term construction period.

- *CM2 Yolo Bypass Fisheries Enhancement*: Implementation of CM2 would involve a number of construction activities within the Yolo and Sacramento Bypasses, including Fremont Weir and stilling basin improvements, Putah Creek realignment activities, Lisbon Weir modification and Sacramento Weir improvements. Some of these activities could involve excavation and grading in tidal perennial aquatic areas to improve passage of fish through the bypasses. Based on hypothetical construction footprints, a total of 8 acres could be permanently lost and another 11 acres could be temporarily removed. This activity would occur primarily in the near-term timeframe.

CM4 Tidal Natural Communities Restoration: Based on the use of hypothetical restoration footprints, implementation of CM4 would affect 18 acres of tidal perennial aquatic community. CM4 involves conversion of existing natural communities to a variety of tidal wetlands, including tidal perennial aquatic, tidal brackish emergent, and tidal freshwater emergent wetlands. Specific locations for these conversions are not known. The 18 acres could remain tidal perennial aquatic with a modified tidal prism, or they could eventually be converted to one of the other tidal wetland types. For purposes of this analysis, a conservative approach has been taken and the effect has been discussed simultaneously with the habitat losses associated with other conservation measures. An estimated 65,000 acres of tidal wetlands and transitional uplands would be restored during tidal habitat restoration, consistent with BDCP Objective L1.3. Of these acres, an estimated 27,000 acres of tidal perennial aquatic habitat would be restored, based on modeling conducted by ESA PWA (refer to Table 5 in BDCP Appendix 3.B, *BDCP Tidal Habitat Evolution Assessment*). This restoration would be consistent with BDCP Objective TPANC1.1. Approximately 3,400 acres of the restoration would occur during the first 10 years of Alternative 9 implementation, which would coincide with the timeframe of water conveyance facilities construction. The remaining restoration would be spread over the following 30 years. Tidal natural communities restoration is expected to be focused in the ROAs identified in Figure 12-1. Some of the restoration would occur in the lower Yolo Bypass, but restoration would also be spread among the Suisun Marsh, South Delta, Cosumnes/Mokelumne and West Delta ROAs.

- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration levee construction would permanently remove 2 acres and temporarily remove 5 acres of tidal perennial aquatic habitat. The construction-related losses would be considered a permanent removal of the tidal perennial aquatic habitats directly affected. This activity is scheduled to start following construction of water conveyance facilities, which is expected to take 10 years. Specific locations for the floodplain restoration have not been identified, but it is expected that much of the activity would occur in the south Delta along the major rivers. Floodplain restoration along the San Joaquin River would improve connectivity for a variety of species that rely on tidal perennial aquatic habitat. The regional and Plan Area landscape linkages along the San Joaquin River are included in Figure 12-2.

- *CM6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in filling of small amounts of tidal perennial aquatic habitat along 20 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur on tidal perennial aquatic habitat margins, including levees and channel banks. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

During the near-term timeframe (the first 10 years of BDCP implementation), Alternative 9 would affect the tidal perennial aquatic community through CM1 construction losses (675 acres permanent and 345 acres temporary) and the CM2 construction losses (8 acres permanent and 11 acres temporary). These losses would occur at channel dredging sites along Middle River and Victoria Canal, at channel widening and operable barrier construction sites at multiple locations in the study area, and in the northern Yolo Bypass. Approximately 11 acres of the inundation and construction-related effects resulting from CM4 would occur during the near-term throughout the ROAs mapped in Figure 12-1.

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and restoration actions associated with BDCP conservation components. Loss of tidal perennial aquatic natural community would be considered both a loss in acreage of a sensitive natural community and a loss of waters of the United States as defined by Section 404 of the CWA. The creation of approximately 3,400 acres of high-value tidal perennial aquatic natural community as part of CM4 during the first 10 years of Alternative 9 implementation would offset this near-term loss, avoiding any adverse effect. Typical project-level mitigation ratios (1:1 for restoration) would indicate 1,050 acres of restoration would be needed to offset (i.e., mitigate) the 1,050 acres of effect (a combination of the permanent and temporary near-term effects listed in Table 12-9-1) associated with near-term activities, including water conveyance facilities construction.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C.

Late Long-Term Timeframe

Implementation of Alternative 9 as a whole would result in relatively minor (approximately 1%) conversions or losses of tidal perennial aquatic community in the study area. These losses or conversions (703 acres of permanent and 361 acres of temporary loss) would be largely associated with construction of the water conveyance facilities (CM1), construction of Yolo Bypass fish improvements (CM2), and inundation during tidal marsh restoration (CM4). Inundation conversions would occur during the course of BDCP restoration activities at various tidal restoration sites throughout the study area. By the end of the Plan timeframe, approximately 27,000 acres of high-value tidal perennial aquatic natural community would be restored (estimated from Table 5 in BDCP Appendix 3.B, *BDCP Tidal Habitat Evolution Assessment*).

NEPA Effects: The creation of approximately 3,400 acres of high-value tidal perennial aquatic natural community as part of CM4 during the first 10 years of Alternative 9 implementation would offset near-term losses associated with construction activities for CM1, CM2, CM4, and CM6, avoiding any adverse effect. Alternative 9, which includes restoration of an estimated 27,000 acres of this natural community over the course of the Plan, would not result in a net long-term reduction in the acreage of a sensitive natural community; the effect would be beneficial.

CEQA Conclusion:

Near-Term Timeframe

Alternative 9 would result in the near-term loss or conversion of approximately 1,050 acres of tidal perennial aquatic natural community due to construction of the water conveyance facilities (CM1) and fish passage improvements (CM2), and inundation during tidal marsh restoration (CM4). The losses would occur primarily along the Middle River and Victoria Canal as these channels are dredged to improve capacity, but would also occur at numerous channel widening, barge unloading and operable barrier construction sites throughout the Delta. Losses would also occur within the northern section of the Yolo Bypass. Inundation conversions would occur at various tidal restoration sites throughout the study area. The losses and conversions would be spread across a 10-year near-term timeframe. These losses and conversions would be offset by planned restoration of 3,400 acres of high-value tidal perennial aquatic natural community scheduled for the first 10 years of Alternative 9 implementation (CM4). AMM1, AMM2, AMM6, AMM7, and AMM10 would also be implemented to minimize impacts. Because of these offsetting near-term restoration activities and AMMs, impacts would be less than significant. Typical project-level mitigation ratios (1:1 for restoration) would indicate that 1,050 acres of restoration would be needed to offset (i.e., mitigate) the 1,050 acres of loss or conversion. The restoration would be initiated at the beginning of Alternative 9 implementation to minimize any time lag in the availability of this habitat to special-status species, and would result in a net gain in acreage of this sensitive natural community.

Late Long-Term Timeframe

At the end of the Plan period, 1,064 acres of the tidal perennial aquatic natural community would be lost or converted and an estimated 27,000 acres of this community would be restored. There would be no net permanent reduction in the acreage of this sensitive natural community within the study area. Therefore, Alternative 9 would not have a substantial adverse effect on this natural community; the impact would be beneficial.

Impact BIO-2: Increased Frequency, Magnitude and Duration of Periodic Inundation of Tidal Perennial Aquatic Natural Community

Two Alternative 9 conservation measures would modify the water depths and inundation/flooding regimes of both natural and man-made waterways in the study area. CM2, which is designed to improve fish passage and shallow flooded habitat for Delta fishes in the Yolo Bypass, would increase periodic inundation of tidal perennial aquatic natural community on small acreages, while CM5 would expose this community to additional flooding as channel margins are modified and levees are set back to improve fish habitat along some of the major rivers and waterways throughout the study area.

- *CM2 Yolo Bypass Fisheries Enhancement*: Operation of the Yolo Bypass under Alternative 9 would result in an increase in the frequency, magnitude and duration of inundation and changes in water depth and velocity of 9–36 acres of tidal perennial aquatic natural community. The methods used to estimate these inundation acreages are described in BDCP Appendix 5.J, *Effects on Natural Communities, Wildlife, and Plants*. The area more frequently affected by inundation would vary with the flow volume that would pass through the newly constructed notch in the Fremont Weir. The 9-acre increase in inundation would be associated with a notch flow of 1,000 cfs, and the 36-acre increase would result from a notch flow of 4,000 cfs. Plan-related increases in flow through Fremont Weir would be expected in 30% of the years. Most of the tidal perennial aquatic community occurs in the southern section of the bypass on Liberty Island, and, to a lesser extent, along the eastern edge of the bypass, including the Tule Canal/Toe Drain. The anticipated change in management of flows in the Yolo Bypass includes more frequent releases in flows into the bypass from the Fremont and Sacramento Weirs, and in some years, later releases into the bypass in spring months (April and May). The modification of periodic inundation events would be expected to be beneficial to the ecological function of tidal perennial aquatic habitat in the bypass as it relates to BDCP covered aquatic species. The Yolo Bypass waterway is the key element in the Yolo Bypass landscape linkage mapped in Figure 12-2 and described in detail in BDCP Chapter 3, Table 3.2-3. The change in periodic inundation in the bypass would not substantially modify its value for special-status or common terrestrial species. Water depths and water flow rates would increase over Existing Conditions and the No Action condition in approximately 30% of the years, but it would not fragment the habitat or make it less accessible to special-status or common terrestrial species. The modifications would not result in a loss of this community. The plant species associated with this community are adapted to inundation. The extended inundation would be designed to expand foraging and spawning habitat for Delta fishes. The effects of these changes in the inundation regime on terrestrial species that rely on tidal perennial aquatic habitats are discussed in detail later in this chapter, under the individual species assessments.

- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration would result in a seasonal increase in the frequency and duration of flooding of 39 acres of tidal perennial aquatic habitat. Specific locations for this restoration activity have not been identified, but they would likely be focused in the south Delta area, along the major rivers and Delta channels. The more frequent exposure of these wetlands to stream flooding events would be beneficial to the ecological function of tidal perennial aquatic habitats, especially as they relate to BDCP target aquatic species. The plant species associated with these tidal perennial aquatic areas are adapted to inundation and would not be substantially modified.

In summary, 48–75 acres of tidal perennial aquatic community in the study area would be subjected to more frequent increases in water depth and velocity from inundation as a result of implementing two Alternative 9 conservation measures (CM2 and CM5). Tidal perennial aquatic community is already, by definition, permanently inundated aquatic habitat of value to terrestrial and aquatic species in the study area; therefore, periodic changes in water depth and velocity would not result in a net permanent reduction in the acreage of this community in the study area.

NEPA Effects: Increasing periodic inundation of tidal perennial aquatic natural community would not have an adverse effect on the community.

CEQA Conclusion: An estimated 48–75 acres of tidal perennial aquatic community in the study area would be subjected to more frequent increases in water depth and velocity from inundation as a result of implementing CM2 and CM5 under Alternative 9. Tidal perennial aquatic community is already, by definition, permanently inundated aquatic habitat of value to terrestrial and aquatic species in the study area. The periodic inundation would not result in a net permanent reduction in the acreage of this community in the study area. Therefore, there would no substantial adverse effect on the community. The impact would be less than significant.

Impact BIO-3: Modification of Tidal Perennial Aquatic Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 9 are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the BDCP facilities and conservation lands that could affect tidal perennial aquatic natural community in the study area. The ongoing actions include the diversion of Sacramento River flows at two newly screened sites at Georgianna Slough and Delta Cross Channel in the north Delta, the operation of multiple operable barriers in Delta waterways, and modified diversions from south Delta channels. These actions are associated with CM1 (see the impact discussion above for effects associated with CM2). The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (CM13), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and modified diversions from south Delta channels*. Changes in releases from reservoirs upstream of the study area, modified diversion of Sacramento River flows at Georgianna Slough and Delta Cross Channel, and modified diversions from south Delta channels (Operational Scenario G) would not result in the permanent reduction in acreage of a sensitive natural community in the study area. Flow levels in the upstream rivers would not change such that the acreage of tidal perennial aquatic community would be reduced on a permanent basis. Some minor increases and some decreases would be expected to occur during some seasons and in some water-year types, but there would be no permanent loss. Similarly, modified diversions of Sacramento River flows at Georgianna Slough and Delta Cross Channel would not result in a permanent reduction in tidal perennial aquatic community downstream of these diversions. Flow volumes in these two diversions and in the downstream channels that had been dredged (Middle River and Victoria Canal) would increase under certain Sacramento River flow conditions and water year types. However, tidal influence in the Sacramento River and Delta waterways would continue to be dominant such that there would be no significant change in water levels that might affect in-stream and adjacent vegetation. Modified diversions from south Delta channels would not create a reduction in this natural community.
- *Access road, water conveyance facility and levee repair*. Periodic repair of access roads, water conveyance facilities and levees associated with the BDCP actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in tidal perennial aquatic habitats. This activity could lead to increased soil erosion, turbidity and runoff entering tidal

perennial aquatic habitats. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan*. Any vegetation removal or earth work adjacent to or within aquatic habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management*. Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites. Vegetation management is also the principal activity associated with *CM13 Invasive Aquatic Vegetation Control*, and is consistent with BDCP Objective TRANPC2.1. Use of herbicides to control nuisance vegetation could pose a long-term hazard to tidal perennial aquatic natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to tidal perennial aquatic areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the BDCP to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments are described in Appendix 3B, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

  Herbicides to remove aquatic invasive species as part of CM13 would be used to restore the normal ecological function of tidal aquatic habitats in planned restoration areas. The treatment activities would be conducted in concert with the California Department of Boating and Waterways' invasive species removal program. Eliminating large stands of water hyacinth and Brazilian waterweed would improve habitat conditions for some aquatic species by removing cover for nonnative predators, improving water flow and removing barriers to movement (see Chapter 11, *Fish and Aquatic Resources*). These habitat changes should also benefit terrestrial species that use tidal perennial aquatic natural community for movement corridors and for foraging. Vegetation management effects on individual species are discussed in the species sections on following pages.

- *Channel dredging*. Long-term operation of the Alternative 9 diversions on the Sacramento River (Georgianna Slough and Delta Cross Channel) would include periodic dredging of sediments that might accumulate in front of intake and fish screens. Maintenance dredging would also be required in Middle River and Victoria Canal to maintain channel capacity. The dredging would occur in tidal perennial aquatic natural community and would result in short-term increases in turbidity and disturbance of the substrate. These conditions would not eliminate the community, but would diminish its value for special-status and common species that rely on it for movement corridor or foraging area. The individual species effects are discussed later in this chapter. *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities* are part of the Plan and would require actions to avoid or minimize dredging effects on tidal perennial aquatic habitats.

- *Habitat enhancement*. The BDCP includes a long-term management element for the natural communities within the Plan Area (CM11). For tidal perennial aquatic natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of tidal perennial aquatic natural community in the study area through changes in flow patterns and changes in periodic flooding of this community. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the Plan, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small reductions in acreage, these reductions would be greatly offset by restoration activities planned as part of *CM4 Tidal Natural Communities Restoration*. The management actions associated with levee repair, periodic dredging and control of invasive plant species would also result in a long-term benefit to the species associated with tidal perennial aquatic habitats by improving water movement.

***NEPA Effects*:** Ongoing operation, maintenance and management activities associated with Alternative 9 would not result in a net permanent reduction in the tidal perennial aquatic natural community within the study area. Therefore, there would be no adverse effect to the community.

***CEQA Conclusion*:** The operation and maintenance activities associated with Alternative 9 would have the potential to create minor losses in total acreage of tidal perennial aquatic natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM3, AMM4, AMM5, AMM6, and AMM10 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would create positive effects, including improved water movement in these habitats. Long-term restoration activities associated with *CM4 Tidal Natural Communities Restoration* would greatly expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in the acreage and value of this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact.

Tidal Brackish Emergent Wetland

Construction, operation, maintenance and management associated with the conservation components of Alternative 9 would have no adverse effect on the habitats associated with the tidal brackish emergent wetland natural community. Habitat restoration and construction associated with CM1, CM2, CM5, and CM6 would not remove tidal brackish emergent wetland; levee breaching and minor construction associated with CM4 may temporarily remove small amounts of this natural community (see Table 12-9-2). Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP to benefit the tidal brackish emergent wetland natural community.

- Restore and protect 65,000 acres of tidal natural communities and transitional uplands to accommodate sea level rise (Objective L1.3 associated with CM4).
- Within the restored and protected tidal natural communities and transitional uplands, include sufficient transitional uplands along the fringes of restored brackish and freshwater tidal emergent wetlands to accommodate up to 3 feet of sea level rise where possible and allow for the future upslope establishment of tidal emergent wetland communities (Objective L1.7, associated with CM4).
- Within the restored and protected tidal natural communities and transitional uplands, restore or create at least 6,000 acres of tidal brackish emergent wetland in Conservation Zone 11 (Objective TBEWNC1.1 associated with CM4).
- Restore connectivity to isolated patches of tidal brackish emergent marsh where isolation has reduced effective use of these marshes by the species that depend on them (Objective TBEWNC1.3 associated with CM4).
- Create topographic heterogeneity in restored tidal brackish emergent wetland to provide variation in inundation characteristics and vegetative composition (Objective TBEWNC1.4 associated with CM4).
- Limit perennial pepperweed to no more than 10% cover in tidal brackish emergent wetland natural community within the reserve system (Objective TBEWNC2.1 associated with CM11).

There is a variety of other, less specific conservation goals and objectives in BDCP Chapter 3, Section 3.3 that would improve the value of tidal brackish emergent wetland natural community for terrestrial species. As explained below, with the restoration and enhancement of these amounts of habitat, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-2. Changes in Tidal Brackish Emergent Wetland Natural Community Associated with Alternative 9 (acres)[a]

	Permanent		Temporary		Periodic[d]	
Conservation Measure[b]	NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	0	0	0	0	0	0
CM2	0	0	0	0	0	0
CM4	Unk.	Unk.	Unk.	Unk.	0	0
CM5	0	0	0	0	0	0
CM6	0	0	0	0	0	0
TOTAL IMPACTS	**0**	**0**	**0**	**0**	**0**	**0**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only.

NT = near-term
LLT = late long-term
Unk. = unknown

Impact BIO-4: Changes in Tidal Brackish Emergent Wetland Natural Community as a Result of Implementing BDCP Conservation Measures

Construction of the Alternative 9 water conveyance facilities (CM1) would not affect tidal brackish emergent wetland natural community.

Restoration of tidal marsh habitats associated with CM4 would require site preparation, earthwork, and other site activities that could remove tidal brackish emergent wetland. Levee modifications, grading or contouring, filling to compensate for land subsidence, and creation of new channels could also result in the removal of tidal brackish emergent wetland. All of this construction and land modification activity that could affect tidal brackish emergent wetland would occur in Suisun Marsh (CZ 11). The acreage of loss has not been calculated because the specific locations for site preparation and earthwork have not been identified, but the loss would likely be very small (less than 1 acre). These activities would occur through the course of the CM4 restoration program. The restoration elements of CM4 would greatly exceed any of the short-term losses described above. At least 6,000 acres of tidal brackish emergent wetland would be restored in the Plan Area (BDCP Objective TBEWNC1.1, associated with CM4), with 2,000 acres of restoration occurring in the near-term timeframe. In addition, the habitat and ecosystem functions of BDCP restored tidal brackish emergent wetland would be maintained and enhanced (CM11). The BDCP beneficial effects evaluation of Alternative 4 (BDCP Chapter 5, Section 5.4.3.2) states that at least 6,000 acres of tidal brackish emergent wetland community would be restored in CZ 11, and that tidal natural communities restoration would decrease habitat fragmentation by providing additional connectivity between isolated patches of tidal brackish emergent wetland. These same conservation actions would be implemented under Alternative 9.

The restoration activities associated with CM4 in Suisun Marsh would result in other effects that could alter the habitat value of tidal brackish emergent wetland. Disturbances associated with levee breaching and grading or contouring would increase opportunities for the introduction or spread of invasive species. Implementation of CM11 would limit this risk through invasive species control and wetland management and enhancement activities to support native species. Tidal flooding of dry areas could also increase the bioavailability of methylmercury in Suisun Marsh. Site-specific conditions would dictate the significance of this hazard to tidal brackish marsh vegetation and associated wildlife. According to the Suisun Marsh Plan EIR/EIS (Bureau of Reclamation et al. 2010, pg. 5.2-18), marsh creation may generate less methylmercury than is currently being generated by managed wetlands. However, this has not been confirmed through comprehensive studies. Because of the difficulty in assessing this risk at a programmatic level, it will need to be considered at a project level. Site-specific restoration plans that address the creation and mobilization of mercury, and monitoring and adaptive management as described in *CM12 Methylmercury Management*, would be available to address the uncertainty of methylmercury levels in restored tidal marsh. Water temperature fluctuations in newly created marsh and the potential for increased nitrogen deposition associated with construction vehicles are also issues of concern that are difficult to quantify at the current stage of restoration design. None of these effects is expected to limit the extent or value of tidal brackish emergent wetland in the study area.

NEPA Effects: The increase of tidal brackish emergent wetland associated with CM4 would be a beneficial effect on the natural community.

CEQA Conclusion: Tidal brackish emergent wetland natural community could experience small losses in acreage in Suisun Marsh (CZ 11) as a result of the large-scale tidal marsh restoration planned as part of CM4. These losses (expected to not exceed 1 acre) would be associated with levee modification, site preparation and other earthwork needed to expose diked lands to tidal influence. Because at least 6,000 acres of tidal brackish emergent wetland would be restored in the Plan Area as part of CM4, including 2,000 acres restored in the near-term timeframe, there would be a large increase in tidal brackish emergent wetland both in the near-term and over the life of the Plan. Indirect effects associated with the expansion of tidal brackish emergent wetland natural community, including the potential spread of invasive species, the generation of methylmercury, increases in marsh water temperatures, and increased nitrogen deposition are not expected to have a significant impact on this natural community in the study area. Therefore, this impact would be beneficial.

Impact BIO-5: Modification of Tidal Brackish Emergent Wetland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 9 are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the BDCP facilities and conservation lands that could affect tidal brackish emergent wetland natural community in the study area. The ongoing actions include the diversion of Sacramento River flows at two newly screened sites at Georgianna Slough and Delta Cross Channel in the north Delta, the operation of multiple operable barriers in Delta waterways, and modified diversions from south Delta channels. These actions are associated with CM1 (see the impact discussion above for effects associated with CM2). The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (CM11), levee repair and replacement of levee armoring, channel dredging at the two diversions with fish screens and in the Middle River and Victoria Canal, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and modified diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, modified diversion of Sacramento River flows at Georgianna Slough and Delta Cross Channel, and modified diversions from south Delta channels (Operational Scenario G) would not result in the permanent reduction in acreage of the tidal brackish emergent wetland natural community in the study area. Flow levels in the upstream rivers would not affect tidal brackish emergent wetland because this community does not exist along upstream rivers. Modified diversions of Sacramento River flows at Georgianna Slough and Delta Cross Channel would not result in a permanent reduction in tidal brackish emergent wetland community downstream of these diversions. Flow volumes in these two diversions and in the downstream channels that had been dredged (Middle River and Victoria Canal) would increase under certain Sacramento River flow conditions and water year types. However, tidal influence in the Sacramento River and Delta waterways would continue to be dominant such that there would be no substantial change in water levels that might affect in-stream and adjacent vegetation. Modified diversions from south Delta channels would not create a reduction in this natural community.

- *Access road and levee repair*. Periodic repair of access roads and levees associated with the BDCP actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in tidal brackish emergent wetland habitats. This activity could lead to increased soil erosion, turbidity and runoff entering these habitats. The activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan*. Any vegetation removal or earth work adjacent to or within aquatic habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management*. Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of restoration sites (*CM11 Natural Communities Enhancement and Management)*. Use of herbicides to control nuisance vegetation could pose a long-term hazard to tidal brackish emergent wetland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to wetland areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the BDCP to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments are described in Appendix 3B, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic environments would also reduce the risk of affecting natural communities adjacent to levees associated with tidal wetland restoration activities.

- *Channel dredging*. Long-term maintenance of tidal channels that support wetland expansion in Suisun Marsh would include periodic dredging of sediments. The dredging would occur adjacent to tidal brackish emergent wetland natural community and would result in short-term increases in turbidity and disturbance of the substrate. These conditions would not eliminate the community, but would diminish its value in the short term for special-status and common species that rely on it for cover, movement corridor or foraging area. The individual species effects are discussed later in this chapter. *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities* are part of the Plan and would require actions to avoid or minimize dredging effects on adjacent sensitive vegetation.

- *Habitat enhancement*. The BDCP includes a long-term management element for the natural communities within the Plan Area (CM11). For tidal brackish emergent wetland natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage and value of tidal brackish emergent wetland natural community in the study area through water operations, levee and road maintenance, channel dredging and vegetation management in or adjacent to this community. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the Plan, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be greatly offset by restoration activities planned as part of *CM4 Tidal Natural Communities Restoration*. The management actions associated with levee repair, periodic dredging and control of invasive plant species would also result in a long-term benefit to the species associated with tidal brackish emergent wetland habitats by improving water movement.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 9 would not result in a net permanent reduction in the tidal brackish emergent wetland natural community within the study area. Therefore, there would be no adverse effect on this community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 9 would have the potential to create minor changes (not exceeding 1 acre) in total acreage of tidal brackish emergent wetland natural community in Suisun Marsh, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM3, AMM4, AMM5, AMM6, and AMM10 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would create positive effects, including improved water movement in these habitats. Long-term restoration activities associated with *CM4 Tidal Natural Communities Restoration* would greatly expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact.

Tidal Freshwater Emergent Wetland

Construction, operation, maintenance and management associated with the conservation components of Alternative 9 would have no long-term adverse effects on the habitats associated with the tidal freshwater emergent wetland natural community. Initial development and construction of CM1, CM2, CM4, CM5, and CM6 would result in both permanent and temporary removal of this community (Table 12-9-3). Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit the tidal freshwater emergent wetland natural community.

- Restore and protect 65,000 acres of tidal natural communities and transitional uplands to accommodate sea level rise (Objective L1.3 associated with CM4).
- Within the 65,000 acres of tidal natural communities and transitional uplands, include sufficient transitional uplands along the fringes of restored brackish and freshwater tidal emergent wetlands to accommodate up to 3 feet of sea level rise where possible and allow for the future upslope establishment of tidal emergent wetland communities (Objective L1.7, associated with CM4).
- Within the 65,000 acres of tidal natural communities, restore or create at least 24,000 acres of tidal freshwater emergent wetland in Conservation Zones 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1, associated with CM4).
- Restore tidal freshwater emergent wetlands in areas that increase connectivity among conservation lands (Objective TFEWNC1.2, associated with CM4).
- Restore and sustain a diversity of marsh vegetation that reflects historical species compositions and high structural complexity (Objective TFEWNC2.1, associated with CM4).
- Create topographic heterogeneity in restored tidal freshwater emergent wetland to provide variation in inundation characteristics and vegetative composition (Objective TFEWNC2.2, associated with CM4).

There is a variety of other, less specific conservation goals and objectives in BDCP Chapter 3, Section 3.3 that would improve the value of tidal freshwater emergent wetland natural community for terrestrial species. As explained below, with the restoration and enhancement of these amounts of habitat, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-3. Changes in Tidal Freshwater Emergent Wetland Natural Community Associated with Alternative 9 (acres)[a]

	Permanent		Temporary		Periodic[d]	
Conservation Measure[b]	NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	62	62	123	123		
CM2	6	6	0	0	24–58

CM5	0	1	0	1		3
CM6	Unk.	Unk.	Unk.	Unk.		
TOTAL IMPACTS	**69**	**70**	**123**	**124**	**24–58**	**3**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
Unk. = unknown

Impact BIO-6: Changes in Tidal Freshwater Emergent Wetland Natural Community as a Result of Implementing BDCP Conservation Measures

Construction and land grading activities that would accompany the implementation of CM1, CM2, CM4, CM5, and CM6 would permanently eliminate an estimated 70 acres and temporarily remove 124 acres of tidal freshwater emergent wetland natural community in the study area. These modifications represent approximately 2% of the 8,856 acres of the community that is mapped in the study area. The majority of the permanent and temporary losses would occur during the first 10 years of Alternative 9 implementation, as water conveyance facilities are constructed and habitat restoration is initiated. Natural communities restoration would add at least 24,000 acres of tidal freshwater emergent wetland natural community during the course of Plan restoration activities, which would greatly expand the area of this natural community and offset the losses. The BDCP beneficial effects evaluation of Alternative 4 (BDCP Chapter 5, Section 5.4.4.2) states that the implementation of *CM4 Tidal Natural Communities Restoration* will restore at least 24,000 acres of tidal freshwater emergent wetland community in Cache Slough (Conservation Zones 1, 2, and 3), the Cosumnes/Mokelumne (Conservation Zone 4), West Delta (Conservation Zone 5 and 6), and South Delta (Conservation Zone 7) ROAs. The BDCP evaluation also states that the objectives in the Plan will promote vegetation diversity and structural complexity (as incorporated into the restoration design) in restored tidal freshwater marsh. These same conservation actions would be implemented under Alternative 9.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of the Alternative 9 water conveyance facilities would permanently remove 62 acres and temporarily remove 123 acres of tidal freshwater emergent wetland community. Most of the permanent loss would occur at the channel dredging sites within the Middle River and Victoria Canal. Middle River dredging would occur from Victoria Canal north to Mildred Island, while Victoria Canal dredging would extend from Middle River westward to Old River. This community exists as fringing vegetation along the banks of these channels and also as fringing vegetation on the islands within the channels. Smaller areas would be permanently lost at operable barrier sites adjacent to Middle River and San Joaquin River. Temporary tidal freshwater emergent wetland removal would occur at dredging work areas along Victoria Canal and Middle River. Detailed mapping of these facilities in relation to natural communities can be found in the Terrestrial Biology Mapbook. These losses would take place during the near-term construction period.

  There is the potential for increased nitrogen deposition associated with construction vehicles during the construction phase of CM1. BDCP Appendix 5.J, Attachment 5J.A, *Construction-Related Nitrogen Deposition on BDCP Natural Communities,* addresses this issue in detail. It has been concluded that this potential deposition would pose a low risk of changing tidal freshwater emergent wetland natural community because the construction would contribute a negligible amount of nitrogen to regional projected emissions. No adverse effect is expected.

- *CM2 Yolo Bypass Fisheries Enhancement*: Implementation of CM2 involves a number of construction or channel modification activities within the Yolo and Sacramento Bypasses, including improvements in flow through the west side channel of the bypass, Putah Creek realignment activities, Lisbon Weir modification and Sacramento Weir improvements. All of these activities could involve excavation and grading in tidal freshwater emergent wetland areas to improve passage of fish through the bypasses. Based on hypothetical construction footprints, a total of 6 acres could be permanently lost to these activities. The loss is expected to occur in the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration*: Based on hypothetical footprints of this restoration activity, initial land grading and levee modification could permanently remove 1 acre of tidal freshwater emergent wetland natural community. This loss would occur in the near-term timeframe and would occur throughout the ROAs identified for tidal wetland restoration. At the same time, an estimated 24,000 acres of tidal freshwater emergent wetland community would be restored during tidal habitat restoration, consistent with BDCP Objective TFEWNC1.1, associated with CM4. Approximately 8,850 acres of the restoration would occur during the first 10 years of Alternative 9 implementation, which would coincide with the timeframe of water conveyance facilities construction. The remaining restoration would be spread over the following 30 years. Tidal wetland communities restoration is expected to be focused in the ROAs identified in Figure 12-1. Restoration would be located and designed to improve habitat connectivity (Objective TFEWNC1.2), improve marsh species diversity (Objective TFEWNC2.1), and provide variation in inundation characteristics (Objective TFEWNC2.2). Some of the restoration would occur in the lower Yolo Bypass, but restoration would also be spread among the Suisun Marsh, South Delta, Cosumnes/Mokelumne and West Delta ROAs.

  The restoration activities associated with CM4 in the Plan Area ROAs would result in other effects that could alter the habitat value of tidal freshwater emergent wetland. Disturbances associated with levee breaching and grading or contouring would increase opportunities for the introduction or spread of invasive species. Implementation of CM11 would limit this risk through invasive species control and wetland management and enhancement activities to support native species. Flooding of dry areas for tidal freshwater marsh creation could also increase the bioavailability of methylmercury, especially in the Cache Slough, Cosumnes/Mokelumne and Suisun Marsh ROAs. Site-specific conditions would dictate the significance of this hazard to marsh vegetation and associated wildlife. Because of the difficulty in assessing this risk at a programmatic level, it will need to be considered at a project level. Site-specific restoration plans that address the creation and mobilization of mercury, and monitoring and adaptive management as described in *CM12 Methylmercury Management*, would be available to address the uncertainty of methylmercury levels in restored tidal marsh.

Water temperature fluctuations in newly created marsh is also an issue of concern that is difficult to quantify at the current stage of restoration design. None of these effects is expected to limit the extent or value of tidal freshwater emergent wetland in the study area.

- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration levee construction would permanently remove 1 acre and temporarily remove 1 acre of tidal freshwater emergent wetland habitat. The construction-related losses would be considered a permanent removal of the habitats directly affected. The majority of seasonally inundated floodplain restoration is expected to occur along the lower San Joaquin River in the south and central Delta areas. This activity is scheduled to start following construction of water conveyance facilities, which is expected to take 10 years. Floodplain restoration along the San Joaquin River would improve connectivity for a variety of species that rely on freshwater marsh and riparian habitats. The regional and Plan Area landscape linkages along the San Joaquin River are included in Figure 12-2.

- *CM6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in filling of small amounts of tidal freshwater emergent wetland habitat along 20 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur on narrow strips of habitat, including levees and channel banks. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

During the near-term timeframe (the first 10 years of BDCP implementation), Alternative 9 would affect the tidal freshwater emergent wetland natural community through CM1 construction losses (62 acres permanent and 123 acres temporary), CM2 construction losses (6 acres permanent), and CM4 construction losses (1 acre permanent). These losses would occur primarily in the southern and central Delta along Middle River and Victoria Canal, north and east of Clifton Court Forebay. Smaller areas would be lost at operable barrier sites along Middle River and San Joaquin River in the central Delta, and at various locations within the Yolo Bypass and the tidal restoration ROAs.

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and restoration actions associated with BDCP conservation components. Loss of tidal freshwater emergent wetland natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. However, the creation of 8,850 acres of tidal freshwater emergent wetland natural community as part of CM4 during the first 10 years of Alternative 9 implementation would more than offset this near-term loss, avoiding any adverse effect. Typical project-level mitigation ratios (1:1 for restoration) would indicate that 192 acres of restoration would be needed to offset (i.e., mitigate) the 192 acres of loss (the total permanent and temporary near-term effects listed in Table 12-9-3).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM10 Restoration of Temporarily Affected Natural Communities.* All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Late Long-Term Timeframe

Implementation of Alternative 9 as a whole would result in relatively minor (approximately 2%) losses of tidal freshwater emergent wetland community in the study area. These losses (70 acres of permanent and 124 acres of temporary loss) would be largely associated with construction of the water conveyance facilities (CM1), construction of Yolo Bypass fish improvements (CM2), and levee modification and land grading associated with tidal marsh restoration (CM4) and floodplain restoration (CM5). The CM4 and CM5 losses would occur during the course of the CM4 and CM5 conservation actions at various tidal and floodplain restoration sites throughout the study area. By the end of the Plan timeframe, a total of 24,000 acres of this natural community would be restored. The restoration would occur over a wide region of the study area, including within the Suisun Marsh, Cosumnes/Mokelumne, Cache Slough, South Delta and Cosumnes/Mokelumne ROAs (see Figure 12-1).

NEPA Effects: The creation of 8,850 acres of tidal freshwater emergent wetland natural community as part of CM4 during the first 10 years of Alternative 9 implementation would more than offset the construction and inundation-related effects of implementing CM1, CM2, CM4 and CM5, avoiding any adverse effect in the near-term. Because of the 24,000 acres of tidal freshwater emergent wetland restoration that would occur over the course of the Plan, Alternative 9 would not result in a net long-term reduction in the acreage of a sensitive natural community; the effect would be beneficial.

CEQA Conclusion:

Near-Term Timeframe

Alternative 9 would result in the loss of approximately 192 acres of tidal freshwater emergent wetland natural community due to construction of the water conveyance facilities (CM1) and fish passage improvements (CM2), and tidal marsh restoration (CM4) in the near-term. The construction losses would occur primarily in the southern and central Delta along Middle River and Victoria Canal, north and east of Clifton Court Forebay. Smaller areas would be lost at operable barrier sites along Middle River and San Joaquin River in the central Delta, and at various locations within the Yolo Bypass and the tidal restoration ROAs. The losses would be spread across a 10-year near-term timeframe and would be offset by planned restoration of 8,850 acres of tidal freshwater emergent wetland natural community scheduled for the first 10 years of Alternative 9 implementation (CM4). AMM1, AMM2, AMM6, AMM7, and AMM10 would also be implemented to minimize impacts. Because of these offsetting near-term restoration activities and AMMs, impacts would be less than significant. Typical project-level mitigation ratios (1:1 for restoration) would indicate that 192 acres of restoration would be needed to offset (i.e., mitigate) the 192 acres of loss. The restoration would be initiated at the beginning of Alternative 9 implementation to minimize any time lag in the availability of this habitat to special-status species, and would result in a net gain in acreage of this sensitive natural community.

Late Long-Term Timeframe

At the end of the Plan period, 194 acres of this community would be lost to conservation activities and 24,000 acres of this community would be restored. There would be no net permanent reduction in the acreage and value of this sensitive natural community within the study area. Therefore, Alternative 9 would not have a substantial adverse effect on this natural community; the impact would be beneficial.

Impact BIO-7: Increased Frequency, Magnitude and Duration of Periodic Inundation of Tidal Freshwater Emergent Wetland Natural Community

Two Alternative 9 conservation measures would modify the inundation/flooding regimes of both natural and man-made waterways in the study area. CM2, which is designed to improve fish passage and shallow flooded habitat for Delta fishes in the Yolo Bypass, would increase periodic inundation of tidal freshwater emergent wetland natural community on small acreages, while CM5 would expose this community to additional flooding as channel margins are modified and levees are set back to improve fish habitat along some of the major rivers and waterways throughout the study area.

- *CM2 Yolo Bypass Fisheries Enhancement*: Operation of the Yolo Bypass under Alternative 9 would result in an increase in the frequency, magnitude and duration of inundation of 24–58 acres of tidal freshwater emergent wetland natural community. The methods used to estimate these inundation acreages are described in BDCP Appendix 5.J, *Effects on Natural Communities, Wildlife, and Plants*. The area more frequently inundated would vary with the flow volume that would pass through the newly constructed notch in the Fremont Weir. The 24-acre increase in inundation would be associated with a notch flow of 1,000 cubic feet per second (cfs), and the 58-acre increase would result from a notch flow of 4,000 cfs. Plan-related increases in flow through Fremont Weir would be expected in 30% of the years. Most of this community occurs in the southern section of the bypass on Liberty Island, on the fringes of tidal perennial aquatic habitats. Smaller areas are scattered among the cropland within the bypass, south of Interstate 80. The anticipated change in management of flows in the Yolo Bypass includes more frequent releases in flows into the bypass from the Fremont and Sacramento Weirs, and in some years, later releases into the bypass in spring months (April and May). The modification of periodic inundation events would not adversely affect the ecological function of tidal freshwater emergent wetland habitats and would not substantially modify its value for special-status or common terrestrial species. The plants in this natural community are adapted to periodic inundation events within the Yolo Bypass. The effects of this inundation on wildlife and plant species are described in detail in later sections of this chapter.
- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration would result in a seasonal increase in the frequency and duration of inundation of 3 acres of tidal freshwater emergent wetland habitats. Specific locations for this restoration activity have not been identified, but they would likely be focused in the south Delta area, along the major rivers and Delta channels. The reconnection of these wetlands to stream flooding events would be beneficial to their ecological function, especially as they relate to BDCP target terrestrial and

aquatic species. Foraging activity and refuge sites would be expanded into areas currently unavailable or infrequently available to some aquatic species.

In summary, 27–61 acres of tidal freshwater emergent wetland natural community in the study area would be subjected to more frequent inundation as a result of implementing two Alternative 9 conservation measures (CM2 and CM5). Tidal freshwater emergent wetland natural community is a habitat of great value to both terrestrial and aquatic species in the study area.

NEPA Effects: Periodic inundation of tidal freshwater emergent wetland natural community associated with Alternative 9 would not result in a net permanent reduction in the acreage and value of this community in the study area. There would be no adverse effect.

CEQA Conclusion: An estimated 27–61 acres of tidal freshwater emergent wetland natural community in the study area would be subjected to more frequent inundation as a result of implementing CM2 and CM5 under Alternative 9. This community is of great value to aquatic and terrestrial species in the study area. The periodic inundation would not result in a net permanent reduction in the acreage and value of this community in the study area. Therefore, there would be a less-than-significant impact on the community.

Impact BIO-8: Modification of Tidal Freshwater Emergent Wetland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 9 are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the BDCP facilities and conservation lands that could affect tidal freshwater emergent wetland natural community in the study area. The ongoing actions include the diversion of Sacramento River flows at two newly screened sites at Georgianna Slough and Delta Cross Channel in the north Delta, the operation of multiple operable barriers in Delta waterways, and modified diversions from south Delta channels. These actions are associated with CM1 (see the impact discussion above for effects associated with CM2). The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (CM13), levee repair and replacement of levee armoring, channel dredging at the two diversions with fish screens and in the Middle River and Victoria Canal, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and modified diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, modified diversion of Sacramento River flows at Georgianna Slough and Delta Cross Channel, and modified diversions from south Delta channels (Operational Scenario G) would not result in the permanent reduction in acreage of a sensitive natural community in the study area. Flow levels in the upstream rivers would not change such that the acreage of tidal freshwater emergent wetland community would be reduced on a permanent basis. Some minor increases and some decreases would be expected to occur during some seasons and in some water-year types, but there would be no permanent loss. Similarly, modified diversions of Sacramento River flows at Georgianna Slough and Delta Cross Channel would not result in a permanent reduction in tidal freshwater emergent wetland community downstream of these diversions. Flow volumes in these two diversions and in the downstream channels that had been dredged (Middle River and Victoria Canal) would increase under certain Sacramento River flow conditions and water year types. However, tidal influence in the Sacramento River and Delta waterways would continue to be dominant such that there would be no substantial change in water levels that might affect in-stream and adjacent vegetation. Modified diversions from south Delta channels would not create a reduction in this natural community.

- *Access road, water conveyance facility and levee repair*. Periodic repair of access roads, water conveyance facilities and levees associated with the BDCP actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in or adjacent to tidal freshwater emergent wetland habitats. This activity could lead to increased soil erosion, turbidity and runoff entering tidal aquatic habitats. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan*. Any vegetation removal or earth work adjacent to or within emergent wetland habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management*. Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*CM11 Natural Communities Enhancement and Management*). Use of herbicides to control nuisance vegetation could pose a long-term hazard to tidal freshwater emergent wetland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to tidal aquatic areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the BDCP to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments are described in Appendix 3B, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Channel dredging*. Long-term operation of the Alternative 9 diversions on the Sacramento River (Georgianna Slough and Delta Cross Channel) would include periodic dredging of sediments that might accumulate in front of intake and fish screens. Maintenance dredging would also be required in Middle River and Victoria Canal to maintain channel capacity. The dredging would occur in the vicinity of tidal freshwater emergent natural community and would result in short-term increases in turbidity and disturbance of the substrate. These conditions would not eliminate the community, but would diminish its value for special-status and common species that rely on it for nesting habitat, cover or foraging area. The individual species effects are discussed later in this chapter. *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities* are part of the Plan and would require actions to avoid or minimize dredging effects on tidal freshwater emergent wetland habitats.

- *Habitat enhancement*. The BDCP includes a long-term management element for the natural communities within the Plan Area (CM11). For tidal freshwater emergent wetland community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of tidal freshwater emergent wetland natural community in the study area through changes in flow patterns, channel and levee maintenance, and vegetation control. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the Plan, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be greatly offset by restoration activities planned as part of *CM4 Tidal Natural Communities Restoration*. The management actions associated with levee repair, periodic dredging and control of invasive plant species would also result in a long-term benefit to the species associated with tidal freshwater emergent wetland habitats by improving water movement.

***NEPA Effects*:** Ongoing operation, maintenance and management activities associated with Alternative 9 would not result in a net permanent reduction in the tidal freshwater emergent wetland natural community within the study area. Therefore, there would be no adverse effect on this natural community.

***CEQA Conclusion*:** The operation and maintenance activities associated with Alternative 9 would have the potential to create minor changes in total acreage of tidal freshwater emergent wetland natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM3, AMM4, AMM5, AMM6, and AMM10 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would create positive effects, including improved water movement in these habitats. Long-term restoration activities associated with *CM4 Tidal Natural Communities Restoration* would expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact on the community.

Valley/Foothill Riparian

Construction, operation, maintenance and management associated with the conservation components of Alternative 9 would have a near-term adverse effect on the habitats associated with the valley/foothill riparian natural community. Initial development and construction of CM1, CM2, CM4, CM5, and CM6 would result in both permanent and temporary removal of this community (see Table 12-9-4). Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit the valley/foothill riparian natural community.

- Restore or create 5,000 acres of valley/foothill riparian natural community, with at least 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM7).
- Protect 750 acres of existing valley/foothill riparian natural community in Conservation Zone 7 by year 10 (Objective VFRNC1.2, associated with CM3).
- Maintain 1,000 acres of early- to mid-successional vegetation with a well-developed understory of dense shrubs on restored seasonally inundated floodplain (Objective VFRNC2.2, associated with CM5 and CM7).
- Maintain 500 acres of mature riparian forest in Conservation Zones 4 or 7 (Objective VFRNC2.3, associated with CM3 and CM7).
- Maintain 500 acres of mature riparian forest (VFRNC2.3) intermixed with a portion of the early- to late-successional riparian vegetation (VFRNC2.2), in large blocks with a minimum patch size of 50 acres and minimum width of 330 feet (Objective VFRNC2.4, associated with CM3 and CM7).
- Maintain or increase abundance and distribution of valley/foothill riparian natural community vegetation alliances that are rare or uncommon as recognized by California Department of Fish and Game (2010), such as button willow thickets alliance and blue elderberry stands alliance (Objective VFRNC3.1).

There is a variety of other, less specific conservation goals and objectives in BDCP Chapter 3, Section 3.3 that would improve the value of valley/foothill riparian natural community for terrestrial species. As explained below, with the restoration and enhancement of these amounts of habitat, in addition to implementation of AMMs and mitigation, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-4. Changes in Valley/Foothill Riparian Natural Community Associated with Alternative 9 (acres)[a]

	Permanent		Temporary		Periodic[d]	
Conservation Measure[b]	NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	61	61	248	248	0	0
CM2	89	89	88	88	51–92	0
CM4	298	552	0	0	0	0
CM5	0	43	0	35	0	266
CM6	Unk.	Unk.	Unk.	Unk.	0	0
TOTAL IMPACTS	**448**	**745**	**336**	**371**	**51–92**	**266**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
Unk. = unknown

Impact BIO-9: Changes in Valley/Foothill Riparian Natural Community as a Result of Implementing BDCP Conservation Measures

Construction, channel dredging, land grading and habitat restoration activities that would accompany the implementation of CM1, CM2, CM4, CM5, and CM6 would permanently eliminate an estimated 745 acres and temporarily remove 371 acres of valley/foothill riparian natural community in the study area. These modifications represent approximately 6% of the 17,966 acres of the community that is mapped in the study area. The majority of the permanent and temporary losses would occur during the first 10 years of Alternative 9 implementation, as Delta channels are dredged, new diversion structures and operable barriers are constructed, and habitat restoration is initiated. Valley/foothill riparian protection (750 acres) and restoration (800 acres) would be initiated during the same period, which would partially offset the losses. By the end of the Plan period, 5,000 acres of this natural community would be restored. The BDCP beneficial effects analysis (BDCP Chapter 5, Section 5.4.5.2) indicates that implementation of Alternative 4 would restore or create 5,000 acres of riparian forest and scrub in Conservation Zones 1, 2, 4, 5, 6, and 7, with at least 3,000 acres occurring on restored seasonally inundated floodplain. Alternative 4 would also protect 750 acres of existing valley/foothill riparian natural community in Conservation Zone 7. These same conservation measures would be implemented under Alternative 9.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of the Alternative 9 water conveyance facilities would permanently remove 61 acres and temporarily remove 248 acres of valley/foothill riparian natural community. Most of the permanent loss would occur as wider and deeper channels are dredged in Middle River and Victoria Canal, and as operable barriers and new Sacramento River diversions are constructed in various waterways across the Delta. Much of the riparian vegetation in this area is composed of dense stands of willows, brambles and blackberry, and associated low profile woody plants. The principal facilities that would cause permanent losses and the general types of riparian vegetation that would be lost are listed below.
  - Victoria Canal dredging: small island patches of riparian dominated by California dogwood.
  - Middle River dredging: large and small patches of riparian on in-channel islands dominated by California dogwood, willow, mixed brambles, tules and bulrush.
  - Canal construction across Old River near Clifton Court Forebay–small patches of riparian on the river margins dominated by blackberry, willow and giant reed;
  - Diversion structures and operable barriers on Sacramento River at Georgianna Slough and Delta Cross Channel: corridors of mixed riparian including valley oak, white alder, willow, mixed brambles and deciduous shrublands.
  - Channel enlargement at the Sacramento River and Meadows Slough: narrow band of riparian dominated by valley oak along the Sacramento River and larger stands of valley oak and willow along Meadows Slough.
  - Operable barrier construction at Mokelumne River and Lost Slough: narrow bands of willow and walnut along the Mokelumne River and larger patches of mixed riparian including walnut, willow, mixed bramble, and white alder along Lost Slough.
  - Operable barrier construction at the San Joaquin River and Fishermans Cut: small patches of willow and mixed brambles.
  - Operable barrier construction on the San Joaquin River at the head of Old River: small stringers and patches of cottonwood, willow and valley oak along the San Joaquin River.

  Temporary losses of riparian community would occur primarily along Middle River between Victoria Canal and Mildred Island, where large dredging work areas and operable barrier work areas would be placed. Some of this vegetation may be temporarily removed as dredging progresses, while other areas may remain in place but be temporarily affected by sedimentation and equipment movement associated with dredging. The riparian vegetation in this area is also composed primarily of dense stands of willows, brambles and blackberry, and associated low profile woody plants. Refer to the Terrestrial Biology Mapbook for a more detailed view of these impact areas. These losses would take place during the near-term construction period.

- *CM2 Yolo Bypass Fisheries Enhancement*: Implementation of CM2 would involve a number of construction activities within the Yolo and Sacramento Bypasses, including Fremont Weir and stilling basin improvements, Putah Creek realignment activities, Lisbon Weir modification and Sacramento Weir improvements. All of these activities could involve excavation and grading in valley/foothill riparian areas to improve passage of fish through the bypasses. Based on hypothetical construction footprints, a total of 89 acres could be permanently lost and another 88 acres could be temporarily removed. Most of the riparian losses would occur at the north end of Yolo Bypass where major fish passage improvements are planned. This vegetation is a mix of valley oak, sycamore, cottonwood and willow trees. The riparian areas here are primarily small, disconnected patches with moderate to low value as wildlife movement corridors. Most of these patches lack structural complexity. Excavation to improve water movement in the Toe Drain and in the Sacramento Weir would remove similar vegetation. These losses would occur primarily in the near-term timeframe.

- *CM4 Tidal Natural Communities Restoration*: Based on the use of hypothetical restoration footprints, implementation of CM4 would permanently inundate or remove 552 acres of valley/foothill riparian community. The losses would be spread among most of the ROAs established for tidal restoration (see Figure 12-1). No losses would occur from Suisun Marsh restoration. These ROAs support a mix of riparian vegetation types, including valley oak stands, extensive willow and cottonwood stringers along waterways, and areas of scrub vegetation dominated by blackberry. These areas are considered of low to moderate habitat value (BDCP Chapter 5, Section 5.4.5). The actual loss of riparian habitat to marsh restoration would be expected to be smaller than predicted by use of the theoretical footprint. As marsh restoration projects were identified and planned, sites could be selected that avoid riparian areas as much as possible.
- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration levee construction would permanently remove 43 acres and temporarily remove 35 acres of valley/foothill riparian natural community. The construction-related losses would be considered a permanent removal of the habitats directly affected. These losses would be expected to occur along the San Joaquin River and other major waterways in CZ 7 (see Figure 12-1). This activity is scheduled to start following construction of water conveyance facilities, which is expected to take 10 years.
- *CM6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in removal of small amounts of valley/foothill riparian habitat along 20 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur along waterway margins where riparian habitat stringers exist, including levees and channel banks. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.
- *CM7 Riparian Natural Community Restoration*: The valley/foothill riparian natural community would be restored primarily in association with the tidal (CM4) and floodplain (CM5) restoration and channel margin enhancements (CM6). Following community-specific goals and objectives in the Plan, a total of 5,000 acres of this community would be restored (BDCP Objective VFRNC1.1) and 750 acres would be protected (BDCP Objective VFRNC1.2) over the life of the Plan. Approximately 800 acres would be restored and the entire 750 acres would be protected in the first 10 years of Plan implementation. Riparian restoration and protection would be focused in CZs 4 and 7 (BDCP Objective VFRNC2.3), with a goal of adding a 500-acre portion of the restoration in one or the other of these zones. A variety of successional stages would also be sought to benefit the variety of sensitive plant and animal species that rely on this natural community in the study area (BDCP Objective VFRNC2.4).

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

During the near-term timeframe (the first 10 years of BDCP implementation), Alternative 9 would affect the valley/foothill riparian natural community through CM1 construction losses (61 acres permanent and 248 acres temporary) and the CM2 construction losses (89 acres permanent and 88 acres temporary). These losses would occur primarily along Middle River as channel dredging proceeds, at various operable barrier and diversion structure construction sites scattered across the Delta, and in the northern Yolo Bypass. Approximately 298 acres of the inundation and construction-related loss from CM4 would occur in the near-term. These losses would occur throughout the ROAs mapped in Figure 12-1.

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and protection/restoration actions associated with BDCP conservation components. Loss of valley/foothill riparian natural community would be considered a loss in acreage of a sensitive natural community, and could be considered a loss of wetlands as defined in Section 404 of the CWA. As indicated above, much of this riparian loss would be in small patches or narrow strips along waterways, with limited structural complexity. The restoration of 800 acres (CM3) and protection (including significant enhancement) of 750 acres of valley/foothill riparian natural community (CM7) during the first 10 years of Alternative 9 implementation would partially offset this near-term loss. At least 400 acres of the protection is planned for the first 5 years of Alternative 9 implementation. The restoration areas would be large areas providing connectivity with existing riparian habitats and would include a variety of trees and shrubs to produce structural complexity. Typical project-level mitigation ratios (1:1 for restoration and 1:1 for protection) would indicate that 784 acres of protection and 784 acres of restoration would be needed to offset (i.e., mitigate) the 784 acres of near-term loss (the combination of permanent and temporary near-term losses listed in Table 12-9-4). The combined 1,550 acres of protection and restoration in the near-term, combined with Plan goals for protecting and restoring high-value riparian habitats, are designed to avoid a temporal lag in the value of riparian habitat available to sensitive species. The restoration and protection acreages contained in the BDCP would not be sufficient to provide the typical level of mitigation for this community; therefore, the effect of Alternative 9 would be adverse. Mitigation would be available to offset this effect.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM18 Swainson's Hawk.* All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Late Long-Term Timeframe

Implementation of Alternative 9 as a whole would result in an estimated 6% loss of valley/foothill riparian community in the study area. These losses (745 acres of permanent and 371 acres of temporary loss) would be largely associated with construction of the water conveyance facilities (CM1), construction of Yolo Bypass fish improvements (CM2), and inundation during tidal marsh restoration (CM4). Inundation losses would occur during the course of BDCP restoration activities at various tidal restoration sites throughout the study area. By the end of the Plan timeframe, a total of 5,000 acres of this natural community would be restored and 750 acres would be protected (CM7 and CM3, respectively). The restoration would occur primarily in CZs 4 and 7, in the Cosumnes/Mokelumne and South Delta ROAs (see Figure 12-1).

NEPA Effects: The restoration of 800 acres and protection (including significant enhancement) of 750 acres of valley/foothill riparian natural community as part of CM7 and CM3 during the first 10 years of Alternative 9 implementation would minimize the near-term loss of this community, but would result in an adverse effect. Because of the Plan's commitment to restoration of 5,000 acres and protection of 750 acres of valley/foothill riparian natural community during the course of the Plan, Alternative 9 would not result in a net long-term reduction in the acreage and value of a sensitive natural community; the effect would be beneficial.

CEQA Conclusion:

Near-Term Timeframe

Alternative 9 would result in the loss of approximately 784 acres of valley/foothill riparian natural community due to construction of the water conveyance facilities (CM1) and fish passage improvements (CM2), and inundation during tidal marsh restoration (CM4) in the near-term. These losses would occur primarily along Middle River as channel dredging proceeds, at various operable barrier and diversion structure construction sites scattered across the Delta, and in the northern Yolo Bypass. The construction losses would be spread across a 10-year near-term timeframe. These losses would be partially offset by planned restoration of 800 acres (CM7) and protection (including significant enhancement) of 750 acres (CM3) of valley/foothill riparian natural community scheduled for the first 10 years of Alternative 9 implementation. At least 400 acres of the protection is planned for the first 5 years of Alternative 9 implementation. Implementation of Plan goals for the location, patch size and composition of riparian community protection and restoration would aid in maintaining the value of riparian habitats in this near-term period. AMM1, AMM2, AMM6, AMM7, AMM10, and AMM18 would also be implemented to minimize impacts. In spite of these near-term restoration and protection activities and AMMs, impacts would be significant. Typical project-level mitigation ratios (1:1 for protection and 1:1 for restoration) would indicate that 784 acres of protection and 784 acres of restoration would be needed to offset (i.e., mitigate) the 784 acres of loss (the combination of permanent and temporary near-term losses listed in Table 12-9-4). Alternative 9 would be short 34 acres of protection in the near-term to meet typical mitigation ratios. The restoration would be initiated at the beginning of Alternative 9 implementation to minimize any time lag in the availability of this habitat to special-status species. With the implementation of Mitigation Measure BIO-9a, *Compensate for Loss of Valley/Foothill Riparian Natural Community*, the impact would be less than significant.

Late Long-Term Timeframe

At the end of the Plan period, 1,116 acres of valley/foothill riparian natural community would be permanently or temporarily removed by conservation actions, 5,000 acres would be restored and 750 acres would be protected. There would be no net permanent reduction in the acreage and value of this sensitive natural community within the study area. Therefore, Alternative 9 would not have a substantial adverse effect on this natural community; the impact would be beneficial.

Mitigation Measure BIO-9a: Compensate for Loss of Valley/Foothill Riparian Natural Community

To fully compensate for loss of valley/foothill riparian natural community as a result of implementing Alternative 9, DWR shall increase its near-term goals for protection of this natural community to 784 acres.

Impact BIO-10: Increased Frequency, Magnitude and Duration of Periodic Inundation of Valley/Foothill Riparian Natural Community

Two Alternative 9 conservation measures would modify the inundation/flooding regimes of both natural and man-made waterways in the study area. CM2, which is designed to improve fish passage and shallow flooded habitat for Delta fishes in the Yolo Bypass, would increase periodic inundation of valley/foothill riparian natural community at scattered locations, while CM5 would expose this community to additional flooding as channel margins are modified and levees are set back to improve fish habitat along some of the major rivers and waterways of the study area.

- *CM2 Yolo Bypass Fisheries Enhancement:* Operation of the Yolo Bypass under Alternative 9 would result in an increase in the frequency, magnitude and duration of inundation of 51–92 acres of valley/foothill riparian natural community. The area more frequently inundated would vary with the flows that would be passed through the newly constructed notch in the Fremont Weir. The 51 acres would be created by a notch flow of 8,000 cfs and the 92 acres would be created by a notch flow of 4,000 cfs. The methods used to estimate these inundation acreages are described in BDCP Appendix 5.J, *Effects on Natural Communities, Wildlife, and Plants*. These increased flow conditions would be expected to occur in no more than 30% of all years (see BDCP Chapter 5, Section 5.4.1.2). The valley/foothill riparian community occurs throughout the bypass, including a large acreage just below Fremont Weir in the north end of the bypass. There are other riparian habitat areas on Liberty Island, and, to a lesser extent, along the eastern and western edges of the bypass, including along the Tule Canal/Toe Drain, the west side channels and the Sacramento Bypass. The anticipated change in management of flows in the Yolo Bypass includes more frequent releases in flows into the bypass from the Fremont and Sacramento Weirs, and in some years, later releases into the bypass in spring months (April and May). The modification of periodic inundation events would not adversely affect riparian habitats, as they have persisted under similar high flows and extended inundation periods in the Yolo Bypass. The effects of this inundation on wildlife and plant species are described in detail in later sections of this chapter.
- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration would result in an increase in the frequency and duration of inundation of 266 acres of valley/foothill riparian habitats. Specific locations for this restoration activity have not been identified, but they would likely be focused in the south Delta area, along the major rivers and Delta channels in CZ 7 (see Figure 12-1). The reconnection of riparian vegetation to periodic stream flooding events would be beneficial to the ecological function of this natural community, especially in the germination and establishment of native riparian plants as flood scour increases.

In summary, 317–368 acres of valley/foothill riparian community in the study area would be subjected to more frequent inundation as a result of implementing two Alternative 9 conservation measures (CM2 and CM5). The valley/foothill riparian community is conditioned to and benefits from periodic inundation; therefore, periodic inundation would not result in a net permanent reduction in the acreage of this community in the study area. The increased inundation could create a beneficial effect on the community as it relates to germination and establishment of native riparian plants.

NEPA Effects: Increasing periodic inundation of valley/foothill riparian natural community in the Yolo Bypass and along south Delta waterways would have a beneficial effect on the community.

CEQA Conclusion: An estimated 317–368 acres of valley/foothill riparian community in the study area would be subjected to more frequent inundation as a result of implementing CM2 and CM5 under Alternative 9. The valley/foothill riparian community is conditioned to and benefits from periodic inundation; therefore, periodic inundation would not result in a net permanent reduction in the acreage of this community in the study area. Increasing periodic inundation of valley/foothill riparian natural community in the Yolo Bypass and along south Delta waterways would have a beneficial impact on the community.

Impact BIO-11: Modification of Valley/Foothill Riparian Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 9 are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the BDCP facilities and conservation lands that could affect valley/foothill riparian natural community in the study area. The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows at two new diversion structures at Georgianna Slough and Delta Cross Channel, the operation of multiple operable barriers in Delta waterways, modified diversions from south Delta channels, and recreational use of reserve areas. These actions are associated with CM1 and CM11 (see the impact discussion above for effects associated with CM2). The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (CM11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified releases and water levels in upstream reservoirs*. Modified releases and water levels at Shasta Lake, Lake Oroville, Whiskeytown Lake, Lewiston Lake, and Folsom Lake would not affect valley/foothill riparian natural community. The anticipated changes in water levels over time with Alternative 9, as compared to no action, would be slightly lower in the October to May timeframe. The small changes in frequency of higher water levels in these lakes would not substantially reduce the small patches of riparian vegetation that occupy the upper fringes of the reservoir pools. Changes in releases that would influence downstream river flows are discussed below.
- *Modified river flows upstream of and within the study area and modified diversions from south Delta channels*. Changes in releases from reservoirs upstream of the study area and their resultant changes in flows in the Sacramento, American and Feather Rivers, modified diversion of Sacramento River flows at Georgianna Slough and Delta Cross Channel, and modified diversions from south Delta channels (Operational Scenario G) would not be expected to result in the permanent reduction in acreage of the valley/foothill riparian natural community along these waterways. There is no evidence that flow levels in the upstream rivers would change such that the acreage of valley/foothill riparian natural community would be reduced on a permanent basis. Riparian habitats along the rivers of the Sacramento Valley have historically been exposed to significant variations in river stage. Based on modeling conducted for the BDCP

(see Appendix 11C, *CALSIM II Model Results Utilized in the Fish Analysis*), flow levels in these upstream rivers could be reduced nearly 20% in certain months of certain water-year types, and could be increased similarly in certain months of certain water-year types. Estimates of average changes range from less than 1% to more than 12% decreases in the July to November time frame when compared to No Action, while estimated average flow levels in the February to May time frame could increase between 1% and 7% with implementation of Alternative 9. Similar ranges in average flow changes below Sacramento are included in Appendix 11C, Section 11C.9. Tidal influence in the Sacramento River and Delta waterways would continue to be dominant such that there would be no substantial change in water levels that might affect in-stream and adjacent vegetation. Modified diversions from south Delta channels would not create a reduction in this natural community.

The periodic changes in flows in the Sacramento River, Feather River, and American River associated with modified reservoir operations, and the increased diversion of Sacramento River flows at Georgiana Slough and Delta Cross Channel associated with Alternative 9 could affect salinity, water temperature, dissolved oxygen levels, turbidity, contaminant levels and dilution capacity in these rivers and Delta waterways. These changes are discussed in detail in Chapter 8, *Water Quality*. Increases in electrical conductivity (salinity) could occur in the west Delta and Suisun Marsh as a result of these changed water operations. These salinity changes may alter the plant composition of riparian habitats along the lower Sacramento and San Joaquin Rivers and west Delta islands. The severity and extent of these salinity changes would be complicated by anticipated sea level rise and the effects of downstream tidal restoration over the life of the Plan. There is the potential that some valley/foothill riparian natural community may be degraded immediately adjacent to river channels. The riparian communities in the west Delta are dominated by willows, cottonwood and mixed brambles. These potential changes are not expected to result in a significant reduction in the acreage and value of valley/foothill riparian natural community in the study area.

- *Access road, water conveyance facilities and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with the BDCP actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in valley/foothill riparian habitats. This activity could lead to increased soil erosion, turbidity and runoff entering these habitats. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan*. Any vegetation removal or earth work adjacent to or within riparian habitats would require use of sediment barriers, soil stabilization and revegetation of disturbed surfaces (*AMM10 Restoration of Temporarily Affected Natural Communities*). Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management*. Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*CM11 Natural Communities Enhancement and Management)*. Use of herbicides to control nuisance vegetation could pose a long-term hazard to valley/foothill riparian natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to riparian areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the BDCP to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments are described in Appendix 3B, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in terrestrial environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Channel dredging*. Long-term operation of the Alternative 9 diversions on the Sacramento River (Georgianna Slough and Delta Cross Channel) would include periodic dredging of sediments that might accumulate in front of intake and fish screens. Maintenance dredging would also be required in Middle River and Victoria Canal to maintain channel capacity. The dredging would occur adjacent to valley/foothill riparian natural community. This activity should not adversely affect riparian plants as long as dredging equipment is kept out of riparian areas and dredge spoil is disposed of outside of riparian corridors. *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities* are part of the Plan and would require actions to avoid or minimize dredging effects on adjacent sensitive vegetation.

- *Habitat enhancement*. The BDCP includes a long-term management element for the natural communities within the Plan Area (CM11). For the valley/foothill riparian natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

- *Recreation.* The BDCP would allow for certain types of recreation in and adjacent to valley/foothill riparian natural community in the reserve system. The activities could include wildlife and plant viewing and hiking. *CM11 Natural Communities Enhancement and Management* (BDCP Chapter 3, Section 3.4.11) describes this program and identifies applicable restrictions on recreation that might adversely affect riparian habitat. The BDCP also includes an avoidance and minimization measure (AMM37) that further dictates limits on recreation activities that might affect this natural community. Priority would be given to use of existing trails and roads, with some potential for new trails. Limited tree removal and limb trimming could also be involved.

The various operations and maintenance activities described above could alter acreage of valley/foothill riparian natural community in the study area through changes in flow patterns and resultant changes in water quality. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Recreation activities could encroach on riparian areas and require occasional tree removal. Other periodic activities associated with the Plan, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be greatly offset by restoration and protection activities planned as part of *CM7 Riparian*

Natural Community Restoration and *CM3 Natural Communities Protection and Restoration*, or minimized by implementation of AMM2, AMM3, AMM4, AMM5, AMM6, AMM10, AMM18, and AMM37. The management actions associated with levee repair, periodic dredging and control of invasive plant species would also result in a long-term benefit to the species associated with riparian habitats by improving water movement in adjacent waterways and by eliminating competitive, invasive species of plants.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 9 would not result in a net permanent reduction in the valley/foothill riparian natural community within the study area. Therefore, there would be no adverse effect to the community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 9 would have the potential to create minor changes in total acreage of valley/foothill riparian natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM3, AMM4, AMM5, AMM6, AMM10, AMM18, and AMM37 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would create positive effects, including reduced competition from invasive, nonnative plants in these habitats. Long-term restoration and protection activities associated with *CM7 Riparian Natural Community Restoration* and *CM3 Natural Communities Protection and Restoration* would expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact.

Nontidal Perennial Aquatic

Construction, operation, maintenance and management associated with the conservation components of Alternative 9 would have no long-term adverse effects on the habitats associated with the nontidal perennial aquatic natural community. Initial development and construction of CM2, CM4, CM5, and CM6 would result in both permanent and temporary removal of this community (see Table 12-9-5). Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit the nontidal perennial aquatic natural community.

- Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater perennial emergent wetland natural communities (Objective NFEW/NPANC1.1, associated with CM10).

There is a variety of other, less specific conservation goals and objectives in BDCP Chapter 3, Section 3.3 that would improve the value of nontidal perennial aquatic natural community for terrestrial species. As explained below, with the restoration and enhancement of these amounts of habitat, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-5. Changes in Nontidal Perennial Aquatic Natural Community Associated with Alternative 9 (acres)[a]

	Permanent		Temporary		Periodic[d]	
Conservation Measure[b]	NT	LLT[c]	NT	LLT[c]	CM2	CM5

TOTAL IMPACTS	**58**	**241**	**12**	**28**	**50–77**	**25**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
Unk. = unknown

Impact BIO-12: Changes in Nontidal Perennial Aquatic Natural Community as a Result of Implementing BDCP Conservation Measures

Construction and land grading activities that would accompany the implementation of CM2, CM4, CM5, and CM6 would permanently eliminate an estimated 241 acres and temporarily remove 28 acres of nontidal perennial aquatic natural community in the study area. These modifications represent approximately 5% of the 5,567 acres of the community that is mapped in the study area. Approximately 26% (70 acres) of the permanent and temporary losses would occur during the first 10 years of Alternative 9 implementation, as habitat restoration is initiated. Natural communities restoration would add 1,200 acres of nontidal marsh over the life of the Plan (CM10), which would expand the area of that habitat and offset the losses. The nontidal marsh restoration would include a mosaic of nontidal perennial aquatic and nontidal freshwater perennial emergent wetland natural communities, as specified in Objective NFEW/NPANC1.1. The BDCP beneficial effects analysis (BDCP Chapter 5, Section 5.4.6.2) indicates that implementation of Alternative 4 would result in the restoration of 1,200 acres of nontidal marsh, and that the restoration will occur in blocks that will be contiguous with the Plan's larger reserve system. The nontidal marsh will be restored in the vicinity of giant garter snake subpopulations identified in the recovery plan for this species (U.S. Fish and Wildlife Service 1998). The same conservation actions would be implemented under Alternative 9.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of the Alternative 9 water conveyance facilities would not affect nontidal perennial aquatic natural community.
- *CM2 Yolo Bypass Fisheries Enhancement*: Implementation of CM2 involves a number of construction activities within the Yolo and Sacramento Bypasses, including Fremont Weir and stilling basin improvements, west side channels modifications, Putah Creek realignment activities, and Sacramento Weir and Tule Canal improvements. All of these activities could involve excavation and grading in nontidal perennial aquatic areas to improve passage of fish through the bypasses. Based on hypothetical construction footprints, a total of 24 acres could be permanently lost and another 12 acres could be temporarily removed. This activity would occur primarily in the near-term timeframe.
- *CM4 Tidal Natural Communities Restoration*: Based on the use of hypothetical restoration footprints, implementation of CM4 would permanently change to tidally inundated or remove 189 acres of nontidal perennial aquatic community. These losses would be expected to occur primarily in the Cache Slough and Cosumnes/Mokelumne ROAs (see Figure 12-1). An estimated 1,200 acres of nontidal marsh would be restored during tidal habitat restoration (BDCP Objective NFEW/NPANC1.1, associated with CM10). Approximately 400 acres of the restoration would occur during the first 10 years of Alternative 9 implementation, which would coincide with the timeframe of water conveyance facilities construction. The remaining restoration would be spread over the following 30 years. Nontidal natural communities restoration is expected to be focused in CZs 2, 4 and/or 5 identified in Figure 12-1.
- *CM5 Seasonally Inundated Floodplain Restoration*: Based on theoretical footprints, floodplain restoration levee construction would permanently remove 28 acres and temporarily remove 16 acres of nontidal perennial aquatic habitat. The construction-related losses would be considered a permanent removal of the nontidal perennial aquatic habitats. It is expected that floodplain restoration would be focused on the south part of the study area, in CZ 7. This activity is scheduled to start following construction of water conveyance facilities, which is expected to take 10 years. Floodplain restoration along the southern Delta rivers would improve connectivity for a variety of species that rely on aquatic and riparian habitats. The regional and Plan Area landscape linkages along the San Joaquin River, Middle River and Old River are included in Figure 12-2. This activity is scheduled to start following construction of water conveyance facilities, which is expected to take 10 years.
- *CM6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in filling of small amounts of nontidal perennial aquatic habitat along 20 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur on the edges of tidal perennial aquatic habitat, including levees and channel banks. Nontidal marsh adjacent to these tidal areas could be affected. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.
- *CM10 Nontidal Marsh Restoration*: CM10 would entail restoration of 1,200 acres of nontidal marsh in CZs 2, 4 and/or 5. The restoration would create a mosaic of nontidal perennial aquatic and nontidal freshwater perennial emergent natural communities. This marsh restoration would occur in 25-acre or larger patches in or near giant garter snake occupied habitat and would be accompanied by adjacent grassland restoration or protection.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

During the near-term timeframe (the first 10 years of BDCP implementation), Alternative 9 would affect the nontidal perennial aquatic community through CM2 construction losses (24 acres permanent and 12 acres temporary). These losses would occur primarily at scattered locations along the west side channels and the channels associated with the Sacramento and Lisbon Weirs in the Yolo Bypass. Approximately 34 acres of the inundation and construction-related losses from CM4 would occur in the near-term. These losses would occur throughout several of the ROAs mapped in Figure 12-1.

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and restoration actions associated with BDCP conservation components. Loss of nontidal perennial aquatic natural community would be considered both a loss in acreage of a sensitive natural community and a loss of waters of the United States as defined by Section 404 of the CWA. The creation of 400 acres of nontidal marsh as part of CM10 during the first 10 years of Alternative 9 implementation would offset this near-term loss, avoiding any adverse effect. Typical project-level mitigation ratios (1:1 for restoration and 1:1 for protection) would indicate 70 acres of restoration and 70 acres of protection would be needed to offset (i.e., mitigate) the 70 acres of loss. While the Plan does not include protection of nontidal perennial aquatic habitat, it includes well in excess of the typical 1:1 restoration acreage (which includes protection in perpetuity), and therefore compensates for the lack of protection.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

Implementation of Alternative 9 as a whole would result in 5% losses of nontidal perennial aquatic community in the study area. These losses (241 acres of permanent and 28 acres of temporary loss) would be largely associated with construction of Yolo Bypass fish improvements (CM2), and change to tidally influenced inundation during tidal marsh restoration (CM4). The changes in tidally influenced inundation would occur during the course of the CM4 restoration activities at various tidal restoration sites throughout the study area. By the end of the Plan timeframe, a total of 1,200 acres of nontidal marsh would be restored. The restoration would occur over a wide region of the study area, including within the Cosumnes/Mokelumne, Cache Slough and South Delta ROAs (see Figure 12-1).

NEPA Effects: During the first 10 years of implementing Alternative 9, creating 400 acres of nontidal marsh as part of CM10 would offset the construction-related and inundation losses of 70 acres of nontidal perennial aquatic natural community. There would be no adverse effect. During the full duration of Plan implementation, Alternative 9 would not result in a net reduction in the acreage of the nontidal perennial aquatic natural community; there would be an expansion of nontidal marsh and the effect would be beneficial.

CEQA Conclusion:

Near-Term Timeframe

Alternative 9 would result in the loss of approximately 70 acres of nontidal perennial aquatic natural community due to construction of fish passage improvements (CM2), and change to tidally influenced inundation during tidal marsh restoration (CM4). The construction losses would occur primarily at scattered locations along the west side channels and the channels associated with the Sacramento and Lisbon Weirs in the Yolo Bypass. The 34 acres of the inundation and construction-related losses from CM4 would occur throughout several of the ROAs mapped in Figure 12-1. The losses would be spread across a 10-year near-term timeframe. These losses would be offset by planned restoration of 400 acres of nontidal marsh scheduled for the first 10 years of Alternative 9 implementation (CM10). Also, AMM1, AMM2, AMM6, AMM7, and AMM10 would be implemented to minimize impacts. Because of these offsetting near-term restoration activities and AMMs, impacts would be less than significant. Typical project-level mitigation ratios (1:1 for restoration and 1:1 for protection) would indicate that 70 acres of restoration and 70 acres of protection would be needed to offset (i.e., mitigate) the 70 acres of loss. While the Plan does not include protection of nontidal perennial aquatic habitat, it includes well in excess of the typical 1:1 restoration acreage (which includes protection in perpetuity), and therefore compensates for the lack of protection. The restoration and protection would be initiated at the beginning of Alternative 9 implementation to minimize any time lag in the availability of this habitat to special-status species, and would result in a net gain in acreage of this sensitive natural community.

Late Long-Term Timeframe

At the end of the Plan period, 269 acres of the natural community would be removed and 1,200 acres of nontidal marsh would be restored. The nontidal marsh would consist of a mosaic of nontidal perennial aquatic and nontidal freshwater perennial emergent wetland natural communities. There would be no net permanent reduction in the acreage of this sensitive natural community within the study area. Therefore, Alternative 9 would not have a substantial adverse effect on this natural community; the impact would be beneficial.

Impact BIO-13: Increased Frequency, Magnitude and Duration of Periodic Inundation of Nontidal Perennial Aquatic Natural Community

Two Alternative 9 conservation measures would modify the inundation/flooding regimes of both natural and man-made waterways in the study area. CM2, which is designed to improve fish passage and shallow flooded habitat for Delta fishes in the Yolo Bypass, would increase periodic inundation of nontidal perennial aquatic natural community on small acreages, while CM5 would expose this community to additional flooding as channel margins are modified and levees are set back to improve fish habitat along some of the major rivers and waterways throughout the study area.

- *CM2 Yolo Bypass Fisheries Enhancement*: Operation of the Yolo Bypass under Alternative 9 would result in an increase in the frequency, magnitude and duration of inundation of 50–77 acres of nontidal perennial aquatic natural community. The methods used to estimate these inundation acreages are described in BDCP Appendix 5.J, *Effects on Natural Communities, Wildlife, and Plant*s. The area more frequently affected by inundation would vary with the flow volume that would pass through the newly constructed notch in the Fremont Weir. The 50-acre increase in inundation would be associated with a notch flow of 3,000 cubic feet per second (cfs), and the 77-acre increase would result from a notch flow of 6,000 cfs. Plan-related increases in flow through Fremont Weir would be expected in 30% of the years. This community occurs in small stringers and patches throughout the bypass, including along the Tule Canal/Toe Drain, the western channels north of Interstate 80, and below the Fremont and Sacramento Weirs. The anticipated change in management of flows in the Yolo Bypass includes more frequent releases in flows into the bypass from the Fremont and Sacramento Weirs, and in some years, later releases into the bypass in spring months (April and May). The modification of periodic inundation events would not adversely affect the ecological function of this natural community and would not substantially modify its value for special-status or common wildlife species. Nontidal perennial aquatic habitats in the Yolo Bypass have developed under a long-term regime of periodic inundation events. The extended inundation would be designed to expand foraging and spawning habitat for Delta fishes. The effects of this inundation on wildlife and plant species are described in detail in later sections of this chapter.

- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration would result in an increase in the frequency and duration of inundation of an estimated 25 acres of nontidal perennial aquatic habitat. Specific locations for this restoration activity have not been identified, but they would likely be focused in the south Delta area, along the major rivers and Delta channels. The reconnection of these wetlands to stream flooding events would be beneficial to the ecological function of nontidal perennial aquatic habitats, especially as they relate to BDCP target aquatic species. The periodic flooding may also encourage germination of nontidal marsh vegetation.

In summary, 75–102 acres of nontidal perennial aquatic community in the study area would be subjected to more frequent inundation as a result of implementing two Alternative 9 conservation measures (CM2 and CM5). Nontidal perennial aquatic community in the Yolo Bypass has developed under a long-term regime of periodic inundation events and inundation along expanded river floodplains would be infrequent.

NEPA Effects: The increased inundation of nontidal perennial aquatic natural community in the Yolo Bypass and along south Delta waterways associated with Alternative 9 would not reduce the acreage of this natural community and could encourage germination of aquatic vegetation. This increased inundation would not be adverse.

CEQA Conclusion: An estimated 75–102 acres of nontidal perennial aquatic community in the study area would be subjected to more frequent inundation as a result of implementing CM2 and CM5 under Alternative 9. Nontidal perennial aquatic community would not be significantly impacted because its habitats in the Yolo Bypass have developed under a long-term regime of periodic inundation events and inundation along expanded river floodplains would be infrequent. The periodic inundation would not result in a net permanent reduction in the acreage of this community in the study area. Therefore, there would be no substantial adverse effect on the community. The impact would be less than significant.

Impact BIO-14: Modification of Nontidal Perennial Aquatic Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 9 are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the BDCP facilities and conservation lands that could affect nontidal perennial aquatic natural community in the study area. The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows at two newly screened sites at Georgianna Slough and Delta Cross Channel in the north Delta, the operation of multiple operable barriers in Delta waterways, and modified diversions from south Delta channels. These actions are associated with CM1 (see the impact discussion above for effects associated with CM2). The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (CM11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified releases and water levels in upstream reservoirs*. Modified releases and water levels at Shasta Lake, Lake Oroville, Whiskeytown Lake, Lewiston Lake, and Folsom Lake would affect nontidal perennial aquatic natural community, in the form of the reservoir pools. The Alternative 9 operations scheme would alter the surface elevations of these reservoir pools as described in Chapter 6, *Surface Water*. These fluctuations would occur within historic ranges and would not adversely affect the natural community. Changes in releases that would influence downstream river flows are discussed below.
- *Modified river flows upstream of and within the study area and modified diversions from south Delta channels*. Changes in releases from reservoirs upstream of the study area, modified diversion of Sacramento River flows at Georgianna Slough and Delta Cross Channel, and modified diversions from south Delta channels (Operational Scenario G) would not result in the permanent reduction in acreage of the nontidal perennial aquatic natural community in the study area. Flow levels in the upstream rivers would not change such that the acreage of nontidal perennial aquatic community would be reduced on a permanent basis. Some minor increases and some decreases would be expected to occur along the major rivers during some seasons and in some water-year types, but there would be no permanent loss. Similarly, increased diversions of Sacramento River flows at Georgianna Slough and Delta Cross Channel would not result in a permanent reduction in nontidal perennial aquatic community downstream of these diversions. Nontidal wetlands below the diversions are not directly connected to the rivers, as this section of Delta waterways is tidally influenced. Modified diversions from south Delta channels would not create a reduction in this natural community.
- *Access road, water conveyance facility and levee repair*. Periodic repair of access roads, water conveyance facilities and levees associated with the BDCP actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in nontidal perennial aquatic habitats. This activity could lead to increased soil erosion, turbidity and runoff entering nontidal perennial aquatic habitats. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan*. Any vegetation removal or earth work adjacent to or within aquatic habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.
- *Vegetation management*. Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*CM11 Natural Communities Enhancement and*

Management). Vegetation management is also the principal activity associated with *CM13 Invasive Aquatic Vegetation Control.* Use of herbicides to control nuisance vegetation could pose a long-term hazard to nontidal perennial aquatic natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to nontidal perennial aquatic areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the BDCP to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments are described in Appendix 3B, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

Herbicides to remove aquatic invasive species as part of CM13 would be used to restore the normal ecological function of tidal and nontidal aquatic habitats in planned restoration areas. The treatment activities would be conducted in concert with the California Department of Boating and Waterways' invasive species removal program. Eliminating large stands of water hyacinth and Brazilian waterweed would improve habitat conditions for some aquatic species by removing cover for nonnative predators, improving water flow and removing barriers to movement (see Chapter 11, *Fish and Aquatic Resources*). These habitat changes should also benefit terrestrial species that use tidal and nontidal perennial aquatic natural community for movement corridors and for foraging. Vegetation management effects on individual species are discussed in the species sections on following pages.

- *Channel dredging*. Channel dredging associated with Alternative 9 would not affect this natural community. Nontidal wetlands are not connected to the tidal channels that would be dredged. *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Reuse and Disposal of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities* are part of the Plan and would require actions to avoid or minimize dredging effects on adjacent sensitive vegetation.
- *Habitat enhancement*. The BDCP includes a long-term management element for the natural communities within the Plan Area (CM11). For nontidal perennial aquatic natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of nontidal perennial aquatic natural community in the study area through changes in flow patterns and changes in periodic inundation of this community. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the Plan would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be greatly offset by restoration activities planned as part of *CM4 Tidal Natural Communities Restoration* and protection actions associated with *CM3 Natural Communities Protection and Restoration*. The management actions associated with levee repair and control of invasive plant species would also result in a long-term benefit to the species associated with nontidal perennial aquatic habitats by improving water movement.

***NEPA Effects*:** Ongoing operation, maintenance and management activities associated with Alternative 9 would not result in a net permanent reduction in the nontidal perennial aquatic natural community within the study area. Therefore, there would be no adverse effect on this natural community.

***CEQA Conclusion*:** The operation and maintenance activities associated with Alternative 9 would have the potential to create minor changes in total acreage of nontidal perennial aquatic natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2–AMM6 and AMM10 would minimize these impacts, and other operations and maintenance activities would create positive effects, including improved water movement in these habitats. Long-term restoration activities associated with *CM4 Tidal Natural Communities Restoration* and protection actions associated with *CM3 Natural Communities Protection and Restoration* would greatly expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact.

Nontidal Freshwater Perennial Emergent Wetland

Construction, operation, maintenance and management associated with the conservation components of Alternative 9 would have no long-term adverse effects on the habitats associated with the nontidal freshwater perennial emergent wetland natural community. Initial development and construction of CM1, CM2, CM4, and CM6 would result in both permanent and temporary removal of this community (see Table 12-9-6). Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit the nontidal freshwater perennial emergent wetland natural community.

- Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater perennial emergent wetland natural communities (Objective NFEW/NPANC1.1, associated with CM10).
- Protect and manage 50 acres of occupied or recently occupied tricolored blackbird nesting habitat located within 5 miles of high-value foraging habitat in Conservation Zones 1, 2, 8 or 11. Nesting habitat will be managed to provide young, lush stands of bulrush/cattail emergent vegetation (Objective TRBL1.1).

There is a variety of other, less specific conservation goals and objectives in BDCP Chapter 3, Section 3.3 that would improve the value of nontidal freshwater perennial emergent wetland natural community for terrestrial species. As explained below, with the restoration and enhancement of these amounts of habitat, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
Unk. = unknown

Impact BIO-15: Changes in Nontidal Freshwater Perennial Emergent Wetland Natural Community as a Result of Implementing BDCP Conservation Measures

Construction and land grading activities that would accompany the implementation of CM1, CM2, CM4, and CM6 would permanently eliminate an estimated 125 acres and temporarily remove 25 acres of nontidal freshwater perennial emergent wetland natural community in the study area. These modifications represent approximately 9% of the 1,509 acres of the community that is mapped in the study area. Approximately 60% (91 acres) of the permanent and temporary losses would occur during the first 10 years of Alternative 9 implementation, as water conveyance facilities are constructed and habitat restoration is initiated. Natural communities restoration would add 1,200 acres (CM10) and natural communities protection would protect 50 acres (CM3) of nontidal marsh over the course of Alternative 9 implementation, which would expand the area of that habitat and offset the losses. The nontidal marsh restoration would include a mosaic of nontidal perennial aquatic and nontidal freshwater perennial emergent wetland natural communities, as specified in BDCP Objective NFEW/NPANC1.1 (Table 3.3-1 in BDCP Chapter 3, *Conservation Strategy*). The nontidal marsh protection would be designed to support tricolored blackbird populations in the study area. The BDCP beneficial effects analysis (BDCP Chapter 5, Section 5.4.6.2) indicates that implementation of Alternative 4 would result in the restoration of 1,200 acres of nontidal marsh. The restoration would occur in blocks that are contiguous with the alternative's larger reserve system. The nontidal marsh would be restored in the vicinity of giant garter snake subpopulations identified in the recovery plan for this species (U.S. Fish and Wildlife Service 1998). The same conservation actions would be implemented under Alternative 9.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of the Alternative 9 water conveyance facilities would permanently remove 1 acre and temporarily remove 24 acres of tidal freshwater perennial emergent wetland community. The permanent loss would occur adjacent to Clifton Court Forebay where the new canal would cross Coney Island (see Terrestrial Biology Mapbook). The temporary losses would occur in temporary dredging work areas along Middle River between Victoria Canal and Mildred Island. These wetlands occur in small patches, primarily on the interiors of islands within the Middle River corridor. These losses would take place during the near-term construction period.
- *CM2 Yolo Bypass Fisheries Enhancement*: Implementation of CM2 involves a number of construction activities within the Yolo and Sacramento Bypasses, including Fremont Weir and stilling basin improvements, west side channels and Tule Canal modifications, Putah Creek realignment activities, Lisbon Weir modification and Sacramento Weir improvements. Some of these activities could involve excavation and grading in nontidal freshwater perennial emergent wetland areas to improve passage of fish through the bypasses. Based on hypothetical construction footprints, a total of 25 acres could be permanently lost and 1 acre could be temporarily removed. These losses would most likely occur in the Tule Canal and west side channels at the north end of the bypass. The habitat there includes narrow bands within these side channels of the bypass and is isolated from other marsh or open water habitats. The narrow bands are bordered by riparian habitats, primarily willows and cottonwoods. This activity would occur in the near-term timeframe.
- *CM4 Tidal Natural Communities Restoration*: Based on the use of hypothetical restoration footprints, implementation of CM4 would permanently inundate or remove 99 acres of nontidal freshwater perennial emergent wetland community. These losses would be expected to occur primarily in the Cache Slough ROA (see Figure 12-1). An estimated 1,200 acres of nontidal marsh would be restored (CM10) and 50 acres would be protected (CM3) during nontidal habitat conservation actions. Approximately 400 acres of the restoration and 25 acres of the protection would occur during the first 10 years of Alternative 9 implementation, which would coincide with the timeframe of water conveyance facilities construction and early tidal marsh restoration. The remaining restoration would be spread over the following 30 years. Nontidal marsh natural communities restoration is expected to be focused in the vicinity of giant garter snake populations in the eastern Delta and near the Yolo Bypass.
- *CM5 Seasonally Inundated Floodplain Restoration*: Based on theoretical footprints, floodplain restoration levee construction would not affect nontidal freshwater perennial emergent wetland natural community.
- *CM6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in filling of small amounts of nontidal freshwater perennial emergent wetland habitat along 20 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur on the edges of tidal perennial aquatic habitat, including levees and channel banks. Nontidal marsh adjacent to these tidal areas could be affected. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.

- *CM10 Nontidal Marsh Restoration*: CM10 would entail restoration of 1,200 acres of nontidal marsh in CZs 2, 4 and/or 5. The restoration would create a mosaic of nontidal perennial aquatic and nontidal freshwater perennial emergent natural communities. This marsh restoration would occur in 25-acre or larger patches in or near giant garter snake occupied habitat and would be accompanied by adjacent grassland restoration or protection.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

During the near-term timeframe (the first 10 years of BDCP implementation), Alternative 9 would affect the nontidal freshwater perennial emergent wetland community through CM1 construction losses (1 acre permanent and 24 acres temporary) and the CM2 construction losses (25 acres permanent and 1 acre temporary). These losses would occur on Coney Island, within the Middle River dredging corridor, and in the Yolo Bypass. Approximately 40 acres of the inundation and construction-related losses from CM4 would occur in the near-term. These losses would occur throughout several of the ROAs mapped in Figure 12-1.

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and restoration actions associated with BDCP conservation components. Loss of nontidal freshwater perennial emergent wetland natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. However, the creation of 400 acres and protection of 25 acres of nontidal marsh as part of CM3 and CM10 during the first 10 years of Alternative 9 implementation would offset this near-term loss, avoiding any adverse effect. Typical project-level mitigation ratios (1:1 for restoration and 1:1 for protection) would indicate 91 acres of restoration and 91 acres of protection would be needed to offset (i.e., mitigate) the 91 acres of loss. While the Plan includes just 25 acres of protection in the near-term, it includes well in excess of the typical 1:1 restoration acreage (which includes protection in perpetuity), and therefore compensates for the shortfall in protection.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

Implementation of Alternative 9 as a whole would result in a 9% loss of nontidal freshwater perennial emergent wetland community in the study area. These losses (125 acres of permanent and 25 acres of temporary loss) would be largely associated with construction of the Yolo Bypass fish passage improvement facilities (CM2) and inundation during tidal marsh restoration (CM4). Inundation losses would occur through the course of the CM4 restoration activities at various tidal restoration sites throughout the study area. By the end of the Plan timeframe, a total of 1,200 acres of nontidal marsh would be restored and 50 acres would be protected. The restoration would occur near giant garter snake occupied habitat in the eastern Delta and near Yolo Bypass, in CZs 2, 4, and

5. The 50 acres of protection would occur in CZ 1, 2, 8, or 11 to provide nesting habitat for tri-colored blackbird (see Figure 12-1).

NEPA Effects: In the near-term, the combination of creating 400 acres and protecting 25 acres of nontidal perennial marsh as part of CM3 and CM10 would offset the near-term losses associated with construction of CM1, CM2, and CM4 facilities, avoiding any adverse effect. With 1,200 acres of nontidal marsh restoration (BDCP Objective NFEW/NPANC1.1) and 50 acres of protection (BDCP Objective TRBL1.1) included with full implementation of the Plan, Alternative 9 would not result in a net long-term reduction in the acreage of a sensitive natural community; the effect would be beneficial.

CEQA Conclusion:

Near-Term Timeframe

Alternative 9 would result in the loss of approximately 91 acres of nontidal freshwater perennial emergent wetland natural community due to construction of the water conveyance facilities (CM1) and fish passage improvements (CM2), and inundation during tidal marsh restoration (CM4). The construction losses would occur on Coney Island, within the Middle River dredging corridor, and in the Yolo Bypass. Approximately 40 acres of the inundation and construction-related losses from CM4 would occur in the near-term. These losses would occur throughout several of the ROAs mapped in Figure 12-1.

The losses would be spread across a 10-year near-term timeframe. These losses would be offset by planned restoration of 400 acres and protection of 25 acres of nontidal marsh scheduled for the first 10 years of Alternative 9 implementation (CM3 and CM10). Also, AMM1, AMM2, AMM6, AMM7, and AMM10 would be implemented to minimize impacts. Because of these offsetting near-term restoration activities and AMMs, impacts would be less than significant. Typical project-level mitigation ratios (1:1 for restoration and 1:1 for protection) would indicate that 91 acres of restoration and 91 acres of protection would be needed to offset (i.e., mitigate) the 91 acres of loss. While the Plan includes just 25 acres of protection in the near-term, it includes well in excess of the typical 1:1 restoration acreage (which includes protection in perpetuity), and therefore compensates for the shortfall in protection. The restoration and protection would be initiated at the beginning of Alternative 9 implementation to minimize any time lag in the availability of this habitat to special-status species, and would result in a net gain in acreage of this sensitive natural community.

Late Long-Term Timeframe

At the end of the Plan period, 150 acres of the natural community would be removed, 1,200 acres of nontidal marsh would be restored (BDCP Objective NFEW/NPANC1.1) and 50 acres of nontidal marsh would be protected (BDCP Objective TRBL1.1). There would be no net permanent reduction in the acreage of this sensitive natural community within the study area. Therefore, Alternative 9 would not have a substantial adverse effect on this natural community; the impact would be beneficial.

Impact BIO-16: Increased Frequency, Magnitude and Duration of Periodic Inundation of Nontidal Freshwater Perennial Emergent Wetland Natural Community

Two Alternative 9 conservation measures would modify the inundation/flooding regimes of both natural and man-made waterways in the study area. CM2, which is designed to improve fish passage and shallow flooded habitat for Delta fishes in the Yolo Bypass, would increase periodic inundation of nontidal freshwater perennial emergent wetland natural community on small acreages, while CM5 would expose this community to additional flooding as channel margins are modified and levees are set back to improve fish habitat along some of the major rivers and waterways throughout the study area.

- *CM2 Yolo Bypass Fisheries Enhancement*: Operation of the Yolo Bypass under Alternative 9 would result in an increase in the frequency and duration of inundation of 6-8 acres of nontidal freshwater perennial emergent wetland natural community. The methods used to estimate these inundation acreages are described in BDCP Appendix 5.J, *Effects on Natural Communities, Wildlife, and Plants*. The area more frequently affected by inundation would vary with the flow volume that would pass through the newly constructed notch in the Fremont Weir. The 6-acre increase in inundation would be associated with a notch flow of 1,000 cubic feet per second (cfs), and the 8-acre increase would result from a notch flow of 6,000 cfs. Plan-related increases in flow through Fremont Weir would be expected in 30% of the years. This community occurs in small stringers and isolated patches along the Tule Canal and western channel in the north end of the bypass. These areas are not connected to other adjacent marsh and open water habitats; they are surrounded by riparian habitat, scoured grassland and agricultural lands. The anticipated change in management of flows in the Yolo Bypass includes more frequent releases in flows into the bypass from the Fremont and Sacramento Weirs, and in some years, later releases into the bypass in spring months (April and May). The modification of periodic inundation events would not adversely affect the ecological function of this natural community and would not substantially modify its value for special-status or common wildlife species. Nontidal freshwater perennial emergent wetland plant species in the Yolo Bypass have developed under a long-term regime of periodic inundation events. The extended inundation would be designed to expand foraging and spawning habitat for Delta fishes. The effects of this increased inundation on terrestrial wildlife and plant species are described in detail in later sections of this chapter.

- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration would result in an increase in the frequency and duration of inundation of an estimated 8 acres of nontidal freshwater perennial emergent wetland habitat. Specific locations for this restoration activity have not been identified, but they would likely be focused in the south Delta area, along the major rivers and Delta channels. The reconnection of these wetlands to stream flooding events would be beneficial to the ecological function of nontidal freshwater perennial emergent wetland habitats, as they relate to BDCP target aquatic species. The added exposure to inundation could also encourage germination of nontidal marsh plant species. Foraging activity and refuge sites would be expanded into areas currently unavailable or infrequently available to some aquatic species.

In summary, 14–16 acres of nontidal freshwater perennial emergent wetland community in the study area would be subjected to more frequent inundation as a result of implementing two Alternative 9 conservation measures (CM2 and CM5). This community would not be adversely affected because its habitats in the Yolo Bypass have developed under a long-term regime of periodic inundation events and inundation along expanded river floodplains would be infrequent.

NEPA Effects: The increased inundation of nontidal freshwater perennial emergent wetland natural community in the Yolo Bypass and in the southern Delta would not reduce the acreage of this natural community and could encourage germination of emergent wetland vegetation. The increased inundation would not be an adverse effect.

CEQA Conclusion: An estimated 14–16 acres of nontidal freshwater perennial emergent wetland community in the study area would be subjected to more frequent inundation as a result of implementing CM2 and CM5 under Alternative 9. This community would not be significantly impacted because its habitats in the Yolo Bypass have developed under a long-term regime of periodic inundation events and inundation along expanded river floodplains would be infrequent. The periodic inundation would not result in a net permanent reduction in the acreage of this community in the study area. Therefore, there would be no substantial adverse effect on the community. The impact would be less than significant.

Impact BIO-17: Modification of Nontidal Freshwater Perennial Emergent Wetland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 9 are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the BDCP facilities and conservation lands that could affect nontidal freshwater perennial emergent wetland natural community in the study area. The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows at two newly screened diversions at Georgianna Slough and Delta Cross Channel, the operation of multiple operable barriers in Delta waterways, and modified diversions from south Delta channels. These actions are associated with CM1 (see the impact discussion above for effects associated with CM2). The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (CM11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified releases and water levels in upstream reservoirs*. Modified releases and water levels at Shasta Lake, Lake Oroville, Whiskeytown Lake, Lewiston Lake, and Folsom Lake would not affect nontidal freshwater perennial emergent wetland natural community. These reservoirs do not support significant stands of freshwater emergent wetlands. Changes in releases that would influence downstream river flows are discussed below.
- *Modified river flows upstream of and within the study area and modified diversions from south Delta channels*. Changes in releases from reservoirs upstream of the study area, modified diversion of Sacramento River flows at Georgianna Slough and Delta Cross Channel, and modified diversions from south Delta channels (Operational Scenario G) would not result in the permanent reduction in acreage of the nontidal freshwater perennial emergent wetland natural community in the study area. Flow levels in the upstream rivers would not change such that the acreage of nontidal freshwater perennial emergent wetland community would be reduced on a permanent basis. Some minor increases and some decreases could be expected to occur during some seasons and in some water-year types, but there would be no permanent loss. Similarly, modified diversions of Sacramento River flows at Georgianna Slough and Delta Cross Channel would not result in a permanent reduction in nontidal freshwater perennial emergent wetland community downstream of these diversions. Flow volumes in these two diversions and in the downstream channels that had been dredged (Middle River and Victoria Canal) would increase under certain Sacramento River flow conditions and water year types. However, tidal influence

in the Sacramento River and Delta waterways would continue to be dominant such that there would be no substantial change in water levels that might affect in-stream and adjacent vegetation. Modified diversions from south Delta channels would not create a reduction in this natural community.

- *Access road, water conveyance facility and levee repair*. Periodic repair of access roads, water conveyance facilities and levees associated with the BDCP actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in nontidal freshwater perennial emergent wetland habitats. This activity could lead to increased soil erosion, turbidity and runoff entering nontidal freshwater perennial habitats. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan*. Any vegetation removal or earth work adjacent to or within aquatic habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.

- Vegetation management. Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*CM11 Natural Communities Enhancement and Management*). Use of herbicides to control nuisance vegetation could pose a long-term hazard to nontidal freshwater perennial emergent wetland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to nontidal perennial wetland areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the BDCP to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments are described in Appendix 3B, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

  Herbicides to remove aquatic invasive species as part of CM13 would be used to restore the normal ecological function of tidal and nontidal aquatic habitats in planned restoration areas. The treatment activities would be conducted in concert with the California Department of Boating and Waterways' invasive species removal program. Eliminating large stands of water hyacinth and Brazilian waterweed would improve habitat conditions for some aquatic species by removing cover for nonnative predators, improving water flow and removing barriers to movement (see Chapter 11, *Fish and Aquatic Resources*). These habitat changes should also benefit terrestrial species that use tidal and nontidal freshwater perennial emergent wetland natural community for movement corridors and for foraging. Vegetation management effects on individual species are discussed in the species sections on following pages.

- *Channel dredging*. Channel dredging associated with Alternative 9 would not affect this natural community. Nontidal freshwater perennial emergent wetlands are not directly connected to the tidal channels that would be dredged. *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control*

Plan, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities* are part of the Plan and would require actions to avoid or minimize dredging effects on adjacent sensitive vegetation.

- Habitat enhancement. The BDCP includes a long-term management element for the natural communities within the Plan Area (CM11). For nontidal freshwater perennial emergent wetland natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of nontidal freshwater perennial emergent wetland natural community in the study area through changes in flow patterns and changes in periodic inundation of this community. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the Plan, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be greatly offset by restoration activities planned as part of *CM10 Nontidal Marsh Restoration* and protection actions associated with *CM3 Natural Communities Protection and Restoration*. The management actions associated with levee repair and control of invasive plant species would also result in a long-term benefit to the species associated with nontidal freshwater perennial emergent wetland habitats by improving water movement.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 9 would not result in a net permanent reduction in the nontidal freshwater perennial emergent wetland natural community within the study area. Therefore, there would be no adverse effect on this natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 9 would have the potential to create minor changes in total acreage of nontidal freshwater perennial emergent wetland natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM3, AMM4, AMM5, AMM6, and AMM10 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would create positive effects, including improved water movement in and adjacent to these habitats. Long-term restoration activities associated with *CM10 Nontidal Marsh Restoration* and protection actions associated with *CM3 Natural Communities Protection and Restoration* would greatly expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact.

Alkali Seasonal Wetland Complex

Construction, operation, maintenance and management associated with the conservation components of Alternative 9 would have no long-term adverse effects on the habitats associated with the alkali seasonal wetland complex natural community. Initial development and construction of CM2 and CM4 would result in permanent removal of this community (see Table 12-9-7). Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit the alkali seasonal wetland natural community.

- Protect 150 acres of alkali seasonal wetland in Conservation Zones 1, 8 and/or 11 among a mosaic of protected grasslands and vernal pool complex (Objective ASWNC1.1, associated with CM3).
- Restore or create alkali seasonal wetlands in Conservation Zones 1, 8, and/or 11 to achieve no net loss of wetted acres (up to 72 acres of alkali seasonal wetland complex restoration) (Objective ASWNC1.2, associated with CM3 and CM9).
- Provide appropriate seasonal flooding characteristics for supporting and sustaining alkali seasonal wetland species (Objective ASWNC2.1, associated with CM3 and CM11).

There is a variety of other, less specific conservation goals and objectives in BDCP Chapter 3, Section 3.3 that would improve the value of alkali seasonal wetland natural community for terrestrial species. As explained below, with the protection, restoration, and enhancement of the amounts of habitat listed in the BDCP objectives, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-7. Changes in Alkali Seasonal Wetland Complex Natural Community Associated with Alternative 9 (acres)[a]

	Permanent		Temporary		Periodic[d]	
Conservation Measure[b]	NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	0	0	0	0	0	0

LLT = late long-term
Unk. = unknown

Impact BIO-18: Changes in Alkali Seasonal Wetland Complex Natural Community as a Result of Implementing BDCP Conservation Measures

Construction, land grading and habitat restoration activities that would accompany the implementation of CM2 and CM4 would permanently eliminate an estimated 72 acres of alkali seasonal wetland complex natural community in the study area. These modifications represent approximately 2% of the 3,723 acres of the community that is mapped in the study area. Most of the losses (58 acres or 80%) would occur during the first 10 years of Alternative 9 implementation, as Yolo Bypass improvements and habitat restoration is initiated. Alkali seasonal wetland complex protection (120 acres) and restoration (an estimated 58 acres, but determined by actual level of effect) would be initiated during the same period, which would offset the losses. By the end of the Plan period, 150 acres of this natural community would be protected and 72 acres would be restored. The BDCP beneficial effects analysis for this community (BDCP Chapter 5, Section 5.4.7.2) states that Alternative 4 would protect 150 acres of alkali seasonal wetland in Conservation Zones 1, 8, or 11, in a mosaic of protected grasslands and vernal pool complex. This would protect currently unprotected high-value alkali seasonal wetland complex in the Plan Area. These same conservation actions would be implemented under Alternative 9.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of the Alternative 9 water conveyance facilities would not directly affect alkali seasonal wetland complex natural community. The construction activity associated with CM1, however, has the potential to indirectly cause increased nitrogen deposition in alkali seasonal wetland habitats in the vicinity of Clifton Court Forebay. A significant number of cars, trucks, and land grading equipment involved in construction of the canals around Clifton Court Forebay would emit small amounts of atmospheric nitrogen from fuel combustion; this material could be deposited in sensitive alkali seasonal wetland areas that are located west of the major construction areas at the forebay. Nitrogen deposition can pose a risk of adding a fertilizer to nitrogen-limited soils and their associated plants. Nonnative invasive species can be encouraged by the added nitrogen available. BDCP Appendix 5.J, Attachment 5J.A, *Construction-Related Nitrogen Deposition on BDCP Natural Communities*, addresses this issue in detail. It has been concluded that this potential deposition would pose a low risk of changing the alkali seasonal wetland complex in the construction area because the construction would occur primarily downwind of the natural community and the construction would contribute a negligible amount of nitrogen to regional projected emissions. No adverse effect is expected.
- *CM2 Yolo Bypass Fisheries Enhancement*: Implementation of CM2 involves a number of construction activities within the Yolo and Sacramento Bypasses, including Fremont Weir and stilling basin improvements, Putah Creek realignment activities, Lisbon Weir modification and Sacramento Weir improvements. Realignment of Putah Creek could involve excavation and grading in alkali seasonal wetland complex as a new channel is constructed. Based on hypothetical construction footprints, a total of 45 acres could be permanently lost. This complex is located immediately south of the existing Putah Creek channel within the bypass and is a relatively large, moderate to high value, contiguous expanse of this community. This loss would occur in the near-term timeframe.

- *CM3 Natural Communities Protection and Restoration*: CM3 proposes to protect at least 150 acres of alkali seasonal wetland complex in CZs 1, 8 and 11 (BDCP Objective ASWNC1.1). The protection would occur in areas containing a mosaic of grassland and vernal pool complex in unfragmented natural landscapes supporting a diversity of native plant and wildlife species. These areas would be both protected and enhanced to increase the cover of alkali seasonal wetland plants relative to nonnative species.
- *CM4 Tidal Natural Communities Restoration*: Based on the use of hypothetical restoration footprints, implementation of CM4 would permanently inundate or remove 13 acres of alkali seasonal wetland complex in the near-term and inundate or remove 27 acres by the end of the Plan timeframe. The losses would be expected to occur in the Cache Slough and Suisun Marsh ROAs established for tidal restoration (see Figure 12-1). The largest losses would likely occur in the Lindsay Slough area and on the northern fringes of Suisun Marsh, north of the Potrero Hills. These losses would not fragment the alkali seasonal wetland communities adjacent to these sloughs because the losses would occur on the edges of the existing habitat.
- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: CM9 includes both vernal pool complex and alkali seasonal wetland complex restoration goals. The intent of the conservation measure is to match the acreage of restoration with the actual acreage lost to other conservation measures (primarily CM2 and CM4). The current estimate for alkali seasonal wetland complex restoration is 58 acres in the near-term and a total of 72 acres by the end of the BDCP restoration period. The goal is for no net loss of this natural community, consistent with BDCP Objective ASWNC1.2. Restoration in the Lindsay Slough area of the Cache Slough ROA and the northern region of the Suisun Marsh ROA would be consistent with essential habitat connectivity goals mapped in Figure 12-2 and described in Table 3.2-3 of BDCP Chapter 3, *Conservation Strategy*.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

During the near-term timeframe (the first 10 years of BDCP implementation), Alternative 9 would affect the alkali seasonal wetland complex natural community through CM2 construction losses (45 acres). These losses would occur in the Yolo Bypass south of Putah Creek. Approximately 13 acres of the inundation and construction-related losses in habitat from CM4 would occur in the near-term. These losses would occur primarily in the Cache Slough and Suisun Marsh ROAs mapped in Figure 12-1.

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and restoration actions associated with BDCP conservation components. Loss of alkali seasonal wetland complex natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. However, the protection of 120 acres of alkali seasonal wetland complex as part of CM3 and the restoration of 58 acres of this community as part of CM9 during the first 10 years of Alternative 9 implementation would offset this near-term loss, avoiding any adverse effect. Typical project-level mitigation ratios (2:1 for protection and 1:1 for restoration) would indicate 116 acres of protection and 58 acres of restoration would be needed to offset (i.e., mitigate) the 58 acres of loss.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

Implementation of Alternative 9 as a whole would result in relatively minor (2%) losses of alkali seasonal wetland natural community in the study area. These losses (72 acres) would be associated with construction of Yolo Bypass fish improvements (CM2) and inundation during tidal marsh restoration (CM4). Inundation losses would occur through the course of the BDCP restoration activities, primarily in the Cache Slough and Suisun Marsh ROAs.

NEPA Effects: In the first 10 years of implementing Alternative 9 conservation measures, 120 acres of alkali seasonal wetland complex would be protected as part of CM3 and 58 acres of this community would be restored as part of CM9. These conservation actions would offset the near-term loss of this community associated with CM2 and CM4, avoiding any adverse effect. By the end of the Plan timeframe, Alternative 9 would protect a total of 150 acres of alkali seasonal wetland natural community (CM3) and would restore up to 72 acres (CM9). The protection and restoration would occur primarily in CZ 1, CZ 8 and/or CZ 11, in the Cache Slough, Suisun Marsh and Clifton Court Forebay areas. Therefore, Alternative 9 would not have an adverse effect on the alkali seasonal wetland complex natural community.

CEQA Conclusion:

Near-Term Timeframe

Alternative 9 would result in the permanent loss of approximately 58 acres of alkali seasonal wetland complex natural community due to construction of fish passage improvements (CM2) and inundation during tidal marsh restoration (CM4). The construction losses would occur primarily in the area just south of Putah Creek in the Yolo Bypass, while inundation losses would occur in the Cache Slough and Suisun Marsh ROAs. The losses would be spread across a 10-year near-term timeframe.

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and other actions associated with BDCP conservation components. Loss of alkali seasonal wetland complex natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. However, the protection of 120 acres of alkali seasonal wetland complex as part of CM3 and the restoration of 58 acres of this community as part of CM9 during the first 10 years of Alternative 9 implementation would offset this near-term loss, avoiding any significant impact. Typical project-level mitigation ratios (2:1 for protection and 1:1 for restoration) would indicate 116 acres of protection and 58 acres or restoration would be needed to offset (i.e., mitigate) the 58 acres of loss. Also, AMM1, AMM2, AMM3, AMM4, and AMM10 would be implemented to minimize impacts. Because of the offsetting protection and restoration activities and AMMs, impacts would be less than significant.

Late Long-Term Timeframe

At the end of the Plan period, 72 acres of alkali seasonal wetland complex natural community would be permanently removed by conservation actions, 150 acres would be protected and up to 72 acres would be restored. The restoration acres actually developed would depend on the number of acres affected during Plan implementation. There would be no net permanent reduction in the acreage of this natural community within the study area. Therefore, Alternative 9 would have a less-than-significant impact on this natural community.

Impact BIO-19: Increased Frequency, Magnitude and Duration of Periodic Inundation of Alkali Seasonal Wetland Complex Natural Community

CM2 Yolo Bypass Fisheries Enhancement would modify the inundation regime of the Yolo Bypass, a man-made waterway. CM2, which is designed to improve fish passage and shallow flooded habitat for Delta fishes in the Yolo Bypass, would increase periodic inundation of alkali seasonal wetland complex natural community at scattered locations in the central and southern sections of the bypass.

Operation of the Yolo Bypass under Alternative 9 would result in an increase in the frequency, magnitude and duration of inundation on an estimated 264–744 acres of alkali seasonal wetland complex natural community. The methods used to estimate these inundation acreages are described in BDCP Appendix 5.J, *Effects on Natural Communities, Wildlife, and Plants*. The area more frequently affected by inundation would vary with the flow volume that would pass through the newly constructed notch in the Fremont Weir. The 264-acre increase in inundation would be associated with a notch flow of 1,000 cubic feet per second (cfs), and the 744-acre increase would result from a notch flow of 4,000 cfs. Plan-related increases in flow through Fremont Weir would be expected in 30% of the years. The alkali seasonal wetland complex natural community occurs primarily in the central and southern reaches of the bypass, south of Putah Creek. The stands in this location are relatively large, with moderate to high value for associated plant and wildlife species. The anticipated change in management of flows in the Yolo Bypass includes more frequent releases in flows into the bypass from the Fremont and Sacramento Weirs, and in some years, later releases into the bypass in spring months (April and May).

NEPA Effects: The modification of periodic inundation events in the Yolo Bypass associated with Alternative 9 would not adversely affect alkali seasonal wetland complex habitats, as they have persisted under similar high flows and extended inundation periods. There is the potential for some change in plant species composition as a result of longer inundation periods, but the natural community would persist.

CEQA Conclusion: An estimated 264–744 acres of alkali seasonal wetland complex natural community in the Yolo Bypass would be subjected to more frequent inundation as a result of implementing CM2 under Alternative 9. This natural community is conditioned to periodic inundation; the slight increase in periodic inundation would not result in a net permanent reduction in the acreage of this community in the study area, although some change in plant species composition could occur. Increasing periodic inundation of alkali seasonal wetland complex natural community in the Yolo Bypass would have a less-than-significant impact on the natural community. The effects of this inundation on wildlife and plant species are described in detail in later sections of this chapter.

Impact BIO-20: Modification of Alkali Seasonal Wetland Complex Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 9 are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the BDCP facilities and conservation lands that could affect alkali seasonal wetland complex natural community in the study area. The ongoing actions include the diversion of Sacramento River flows at two newly screened diversions at Georgianna Slough and Delta Cross Channel, modified diversions from south Delta channels, and recreation in and adjacent to Plan reserves. These actions are associated with CM1 and CM11 (see the impact discussion above for effects associated with CM2). The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (CM11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and modified diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, modified diversion of Sacramento River flows at Georgianna Slough and Delta Cross Channel, and modified diversions from south Delta channels (Operational Scenario G) would not affect alkali seasonal wetland complex natural community. This natural community does not exist within or adjacent to the active Sacramento River system channels and Delta waterways that would be affected by modified flow levels.

- *Access road, water conveyance facility and levee repair*. Periodic repair of access roads, water conveyance facilities and levees associated with the BDCP actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in or adjacent to alkali seasonal wetland complex habitats. This activity could lead to increased soil erosion and runoff entering these habitats. These activities would be subject to normal erosion and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan*. Any vegetation removal or earth work adjacent to or within alkali seasonal wetland complex habitats would require use of sediment barriers, soil stabilization and revegetation of disturbed surfaces as required by *AMM10 Restoration of Temporarily Affected Natural Communities*. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management*. Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (CM11 Natural Communities Enhancement and Management). Use of herbicides to control nuisance vegetation could pose a long-term hazard to alkali seasonal wetland complex natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to alkali seasonal wetland complex areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the BDCP to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments are described in Appendix 3B, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in terrestrial environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Habitat enhancement*. The BDCP includes a long-term management element for the natural communities within the Plan Area (CM11). For the alkali seasonal wetland complex natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.
- *Recreation.* The BDCP would allow for certain types of recreation in and adjacent to alkali seasonal wetland natural community in the reserve system. The activities could include wildlife and plant viewing and hiking. *CM11 Natural Communities Enhancement and Management* (BDCP Chapter 3, Section 3.4.11) describes this program and identifies applicable restrictions on recreation that might adversely affect alkali seasonal wetland habitat. BDCP also includes an avoidance and minimization measure (AMM37) that further dictates limits on recreation activities that might affect this natural community. Most recreation would be docent-led wildlife and botanical tours, using existing trails and roads in the vicinity of the reserves. No new trails would be constructed.

The various operations and maintenance activities described above could alter acreage of alkali seasonal wetland complex natural community in the study area. Activities could introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the Plan, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be offset by protection and restoration activities planned as part of *CM3 Natural Communities Protection and Restoration*, and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, or minimized by implementation of AMM2, AMM4, AMM5, AMM10, and AMM37. The management actions associated with control of invasive plant species would also result in a long-term benefit to the species associated with alkali seasonal wetland complex habitats by eliminating competitive, invasive species of plants.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 9 would not result in a net permanent reduction in the alkali seasonal wetland natural community within the study area. Therefore, there would be no adverse effect on this natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 9 would have the potential to create minor changes in total acreage of alkali seasonal wetland complex natural community in the study area, and could create temporary increases in sedimentation in this community. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, AMM5, AMM10 and AMM37 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would create positive effects, including reduced competition from invasive, nonnative plants in these habitats. Long-term restoration activities associated with *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* and protection actions associated with *CM3 Natural Communities Protection and Restoration* would ensure that the acreage of this natural community would not decrease in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this natural community within the study area. Therefore, there would be a less-than-significant impact.

Vernal Pool Complex

Construction, operation, maintenance and management associated with the conservation components of Alternative 9 would have no long-term adverse effects on the habitats associated with the vernal pool complex natural community. Initial development and construction of CM4 would result in permanent removal of 372 acres of this community (see Table 12-9-8). Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit the vernal pool complex natural community.

- Protect 600 acres of existing vernal pool complex in Conservation Zones 1, 8, and 11, primarily in core vernal pool recovery areas (Objective VPNC1.1, associated with CM3).
- Restore vernal pool complex in Conservation Zones 1, 8, and/or 11 to achieve no net loss of vernal pool acreage (up to 67 acres of vernal pool complex restoration, assuming that all anticipated impacts [10 wetted acres] occur and that the restored vernal pool complex has 15% density of vernal pools) (Objective VPNC1.2, associated with CM3 and CM9).

There is a variety of other, less specific conservation goals and objectives in BDCP Chapter 3, Section 3.3 that would improve the value of vernal pool complex natural community for terrestrial species. As explained below, with the protection, restoration and enhancement of the amounts of habitat listed in the BDCP objectives, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-8. Changes in Vernal Pool Complex Natural Community Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Permanent		Temporary		Periodic[d]	
	NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	0	0	0	0	0	0
CM2	0	0	0	0	0–4	0
CM4	201	372	0	0	0	0
CM5	0	0	0	0	0	0
CM6	Unk.	Unk.	Unk.	Unk.	0	0
TOTAL IMPACTS	**201**	**372**	**0**	**0**	**0–4**	**0**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
Unk. = unknown

Impact BIO-21: Changes in Vernal Pool Complex Natural Community as a Result of Implementing BDCP Conservation Measures

Construction, land grading and habitat restoration activities that would accompany the implementation of CM4 could permanently eliminate an estimated 372 acres of vernal pool complex natural community in the study area. This modification represents approximately 3% of the 12,133 acres of the community that is mapped in the study area. An estimated 201 acres of this loss would occur during the first 10 years of Alternative 9 implementation, as tidal marsh restoration is initiated. Vernal pool complex protection (400 acres) and restoration (an estimated 40 acres, with actual restoration based on level of effect) would be initiated during the same period to counteract the loss of habitat. By the end of the Plan period, 600 acres of this natural community would be protected and up to 67 acres would be restored. There is also a commitment to having restoration activities keep pace with actual loss of vernal pool habitat through the course of CM4 activities (BDCP Chapter 3, Section 3.4.4.27). Because of the high sensitivity of this natural community and its shrinking presence in the Plan Area, avoidance and minimization measures have been built into the BDCP to eliminate the majority of this potential loss. The BDCP beneficial effect analysis (BDCP Chapter 5, Section 5.4.8.2) indicates that implementation of Alternative 4 would protect at least 600 acres of vernal pool complex in Conservation Zones 1, 8, and 11 and additional vernal pool complex would be restored to achieve no net loss of this community. The same conservation actions would be implemented under Alternative 9.

The individual effects of the relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of the Alternative 9 water conveyance facilities would not directly affect vernal pool complex natural community. Because of the close proximity of construction activity to adjacent vernal pool complex near Clifton Court Forebay, there is the potential for indirect loss or damage to vernal pools from changes in pool hydrology or deposition of construction-related sediment. These potential indirect effects are discussed in detail in the vernal pool crustaceans impact analysis later in this chapter.

  The construction activity associated with CM1 also has the potential to lead indirectly to increased nitrogen deposition in vernal pool complex habitats in the vicinity of Clifton Court Forebay. A significant number of cars, trucks, and land grading equipment involved in construction of canals in the vicinity of the forebay would emit small amounts of atmospheric nitrogen from fuel combustion; this material could be deposited in sensitive vernal pool areas that are located west of the major construction areas at Clifton Court Forebay. Nitrogen deposition can pose a risk of adding a fertilizer to nitrogen-limited soils and their associated plants. Nonnative invasive species can be encouraged by the added nitrogen available. BDCP Appendix 5.J, Attachment 5J.A, *Construction-Related Nitrogen Deposition on BDCP Natural Communities*, addresses this issue in detail. It has been concluded that this potential deposition would pose a low risk of changing the vernal pool complex in the construction areas because the construction would contribute a negligible amount of nitrogen to regional projected emissions. Also, the construction at Clifton Court Forebay would occur primarily downwind of the natural community. No adverse effect is expected.

- *CM3 Natural Communities Protection and Restoration*: CM3 proposes to protect at least 600 acres of vernal pool complex in CZs 1, 8 and 11 (BDCP Objective VPNC1.1). The protection would occur in areas containing a mosaic of grassland and vernal pool complex in unfragmented natural landscapes supporting a diversity of native plant and wildlife species. These areas would be both protected and enhanced to increase the cover of vernal pool complex plants relative to nonnative species.

- *CM4 Tidal Natural Communities Restoration:* Based on the use of hypothetical restoration footprints, implementation of CM4 tidal marsh restoration in CZs 1 and 11 (Cache Slough and Suisun Marsh ROAs; see Figure 12-1) could permanently inundate or remove 201 acres of vernal pool complex in the near-term timeframe. By the end of the Plan period, a total of 372 acres could be affected. The principal areas likely to be affected include the Cache Slough drainage just west of the Yolo Bypass and the Nurse Slough drainage just east of the Potrero Hills.

- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: BDCP CM9 includes both vernal pool complex and alkali seasonal wetland complex restoration goals. The current estimate for vernal pool complex restoration is 40 acres in the near-term and a total of 67 acres by the end of the BDCP restoration period. This restoration conservation measure includes a "no net loss" policy normally applied to this natural community (BDCP Objective VPNC1.2).

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

During the near-term timeframe (the first 10 years of BDCP implementation), Alternative 9 could affect 201 acres of vernal pool complex natural community through inundation or construction-related losses in habitat from CM4 activities. This loss would likely occur in the Cache Slough or Suisun Marsh ROAs mapped in Figure 12-1.

The construction or inundation loss of this special-status natural community would represent an adverse effect if it were not offset by avoidance and minimization measures and restoration actions associated with BDCP conservation components. Loss of vernal pool complex natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. The protection of 400 acres of vernal pool complex as part of CM3 and the restoration of up to 40 acres of this community as part of CM9 during the first 10 years of Alternative 9 implementation would partially offset this near-term loss. The Plan focuses this protection in the core vernal pool areas identified in the USFWS vernal pool recovery plan (U.S. Fish and Wildlife Service 2005). The core areas exist in CZ 1, CZ 8 and CZ 11 (see Figure 12-1). Typical project-level mitigation ratios (2:1 for protection and 1:1 for restoration) would indicate 402 acres of protection and 201 acre of restoration would be needed to offset (i.e., mitigate) the 201 acre of loss. Without additional avoidance and minimization measures to reduce the potential effect, the proposed protection and restoration would not meet the typical mitigation for vernal pool complex losses.

To avoid this adverse effect, the Plan includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities,* and *AMM12 Vernal Pool Crustaceans.* AMM12 limits the direct removal of vernal pool crustacean habitat to no more than 10 wetted acres and the indirect effect to no more than 20 wetted acres through the life of the Plan. This is equivalent to the direct removal of approximately 67 acres and the indirect removal of approximately 134 acres of vernal pool complex natural community. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. With these AMMs in place, Alternative 9 would not adversely affect vernal pool complex natural community in the near-term.

Late Long-Term Timeframe

The late long-term effect on vernal pool complex natural community would be 372 acres of permanent loss. These losses would be associated with the ongoing restoration of tidal wetland in the Cache Slough and Suisun Marsh ROAs. However, 600 acres would be protected (CM3) and up to 67 acres would be restored (CM9) through the course of the BDCP implementation. In addition, the avoidance and minimization measures listed above would reduce the actual loss of this community to no more than 10 wetted acres of vernal pool crustacean habitat from direct activities and 20 acres of habitat from indirect effects.

NEPA Effects: The conservation measures associated with Alternative 9 include protection of 400 acres (CM3) and restoration of an estimated 40 acres (CM9) of vernal pool complex in the near-term time frame. The Plan focuses the protection in the core vernal pool areas identified in the USFWS vernal pool recovery plan (U.S. Fish and Wildlife Service 2005). The core areas exist in CZ 1, CZ 8 and CZ 11 (see Figure 12-1). In addition, Alternative 9 includes AMM12 which limits the removal of vernal pool crustacean habitat to no more than 10 wetted acres and the indirect effect to no more than 20 wetted acres through the life of the Plan. With this and other AMMs in place, Alternative 9 would not adversely affect vernal pool complex natural community in the near-term. With these conservation measures and AMMs in effect through the entire Plan period, Alternative 9 would not have an adverse effect on the vernal pool complex natural community in the long term.

***CEQA Conclusion*:**

Near-Term Timeframe

During the 10-year near-term time frame, Alternative 9 could result in the loss of approximately 201 acres of vernal pool complex natural community due to inundation during tidal marsh restoration (CM4). The loss would likely occur in the Cache Slough or Suisun Marsh ROAs.

The inundation loss of this special-status natural community would represent a significant impact if it were not offset by avoidance and minimization measures and other actions associated with BDCP conservation components. Loss of vernal pool complex natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. The protection of 400 acres of vernal pool complex as part of CM3 and the restoration of an estimated 40 acres of this community as part of CM9 during the first 10 years of Alternative 9 implementation would partially offset this near-term loss. CM9 also includes a commitment to have vernal pool restoration keep pace with loss of this natural community. Typical project-level mitigation ratios (2:1 for protection and 1:1 for restoration) would indicate 402 acres of protection and 201 acres of restoration would be needed to offset (i.e., mitigate) the 201 acre of loss. Without additional avoidance and minimization measures to reduce the potential impact, the proposed protection and restoration would not meet the typical mitigation for vernal pool complex losses. However, Alternative 9 also includes AMM1, AMM2, AMM3, AMM4, AMM10, and AMM12 to minimize impacts. AMM12 places a strict limit on the acres of wetted vernal pool crustacean habitat that can be lost to conservation actions (10 acres of direct and 20 acres of indirect loss; equivalent to approximately 67 acres of direct loss and 134 acres of indirect loss of vernal pool natural community). Because of the offsetting protection and restoration activities and implementation of AMMs, impacts would be less than significant.

Late Long-Term Timeframe

At the end of the Plan period, 372 acres of vernal pool complex natural community could be permanently removed. Through CM3 and CM9, 600 acres of vernal pool complex natural community would be protected and up to 67 acres would be restored. In addition, AMM12 would limit the acres of wetted vernal pool crustacean habitat loss to 10 acres from direct actions and 20 acres from indirect actions. There would be no net permanent reduction in the acreage of this natural community within the study area. Alternative 9 would have a less-than-significant impact on this natural community.

Impact BIO-22: Increased Frequency, Magnitude and Duration of Periodic Inundation of Vernal Pool Complex Natural Community

CM2 Yolo Bypass Fisheries Enhancement would modify the inundation regime of the Yolo Bypass, a man-made waterway. CM2, which is designed to improve fish passage and shallow flooded habitat for Delta fishes in the Yolo Bypass, could increase periodic inundation of a small acreage of vernal pool complex natural community in the southern section of the bypass, south of Putah Creek.

Operation of the Yolo Bypass under Alternative 9 would result in an increase in the frequency, magnitude and duration of inundation on an estimated 0–4 acres of vernal pool complex natural community. The methods used to estimate this inundation acreage are described in BDCP Appendix

5.J, *Effects on Natural Communities, Wildlife, and Plants*. The area more frequently affected by inundation would vary with the flow volume that would pass through the newly constructed notch in the Fremont Weir. The 4-acre increase in inundation would only occur at the highest modeled flow regime, 8,000 cfs. Plan-related increases in flow through Fremont Weir would be expected in 30% of the years. The vernal pool complex natural community that would likely be affected occurs in the southern reaches of the bypass, south of Putah Creek. There are several relatively large, contiguous areas of vernal pools on the western edge of the bypass in this area. The anticipated change in management of flows in the Yolo Bypass includes more frequent releases in flows into the bypass from the Fremont and Sacramento Weirs, and in some years, later releases into the bypass in spring months (April and May).

NEPA Effects: The modification of periodic inundation events in the Yolo Bypass associated with Alternative 9 water operations would not adversely affect vernal pool complex habitats, as they have persisted under similar high flows and extended inundation periods. There is the potential, however, for some change in plant species composition as a result of longer inundation periods.

CEQA Conclusion: An estimated 0–4 acres of vernal pool complex natural community in the Yolo Bypass would be subjected to more frequent inundation as a result of implementing CM2 under Alternative 9. This natural community is conditioned to periodic inundation; the slight increase in periodic inundation would not result in a net permanent reduction in the acreage of this community in the study area, although some change in plant species composition could occur. Increasing periodic inundation of vernal pool complex natural community in the Yolo Bypass would have a less-than-significant impact on the community.

Impact BIO-23: Modification of Vernal Pool Complex Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 9 are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the BDCP facilities and conservation lands that could affect vernal pool complex natural community in the study area. The ongoing actions include the diversion of Sacramento River flows into newly screened diversion structures at Georgianna Slough and Delta Cross Channel, operation of multiple operable barriers in Delta waterways, modified diversions from south Delta channels, and recreation activities in Plan reserves. These actions are associated with CM1 and CM11 (see the impact discussion above for effects associated with CM2). The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (CM11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and modified diversions from south Delta channels*. Changes in releases from reservoirs upstream of the study area, modified diversion of Sacramento River flows at newly screened diversions into Georgianna Slough and Delta Cross Channel, operation of multiple operable barriers in Delta waterways, and modified diversions from south Delta channels (Operational Scenario G) would not affect vernal pool complex natural community. This natural community does not exist within or adjacent to the active Sacramento River system channels and Delta waterways.

- *Access road, water conveyance facility and levee repair*. Periodic repair of access roads, water conveyance facilities and levees associated with the BDCP actions have the potential to require removal of adjacent vegetation and could entail earth and rock work adjacent to vernal pool complex habitats. This activity could lead to increased soil erosion and runoff entering these habitats. These activities would be subject to normal erosion and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan*. Any vegetation removal or earth work adjacent to vernal pool complex habitats would require use of sediment barriers, soil stabilization and revegetation of disturbed surfaces as part of *AMM10 Restoration of Temporarily Affected Natural Communities*. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management*. Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*CM11 Natural Communities Enhancement and Management*). Use of herbicides to control nuisance vegetation could pose a long-term hazard to vernal pool complex natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to vernal pool complex areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the BDCP to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments are described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in terrestrial or aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Habitat enhancement*. The BDCP includes a long-term management element for the natural communities within the Plan Area (CM11). For the vernal pool complex natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

- *Recreation.* The BDCP would allow for certain types of recreation in and adjacent to vernal pool complexes in the reserve system. The activities could include wildlife and plant viewing and hiking. *CM11 Natural Communities Enhancement and Management* (BDCP Chapter 3, Section 3.4.11) describes this program and identifies applicable restrictions on recreation that might adversely affect vernal pool habitat. BDCP also includes an avoidance and minimization measure (AMM37) that further dictates limits on recreation activities that might affect vernal pools. Recreational trails would be limited to existing trails and roads. New trail construction would be prohibited within the vernal pool complex reserves. It is expected that most activities would be docent-led tours of reserves, minimizing adverse effects.

The various operations and maintenance activities described above could alter acreage of vernal pool complex natural community in the study area. Activities could introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the Plan, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be greatly offset by restoration activities planned as part of *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, or minimized by implementation of AMM2, AMM4, AMM5, AMM10 and AMM37. The management actions associated with control of invasive plant species would also result in a long-term benefit to the species associated with vernal pool complex habitats by eliminating competitive, invasive species of plants.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 9 would not result in a net permanent reduction in the vernal pool complex natural community within the study area. Therefore, there would be no adverse effect on this community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 9 would have the potential to create minor changes in total acreage of vernal pool complex natural community in the study area, and could create temporary increases in sedimentation or damage from recreational activity in this community. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, AMM5, AMM10 and AMM37 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would create positive effects, including reduced competition from invasive, nonnative plants in these habitats. Long-term restoration activities associated with *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* and protection actions associated with *CM3 Natural Communities Protection and Restoration* would ensure that the acreage of this natural community would not decrease in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this natural community within the study area. Therefore, there would be a less-than-significant impact.

Managed Wetland

The conservation components of Alternative 9 would reduce the acreage of managed wetland currently found in the study area. Initial development and construction of CM1, CM2, CM4, and CM6 would result in both permanent and temporary removal of this community (see Table 12-9-9). Full implementation of Alternative 9 would also include the following conservation action over the term of the BDCP to benefit the managed wetland natural community.

- Protect and enhance 8,100 acres of managed wetland, at least 1,500 acres of which are in the Grizzly Island Marsh Complex (Objective MWNC1.1, associated with CM3).
- Create 320 acres of managed wetlands consisting of greater sandhill crane roosting habitat in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in Conservation Zones 3, 4, 5, or 6, with consideration of sea level rise and local seasonal flood events (Objective GSHC1.3, associated with CM10).
- Create two wetland complexes within the SLNWR refuge boundary. Each complex will consist of at least three wetlands totaling 90 acres of greater sandhill crane roosting habitat. One of the

wetland complexes may be replaced by 180 acres of cultivated lands that are flooded following harvest for crane roosting and foraging habitat (Objective GSHC1.4, associated with CM10).

In addition to this conservation action, creation of similar habitat values by restoring tidal brackish emergent wetland and tidal freshwater emergent wetland as part of CM4 would further offset the losses of managed wetland. The net effect would be a substantial decrease in the amount of managed wetlands, but an increase in similar habitat value for special-status and common species as the managed wetland is converted to tidal marsh. Impacts to this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes. Refer to the *Shorebirds and Waterfowl* impact discussion at the end of this section (Section 12.3.3.16) for further consideration of the effects of removing managed wetland natural community.

Table 12-9-9. Changes in Managed Wetland Associated with Alternative 9 (acres)[a]

	Permanent		Temporary		Periodic[d]	
Conservation Measure[b]	NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	9	9	23	23	0	0

TOTAL IMPACTS	**5,751**	**13,779**	**67**	**67**	931–2,612	**6**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
Unk. = unknown

Impact BIO-24: Changes in Managed Wetland Natural Community as a Result of Implementing BDCP Conservation Measures

Construction, channel dredging, land grading and habitat restoration activities that would accompany the implementation of CM1, CM2, CM4, and CM6 would permanently eliminate an estimated 13,779 acres of managed wetland in the study area. This modification represents approximately 19% of the 70,798 acres of managed wetland that is mapped in the study area. This loss would occur through the course of BDCP restoration activity, as construction and tidal marsh restoration proceeds. Managed wetland protection (8,100 acres) and restoration (500 acres) would take place over the same period, but would not replace the acreage lost. The BDCP beneficial effects analysis for Alternative 4 (BDCP Chapter 5, Section 5.4.9.2) states that at least 8,100 acres of managed wetlands would be protected, of which at least 1,500 acres will be located within the Grizzly Island marsh complex, consistent with the U.S. Fish and Wildlife Service salt marsh harvest mouse recovery plan. Although the primary purpose of the 1,500 acres of protection is to protect and enhance habitat for the salt marsh harvest mouse, it is also expected to benefit the managed wetland natural community and the diversity of species that use it, including migratory waterfowl and the western pond turtle. These same conservation actions would be implemented under Alternative 9.

The individual effects of the relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of the Alternative 9 water conveyance facilities would permanently remove 9 acres and temporarily remove 23 acres of managed wetland community. The permanent losses would occur at canal construction sites over the Old River just south of Clifton Court Forebay and across Coney Island, and at a spoil storage site adjacent to the operable barrier constructed at the northern junction of Old River and the San Joaquin River at Franks Tract. The temporary losses would occur at the Old River canal crossing adjacent to Clifton Court Forebay, at the Old River/San Joaquin River operable barrier at Franks Tract, and at a work area adjacent to the Delta Cross Channel diversion construction site (see Terrestrial Biology Mapbook). These losses would take place during the near-term construction period.
- *CM2 Yolo Bypass Fisheries Enhancement*: Implementation of CM2 involves a number of construction activities that could permanently or temporarily remove managed wetland, including west side channels modifications, Putah Creek realignment activities, Lisbon Weir modification and Sacramento Weir improvements. All of these activities could involve excavation and grading in managed wetland areas to improve passage of fish through the bypasses. Based on hypothetical construction footprints, a total of 24 acres could be permanently removed and 44 acres could be temporarily removed. This activity would occur in the near-term timeframe.
- *CM4 Tidal Natural Communities Restoration*: Based on the use of hypothetical restoration footprints, implementation of CM4 would permanently inundate or remove 13,746 acres of managed wetland community. These losses would be expected to occur primarily in the Suisun Marsh ROA, but could also occur in the Cache Slough and West Delta ROAs (see Figure 12-1). These acres of managed wetland would be converted to natural wetland, including large acreages of tidal brackish emergent wetland and tidal freshwater emergent wetland. These natural wetlands provide comparable or improved habitat for the special-status species that occupy managed wetland. The newly created tidal marsh would not create a barrier or result in fragmentation of managed wetland, as most species are capable of utilizing both communities. An estimated 500 acres of managed wetland would be restored and 8,100 acres would be enhanced and protected through *CM3 Natural Communities Protection and Restoration,* as established by BDCP Objective MWNC1.1. All of the restoration and 4,800 acres of the protection would occur during the first 10 years of Alternative 9 implementation, which would coincide with the timeframe of water conveyance facilities construction and early implementation of CM4. The remaining restoration would be spread over the following 30 years. Managed wetland restoration is expected to include at least 320 acres in CZs 3, 4, 5 and 6 (Figure 12-1) to benefit sandhill crane, as stated in BDCP Objective GSHC1.3. The enhancement and protection would be focused in Suisun Marsh, but could also occur in CZs with existing managed wetland (CZs 1, 2, 4, 5, 6, and 7).

- *CM6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in filling of small amounts of managed wetland habitat along 20 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur on the edges of tidal perennial aquatic habitat, including levees and channel banks. Managed wetland adjacent to these tidal areas could be affected. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

During the near-term timeframe (the first 10 years of BDCP implementation), Alternative 9 would permanently remove 5,751 acres and temporarily remove 67 acres of managed wetland through inundation or construction-related losses in habitat from CM1, CM2, and CM4 activities. Thirty-two acres of this loss would be associated with construction of the water conveyance facilities (CM1). These losses would occur in various locations, but the majority of the near-term loss would occur in Suisun Marsh and the lower Yolo Bypass as tidal marsh is restored.

The construction or inundation loss of this special-status natural community would represent an adverse effect if it were not offset by other conservation actions. Loss of managed wetland natural community would be considered both a loss in acreage of a sensitive natural community and potentially a loss of wetland as defined by Section 404 of the CWA. Many managed wetland areas are interspersed with small natural wetlands that would be regulated under Section 404. The restoration of 500 acres (CM10) and protection and enhancement of 4,800 acres (CM3) of managed wetland during the first 10 years of Alternative 9 implementation would fully offset the losses associated with CM1, but would only partially offset the total near-term loss. The typical project-level mitigation ratio (1:1 for protection) would indicate 32 acres of protection would be needed to offset the 32 acres of loss associated with CM1; a total of 5,818 acres of protection would be needed to offset (i.e., mitigate) the 5,818 acres of permanent and temporary loss from all near-term actions. The combined protection and restoration proposed for managed wetland in the near-term would fall 518 acres short of full replacement. However, the CM4 marsh restoration activities that would be creating this loss would be simultaneously creating 2,000 acres of tidal brackish emergent wetland and 8,850 acres of tidal freshwater emergent wetland in place of the managed wetland in the near-term. This acreage would significantly exceed the number of acres of managed wetlands lost. Mitigation measures would also be undertaken to reduce the effects of managed wetland loss on waterfowl in Suisun Marsh (Mitigation Measure BIO-179a) and the Yolo/Delta basins (Mitigation Measure 179b) if the protection and enhancement actions of CM3 and CM10 were not sufficient to replace the value of managed wetlands for waterfowl in these basins. Refer to the *General Terrestrial Biology Effects* discussion later in this section (Section 12.3.3.16).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

In spite of the managed wetland protection, restoration and avoidance measures contained in Alternative 9, there would be a net reduction in the acreage of this special-status natural community in the near-term. This would be an adverse effect when judged by the significance criteria listed earlier in this chapter. However, the conversion of these managed habitats to natural tidal wetland types that support similar ecological functions (2,000 acres of tidal brackish emergent wetland and 8,850 acres of tidal freshwater emergent wetland) would offset this adverse effect. Also, there are other conservation actions contained in the BDCP (CM3 and CM11) that would improve management and enhance existing habitat values, further offsetting the effects of managed wetland loss on covered and noncovered special-status terrestrial species and on common species that rely on this natural community for some life phase. As a result, there would be no adverse effect.

Late Long-Term Timeframe

At the end of the Plan period, 13,779 acres of managed wetland natural community would be permanently removed by conservation actions, 8,100 acres would be protected and 500 acres would be restored. There would be a net permanent reduction in the acreage of this special-status natural community within the study area. Simultaneously, there would be the creation of 6,000 acres of tidal brackish emergent wetland and 24,000 acres of tidal freshwater emergent wetland in place of this managed wetland.

NEPA Effects: Alternative 9 would result in a loss 13,779 acres of managed wetland within the study area; however, it would also protect and enhance 8,100 acres and restore 500 acres of this habitat. In addition, Alternative 9 would restore 6,000 acres of tidal brackish emergent wetland and 24,000 acres of tidal freshwater emergent wetland that support similar ecological functions to those of managed wetland. Therefore, there would be no adverse effect on managed wetland natural community.

CEQA Conclusion:

Near-Term Timeframe

During the near-term timeframe (the first 10 years of BDCP implementation), Alternative 9 would permanently remove 5,571 acres and temporarily remove 67 acres of managed wetland through inundation or construction-related losses in habitat from CM1, CM2, and CM4 activities. Thirty-two acres of this loss would be associated with construction of the water conveyance facilities (CM1). These losses would occur in various locations, but the majority of the near-term loss would occur in Suisun Marsh and the lower Yolo Bypass as tidal marsh is restored.

The construction or inundation loss of this special-status natural community would represent a significant impact if it were not offset by other conservation actions. Loss of managed wetland natural community would be considered both a loss in acreage of a sensitive natural community and potentially a loss of wetland as defined by Section 404 of the CWA. The restoration of 500 acres and protection and enhancement of 4,800 acres of managed wetland as part of CM3 and CM10 during the first 10 years of Alternative 9 implementation would fully offset the losses associated with CM1, but would only partially offset the total near-term loss. The typical project-level mitigation ratio (1:1 for protection) would indicate 32 acres of protection would be needed to offset the 32 acres of loss associated with CM1; a total of 5,818 acres of protection would be needed to offset (i.e., mitigate) the 5,818 acres of permanent and temporary loss from all near-term actions. The combined protection and restoration proposed for managed wetland in the near-term would fall 518 acres short of full replacement. However, the CM4 marsh restoration activities that would be creating this loss would be simultaneously creating 2,000 acres of tidal brackish emergent wetland and 4,800 acres of tidal freshwater emergent wetland in place of the managed wetland in the near-term. This acreage would significantly exceed the number of acres of managed wetland lost. Mitigation measures would also be undertaken to reduce the effects of managed wetland loss on waterfowl in Suisun Marsh (Mitigation Measure BIO-179a) and the Yolo/Delta basins (Mitigation Measure 179b) if the protection and enhancement actions of CM3 and CM10 were not sufficient to replace the value of managed wetlands for waterfowl in these basins. Refer to the *General Terrestrial Biology Effects* discussion later in this section (Section 12.3.3.16).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

In spite of the managed wetland protection, restoration and avoidance measures contained in Alternative 9, there would be a net reduction in the acreage of this special-status natural community in the near-term. This would be a significant impact when judged by the significance criteria listed earlier in this chapter. However, the conversion of these managed habitats to natural tidal wetland types that support similar ecological functions (2,000 acres of tidal brackish emergent wetland and 4,800 acres of tidal freshwater emergent wetland) would eliminate this significant impact. Also, there are other conservation actions contained in the BDCP (CM3 and CM11) that would improve management and enhance existing habitat values, further offsetting the impacts of managed wetland loss on covered and noncovered special-status terrestrial species and on common species that rely on this natural community for some life phase. As a result, there would be a less-than-significant impact.

Late Long-Term Timeframe

At the end of the Plan period, 13,779 acres of managed wetland natural community would be permanently removed by conservation actions, 8,100 acres would be protected and 500 acres would be restored. There would be a net permanent reduction in the acreage of this special-status natural community within the study area. Simultaneously, there would be the creation of 6,000 acres of tidal brackish emergent wetland and 24,000 acres of tidal freshwater emergent wetland in place of this managed wetland. Because these natural wetlands support similar ecological functions to those of managed wetland, there would be a less-than-significant impact.

Impact BIO-25: Increased Frequency, Magnitude and Duration of Periodic Inundation of Managed Wetland Natural Community

Two Alternative 9 conservation measures would modify the inundation/flooding regimes of both natural and man-made waterways in the study area. CM2, which is designed to improve fish passage and shallow flooded habitat for Delta fishes in the Yolo Bypass, would increase periodic inundation of managed wetland on wildlife management areas and duck clubs scattered up and down the central and southern bypass. CM5 would expose this community to additional flooding as channel margins are modified and levees are set back to improve fish habitat along some of the major rivers and waterways in the south Delta.

- *CM2 Yolo Bypass Fisheries Enhancement*: Operation of the Yolo Bypass under Alternative 9 would result in an increase in the frequency, magnitude and duration of inundation of 931–2,612 acres of managed wetland natural community. The methods used to estimate these inundation acreages are described in BDCP Appendix 5.J, *Effects on Natural Communities, Wildlife, and Plants*. The area more frequently affected by inundation would vary with the flow volume that would pass through the newly constructed notch in the Fremont Weir. The 931-acre increase in inundation would be associated with a notch flow of 8,000 cubic feet per second (cfs), and the 2,612-acre increase would result from a notch flow of 4,000 cfs. Plan-related increases in flow through Fremont Weir would be expected in 30% of the years. Based on the theoretical modeling that has been completed to-date, the largest acreages would be associated with the Sacramento Bypass Wildlife Area, the Yolo Bypass Wildlife Area, and private managed wetlands south of Putah Creek. The anticipated change in management of flows in the Yolo Bypass includes more frequent releases in flows into the bypass from the Fremont and Sacramento Weirs, and in some years, later releases into the bypass in spring months (April and May). With larger flows, the water depths may also increase over Existing Conditions. While the managed wetlands of the Yolo Bypass are conditioned to periodic inundation events, the more frequent and extended inundation periods may make it more difficult to actively manage the areas for maximum food production for certain species (waterfowl primarily) and may alter the plant assemblages in some years. The effects of this periodic inundation on birds and other terrestrial species are discussed later in this chapter. The additional inundation would not be expected to reduce the acreage of managed wetland on a permanent basis. The extended inundation would be designed to expand foraging and spawning habitat for Delta fishes.

- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration would result in an increase in the frequency and duration of inundation of an estimated 6 acres of managed wetland. Specific locations for this restoration activity have not been identified, but they would likely be focused in the south Delta area, along the major rivers and Delta channels. The connection of these wetlands to stream flooding events would be beneficial to the ecological function of managed wetlands, especially as they relate to BDCP target aquatic species. Foraging activity and refuge sites would be expanded into areas currently unavailable or infrequently available to some aquatic species. The more frequent flooding would periodically interfere with management activities associated with terrestrial species (primarily waterfowl) and may result in changes in plant composition and management strategies over time.

In summary, 937–2,618 acres of managed wetland community in the study area would be subjected to more frequent inundation as a result of implementing two Alternative 9 conservation measures (CM2 and CM5).

NEPA Effects: Managed wetland community would not be adversely affected because much of the acreage affected is conditioned to periodic inundation. The more frequent inundation could create management problems associated with certain species, especially waterfowl, and result in changes over time in plant species composition. The total acreage of managed wetland would not be expected to change permanently as a result of the periodic inundation.

CEQA Conclusion: An estimated 937–2,618 acres of managed wetland community in the study area would be subjected to more frequent inundation as a result of implementing CM2 and CM5 under Alternative 9. Managed wetland community would not be significantly impacted because periodic inundation is already experienced by most of the land that would be affected. There could be increased management problems and a long-term shift in plant species composition. The periodic inundation would not be expected to result in a net permanent reduction in the acreage of this community in the study area. Therefore, there would be a less-than-significant impact on the community.

Impact BIO-26: Modification of Managed Wetland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 9 are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the BDCP facilities and conservation lands that could affect managed wetland natural community in the study area. The ongoing actions include the diversion of Sacramento River flows into two newly screened diversions at Georgianna Slough and Delta Cross Channel, operation of multiple operable barriers in Delta waterways, modified diversions from south Delta channels, and recreational use of reserve areas. These actions are associated with CM1 and CM11 (see the above impact discussion for effects associated with CM2). The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (CM11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and modified diversions from south Delta channels*. Changes in releases from reservoirs upstream of the study area, modified diversion of Sacramento River flows at two newly screened diversions at Georgianna Slough and Delta Cross Channel, operation of multiple operable barriers in Delta waterways, and modified diversions from south Delta channels (Operational Scenario G) would not result in the reduction in acreage of the managed wetland natural community in the study area. Flow levels in the upstream rivers would not change to the degree that water levels in adjacent managed wetlands would be altered. Similarly, modified diversions of Sacramento River flows in at Georgianna Slough and Delta Cross Channel would not result in a permanent reduction in the managed wetland community downstream of these diversions. The majority of the managed wetlands below the diversions is not directly connected to the rivers. Modified diversions from south Delta channels would not create a reduction in this natural community.

- *Access road, water conveyance facility and levee repair*. Periodic repair of access roads, water conveyance facilities and levees associated with the BDCP actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in managed wetland habitats. This activity could lead to increased soil erosion, turbidity and runoff entering managed wetlands. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan*. Any vegetation removal or earth work adjacent to or within managed wetland habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management*. Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*CM11 Natural Resources Enhancement and Management)*. Use of herbicides to control nuisance vegetation could pose a long-term hazard to managed wetland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the community, or direct discharge of herbicides to managed wetland areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the BDCP to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments are described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic and terrestrial environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

Herbicides to remove aquatic invasive species as part of CM13 would be used to restore the normal ecological function of tidal and nontidal aquatic habitats in planned restoration areas. The treatment activities would be conducted in concert with the California Department of Boating and Waterways' invasive species removal program. Eliminating large stands of water hyacinth and Brazilian waterweed would improve habitat conditions for some aquatic species by removing cover for nonnative predators, improving water flow and removing barriers to movement (see Chapter 11, *Fish and Aquatic Resources*). These habitat changes should also benefit terrestrial species that use managed wetland natural community for movement corridors and for foraging. Vegetation management effects on individual species are discussed in the species sections on following pages.

- *Habitat enhancement*. The BDCP includes a long-term management element for the natural communities within the Plan Area (CM11). For the managed wetland natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

- *Recreation.* The BDCP would allow hunting, fishing and hiking in managed wetland reserve areas. *CM11 Natural Communities Enhancement and Management* (BDCP Chapter 3, Section 3.4.11) describes this program and identifies applicable restrictions on recreation that might adversely affect managed wetland habitat. BDCP also includes an avoidance and minimization measure (AMM37) that further dictates limits on recreation activities that might affect this natural community. Hunting would be the dominant activity in fall and winter months, while fishing and hiking would be allowed in non-hunting months.

The various operations and maintenance activities described above could alter acreage of managed wetland natural community in the study area through facilities maintenance, vegetation management and recreation. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the Plan, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural*

Communities Enhancement and Management, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be offset by restoration activities planned as part of *CM4 Tidal Natural Communities Restoration, CM10 Nontidal Marsh Restoration* and protection and restoration actions associated with *CM3 Natural Communities Protection and Restoration*. Recreation activity effects would be minimized by AMM37 (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). The management actions associated with levee repair and control of invasive plant species would also result in a long-term benefit to the species associated with managed wetland habitats by improving water movement.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 9 would not result in a net permanent reduction in acreage of the managed wetland natural community within the study area. Therefore, there would be no adverse effect on this natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 9 would have the potential to create minor changes in total acreage of managed wetland natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Hunting could intermittently reduce the availability of this community to special-status and common wildlife species. Implementation of environmental commitments and AMM2, AMM4, AMM5 and AMM37 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would create positive effects, including improved water movement in and adjacent to these habitats. Long-term restoration activities associated with *CM10 Nontidal Marsh Restoration and CM4 Tidal Natural Communities Restoration* and protection and restoration actions associated with *CM3 Natural Communities Protection and Restoration* would expand the ecological functions of this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact.

Other Natural Seasonal Wetland

The other natural seasonal wetlands natural community encompasses all the remaining natural (not managed) seasonal wetland communities other than vernal pools and alkali seasonal wetlands. These areas mapped by CDFW (Hickson and Keeler-Wolf 2007) and ICF biologists (the eastern area of additional analysis; see Figure 12-1) consist of seasonally ponded, flooded, or saturated soils dominated by grasses, sedges, or rushes. The largest segments of this community in the study area are located along the Cosumnes River northeast of Thornton, and in the eastern extension of the study area northwest of Rio Vista. Most of the smaller mapped areas are located in the Suisun Marsh ROA on the western edge of the Montezuma Hills and in the interior of the Potrero Hills. There are also other natural seasonal wetlands mapped along Old River and Middle River in CZ 7 (Figure 12-1). The only BDCP conservation component that would potentially affect this natural community is the seasonally inundated floodplain restoration conservation measure (CM5) (see Table 12-9-10).

Table 12-9-10. Changes in Other Natural Seasonal Wetland Associated with Alternative 9 (acres)[a]

TOTAL IMPACTS	**0**	**0**	**0**	**0**	**0**	**0**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only.
NT = near-term
LLT = late long-term
Unk. = unknown

Impact BIO-27: Modification of Other Natural Seasonal Wetland Natural Community as a Result of Implementing BDCP Conservation Measures

Based on theoretical footprints for this activity, *CM5 Seasonally Inundated Floodplain Restoration* could expose 2 acres of other natural seasonal wetland community to additional flooding as channel margins are modified and levees are set back to improve fish habitat along some of the major rivers and waterways throughout the study area. Specific locations for this restoration activity have not been identified, but they would likely be focused in the south Delta area, along the major rivers and Delta channels, including the channels of Old River and Middle River. Several small patches of other natural seasonal wetland natural community are mapped along these waterways. The exposure of these seasonal wetlands to increased but infrequent episodes of stream flooding would not alter their ecological function or species composition. Their value to special-status and common plants and wildlife in the study area would not be affected. The effects of this inundation on wildlife and plant species are described in detail in later sections of this chapter.

NEPA Effects: Alternative 9 conservation actions would not adversely affect other natural seasonal wetland natural community because the small increase in periodic flooding of up to 2 acres would not alter its function or general species makeup.

CEQA Conclusion: An estimated 2 acres of other natural seasonal wetland community in the study area would be subjected to more frequent inundation from flood flows as a result of implementing CM5 under Alternative 9. This community would not be significantly impacted because a small increase in periodic flooding would not alter its ecological function or species composition. The periodic inundation would not result in a net permanent reduction in the acreage of this community in the study area. Therefore, there would be no substantial adverse effect on the community. The impact would be less than significant.

Impact BIO-28: Modification of Other Natural Seasonal Wetland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 9 are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the BDCP facilities and conservation lands that could affect other natural seasonal wetland natural community in the study area. The ongoing actions include the diversion of Sacramento River flows at Georgianna Slough and Delta Cross Channel, operation of multiple operable barriers in Delta waterways, and modified diversions from south Delta channels. These actions are associated with CM1. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (CM11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and modified diversions from south Delta channels*. Changes in releases from reservoirs upstream of the study area, modified diversion of Sacramento River flows at Georgianna Slough and Delta Cross Channel, operation of multiple operable barriers in Delta waterways, and modified diversions from south Delta channels (Operational Scenario G) would not affect other natural seasonal wetland natural community. The small areas mapped in the study area are not in or adjacent to streams that would experience changes in water levels as a result of these operations.
- *Access road, water conveyance facility and levee repair*. Periodic repair of access roads, water conveyance facilities and levees associated with the BDCP actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in or adjacent to other natural seasonal wetland habitats. This activity could lead to increased soil erosion and runoff entering these habitats. These activities would be subject to normal erosion and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan*. Any vegetation removal or earth work adjacent to or within other natural seasonal wetland habitats would require use of sediment barriers, soil stabilization and revegetation of disturbed surfaces, as required by *AMM10 Restoration of Temporarily Affected Natural Communities*. Proper implementation of these measures would avoid permanent adverse effects on this community.
- *Vegetation management*. Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*CM11 Natural Communities Enhancement and Management)*. Use of herbicides to control nuisance vegetation could pose a long-term hazard to the other natural seasonal wetland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to wetland areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the BDCP to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments are described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in terrestrial or aquatic environments would also

reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Habitat enhancement*. The BDCP includes a long-term management element for the natural communities within the Plan Area (CM11). For the other natural seasonal wetland natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of other natural seasonal wetland natural community in the study area. Activities could introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the Plan, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be minor when compared to the restoration activities planned as part of *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, or minimized by implementation of AMM2, AMM4, AMM5, and AMM10. The vernal pool complex conservation measure includes restoration of 139 acres of seasonal wetlands with similar ecological values as the other natural seasonal wetland community. The management actions associated with control of invasive plant species would also result in a long-term benefit to the species associated with other natural seasonal wetland habitats by eliminating competitive, invasive species of plants.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 9 would not result in a net permanent reduction in the other natural seasonal wetland natural community within the study area. Therefore, there would be no adverse effect on this natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 9 would have the potential to create minor changes in total acreage of other natural seasonal wetland natural community in the study area, and could create temporary increases sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, AMM5, and AMM10 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would create positive effects, including reduced competition from invasive, nonnative plants in these habitats. Long-term restoration activities associated with *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* and protection actions associated with *CM3 Natural Communities Protection and Restoration* would ensure that the ecological values provided by this small natural community would not decrease in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this natural community within the study area. Therefore, there would be a less-than-significant impact.

Grassland

Construction, operation, maintenance and management associated with the conservation components of Alternative 9 would have no long-term adverse effects on the habitats associated with the grassland natural community. Initial development and construction of CM1, CM2, CM4, CM5, CM6, CM7, CM11 and CM18 would result in both permanent and temporary removal of this community (see Table 12-9-11). Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit the grassland natural community.

- Protect 8,000 acres of grassland with at least 2,000 acres protected in Conservation Zone 1, at least 1,000 acres protected in Conservation Zone 8, and at least 2,000 acres protected in Conservation Zone 11 (Objective GNC1.1, associated with CM3).
- Restore 2,000 acres of grasslands to connect fragmented patches of protected grassland and to provide upland habitat adjacent to riparian, tidal, and nontidal natural communities for wildlife foraging and upland refugia (Objective GNC1.2, associated with CM3 and CM8).
- Of the 8,000 acres of grassland protected and at least 2,000 acres of grassland restored, protect or restore grasslands adjacent to restored tidal brackish emergent wetlands to provide 200 feet of adjacent grasslands beyond the sea level rise accommodation (Objective GNC1.4, associated with CM3 and CM8).

There is a variety of other, less specific conservation goals and objectives in BDCP Chapter 3, Section 3.3 that would improve the value of grassland natural community for terrestrial species. As explained below, with the protection, restoration and enhancement of the amounts of habitat listed in the BDCP objectives, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-11. Changes in Grassland Natural Community Associated with Alternative 9 (acres)[a]

Impact BIO-29: Changes in Grassland Natural Community as a Result of Implementing BDCP Conservation Measures

Construction, channel dredging, land grading and habitat restoration activities that would accompany the implementation of CM1, CM2, CM4, CM5, CM6, CM7, CM11 and CM18 would permanently eliminate an estimated 2,138 acres and temporarily remove 617 acres of grassland natural community in the study area. These modifications represent approximately 3% of the 78,047 acres of the community that is mapped in the study area. Approximately 56% (1,553 acres) of the permanent and temporary losses would occur during the first 10 years of Alternative 9 implementation, as water conveyance facilities are constructed and habitat restoration is initiated. Grassland protection (2,000 acres) and restoration (1,140 acres) would be initiated during the same period. By the end of the Plan period, 2,000 acres of this natural community would be restored and 8,000 acres would be protected. There would be a net reduction in grassland acreage, but an increase in grassland value in the study area. The BDCP beneficial effects analysis for grassland, which was developed for Alternative 4 (BDCP Chapter 5, Section 5.4.11.2), indicates that 8,000 acres of grasslands would be protected in Conservation Zones 1, 2, 4, 5, 7, 8, and 11, and 2,000 acres of grassland would be restored. Grassland protection and restoration would improve connectivity among habitat areas in and adjacent to the Plan Area, improve genetic interchange among native species' populations, and contribute to the long-term conservation of grassland-associated covered species. The same conservation actions would be implemented for Alternative 9.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of the Alternative 9 water conveyance facilities would permanently remove 82 acres and temporarily remove 344 acres of grassland natural community. The permanent losses would occur at numerous locations where dredging, construction of operable barriers and canals, and channel enlargement would be undertaken. The main locations affected and the types of grassland lost are listed below (see Terrestrial Biology Mapbook for location details).
    - Permanent and temporary losses of thin bands of ruderal herbaceous grasses and forbs at the canal construction site connecting Clifton Court Forebay with the export pipelines.
    - Permanent and temporary losses of thin bands of ruderal herbaceous grasses and forbs at the canal construction site that connects Clifton Court Forebay with Victoria Canal.
    - Permanent and temporary losses of thin bands of ruderal herbaceous grasses and forbs along Victoria Canal where access roads and a barge unloading facility would be constructed.
    - Permanent and temporary losses of thin bands of ruderal herbaceous grasses and forbs along the edges of Middle River between Victoria Canal and Mildred Island where access roads and dredging work areas would be established.
    - Permanent losses of rye grassland from the channel enlargement connecting the Sacramento River with the Meadows Slough.
    - Permanent and temporary losses of rye grassland from channel enlargement in the Meadows Slough east of the Sacramento River.
    - Permanent and temporary losses of ruderal herbaceous grasses and forbs at intake and fish screen construction sites at Delta Cross Channel junction with Sacramento River.
    - Permanent and temporary losses of thin bands of ruderal herbaceous grasses and forbs at these operable barrier construction sites (some with barge unloading facilities):
        - Connection Slough at its junction with Middle River.
        - Middle River just south of its junction with Victoria Canal.
        - Old River at its northern junction with the San Joaquin River.
        - Fishermans Cut at its junction with the San Joaquin River.
        - Three Mile Slough at its junction with the Sacramento River.

These losses would take place during the near-term construction period.

The construction activity associated with CM1 also has the potential to lead to increased nitrogen deposition in grassland habitats in the vicinity of Clifton Court Forebay. A significant number of cars, trucks, and land grading equipment involved in construction of canals in and around the forebay would emit small amounts of atmospheric nitrogen from fuel combustion; this material could be deposited in sensitive grassland areas that are located west of the major construction areas at Clifton Court Forebay. Nitrogen deposition can pose a risk of adding a fertilizer to nitrogen-limited soils and their associated plants. Nonnative invasive species can be encouraged by the added nitrogen available. BDCP Appendix 5.J, Attachment 5J.A, *Construction-Related Nitrogen Deposition on BDCP Natural Communities*, addresses this issue in detail. It has been concluded that this potential deposition would pose a low risk of changing the grassland in and adjacent to the construction areas because the construction would contribute a negligible amount of nitrogen to regional projected emissions and the existing grassland is dominated by nonnative invasive species of plants. Also, the construction at Clifton Court Forebay would occur primarily downwind of the natural community. No adverse effect is expected.

- *CM2 Yolo Bypass Fisheries Enhancement*: Implementation of CM2 involves a number of construction activities within the Yolo and Sacramento Bypasses, including Fremont Weir and stilling basin improvements, Putah Creek realignment activities, Toe Drain/Tule Canal and Lisbon Weir modification and Sacramento Weir improvements. All of these activities could involve excavation and grading in grassland areas to improve passage of fish through the bypasses. Based on hypothetical construction footprints, a total of 388 acres could be permanently lost and another 239 acres could be temporarily removed. Most of the grassland losses would occur at the north end of the bypass below Fremont Weir where a large expanse of grassland is present, along the Toe Drain/Tule Canal, and along the west side channels. These grasslands are composed primarily of upland annual grassland and forbs. Some of this grassland removal along the side channels of the bypass could pose barriers to grassland species moving within the bypass. These losses would occur primarily in the near-term timeframe.

- *CM4 Tidal Natural Communities Restoration*: Based on the use of hypothetical restoration footprints, implementation of CM4 would permanently inundate or remove 448 acres of grassland in the near-term and inundate or remove 1,122 acres of grassland by the end of the Plan timeframe. The losses would occur in a number of ROAs established for tidal restoration (see Figure 12-1). The largest losses would likely occur in the vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the upslope fringes of Suisun Marsh, and along narrow bands adjacent to waterways in the South Delta ROA. Most of this grassland is ruderal herbaceous vegetation with low habitat value; some of the larger patches of grassland in the Cache Slough ROA are annual grassland with higher values.

- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration levee construction would permanently remove 51 acres and temporarily remove 34 acres of grassland natural community. The construction-related losses would be considered a permanent removal of the habitats. These losses would be expected to occur along the San Joaquin River and other major waterways in CZ 7 (see Figure 12-1). The grassland in this area is primarily composed of narrow bands and small patches of ruderal herbaceous grasses and forbs. This activity is scheduled to start following construction of water conveyance facilities, which is expected to take 10 years.

- *CM6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in removal of small amounts of grassland natural community along 20 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur along waterway margins where grassland habitat stringers exist, including along levees and channel banks. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.

- *CM7 Riparian Natural Community Restoration;* Riparian natural community restoration would occur in a variety of settings in the Plan Area, with an emphasis on improving connectivity of existing riparian areas and stream/river corridors, to benefit the movement and interchange of special-status and common species that use these areas. Large tracts would be restored in concert with floodplain restoration (CM5), while narrower bands would be developed as part of channel margin enhancement (CM6) and tidal marsh restoration (CM4). In the process of expanding woody riparian habitat, existing nonnative grassland would be removed. While specific locations for these restoration activities have not been fully developed, use of theoretical footprints for this activity indicate that up to 410 acres of grassland could be lost through the course of Alternative 9 implementation. A majority of this activity would occur in the South Delta and Cosumnes/Mokelumne ROAs (see Figure 12-1).
- *CM8 Grassland Natural Community Restoration*: The grassland natural community would be restored primarily on the fringes of the Delta, where upland areas merge with Delta wetland and agricultural lands. Restoration would focus on CZs 1, 8, and 11, as proposed by BDCP Objective GNC1.1 (Figure 12-1), with a goal of improving habitat connectivity and increasing the diversity of grassland species (BDCP Objective GNC1.2). Some of the planned 2,000 acres of restoration would occur around existing populations of giant garter snake in the east Delta and the Yolo Bypass area.
- *CM11 Natural Communities Enhancement and Management:* Natural communities enhancement and management would include a wide range of activities designed to improve habitat conditions in restored and protected lands associated with the BDCP. This measure also promotes sound use of pesticides, vector control activities, invasive species control and fire management in preserve areas. To improve the public's ability to participate in recreational activities in and adjacent to restored and protected habitats, a system of trails is proposed. The location and extent of this system are not yet known, so the analysis of this activity is programmatic. At the current level of planning, it is assumed that the trail system would be located entirely in grassland habitats and would include up to 50 acres of habitat loss.
- *CM18. Conservation Hatcheries:* The BDCP includes a proposal to design and construct a conservation hatchery to maintain populations of delta smelt and longfin smelt. The location of this facility is not yet firmly established, but for planning purposes it has been assumed that it would be constructed in the vicinity of Rio Vista and would be located in grassland habitat. The grassland in the Rio Vista area includes both California annual grassland and ruderal herbaceous grasses and forbs. The current estimate of the land needed for this facility is 35 acres.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

During the near-term timeframe (the first 10 years of BDCP implementation), Alternative 9 would affect the grassland natural community through CM1 construction losses (82 acres permanent and 344 acres temporary), CM2 construction losses (388 acres permanent and 239 acres temporary), CM11 recreational trail construction (13 acres permanent), CM18 fish hatchery construction (35 acres permanent), and CM7 riparian habitat restoration (4 acres permanent). These losses would occur at multiple locations, including canal, channel enlargement and operable barrier construction sites; adjacent to dredging operations along Middle River; in the northern Yolo Bypass; along the east and west channels within the Yolo Bypass; and at currently unspecified sites for hatchery and recreational trail construction and riparian restoration. Approximately 448 acres of the inundation and construction-related losses in habitat from CM4 would occur in the near-term. These tidal restoration-related losses would occur throughout the ROAs mapped in Figure 12-1.

The construction losses of this natural community would not represent an adverse effect based on the significance criteria used for this chapter because grassland is not considered a special-status or sensitive natural community. Most Central Valley grasslands are dominated by nonnative annual grasses and herbs. However, the importance of grassland as a habitat that supports life stages of numerous special-status plants and wildlife is well documented (see BDCP Chapter 3, *Conservation Strategy*). The significance of losses in grassland habitat is, therefore, discussed in more detail in species analyses later in this chapter. The combination of restoring 1,140 acres (CM8) and protecting 2,000 acres (CM3) of grassland natural community during the first 10 years of BDCP implementation, and the commitment to restore temporarily affected grassland (583 acres) to its pre-project condition within 1 year of completing construction as required by *AMM10 Restoration of Temporarily Affected Natural Communities*, would offset this near-term loss, avoiding any loss in the value of this habitat for special-status species. The restoration of grassland would include protection in perpetuity, and the protected and restored habitat would be managed and enhanced to benefit special-status and common wildlife species (CM3 and CM11). The typical project-level mitigation ratio (2:1 for protection) would indicate that 3,106 acres of protection would be needed to offset (i.e., mitigate) the 1,553 acres of near-term temporary and permanent loss. The combination of protection and restoration (2,000 acres of protection and 1,140 acres of restoration), along with the enhancement and management associated with CM3 and CM11 contained in the BDCP is designed to avoid a temporal lag in the value of grassland habitat available to sensitive species. There would be no adverse effect.

The Plan also includes commitments to implement *AMM1 Worker Awareness training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

Implementation of Alternative 9 as a whole would result in approximately 3% losses of grassland natural community in the study area. These losses (2,138 acres of permanent and 617 acres of temporary loss) would be largely associated with construction of the water conveyance facilities (CM1), construction of Yolo Bypass fish improvements (CM2), inundation during tidal marsh restoration (CM4), and riparian habitat restoration (CM7). Inundation losses would occur through the course of BDCP restoration activities at various tidal restoration sites throughout the study area.

***NEPA Effects*:** By the end of the Plan timeframe, a total of 2,000 acres of this natural community would be restored (CM8) and 8,000 acres would be protected (CM3). The restoration would occur primarily in CZ 1, CZ 8, and CZ 11, in the Cache Slough, Suisun Marsh and Clifton Court Forebay areas. Temporarily affected grassland would also be restored following construction activity. The 2,000 acres of restoration associated with CM8, and the restoration of temporarily affected grassland required by AMM10 (617 acres for Alternative 9) would not totally replace the grassland acres lost through the Plan timeframe (2,755 acres). There would be a permanent loss of 138 acres of grassland in the study area. However, the combination of restoration, protection and enhancement of grassland associated with Alternative 9 would improve the habitat value of this community in the study area; there would not be an adverse effect on the grassland natural community.

CEQA Conclusion:

Near-Term Timeframe

Alternative 9 would result in the loss of approximately 1,553 acres of grassland natural community in the near-term (a combination of the temporary and permanent losses listed in Table 12-9-11) due to construction of the water conveyance facilities (CM1), fish passage improvements (CM2), riparian habitat restoration (CM7), recreational trail development (CM11), fish hatchery construction (CM18), and inundation during tidal marsh restoration (CM4). The construction losses would occur at multiple canal and operable barrier construction sites, at channel enlargement sites, at dredging locations along Middle River and Victoria Canal, within the northern section of the Yolo Bypass, and at currently unspecified sites for hatchery and recreational trail construction and riparian habitat restoration. Inundation losses would occur at various tidal restoration sites throughout the study area. The construction losses would be spread across a 10-year near-term timeframe.

The construction losses of this natural community would not represent a significant impact based on the significance criteria used for this chapter because grassland is not considered a special-status or sensitive natural community. Nonetheless, these losses would be offset by planned restoration of 1,140 acres and protection of 2,000 acres of grassland natural community scheduled for the first 10 years of Alternative 9 implementation, and restoration of temporarily affected grassland (583 acres for Alternative 9) as dictated by AMM10. Also, AMM1, AMM2, AMM6, and AMM7 would be implemented to minimize impacts. Because of these offsetting near-term restoration and protection activities and AMMs, impacts would be less than significant. Typical project-level mitigation ratios (2:1 for protection) would indicate that 3,106 acres of protection would be needed to offset (i.e., mitigate) the 1,553 acres of loss. The combination of two approaches (protection and restoration) contained in the BDCP conservation measures and avoidance and minimization measures is designed to avoid a temporal lag in the value of grassland habitat available to special-status species. The protection and restoration would be initiated at the beginning of Alternative 9 implementation to minimize any time lag in the availability of this habitat to special-status species.

Late Long-Term Timeframe

At the end of the Plan period, 2,755 acres of grassland natural community would be permanently or temporarily removed by conservation actions, 2,000 acres would be restored and 8,000 acres would be protected. Temporarily affected areas would also be restored (617 acres for Alternative 9). While there would be a net permanent reduction in the acreage of this natural community within the study area (total loss of 138 acres), there would be an increase in the value of grassland for special-status and common species in the study area through the combination of conservation actions (CM3 and CM8) and avoidance and minimization measures (AMM1, AMM2, AMM6, AMM7, and AMM10). Therefore, Alternative 9 would have a less-than-significant impact on this natural community.

Impact BIO-30: Increased Frequency, Magnitude and Duration of Periodic Inundation of Grassland Natural Community

Two Alternative 9 conservation measures would modify the inundation/flooding regimes of both natural and man-made waterways in the study area. CM2, which is designed to improve fish passage and shallow flooded habitat for Delta fishes in the Yolo Bypass, would increase periodic inundation of grassland natural community at scattered locations, while CM5 would expose this community to additional flooding as channel margins are modified and levees are set back to improve fish habitat along some of the major rivers and waterways of the study area.

- *CM2 Yolo Bypass Fisheries Enhancement:* Operation of the Yolo Bypass under Alternative 9 would result in an increase in the frequency, magnitude and duration of inundation of 385–1,277 acres of grassland natural community. The methods used to estimate this inundation acreage are described in BDCP Appendix 5.J, *Effects on Natural Communities, Wildlife, and Plants*. The area more frequently affected by inundation would vary with the flow volume that would pass through the newly constructed notch in the Fremont Weir. The 385-acre increase in inundation would occur at the 1,000 cfs flow regime, while the 1,277-acre increase would occur at the 4,000 cfs flow regime. Plan-related increases in flow through Fremont Weir would be expected in 30% of the years. The grassland community occurs throughout the bypass, including a large acreage just below Fremont Weir in the north end of the bypass, in stringers along the internal waterways of the bypass and in larger patches in the lower bypass. The anticipated change in management of flows in the Yolo Bypass includes more frequent releases in flows into the bypass from the Fremont and Sacramento Weirs, and in some years, later releases into the bypass in spring months (April and May). The modification of periodic inundation events would not adversely affect grassland habitats, as they have persisted under similar high flows and extended inundation periods. There is the potential for some change in grass species composition as a result of longer inundation periods. The effects of this inundation on wildlife and plant species are described in detail in later sections of this chapter.
- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration would result in an increase in the frequency and duration of inundation of 85 acres of grassland habitats (a combination of the temporary and permanent losses listed in Table 12-9-11). Specific locations for this restoration activity have not been identified, but they would likely be focused in the south Delta area, along the major rivers and Delta channels in CZ 7 (see Figure 12-1). The increase in periodic stream flooding events would not adversely affect the habitat values and functions of grassland natural community.

In summary, 899–1,791 acres of grassland natural community in the study area would be subjected to more frequent inundation as a result of implementing two Alternative 9 conservation measures (CM2 and CM5).

NEPA Effects: The grasslands in the Yolo Bypass and along river floodplains in the south Delta are conditioned to periodic inundation; therefore, periodic inundation would not result in a net permanent reduction in the acreage and value of this community in the study area. Increasing periodic inundation of grassland natural community in the Yolo Bypass and along south Delta waterways would not constitute an adverse effect.

CEQA Conclusion: An estimated 899–1,791 acres of grassland natural community in the study area would be subjected to more frequent inundation as a result of implementing CM2 and CM5 under Alternative 9. The grassland natural community is conditioned to periodic inundation; therefore, periodic inundation would not result in a net permanent reduction in the acreage of this community in the study area. Increasing periodic inundation of grassland natural community in the Yolo Bypass and along south Delta waterways would have a less-than-significant impact on the community.

Impact BIO-31: Modification of Grassland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 9 are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the BDCP facilities and conservation lands that could affect grassland natural community in the study area. The ongoing actions include the diversion of Sacramento River flows at two newly screened sites at Georgianna Slough and Delta Cross Channel in the north Delta, operation of multiple operable barriers in Delta waterways, and modified diversions from south Delta channels. These actions are associated with CM1 (see the impact discussion above for effects associated with CM2). The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (CM13), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and modified diversions from south Delta channels* Changes in releases from reservoirs upstream of the study area, modified diversion of Sacramento River flows at Georgianna Slough and Delta Cross Channel in the north Delta, modified diversions from south Delta channels (Operational Scenario G) would not result in the permanent reduction in acreage of grassland natural community in the study area. Flow levels in the upstream rivers would not change such that the acreage of this community would be reduced on a permanent basis. The grassland along rivers upstream of planned north Delta diversions is primarily ruderal vegetation on levee banks and is dependent on winter and spring rains for germination and growth rather on than river levels. Similarly, modified diversions of Sacramento River flows at Georgianna Slough and Delta Cross Channel would not result in a permanent reduction in grassland natural community downstream of these diversions. The reductions in flows below the intakes would occur primarily in the wet months when the existing nonnative annual grasslands along river levees are dormant, and like upstream grassland, this community is dependent on winter and spring rains for germination and growth in the winter and spring months, not on river stage. Anticipated small changes in river salinity in the west Delta and Suisun Marsh would not create a substantial change in grassland acreage in these areas. Modified diversions from south Delta channels would not create a reduction in this natural community.
- *Access road, water conveyance facility and levee repair*. Periodic repair of access roads, water conveyance facilities and levees associated with the BDCP actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in grassland habitats. This activity could lead to increased soil erosion and runoff entering these habitats. These activities would be subject to normal erosion and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan*. Any vegetation removal or earth work adjacent to or within grassland habitats would require use of sediment barriers, soil stabilization and revegetation of disturbed surfaces (*AMM10 Restoration of Temporarily Affected Natural Communities*). Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management*. Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*CM11 Natural Communities Enhancement and Management)*. Use of herbicides to control nuisance vegetation could pose a long-term hazard to grassland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to grassland areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the BDCP to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments are described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in terrestrial environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.
- *Channel dredging*. Long-term operation of the Alternative 9 intakes at Georgianna Slough and Delta Cross Channel would include periodic dredging of sediments that might accumulate in front of intake screens. Periodic dredging would also be needed to maintain channel capacity in Middle River and Victoria Canal. The dredging could occur adjacent to grassland natural community. This activity should not permanently reduce the acreage of grassland natural community because it is periodic in nature; the grassland in the vicinity of the proposed intakes and dredged channels is ruderal grasses and herbs with low habitat value. *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities* are part of the Plan and would require actions to avoid or minimize dredging effects on adjacent sensitive vegetation.
- *Habitat enhancement*. The BDCP includes a long-term management element for the natural communities within the Plan Area (CM11). For the grassland natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of grassland natural community in the study area through changes in flow patterns and periodic facilities maintenance and dredging. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the Plan, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be offset by restoration activities planned as part of *CM8 Grassland Natural Community*

Restoration, or minimized by implementation of AMM2, AMM3, AMM4, AMM5, AMM6, and AMM10. The management actions associated with levee repair, periodic dredging and control of invasive plant species would also result in a long-term benefit to the species associated with grassland habitats by improving water movement in adjacent waterways and by eliminating competitive, invasive species of plants.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 9 would not result in a net permanent reduction in the grassland natural community within the study area. Therefore, there would be no adverse effect on this natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 9 would have the potential to create minor changes in total acreage of grassland natural community in the study area, and could create temporary increases sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM3, AMM4, AMM5, AMM6, and AMM10 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *CM3 Natural Communities Protection and Restoration* and *CM11 Natural Communities Enhancement and Management*, would create positive effects, including reduced competition from invasive, nonnative plants in these habitats. Long-term restoration activities associated with *CM8 Grassland Natural Community Restoration* and protection actions associated with *CM3 Natural Communities Protection and Restoration* would increase the value of this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in the value of this natural community within the study area. Therefore, there would be a less-than-significant impact.

Inland Dune Scrub

The inland dune scrub natural community is composed of vegetated, stabilized sand dunes associated with river and estuarine systems. In the study area, the inland dune scrub community includes approximately 19 acres of remnants of low-lying ancient stabilized dunes related to the Antioch Dunes formation located near the town of Antioch (CZ 10; see Figure 12-1). While this community is within the BDCP Plan Area, none of the Alternative 9 conservation measures or covered actions is expected to affect it.

Cultivated Lands

Cultivated lands is the major land cover type in the study area (487,106 acres; see Table 12-1 in Section 12.1.2, *Land Cover Types*). The Delta, the Yolo Bypass and the Cache Slough drainage are dominated by various types of agricultural activities, with crop production the dominant element (see Figure 12-1). Major crops and cover types in agricultural production include grain and hay crops (wheat, oats and barley), field crops (corn, beans and safflower), truck crops (tomatoes, asparagus and melons), pasture (alfalfa, native and nonnative pasture), rice, orchards, and vineyards. Tables 12-2 and 12-3 list special-status wildlife species supported by cultivated lands.

The effects of Alternative 9 on cultivated lands are discussed from various perspectives in this document. Chapter 14, *Agricultural Resources*, includes a detailed analysis of cropland conversion as it relates to agricultural productivity. Many of the discussions of individual terrestrial plant and wildlife species in this chapter also focus on the relevance of cultivated land loss. Because cultivated lands is not a natural community and because the effects of its loss are captured in the individual species analyses below, there is no separate analysis of this land cover type presented here. Table

14-8 in Chapter 14 provides a comparison of important farmland losses that would result from construction of CM1 water conveyance facilities for each alternative, and Table 14A-1 in Appendix 14A, *Individual Crop Effects as a Result of BDCP Water Conveyance Facility Construction,* provides a similar comparison for losses of individual crops. Table 12-ES-1 in this chapter's Summary of Effects identifies the total cultivated land loss for all project alternatives. For Alternative 9, the total loss (permanent and temporary) is estimated to be 55,091 acres. The majority of the permanent loss would be associated with habitat restoration activities, including Yolo Bypass fisheries enhancement (CM2; 629 acres), tidal marsh restoration (CM4; 39,565 acres), floodplain restoration (CM5; 2,087 acres), riparian natural community restoration (CM7; 960 acres), grassland restoration (CM8; 2,000 acres) and nontidal marsh restoration (CM10; 1,950 acres). Construction of the through-Delta water conveyance facilities (CM1) would permanently remove 350 acres of cultivated land.

Developed Lands

Additional lands in the study area that were not designated with a natural community type have been characterized here as developed lands. Developed lands include lands with residential, industrial, and urban land uses, as well as landscaped areas, riprap, road surfaces and other transportation facilities. Developed lands support some common plant and wildlife species, whose abundance and species richness vary with the intensity of development. One special-status species, the giant garter snake, is closely associated with a small element of developed lands; specifically, embankments and levees near water that are covered with riprap. There are approximately 90,660 acres of developed lands in the study area.

As with cultivated lands, no effort has been made to analyze the effects of BDCP covered actions on this land cover type. It is not a natural community. The effects of its conversion are discussed in Chapter 13, *Land Use*. Where the loss of developed lands may affect individual special-status species or common species, the impact analysis is contained in that species discussion.

Wildlife Species

Vernal Pool Crustaceans

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on vernal pool crustaceans (California linderiella, Conservancy fairy shrimp, longhorn fairy shrimp, midvalley fairy shrimp, vernal pool fairy shrimp, and vernal pool tadpole shrimp). The habitat model used to assess effects for the vernal pool crustaceans consists of: vernal pool complex, which consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly affected by agricultural or development practices; alkali seasonal wetlands in CZ 8; and degraded vernal pool complex, which consists of low-value ephemeral habitat ranging from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, discing, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. For the purpose of the effects analysis, vernal pool complex is categorized as high-value for vernal pool crustaceans and degraded vernal pool complex is categorized as low-value for these species. Alkali seasonal wetlands in CZ 8 were included in the model as high-value habitat for vernal pool crustaceans. Also included as low-value for vernal pool crustaceans are areas along the eastern boundary of Conservation Zone 11 that are mapped as vernal pool complex because they flood seasonally and support typical vernal pool plants, but which do not include topographic depressions that are characteristic of vernal pool crustacean habitat.

Construction and restoration associated with Alternative 9 conservation measures would result in permanent losses (see Table 12-9-12) and indirect conversions of vernal pool crustacean modeled habitat. The majority of the losses would take place over an extended period of time as tidal marsh is restored in the Plan Area. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit vernal pool crustaceans (BDCP Chapter 3, *Conservation Strategy*).

- Protect 600 acres of vernal pool complex in CZ 1, CZ 8, or CZ 11, primarily in core vernal pool recovery areas (Objective VPNC1.1, associated with CM3).
- Restore vernal pool complex in CZ 1, CZ 8, and CZ 11 to achieve no net loss of vernal pool acreage (up to 67 acres of vernal pool complex restoration [10 wetted acres])(Objective VPNC1.2, associated with CM9).
- Increase size and connectivity of protected vernal pool complexes in plan area and increase connectivity with complexes outside the Plan Area (Objective VPNC1.3)
- Protect the range of inundation characteristics of vernal pools in the Plan Area (Objective VPNC1.4)
- Maintain and enhance vernal pool complexes to provide appropriate inundation (ponding) for supporting and sustaining vernal pool species (Objective VPNC2.1)
- Protect one currently unprotected occurrence of conservancy fairy shrimp (Objective VPC1.1)

As explained below, with the restoration or protection of these amounts of habitat, in addition to implementation of AMMs, impacts on vernal pool crustaceans would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-12. Changes in Vernal Pool Crustacean Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	High-value	0	0	0	0	NA	NA
	Low-value	0	0	0	0	NA	NA
Total Impacts CM1		**0**	**0**	**0**	**0**		
CM2–CM18 [b]	High-value	0	0	0	0	0–4	0
	Low-value	201	372	0	0	0	0
Total Impacts CM2–CM18		**201**	**372**	**0**	**0**	**0–4**	**0**
TOTAL IMPACTS		**201**	**372**	**0**	**0**	**0–4**	**0**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-32: Loss or Conversion of Habitat for and Direct Mortality of Vernal Pool Crustaceans

Alternative 9 conservation measures would result in the direct, permanent loss of up to 372 acres modeled vernal pool crustacean habitat, all of which would be to low-value habitat and would all be based on the hypothetical footprints for tidal natural communities restoration (CM4). In addition, the conservation measures could result in the indirect conversion due to hydrologic changes of an additional 135 acres of vernal pool crustacean habitat (89 acres of high-value habitat and 45 acres of low-value habitat) from the hypothetical footprints for tidal restoration (CM4). Tidal restoration activities may result in the modification of hardpan and changes to the perched water table, which could lead to alterations in the rate, extent, and duration of inundation of nearby vernal pool crustacean habitat. USFWS typically considers construction within 250 feet of vernal pool crustacean habitat to constitute a possible conversion of crustacean habitat unless more detailed information is provided to further refine the limits of any such effects. For the purposes of this analysis, the 250-foot buffer was applied to the water conveyance facilities work areas where surface and subsurface disturbance activities would take place and to restoration hypothetical footprints. Habitat enhancement and management activities (CM11), which include disturbance or removal of nonnative vegetation, could result in local adverse habitat effects.

Alternative 9 would also result in impacts on critical habitat for Conservancy fairy shrimp (248 acres), vernal pool fairy shrimp (270 acres), and vernal pool tadpole shrimp (270 acres). The hypothetical tidal restoration (CM4) footprints in CZ 11 account for all of these effects. *AMM12*

Vernal Pool Crustaceans would ensure that there would be no adverse modification of the primary constituent elements of critical habitat for these species.

Because the estimates of habitat loss resulting from tidal inundation are based on projections of where restoration may occur, actual effects are expected to be lower because sites would be selected and restoration projects designed to minimize or avoid effects on the covered vernal pool crustaceans. As specified in *AMM12 Vernal Pool Crustaceans* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, the BDCP Implementation Office would ensure that tidal restoration projects and other covered activities would be designed such that no more than a total of 10 wetted acres of vernal pool crustacean habitat are permanently lost. *AMM12* would also ensure that no more than 20 wetted acres of vernal pool crustacean habitat are indirectly affected by alterations to hydrology resulting from adjacent BDCP covered activities, in particular tidal restoration. The term *wetted acre*s refers to an area that would be defined by the three parameter wetland delineation method used by USACE to determine the limits of a wetland, which involves an evaluation of wetland soil, vegetation, and hydrology characteristics. This acreage differs from vernal pool complex acreages in that a vernal pool complex is composed of individual wetlands (vernal pools) and those upland areas that are in between and surrounding them, which provide the supporting hydrology (surface runoff and groundwater input), organic and nutrient inputs, and refuge for the terrestrial phase of some vernal pool species.

A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM4 Tidal Natural Communities Restoration:* Tidal natural communities restoration would result in the permanent loss of approximately 372 acres of low-value vernal pool crustacean habitat, which consists of degraded vernal pool complex. The BDCP describes degraded vernal pool complex as areas of low- value ephemeral habitat ranging from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, discing, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. The actual density of vernal pools or other aquatic features in these areas is unknown, but a 2012 review of Google Earth imagery found that these habitats appear to generally have low densities. However, areas mapped as degraded vernal pool complex may still provide habitat for vernal pool crustaceans as evidenced by records of vernal pool fairy shrimp, vernal pool tadpole shrimp, and California linderiella occurring in degraded vernal pool complex in CZ 4 (California Department of Fish and Wildlife 2013). Helm (1998) notes that many vernal pool crustaceans can occur in degraded vernal pool habitats and artificial habitats. In CZs 2 and 4, there are several records of covered vernal pool crustaceans occurring outside of modeled habitat in areas that appear to be road side ditches. So though degraded vernal pool complexes may not represent botanically diverse vernal pools they still can provide habitat for vernal pool crustaceans and thus the loss of 372 acres of degraded vernal pool complex may result in the loss of occupied vernal pool crustacean habitat. In addition, tidal restoration could result in the indirect conversion of 136 acres of vernal pool crustacean habitat, which consist of 89 acres of high-value and 45 acres of low-value habitat. The hypothetical restoration footprints overlap with a CNDDB record for vernal pool fairy shrimp near the current edge of Suisun Marsh. Tidal natural community restoration under Alternative 9 would also result in impacts on critical habitat for Conservancy fairy shrimp (248 acres), vernal pool tadpole shrimp (270 acres), and vernal pool fairy shrimp (270 acres). *AMM12 Vernal Pool Crustaceans* would ensure that there would be no adverse modification of the primary constituent elements of critical habitat for these species.

- *CM11 Natural Communities Enhancement and Management:* As described in the BDCP, restoration/creation of vernal pools to achieve no net loss and the protection of 600 acres of vernal pool complex would benefit vernal pool crustaceans (Table 12-9-12). A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in BDCP-protected habitats may result in localized ground disturbances that could temporarily affect vernal pool crustacean habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on vernal pool crustacean habitat and are expected to result in overall improvements to and maintenance of vernal pool crustacean habitat values over the term of the BDCP. Human presence for recreation activities could result in the injury or mortality of, and degreation of habitat for, vernal pool crustaceans through trampling pool edges, increased turbidity, unauthorized collection, and introduction of trash. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included. Table 12-9-13 was prepared to further analyze BDCP effects on vernal pool crustaceans using wetted acres of habitat in order to compare the effects of this alternative with the effect limits established in BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*, and *AMM12 Vernal Pool Crustaceans*, which are measured in wetted acres of vernal pool crustacean habitat. Wetted acres were estimated by using the BDCP's assumption that restored vernal pool complexes would have a 15% density of vernal pools (i.e., of 100 acres of vernal pool complex 15 acres would constitute vernal pools and the remaining 85 acres supporting uplands). Based on an informal evaluation of aerial photographs of the Plan Area it is likely that the actual densities within the Plan Area are approximately 10%, but the 15% density value was chosen as a conservative estimate for determining effects.

Table 12-9-13. Estimated Effects on Wetted Vernal Pool Crustacean Habitat under Alternative 9 (acres)

		Direct Loss		Indirect Conversion	
		Near-Term	Late Long-Term	Near-Term	Late Long-Term
BDCP Impact Limit[a]		5	10	10	20
Alternative 9 Impact[b]	CM1[c]	0	0	0	0
	CM4[d]	30.2	55.8	11.0	20.3
Total		**30.2**	**55.8**	**11.0**	**20.3**

[a] Because roughly half of the impacts would occur in the near–term, it is assumed that the impact limit in the near-term would be 5 wetted acres for direct loss and 10 acres for indirect.

[b] These acreages were generated by assuming that the modeled habitat identified in Table 12-9-12 has densities of wetted vernal pool crustacean habitat at 15%. The direct effects numbers include permanent and temporary impacts.

[c] The temporary impacts from transmission line construction associated with CM1 would be zero because the commitment in AMM30, which calls for temporary transmission lines to avoid removal of alkali seasonal wetland and vernal pool wetted acres. This would lower CM1 impacts to 2.3 acres.

[d] These impacts are based on the hypothetical restoration footprints and would likely be lower based on the BDCP's commitment to minimize and avoid effects on vernal pool crustacean habitat as much as practicable. The values for near-term indirect effects were assumed to be slightly more than half of what the late long-term value would be.

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA and would be less than significant under CEQA. Table 12-9-12 lists the impacts on modeled vernal pool crustacean habitat that is based on the natural community mapping done within the study area. The impacts from tidal natural communities restoration (CM4) are based on hypothetical footprints and do not reflect actual impacts on vernal pool crustacean habitat considering the BDCP's commitment to design restoration projects to minimize or avoid effects on covered vernal pool crustaceans (see AMM12). As seen in Table 12-9-13, Alternative 9 would not meet the Plan's near-term biological goals and objectives for direct loss and indirect conversion unless near-term tidal restoration projects are designed to ensure that they do not exceed these impact limits.

Typical NEPA and CEQA project-level mitigation ratios for vernal pools affected by CM1 would be 1:1 for restoration and 2:1 for protection. Typically, indirect conversion impacts are mitigated by protecting vernal pools at a 2:1 ratio. If impacts on wetted vernal pools from tidal restoration stay within the limit presented in Table 12-9-13, the near-term effects of tidal restoration would require up to 5 wetted acres of vernal pool restoration and up to 30 wetted acres of vernal pool protection (or 200 acres of vernal pool complex protection using the 15% density assumption).

The BDCP has committed to near-term goal of protecting 400 acres of vernal pool complex (see Table 3-4 in Chapter 3, *Description of Alternatives*) by protecting at least 2 wetted acres of vernal pools for each wetted acre directly or indirectly affected. The BDCP has also committed to restoring/creating vernal pools such that there is no net loss of vernal pool acreage. The amount of restoration would be determined during implementation based on the following criteria.

- If restoration is completed (i.e., restored natural community meets all success criteria) prior to impacts, then 1.0 wetted acre of vernal pools would be restored for each wetted acre directly affected (1:1 ratio).
- If restoration takes place concurrent with impacts (i.e., restoration construction is completed, but restored habitat has not met all success criteria, prior to impacts occurring), then 1.5 wetted acres of vernal pools would be restored for each wetted acre directly affected (1.5:1 ratio).

The species-specific biological goals and objectives would also inform the near-term protection and restoration efforts. These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of protection and restoration contained in the near-term Plan goals would keep pace with the loss of habitat and effects on vernal pool crustacean habitat.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM12 Vernal Pool Crustaceans,* and *AMM37 Recreation*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The BDCP states that covered activities would not result in more than 10 wetted acres of direct loss and no more than 20 wetted acres of indirect conversion effects on vernal pools by the late long-term (see Objective VPNC1.2 and AMM12). As seen in Table 12-9-13, Alternative 9 would not meet the Plan's late long-term biological goals and objectives for direct and indirect effects unless tidal restoration projects are designed to ensure that that they do not exceed these impact limits.

The Plan has committed to a late long-term goal of protecting 600 acres of vernal pool complex in either Conservation Zones 1, 8, or 11, primarily in core vernal pool recovery areas (Objective VPNC1.1) by protecting at least 2 wetted acres of vernal pools protected for each wetted acre directly or indirectly affected. The Plan also includes a commitment to restore or create vernal pools such that the Plan results in no net loss of vernal pool acreage (Objective VPNC1.2). The protection and restoration would be achieved using the criteria presented above as well as by following the other specific biological goals and objectives, which include:

- Increasing the size and connectivity of protected vernal pool complexes (Objective VPNC1.3)
- Protecting the range of inundation characteristics that are currently represented by vernal pool throughout the Plan Area (Objective VPNC1.4)
- Protecting one currently unprotected occurrence of conservancy fairy shrimp (Objective VPC1.1)

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration and protection of alkali seasonal wetlands that could overlap with the species model, could result in the restoration of 51 acres and the protection of 608 acres of modeled habitat for vernal pool crustaceans.

NEPA Effects: The near-term loss of vernal pool crustacean habitat under Alternative 9 would not be adverse under NEPA because the BDCP has committed to avoiding and minimizing effects from tidal restoration and to restoring and protecting an acreage that meets or exceeds the typical mitigation ratios described above. In the absence of other conservation actions, the modification of vernal pool crustacean habitat and potential mortality of a special-status species resulting from Alternative 9 in the late long-term would represent an adverse effect. However, the BDCP has committed to impact limits for vernal pool crustacean habitat and to habitat protection, restoration, management, and enhancement associated with CM3, CM9, and CM11. This habitat protection, restoration, management and enhancement would be guided by species-specific goals and objectives, and by AMM1–AMM6, AMM10, AMM12, AMM30, and AMM37, which would be in place throughout the period of construction. Considering these commitments, losses and conversion of vernal pool crustacean habitat under Alternative 9 would not be an adverse effect.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the impacts of construction would be less than significant. Table 12-9-12 lists the impacts on modeled vernal pool crustacean habitat that is based on the natural community mapping done within the study area. The impacts from tidal natural communities restoration (CM4) are based on hypothetical footprints and do not reflect actual impacts on vernal pool crustacean habitat considering the BDCP's commitment to design restoration projects to minimize or avoid effects on covered vernal pool crustaceans (see AMM12). As seen in Table 12-9-13, Alternative 9 would not meet the Plan's near-term biological goals and objectives for direct and indirect effects unless near-term tidal restoration projects are designed to ensure that they do not exceed these impact limits.

Typical NEPA and CEQA project-level mitigation ratios for vernal pools affected by CM1 would be 1:1 for restoration and 2:1 for protection. Typically, indirect conversion impacts are mitigated by protecting vernal pools at a 2:1 ratio. If impacts on wetted vernal pools from tidal restoration stay within the near-term effect limit presented in Table 12-9-13, the near-term effects of tidal restoration would require up to 5 wetted acres of vernal pool restoration and up to 30 wetted acres of vernal pool protection (or 200 acres of vernal pool complex protection using the 15% density assumption).

The BDCP has committed to near-term goal of protecting 400 acres of vernal pool complex (see Table 3-4 in Chapter 3, *Description of Alternatives*) by protecting at least 2 wetted acres of vernal pools for each wetted acre directly or indirectly affected. The BDCP has also committed to restoring/creating vernal pools such that there is no net loss of vernal pool acreage. The amount of restoration would be determined during implementation based on the following criteria.

- If restoration is completed (i.e., restored natural community meets all success criteria) prior to impacts, then 1.0 wetted acre of vernal pools would be restored for each wetted acre directly affected (1:1 ratio).
- If restoration takes place concurrent with impacts (i.e., restoration construction is completed, but restored habitat has not met all success criteria, prior to impacts occurring), then 1.5 wetted acres of vernal pools would be restored for each wetted acre directly affected (1.5:1 ratio).

The species-specific biological goals and objectives would also inform the near-term protection and restoration efforts. These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of protection and restoration contained in the near-term Plan goals would keep pace with the loss of habitat and effects on vernal pool crustacean habitat.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM12 Vernal Pool Crustaceans,* and *AMM37 Recreation*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

The natural community restoration and protection activities are expected to be concluded in the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts on constitute adequate mitigation for CEQA purposes. These commitments, implemented together with the AMMs and biological goals and objectives, are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be less than significant under CEQA.

Late Long-Term Timeframe

The BDCP states that covered activities would not result in more than 10 wetted acres of direct loss and no more than 20 wetted acres of indirect conversion effects on vernal pools by the late long-term (see Objective VPNC1.2 and AMM12). As seen in Table 12-9-13, Alternative 9 would not meet the Plan's late long-term biological goals and objectives for direct and indirect effects unless near-term tidal restoration projects are designed to ensure that that they do not exceed these impact limits.

The Plan has committed to late long-term goal of protecting 600 acres of vernal pool complex in either Conservation Zones 1, 8, or 11, primarily in core vernal pool recovery areas (Objective VPNC1.1) by protecting at least 2 wetted acres of vernal pools protected for each wetted acre directly or indirectly affected. The Plan also includes a commitment to restore or create vernal pools such that the Plan results in no net loss of vernal pool acreage. The protection and restoration would be achieved using the criteria presented above as well as by following the other specific biological goals and objectives, which include:

- Increasing the size and connectivity of protected vernal pool complexes (Objective VPNC1.3)
- Protecting the range of inundation characteristics that are currently represented by vernal pool throughout the Plan Area (Objective VPNC1.4)
- Protecting one currently unprotected occurrence of conservancy fairy shrimp (Objective VPC1.1)

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration and protection of alkali seasonal wetlands that could overlap with the species model, could result in the restoration of 51 acres and the protection of 608 acres of modeled habitat for vernal pool crustaceans.

The effects on vernal pool crustacean habitat from Alternative 9 would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of other conservation actions. However, the BDCP has committed to impact limits for vernal pool crustacean habitat and to habitat protection, restoration, and management and enhancement associated with CM3, CM9, and CM11. These conservation activities would be guided by species-specific goals and objectives, and by AMM1–AMM6, AMM10, AMM12, and AMM37, which would be in place throughout the time period any construction activity would be occurring. Considering these commitments, Alternative 9 over the term of the BDCP would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of vernal pool crustaceans. Therefore, Alternative 9 would have a less-than-significant impact on vernal pool crustaceans.

Impact BIO-33: Indirect Effects of Plan Implementation on Vernal Pool Crustaceans

Construction and maintenance activities associated with restoration actions could indirectly affect vernal pool crustaceans and their habitat in the vicinity of construction and restoration areas, and maintenance activities. These potential effects would be minimized or avoided through AMM1–6, 10, and 12, which would be in effect throughout the Plan's construction phase.

***NEPA Effects*:** Restoration activities could indirectly affect vernal pool crustaceans and their habitat in the vicinity of construction areas. Ground-disturbing activities, stockpiling of soils, and maintenance and refueling of heavy equipment could result in the inadvertent release of sediment and hazardous substances into this habitat. These potential effects would be avoided and minimized through AMM1–AMM6, which would be in effect throughout the Plan's construction phase. The indirect effects of Alternative 9 on vernal pool crustacean habitat would not be adverse under NEPA.

CEQA Conclusion: Construction and maintenance activities associated with water conveyance facilities, and restoration actions could indirectly impact vernal pool crustaceans and their habitat in the vicinity of construction and restoration areas, and maintenance activities. These potential impacts would be minimized or avoided through AMM1–AMM6, AMM10, and AMM12, which would be in effect throughout the construction phase. The indirect impacts of Alternative 9 would be less than significant under CEQA.

Impact BIO-34: Periodic Effects of Inundation of Vernal Pool Crustacean Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass under *CM2 Yolo Bypass Fisheries Enhancement* would periodically affect 0 to 4 acres of modeled vernal pool crustacean habitat (Table 12-9-12). There would be no periodic effects resulting from *CM5 Seasonally Inundated Floodplain Restoration*.

NEPA Effects: BDCP Appendix 5.J, *Effects on Natural Communities, Wildlife, and Plants*, describes the methods used to estimate periodic inundation effects in the Yolo Bypass. Based on this method, periodic inundation could affect vernal pool crustaceans occupying areas ranging from 0 acres of habitat during most notch flows to an estimated 4 acres during a notch flow of 6,000 cubic feet per second (cfs). BDCP-associated inundation of areas that would not otherwise have been inundated is expected to occur in no more than 30% of all years, because Fremont Weir is expected to overtop the remaining 70% of all years, and during those years notch operations would not typically affect the maximum extent of inundation. In more than half of all years under Existing Conditions, an area greater than the BDCP-related inundation area already inundates in the bypass. Yolo Bypass flooding is expected to have a minimal effect on vernal pool crustaceans and would thus not be adverse under NEPA.

CEQA Conclusion: Alternative 9 would periodically inundate at most 4 acres of vernal pool crustacean habitat during the maximum flows over the Fremont Weir. The periodic inundation is not anticipated to result in a conversion of vernal pool crustacean habitat into different wetland habitat. BDCP-associated inundation of areas that would not otherwise have been inundated is expected to occur in no more than 30% of all years, because Fremont Weir is expected to overtop the remaining 70% of all years, and during those years notch operations would not typically affect the maximum extent of inundation. In more than half of all years under Existing Conditions, an area greater than the BDCP-related inundation area already inundates in the bypass. Yolo Bypass flooding is expected to have a minimal effect on vernal pool crustaceans and would thus result in less-than-significant impacts on the species.

Valley Elderberry Longhorn Beetle

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation measures, on the valley elderberry longhorn beetle. That habitat model used to assess the effects for valley elderberry longhorn beetle is based on riparian habitat and nonriparian habitat (channels and grasslands within 200 feet of channels). Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of valley elderberry longhorn beetle modeled habitat as indicated in Table 12-9-14. The majority of the losses would take place over an extended period of time as the restoration conservation measures are being implemented. In addition, an estimated 15 elderberry shrubs could be impacted by the Alternative 9 conveyance alignment (CM1). Full implementation of the Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit valley elderberry longhorn beetle (BDCP Chapter 3, *Conservation Strategy*).

- Mitigate impacts on elderberry shrubs consistent with USFWS conservation guidelines for the species (Objective VELB1.1)
- Site elderberry longhorn beetle habitat restoration adjacent to occupied habitat (Objective VELB1.2)
- Restore 5,000 acres of valley/foothill riparian (Objective VFRNC1.1, associated with CM7)
- Protect 750 acres of valley/foothill riparian (Objective VFRNC1.2, associated with CM3)
- Maintain or increase the abundance and distribution of rare or uncommon vegetation alliances, such as *Sambuca nigra* (blue elderberry stands) alliance (Objective VFRNC3.1, associated with CM7 and CM11)

As explained below, with the restoration or protection of these amounts of habitat, impacts on valley elderberry longhorn beetle would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-14. Changes in Valley Elderberry Longhorn Beetle Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent NT	Permanent LLT[c]	Temporary NT	Temporary LLT[c]	Periodic[d] CM2	Periodic[d] CM5
CM1	Riparian	61	61	248	248	NA	NA
	Nonriparian	75	75	280	280	NA	NA
Total Impacts CM1		**136**	**136**	**528**	**528**	**NA**	**NA**
CM2–CM18	Riparian	381	678	76	111	44–80	266
	Nonriparian	142	311	94	108	103–244	287
Total Impacts CM2–CM18		**523**	**989**	**170**	**219**	**161–325**	**553**
TOTAL IMPACTS		**659**	**1,125**	**698**	**747**	**161–325**	**553**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-35: Loss of Valley Elderberry Longhorn Beetle Habitat

Alternative 9 conservation measures would result in the permanent and temporary loss combined of up to 1,872 acres of modeled valley elderberry longhorn beetle habitat (1,098 acres of riparian habitat and 774 acres of nonriparian habitat), and an estimated 15 elderberry shrubs from CM1, which represent potential habitat for the species (Table 12-9-14). Due to the limitation of the habitat suitability model, all of these effects are assumed to be a large overestimate of the true effect on potential valley elderberry longhorn beetle habitat. Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Fremont Weir/Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), and floodplain restoration (CM5). Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate valley elderberry longhorn beetle habitat. Timely implementation of the near-term habitat protection and restoration contained in the Plan and implementation of AMMs committed to in the Plan would result in no adverse effects under NEPA and less-than-significant impacts under CEQA. Each of these activities is described below.

- *CM1 Water Facilities and Operation*: Construction of Alternative 9 conveyance facilities would result in the permanent and temporary combined loss of approximately 664 acres of modeled valley elderberry longhorn beetle habitat, composed of 309 acres of riparian habitat and 355 acres of nonriparian habitat (Table 12-9-14). In addition, an estimated 15 shrubs could be removed as a result of conveyance facility construction. The exact number of shrubs to be impacted would be determined during pre-construction surveys of the footprints of the conveyance facility and associated work areas as part of the implementation of *AMM15 Valley Elderberry Longhorn Beetle*. Most of these impacts are associated with the channel enlargement and operable barrier construction. There are no records of valley elderberry longhorn beetle within these impact areas. The portion of the above impacts that result from temporary habitat loss includes 528 acres of modeled valley elderberry longhorn beetle habitat (248 acres riparian and 280 acres nonriparian habitat). Elderberry shrubs could be affected from ground-disturbing activities associated with conveyance construction footprints, temporary access roads, and staging areas.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction activity associated with fisheries improvements in the Yolo Bypass would result in the permanent and temporary removal of approximately 295 acres of modeled valley elderberry longhorn beetle habitat, composed of 159 acres of riparian habitat and 136 acres of nonriparian habitat. Approximately 125 acres of permanent impacts (83 acres of riparian and 41 acres of nonriparian) would mostly occur at the north end of the Yolo Bypass from Fremont Weir improvements. The 170 acres of temporary impacts (76 acres of riparian and 94 acres of nonriparian) would mostly be from work on the Freemont Weir, the Sacramento Weir, and levees along the Bypass. Elderberry shrubs could be affected from ground-disturbing activities associated with the re-contouring of surface topography, excavation or modification of channels, levee modification, and removal of riprap and other protections from channel banks.

- *CM4 Tidal Natural Communities Restoration*: Tidal natural communities restoration would result in the permanent loss of approximately 8131 acres of modeled valley elderberry longhorn beetle habitat, composed of 552 acres of riparian and 260 acres of nonriparian habitat. The majority of these impacts would be associated with tidal restoration in the Delta and only 42 acres of these impacts (all nonriparian) would be from tidal restoration in Suisun Marsh. Elderberry shrubs could be affected from ground-disturbing activities associated with the re-contouring of surface topography, excavation or modification of channels, type conversion from riparian and grasslands to tidal habitat, levee removal and modification, and removal of riprap and other protections from channel banks.

- *CM5 Seasonally Inundated Floodplain Restoration*: Levee construction associated with floodplain restoration in the south Delta (CZ 7) would result in the permanent and temporary removal of approximately 101 acres of valley elderberry longhorn beetle habitat, composed of 78 acres of riparian and 23 acres of nonriparian. Approximately half of these impacts (52 acres) would be permanent impacts from levee construction and the other half (49 acres) would be temporary impacts associated with the levee construction. There is one CNDDB record of valley elderberry longhorn beetle occurring in CZ 7 just wet of Middle River on Union Island. This record and other elderberry shrubs could be affected from ground-disturbing activities associated with the re-contouring of surface topography, excavation or modification of channels, levee removal and modification, and removal of riprap and other protections from channel banks.
- *CM11 Natural Communities Enhancement and Management*: Activities associated with natural communities enhancement and management, such as grazing practices and ground disturbance or herbicide use in the control of nonnative vegetation, intended to maintain and improve habitat functions of BDCP protected habitats for covered species could result in loss of elderberry shrubs and the potential for injury or mortality to beetles. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs discussed below.
- Operations and maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect valley elderberry beetle. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas could affect elderberry shrubs occupied by the species. These effects, however, would be reduced by AMMs described below.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA and would be less than significant under CEQA. Alternative 9 would result in permanent and temporary impacts on 1,357 acres of modeled habitat (766 acres of riparian and 591 acres of nonriparian) for valley elderberry longhorn beetle in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 309 acres of riparian and 355 acres of nonriparian), and implementing other conservation measures (Yolo Bypass fisheries improvements [CM2] and tidal restoration [CM4], 693 acres of modeled habitat). The other conservation measures account for 457 of the 766 acres (60%) of impacts on riparian habitat. Based on the DHCCP survey data of the conveyance planning area, an estimated 15 elderberry shrubs would be impacted by conveyance construction in the near-term by CM1 (see Section 12.3.2.3 for a discussion on the methods used to make this estimate).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 and that are identified as habitat for valley elderberry longhorn beetle in Chapter 3 of the BDCP would be 1:1 for restoration and 1:1 for protection for riparian habitat. Using these typical ratios would indicate that 309 acres of the riparian habitat should be restored/created and 309 acres of existing riparian should be protected to mitigate the CM1 losses of valley elderberry longhorn beetle habitat. The near-term effects of other conservation actions would require 457 acres of riparian restoration and 457 acres of riparian protection using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 750 acres of riparian and restoring 800 acres of riparian habitat in the Plan Area. These conservation actions would occur in the same timeframe as the construction and early restoration losses. In addition, BDCP Objectives VELB 1.1 and 1.2 call for implementing the USFWS conservation guidelines for valley elderberry longhorn beetle (transplanting elderberry shrubs and planting elderberry seedlings and associated natives) and siting elderberry restoration within drainages immediately adjacent to or in the vicinity of sites confirmed to be occupied by valley elderberry longhorn beetle. These objectives would be met through the implementation of CM7 *Riparian Natural Community Restoration*. CM7 *Riparian Natural Community Restoration* specifically calls for the planting of elderberry shrubs in large, contiguous clusters with a mosaic of associated natives as part of riparian restoration consistent with USFWS conservation guidelines (U.S. Fish and Wildlife Service 1999a). These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of protection proposed in the near-term Plan goals are just slightly less (16 acres less) than what would be considered the typical mitigation requirements for riparian natural community impacts. However, the Plan's commitments in BDCP Objectives VELB 1.1 and 1.2 would satisfy typical mitigation requirements for valley elderberry longhorn beetle and thus the Plan would sufficiently reduce the effects from CM1 and other near-term conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness training*, *AMM*2 *Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM15 Valley Elderberry Longhorn Beetle*. AMM15 requires surveys for elderberry shrubs within 100 feet of any ground disturbing activities, the implementation of avoidance and minimize measures for any shrubs that are identified within this 100-foot buffer, and transplanting shrubs that can't be avoided. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and RTM storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 34,456 acres of modeled habitat (17,786 acres of riparian and 16,670 acres of nonriparian) for valley elderberry longhorn beetle. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 1,872 acres of modeled valley elderberry longhorn beetle habitat (1,098 acres of riparian habitat and 774 acres of nonriparian habitat)during the term of the Plan (5% of the modeled habitat in the study area).

The locations of these losses are described above in the analyses of individual conservation measures. These losses would not fragment any known populations of valley elderberry longhorn beetle. The Plan includes a commitment to protect 750 acres of riparian habitat and restoring/creating 5,000 acres of riparian habitat in the Plan Area. According to Objective VELB1.2, the restoration of elderberry longhorn beetle habitat would occur adjacent to occupied habitat, which would provide connectivity between occupied and restored habitats and improve the species' ability to disperse within and outside the Plan Area. Other factors relevant to effects on valley elderberry longhorn beetle include:

- Habitat loss is widely dispersed throughout the study area and would not be concentrated in any one location.
- There would be a temporal loss of riparian habitat during the near-term evaluation period because most of the affected riparian vegetation would be removed during the near-term timeframe, while large quantities of riparian habitat would not be restored until the early and late long-term timeframes. Effects on valley elderberry longhorn beetle of this temporal loss of riparian vegetation are expected to be minimal because much of the riparian habitat in the Plan Area is not known to be currently occupied by the species, because all elderberry shrubs that are suitable for transplantation would be moved to conservation areas in the Plan Area, and because most of the affected community is composed of small patches of riparian scrub and herbaceous vegetation that are fragmented and distributed across the agricultural landscape of the Plan Area and thus are likely to provide no or low-value habitat for the beetle.
- Temporarily disturbed areas would be restored within 1 year following completion of construction and management activities. Under AMM10, a restoration and monitoring plan would be developed prior to initiating any construction-related activities associated with the conservation measures or other covered activities that would result in temporary effects on natural communities.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as other actions that overlap with the nonriparian portions of the species model, could result in the restoration of 4,857 acres (riparian) and the protection of 2,363 acres (729 acres of riparian and 1,634 acres of nonriparian channels and grassland) of modeled habitat for valley elderberry longhorn beetle.

NEPA Effects**:** The near-term loss of valley elderberry longhorn beetle habitat under Alternative 9 would not be adverse because the BDCP has committed to restoring and protecting an acreage that exceeds the typical mitigation ratios described above, in addition to avoiding impacts on shrubs and transplanting those that can't be avoided. In the absence of other conservation actions, the losses of valley elderberry longhorn beetle habitat and potential for direct mortality of a special-status species associated with Alternative 9 in the late long-term would represent an adverse effect. However, with habitat protection and restoration associated with CM7, guided by species-specific goals and objectives and by AMM1–AMM6, AMM10, and AMM15, which would be in place throughout the construction period, the effects of Alternative 9 as a whole on valley elderberry longhorn beetle would not be adverse under NEPA.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the impacts of construction would be less than significant. Alternative 9 would result in permanent and temporary impacts on 1,357 acres of modeled habitat (766 acres of riparian and 591 acres of nonriparian) for valley elderberry longhorn beetle in the study area in the near-term. These impacts would result from the construction of the water conveyance facilities (CM1, 309 acres of riparian and 355 acres of nonriparian), and implementing other conservation measures (Yolo Bypass fisheries improvements [CM2] and tidal restoration [CM4], 693 acres of modeled habitat). The other conservation measures account for 457 of the 766 acres (60%) of impacts on riparian habitat. Based on the DHCCP survey data of the conveyance planning area, an estimated 15 elderberry shrubs would be impacted by conveyance construction in the near-term by CM1 (see Section 12.3.2.3 for a discussion on the methods used to make this estimate).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 and that are identified in the biological goals and objectives for valley elderberry longhorn beetle in Chapter 3 of the BDCP would be 1:1 for restoration and 1:1 for protection for riparian habitat. Using these typical ratios would indicate that 309 acres of the riparian habitat should be restored/created and 309 acres of existing riparian should be protected to mitigate the CM1 losses of valley elderberry longhorn beetle habitat. The near-term effects of other conservation actions would require 457 acres of riparian restoration and 457 acres of riparian protection using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 750 acres of riparian and restoring 800 acres of riparian habitat in the Plan Area. These conservation actions would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects on valley elderberry longhorn beetle. In addition, BDCP Objectives VELB 1.1 and 1.2, which call for implementing the USFWS conservation guidelines for valley elderberry longhorn beetle (transplanting elderberry shrubs and planting elderberry seedlings and associated natives) and siting elderberry restoration within drainages immediately adjacent to or in the vicinity of sites confirmed to be occupied by valley elderberry longhorn beetle. These objectives would be met through the implementation of *CM7 Riparian Natural Community Restoration*. CM7 specifically calls for the planting of elderberry shrubs in large, contiguous clusters with a mosaic of associated natives as part of riparian restoration consistent with USFWS conservation guidelines (U.S. Fish and Wildlife Service 1999a). These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of protection proposed in the near-term Plan goals are just slightly less (16 acres less) than what would be considered the typical mitigation requirements for riparian natural community impacts. However, the Plan's commitments in BDCP Objectives VELB 1.1 and 1.2 would satisfy typical mitigation requirements for valley elderberry longhorn beetle and thus the Plan would sufficiently reduce the effects from CM1 and other near-term conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness training*, *AMM*2 *Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and*

Countermeasure Plan, *AMM6 Disposal and Reuse of Spoils,* and *AMM15 Valley Elderberry Longhorn Beetle*. AMM15 requires surveys for elderberry shrubs within 100 feet of any ground disturbing activities; the implementation of avoidance and minimize measures for any shrubs that are identified within this 100-foot buffer, and transplanting shrubs that can't be avoided. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and RTM storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

The acres of protection proposed in the near-term Plan goals are just slightly less (16 acres less) than what would be considered the typical mitigation requirements for riparian natural community impacts. However, the Plan's commitments in BDCP Objectives VELB 1.1 and 1.2 would satisfy typical mitigation requirements for valley elderberry longhorn beetle and thus the Plan would sufficiently reduce the effects from CM1 and other near-term conservation measures. These commitments, implemented together with the AMMs, are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be less than significant under CEQA.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 1,872 acres of modeled valley elderberry longhorn beetle habitat (1,098 acres of riparian habitat and 774 acres of nonriparian habitat)during the term of the Plan (5% of the modeled habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. These losses would not fragment any known populations of valley elderberry longhorn beetle. The Plan includes a commitment to protect 750 acres of riparian habitat and restoring/creating 5,000 acres of riparian habitat in the Plan Area. According to Objective VELB1.2, the restoration of elderberry longhorn beetle habitat would occur adjacent to occupied habitat, which would provide connectivity between occupied and restored habitats and improve the species' ability to disperse within and outside the Plan Area. The BDCP also includes a number of AMM1–AMM6, AMM10, and AMM15) directed at minimizing or avoiding potential impacts on valley elderberry longhorn beetle. The large acreages of conservation would adequately compensate for the modeled habitats lost to construction and restoration activities.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as other actions that overlap with the nonriparian portions of the species model, could result in the restoration of 4,857 acres (riparian) and the protection of 2,363 acres (729 acres of riparian and 1,634 acres of nonriparian channels and grassland) of modeled habitat for valley elderberry longhorn beetle.

Considering these protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for habitats lost to construction and restoration activities, implementation of Alternative 9 as a whole would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the alternative would have a less-than-significant impact on valley elderberry longhorn beetle.

Impact BIO-36: Indirect Effects on Valley Elderberry Longhorn Beetle and its Habitat

Construction activities associated with water conveyance facilities, conservation components and ongoing habitat enhancement, as well as operation and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances with localized impacts on valley elderberry longhorn beetle over the term of the BDCP. Construction related effects could result from ground-disturbing activities, stockpiling of soils, and maintenance and refueling of heavy equipment could result in dust and the inadvertent release of hazardous substances in areas where elderberry shrubs occur. A GIS analysis (see Section 12.3.2.3 for a discussion on the methods used to make this estimate) estimates that approximately 103 shrubs could be indirectly affected by conveyance facilities construction (CM1). Restoration activities could result in excavation or modification of channels, type conversion from riparian and grasslands to tidal habitat, levee removal and modification, and removal of riprap and other protections from channel banks that occur within 100 feet of an elderberry shrubs. These potential effects would be minimized or avoided through AMM1–AMM6, AMM10, and AMM15, which would be in effect throughout the Plan's construction phase.

NEPA Effects: The indirect effects on valley elderberry longhorn beetle as a result of implementing Alternative 9 conservation actions would not have an adverse effect on valley elderberry longhorn beetle.

CEQA Conclusion: Ground-disturbing activities, stockpiling of soils, and the potential release of dust and hazardous substances would accompany construction of the water conveyance facilities. An estimated 103 shrubs could be indirectly affected by conveyance facilities construction (CM1). In addition, ground-disturbing activities associated with the re-contouring of surface topography, excavation or modification of channels, type conversion from riparian and grasslands to tidal habitat, levee removal and modification, and removal of riprap and other protections from channel banks could indirectly affected elderberry shrubs that occur within 100 feet of these restoration activities. With the implementation of AMM1–AMM6, AMM10, and AMM15 as part of Alternative 9 construction, operation, and maintenance, the BDCP would avoid the potential for substantial adverse indirect effects on valley elderberry longhorn beetle in that the Plan would not result in a substantial reduction in numbers or a restriction in the range of valley elderberry longhorn beetle. Therefore, the indirect effects under this alternative would have a less-than-significant impact on valley elderberry longhorn beetle.

Impact BIO-37: Periodic Effects of Inundation of Valley Elderberry Longhorn Beetle Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from *CM2 Yolo Bypass Fisheries Enhancement* would periodically affect 161 to 325 acres of modeled valley elderberry longhorn beetle habitat (Table 12-9-14).

CM5 Seasonally Inundated Floodplain Restoration would periodically inundate 553 acres of modeled valley elderberry longhorn beetle habitat (Table 12-9-14).

It is unknown at this time how much of the modeled habitat that would be inundated as a result of CM2 and CM5 actually contains elderberry shrubs. Elderberry shrubs have been found to be intolerant of long periods of inundation and there is evidence that they die very quickly after even short periods of flooding (River Partners 2008). During monitoring of a restoration project at the San Joaquin River National Wildlife Refuge, River Partners found that nearly all (99% to 100%) of the 4-year-old elderberry shrubs in restoration plots died after 15–17 weeks of inundation, and

River Partners noted in general that the shrubs died very quickly after even short periods of flooding (River Partners 2008). Talley et al (2006) in their report assisting the USFWS 5-year review of the species, note that elderberry shrubs respond negatively to saturated soil conditions and that they can only tolerate temporary root crown inundation. Therefore, in the areas that would be periodically inundated by the implementation of CM2 it is likely that there are few, if any, mature shrubs in these areas because under current conditions they would be inundated in about 50% of all years for approximately 7 weeks. The areas affected by CM5 are not currently inundated and thus elderberry shrubs could present in these areas.

The periodic effects on modeled habitat for valley elderberry longhorn beetle associated with implementing Alternative 9 could adversely affect valley elderberry longhorn beetle habitat (elderberry shrubs) and make modeled habitat there unsuitable for future elderberry establishment. Based on the information presented above, the current conditions in those areas that would be periodically inundated in Yolo Bypass (CM2) are not likely very suitable for elderberry shrubs and thus CM2 would likely have minimal effects, if any, on the species. The modeled habitat that would be periodically inundated from the implementation of CM5 could result in adverse effects on valley elderberry longhorn beetle.

***NEPA Effects*:** Periodic effects of the inundation of valley elderberry longhorn beetle habitat as a result of implementing Alternative 9 conservation actions would not be adverse under NEPA when taking into consideration CM7 habitat protection and restoration. This habitat protection and restoration would be guided by species-specific goals and objectives, and by AMM1–AMM6, AMM10, and AMM15, which would be in place throughout the time period that periodic effects would occur.

***CEQA Conclusion*:** Alternative 9 (CM2 and CM5) would have periodic impacts on modeled valley elderberry longhorn beetle habitat. The periodic inundation of between 161 and 325 acres (CM2) and 553 acres (CM5) of modeled habitat could result in the death of elderberry shrubs that may occur there and thus potentially impact valley elderberry longhorn beetle. The Plan includes the restoration of 5,000 acres of riparian habitat (Objective VFRNC1.1) and the protection of 750 acres riparian habitat (VFRNC1.2) would include areas for elderberry restoration and protection. The BDCP also includes AMM1–AMM6, AMM10, and AMM15, which would minimize and avoid impacts on valley elderberry longhorn beetle prior to Yolo Bypass fisheries enhancement and floodplain restoration activities. AMM15, which includes measure for following the USFWS conservation guidelines for valley elderberry longhorn beetle (U.S. Fish and Wildlife Service 1999a), would be used to identify shrubs for transplanting to conservation areas that otherwise could be adversely affected by periodic inundation in Yolo Bypass and floodplain restoration areas. These conservation actions would compensate for the periodic impacts on valley elderberry longhorn beetle.

Considering these protection and restoration provisions and avoidance and minimization measures, implementation of Alternative 9 as a whole would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, periodic effects of inundation resulting from Alternative 9 would have a less-than-significant impact on valley elderberry longhorn beetle.

Nonlisted Vernal Pool Invertebrates

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on other, noncovered vernal pool invertebrates that are not covered by the plan (Blennosperma vernal pool andrenid bee, hairy water flea, Ricksecker's water scavenger beetle, curved-foot hygrotus beetle, molestan blister beetle).

Little is known about the range of these species so it is assumed that they have potential to occur in the same areas described by the vernal pool crustacean modeled habitat. That habitat model consists of: vernal pool complex, which consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly affected by agricultural or development practices; alkali seasonal wetlands in CZ 8; and degraded vernal pool complex, which consists of low-value ephemeral habitat ranging from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, discing, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. For the purpose of the effects analysis, vernal pool complex is categorized as high-value and degraded vernal pool complex is categorized as low-value for these species. Alkali seasonal wetlands in CZ 8 were also included as high-value habitat for vernal pool crustaceans in the model. Also included as low-value for vernal pool habitat are areas along the eastern boundary of CZ 11 that are mapped as vernal pool complex because they flood seasonally and support typical vernal pool plants, but do not include topographic depressions that are characteristic of vernal pools.

Construction and restoration associated with Alternative 9 conservation measures would result in permanent losses of habitat for nonlisted vernal pool invertebrates as indicated in Table 12-9-15 and indirect conversions of vernal pool habitat. The majority of the losses would take place over an extended period of time as tidal marsh is restored in the Plan Area. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP that would benefit nonlisted vernal pool invertebrates (BDCP Chapter 3, *Conservation Strategy*).

- Protect 600 acres of vernal pool complex in CZ 1, CZ 8, or CZ 11, primarily in core vernal pool recovery areas (ObjectiveVPNC1.1, associated with CM3).
- Restore vernal pool complex in CZ 1, CZ 8, and CZ 11 to achieve no net loss of vernal pool acreage (up to 67 acres of vernal pool complex restoration [10 wetted acres])(Objective VPNC1.2, associated with CM9).
- Increase size and connectivity of protected vernal pool complexes in plan area and increase connectivity with complexes outside the Plan Area (ObjectiveVPNC1.3)
- Protect the range of inundation characteristics of vernal pools in the Plan Area (Objective VPNC1.4)
- Maintain and enhance vernal pool complexes to provide appropriate inundation (ponding) for supporting and sustaining vernal pool species (Objective VPNC2.1)

As explained below, with the restoration or protection of these amounts of habitat, impacts on nonlisted vernal pool invertebrates would be adverse for NEPA purposes and would be significant for CEQA purposes.

Table 12-9-15. Changes in Nonlisted Vernal Pool Invertebrate Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	High-value	0	0	0	0	NA	NA
	Low-value	0	0	0	0	NA	NA
Total Impacts CM1		**0**	**0**	**0**		**NA**	**NA**
CM2–CM18[e]	High-value	0	0	0	0	0-4	0
	Low-value	201	372	0	0	0	0
Total Impacts CM2–CM18		**201**	**372**	**0**	**0**	**0-4**	**0**
TOTAL IMPACTS		**201**	**372**	**0**	**0**	**0-4**	**0**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

[e] Includes indirect conversion impacts

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-38: Loss or Conversion of Habitat for and Direct Mortality of Nonlisted Vernal Pool Invertebrates

Alternative 9 conservation measures would result in the direct, permanent loss of up to 372 acres of low-value vernal pool habitat from tidal habitat restoration (CM4). In addition, the conservation measures could result in the indirect conversion due to hydrologic changes of an additional 135 acres of vernal pool habitat (89 acres of high-value habitat and 45 acres of low-value habitat) from tidal restoration (CM4). Tidal restoration activities may result in the modification of hardpan and changes to the perched water table, which could lead to alterations in the rate, extent, and duration of inundation of nearby vernal pool habitat. USFWS typically considers construction within 250 feet of vernal pools to constitute a possible conversion of the habitat unless more detailed information is provided to further refine the limits of any such effects. For the purposes of this analysis, the 250-foot buffer was applied to the water conveyance facilities work areas where surface and subsurface disturbance activities would take place and to restoration hypothetical footprints. Habitat enhancement and management activities (CM11), which include disturbance or removal of nonnative vegetation, could result in local adverse habitat effects.

Because the estimates of habitat loss resulting from tidal inundation are based on projections of where restoration may occur, actual effects are expected to be lower because sites would be selected and restoration projects designed to minimize or avoid effects on vernal pools and alkali seasonal wetlands. As specified in the BDCP, the BDCP Implementation Office would ensure that tidal restoration projects and other covered activities would be designed such that no more than a total of

10 wetted acres of vernal pool habitat are directly affected and that no more than 20 wetted acres of vernal pool habitat are indirectly affected by BDCP covered activities (AMM12). The term *wetted acres* refers to an area that would be defined by the three parameter wetland delineation method used by USACE to determine the limits of a wetland, which includes an evaluation of wetland soil, vegetation, and hydrology characteristics. This acreage differs from vernal pool complex acreages in that a vernal pool complex is composed of individual wetlands (vernal pools) and those upland areas that are in between and surrounding them, which provide the supporting hydrology (surface runoff and groundwater input), organic and nutrient inputs, and refuge for the terrestrial phase of some vernal pool species.

A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM4 Tidal Natural Communities Restoration:* Tidal natural communities restoration would result in the permanent loss of approximately 372 acres of low-value vernal pool habitat, which consists of degraded vernal pool complex. The BDCP describes degraded vernal pool complex as areas of low-value ephemeral habitat ranging from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, discing, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. The actual density of vernal pools or other aquatic features in these areas is unknown, but a 2012 review of Google Earth imagery found that these habitats appear to generally have low densities. However, areas mapped as degraded vernal pool complex may still provide habitat for vernal pool species as evidenced by records of vernal pool fairy shrimp, vernal pool tadpole shrimp, and California linderiella occurring in degraded vernal pool complex in CZ 4 (California Department of Fish and Wildlife 2013). So though degraded vernal pool complexes may not represent botanically diverse vernal pools they still can provide habitat for vernal pool invertebrates and thus the loss of 372 acres of degraded vernal pool complex may result in the loss of occupied vernal pool invertebrate habitat. In addition, tidal restoration could result in the indirect conversion of 135 acres of vernal pool habitat, which consist of 89 acres of high-value and 45 acres of low-value habitat. No records of nonlisted vernal pool invertebrates would be directly impacted by conservation actions.

- *CM11 Natural Communities Enhancement and Management:* As described in the BDCP, restoration/creation of vernal pools to achieve no net loss and the protection of 600 acres of vernal pool complex would benefit vernal pool invertebrates (Table 12-9-15). A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in BDCP-protected habitats may result in localized ground disturbances that could temporarily affect vernal pool invertebrate habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on vernal pool invertebrate habitat and are expected to result in overall improvements to and maintenance of vernal pool habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included. Table 12-9-16 was prepared to further analyze BDCP effects on nonlisted vernal pool invertebrates using wetted acres of nonlisted vernal pool invertebrate habitat in order to compare to the effects of this alternative with the effect limits established in BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*, and AMM12, which are measured in wetted acres of vernal pool species habitat. Based on an informal evaluation of aerial photographs of the Plan Area it is likely that the actual densities within the Plan Area are approximately 10%, but the 15% density value was chosen as a conservative estimate for determining effects.

Table 12-9-16. Estimated Effects on Wetted Nonlisted Vernal Pool Invertebrate Habitat under Alternative 9 (acres)

		Direct Loss		Indirect Conversion	
		Near-Term	Late Long-Term	Near-Term	Late Long-Term
BDCP Impact Limit[a]		5	10	10	20
Alternative 9 Impact [b]	CM1[c]	0	0	0	0
	CM4[d]	30.2	55.8	11.0	20.3
Total		**30.2**	**55.8**	**11.0**	**20.3**

[a] Because roughly half of the impacts would occur in the near–term, it is assumed that the impact limit in the near-term would be 5 wetted acres for direct loss and 10 acres for indirect.

[b] These acreages were generated by assuming that the modeled habitat identified in Table 12-9-15 has densities of wetted vernal pool species habitat at 15%. The direct effects numbers include permanent and temporary impacts.

[c] The temporary impacts from transmission line construction associated with CM1 would be zero because the commitment in AMM30, which calls for temporary transmission lines to avoid removal of alkali seasonal wetland and vernal pool wetted acres. This would lower CM1 impacts to 2.3 acres.

[d] These impacts are based on the hypothetical restoration footprints and would likely be lower based on the BDCP's commitment to minimize and avoid effects on nonlisted vernal pool invertebrate habitat as much as practicable. The values for near-term indirect effects were assumed to be slightly more than half of what the late long-term value would be.

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA and would be less than significant under CEQA. Table 12-9-16 above lists the impacts on nonlisted vernal pool invertebrate habitat that is based on the natural community mapping done within the study area. The impacts from tidal natural communities restoration (CM4) are based on hypothetical footprints and do not reflect actual impacts on vernal pool habitat considering the BDCP's commitment to design restoration projects to minimize or avoid effects on vernal pools (see AMM12). As seen in Table 12-9-16, Alternative 9 would not meet the Plan's near-term biological goals and objectives for direct and indirect effects unless near-term tidal restoration projects are designed to ensure that they do not exceed these impact limits.

Typical NEPA and CEQA project-level mitigation ratios for vernal pools affected by CM1 would be 1:1 for restoration and 2:1 for protection. Typically, indirect impacts are mitigated by protecting vernal pool species habitat at a 2:1 ratio. If impacts on wetted vernal pools from tidal restoration stay within the near-term effect limit presented in Table 12-9-16, the near-term effects of tidal restoration would require up to 5 acres of vernal pool restoration and up to 30 wetted acres of vernal pool protection (or 200 acres of vernal pool complex protection using the 15% density assumption).

The BDCP has committed to near-term goal of protecting 400 acres of vernal pool complex (see Table 3-4 in Chapter 3, *Description of Alternatives*) by protecting at least 2 wetted acres of vernal pools for each wetted acre directly or indirectly affected. The BDCP has also committed to restoring/creating vernal pools such that there is no net loss of vernal pool acreage. The amount of restoration would be determined during implementation based on the following criteria.

- If restoration is completed (i.e., restored natural community meets all success criteria) prior to impacts, then 1.0 wetted acre of vernal pools would be restored for each wetted acre directly affected (1:1 ratio).
- If restoration takes place concurrent with impacts (i.e., restoration construction is completed, but restored habitat has not met all success criteria, prior to impacts occurring), then 1.5 wetted acres of vernal pools would be restored for each wetted acre directly affected (1.5:1 ratio).

The species-specific biological goals and objectives would also inform the near-term protection and restoration efforts. These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of protection and restoration contained in the near-term Plan goals would keep pace with the loss of habitat and effects on nonlisted vernal pool invertebrate habitat.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM10 Restoration of Temporarily Affected Natural Communities, AMM30 Transmission Line Design and Alignment Guidelines,* and *AMM37 Recreation*. *AMM12 Vernal Pool Crustaceans*, although developed for vernal pool crustaceans, includes measures to avoid and minimize direct and indirect effects on vernal pools and would thus be applicable to nonlisted vernal pool invertebrates as well. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The BDCP states that covered activities would not result in more than 10 wetted acres of direct loss and no more than 20 wetted acres of indirect conversion effects on vernal pools by the late long-term (see Objective VPNC1.2 and AMM12). As seen in Table 12-9-16, Alternative 9 would not meet the Plan's late long-term biological goals and objectives for direct and indirect effects unless tidal restoration projects are designed to ensure that that they do not exceed these impact limits.

The Plan has committed to late long-term goal of protecting 600 acres of vernal pool complex in either Conservation Zones 1, 8, or 11, primarily in core vernal pool recovery areas (Objective VPNC1.1) by protecting at least 2 wetted acres of vernal pools protected for each wetted acre directly or indirectly affected. The Plan also includes a commitment to restore or create vernal pools such that the Plan results in no net loss of vernal pool acreage (Objective VPNC1.2). The protection and restoration would be achieved using the criteria presented above as well as by the following other specific biological goals and objectives.

- Increasing the size and connectivity of protected vernal pool complexes (Objective VPNC1.3).
- Protecting the range of inundation characteristics that are currently represented by vernal pool throughout the Plan Area (Objective VPNC1.4).

NEPA Effects: The near-term loss of vernal pool habitat under Alternative 9 would not be adverse under NEPA because the BDCP has committed to avoiding and minimizing effects from tidal restoration and to restoring and protecting an acreage that meets or exceeds the typical mitigation ratios described above. In the absence of other conservation actions, he potential modification of vernal pool habitat and potential mortality of special-status species resulting from Alternative 9 in the late long-term would represent an adverse effect. However, the BDCP has committed to impact limits for vernal pool habitat and to habitat protection, restoration, management and enhancement associated with CM3, CM9, and CM11. This habitat protection, restoration, management, and enhancement would be guided by species-specific goals and objectives, and by AMM1–AMM6, AMM10, AMM12, AMM30, and AMM37, which would be in place throughout the time period of construction. Considering these commitments, losses and conversions of nonlisted vernal pool invertebrates habitat under Alternative 9 would not be adverse.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the impacts of construction would be less than significant. Table 12-9-15 lists the impacts on nonlisted vernal pool invertebrate habitat that is based on the natural community mapping done within the study area. The impacts from tidal natural communities restoration (CM4) are based on hypothetical footprints and do not reflect actual impacts on vernal pool habitat considering the BDCP's commitment to design restoration projects to minimize or avoid effects on vernal pools (see AMM12). As seen in Table 12-9-16, Alternative 9 would not meet the Plan's near-term biological goals and objectives for direct and indirect effects unless near-term tidal restoration projects are designed to ensure that they do not exceed these impact limits.

Typical NEPA and CEQA project-level mitigation ratios for vernal pools affected by CM1 would be 1:1 for restoration and 2:1 for protection. Typically, indirect impacts are mitigated by protecting vernal pools at a 2:1 ratio. If impacts on wetted vernal pools from tidal restoration stay within the near-term effect limit presented in Table 12-9-16, the near-term effects of tidal restoration would require up to 5 acres of vernal pool restoration and up to 30 wetted acres of vernal pool protection (or 200 acres of vernal pool complex protection using the 15% density assumption).

The BDCP has committed to near-term goal of protecting 400 acres of vernal pool complex (see Table 3-4 in Chapter 3, *Description of Alternatives*) by protecting at least 2 wetted acres of vernal pools for each wetted acre directly or indirectly affected. The BDCP has also committed to restoring/creating vernal pools such that there is no net loss of vernal pool acreage. The amount of restoration would be determined during implementation based on the following criteria.

- If restoration is completed (i.e., restored natural community meets all success criteria) prior to impacts, then 1.0 wetted acre of vernal pools would be restored for each wetted acre directly affected (1:1 ratio).

- If restoration takes place concurrent with impacts (i.e., restoration construction is completed, but restored habitat has not met all success criteria, prior to impacts occurring), then 1.5 wetted acres of vernal pools would be restored for each wetted acre directly affected (1.5:1 ratio).

The species-specific biological goals and objectives would also inform the near-term protection and restoration efforts. These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of protection and restoration contained in the near-term Plan goals would keep pace with the loss of habitat and effects on nonlisted vernal pool invertebrates.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities,* and *Alignment Guidelines,* and *AMM37 Recreation*. *AMM12 Vernal Pool Crustaceans*, though developed for vernal pool crustaceans, includes measures to avoid and minimize direct and indirect effects on vernal pools and would thus be applicable to nonlisted vernal pool invertebrates as well. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

The natural community restoration and protection activities are expected to be concluded in the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts on constitute adequate mitigation for CEQA purposes. These commitments, implemented together with the AMMs and biological goals and objectives, are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be less than significant under CEQA.

Late Long-Term Timeframe

The BDCP states that covered activities would not result in more than 10 wetted acres of direct loss and no more than 20 wetted acres of indirect effects on vernal pools by the long-term term (see Objective VPNC1.2 and AMM12). As seen in Table 12-9-16, Alternative 9 would not meet the Plan's late long-term biological goals and objectives for direct and indirect effects unless near-term tidal restoration projects are designed to ensure that that they do not exceed these impact limits.

The Plan has committed to late long-term goal of protecting 600 acres of vernal pool complex in either Conservation Zones 1, 8, or 11, primarily in core vernal pool recovery areas (Objective VPNC1.1) by protecting at least 2 wetted acres of vernal pools protected for each wetted acre directly or indirectly affected. The Plan also includes a commitment to restore or create vernal pools such that the Plan results in no net loss of vernal pool acreage. The protection and restoration would be achieved using the criteria presented above as well as by following the other specific biological goals and objectives, which include:

- Increasing the size and connectivity of protected vernal pool complexes (Objective VPNC1.3)
- Protecting the range of inundation characteristics that are currently represented by vernal pool throughout the Plan Area (Objective VPNC1.4)

The effects on nonlisted pool invertebrate species habitat from Alternative 9 would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of other conservation actions. However, the BDCP has committed to impact limits for vernal pools and alkali seasonal wetlands and to habitat protection, restoration, and management and enhancement associated with CM3, CM9, and CM11. These conservation activities would be guided by species-specific goals and objectives, and AMM1–AMM6, AMM10, AMM12, and AMM37, which would be in place throughout the time period any construction activity would be occurring. Considering these commitments, Alternative 9 over the term of the BDCP would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of nonlisted vernal pool invertebrates. Therefore, Alternative 9 would have a less-than-significant impact on nonlisted vernal pool invertebrates.

Impact BIO-39: Indirect Effects of Plan Implementation on Nonlisted Vernal Pool Invertebrates

Construction and maintenance activities associated with water conveyance facilities, and restoration actions could indirectly affect nonlisted vernal pool invertebrates and their habitat in the vicinity of construction and restoration areas, and maintenance activities. These potential effects would be minimized or avoided through AMM1–AMM6, and AMM10, which would be in effect throughout the Plan's construction phase.

***NEPA Effects*:** Water conveyance facilities construction and restoration activities could indirectly affect nonlisted vernal pool invertebrates and their habitat in the vicinity of construction areas. Ground-disturbing activities, stockpiling of soils, and maintenance and refueling of heavy equipment could result in the inadvertent release of sediment and hazardous substances into this habitat. These potential effects would be avoided and minimized through AMM1–AMM6, which would be in effect throughout the Plan's construction phase. Nonlisted vernal pool invertebrates and their habitat could be periodically indirectly affected by maintenance activities at water conveyance facilities. Embankment maintenance activities around Clifton Court Forebays could result in the inadvertent discharge of sediments and hazardous materials into nonlisted vernal pool invertebrate habitat that occurs along the southern and western boundaries of the forebays. These potential effects would be avoided and minimized through AMM1–AMM6, which would be in effect throughout the term of the Plan. The indirect effects of plan implementation under Alternative 9 would not be adverse.

***CEQA Conclusion*:** Construction and maintenance activities associated with water conveyance facilities, and restoration actions could indirectly impact nonlisted vernal pool invertebrates and their habitat in the vicinity of construction and restoration areas, and maintenance activities. These potential impacts would be minimized or avoided through AMM1–AMM6, and AMM10, which would be in effect throughout the Plan's construction phase. The indirect impacts of Alternative 9 would be less than significant.

Impact BIO-40: Periodic Effects of Inundation of Nonlisted Vernal Pool Invertebrates' Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from *CM2 Yolo Bypass Fisheries Enhancement* would periodically affect 0 to 4 acres of modeled habitat for nonlisted vernal pool invertebrates (Table 12-9-15). There would be no periodic effects resulting from *CM5 Seasonally Inundated Floodplain Restoration*

***NEPA Effects*:** BDCP Appendix 5.J, *Effects on Natural Communities, Wildlife, and Plants*, describes the methods used to estimate periodic inundation effects in the Yolo Bypass. Based on this method, periodic inundation could affect nonlisted vernal pool invertebrates occupying areas ranging from 0 acres of habitat during most notch flows, to an estimated 4 acres during a notch flow of 6,000 cfs. BDCP-associated inundation of areas that would not otherwise have been inundated is expected to occur in no more than 30% of all years, because Fremont Weir is expected to overtop the remaining 70% of all years, and during those years notch operations would not typically affect the maximum extent of inundation. In more than half of all years under Existing Conditions, an area greater than the BDCP-related inundation area already inundates in the bypass. Yolo Bypass flooding is expected to have a minimal effect on nonlisted vernal pool invertebrates and would thus not be adverse under NEPA.

***CEQA Conclusion*:** Alternative 9 would periodically inundate at most 4 acres of nonlisted vernal pool invertebrates' habitat during the maximum flows over the Fremont Weir. The periodic inundation is not anticipated to result in a conversion of nonlisted vernal pool invertebrates' habitat into different wetland habitat. BDCP-associated inundation of areas that would not otherwise have been inundated is expected to occur in no more than 30% of all years, because Fremont Weir is expected to overtop the remaining 70% of all years, and during those years notch operations would not typically affect the maximum extent of inundation. In more than half of all years under Existing Conditions, an area greater than the BDCP-related inundation area already inundates in the bypass. Yolo Bypass flooding is expected to have a minimal effect on nonlisted vernal pool invertebrates and would thus result in less-than-significant impacts on the species.

Sacramento and Antioch Dunes Anthicid Beetles

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on Sacramento and Antioch Dunes anthicid beetles. Potential habitat in the study area includes the inland dune scrub at Antioch Dunes NWR, sand bars along the Sacramento and San Joaquin Rivers, and sandy dredge spoil piles (California Department of Fish and Game 2006c and 2006d).

The construction, and operations and maintenance of the water conveyance facilities under Alternative 9 would not likely affect Sacramento and Antioch Dunes anthicid beetles. The channel work and associated infrastructure would generally avoid affects to channel margins where sand bars are likely to form. Conveyance construction would not affect inland dune scrub at Antioch Dunes NWR. No dredge spoil areas that could be occupied by Sacramento anthicid beetle were identified within conveyance facilities footprints during a review of Google Earth imagery. Also, a review of the locations of the Alternative 9 operable barriers and areas of channel modifications on Google Earth imagery did not reveal any sandbars in the channels or along the channel margins. These portions of the Delta have steep, riprap lined channel banks that are likely not conducive to the formation of sandbars and flows there are slow enough that sand deposits are unlikely.

Implementation of BDCP restoration based conservation measures could affect habitat for Sacramento and Antioch Dunes anthicid beetles. Both species are known to utilize interior sand dunes and sandbar habitat. The only interior sand dune habitat within the Plan Area is at Antioch Dunes, which would not be impacted by the Alternative 9 conservation measures. Both species are known to occur along the Sacramento River and San Joaquin Rivers. The implementation of BDCP restoration actions, and other covered activities could affect habitat for Sacramento and Antioch Dunes anthicid beetles along channels throughout the Plan Area; however the extent of these habitats in the Plan Area is unknown because these areas were not identified at the scale of mapping done within the study area. Because of current and historic channel modifications (channel straightening and dredging) and levee construction throughout the Delta, sandbar habitat is likely very limited and restricted to channel margins. The implementation of *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration*, and *CM6 Channel Margin Enhancement* could impact sandbar habitat along the river channels and possibly sandy, dredge piles on Delta islands.

Over the term of the BDCP, Alternative 9 would likely result in beneficial effects on Sacramento and Antioch Dunes anthicid beetles. The following Alternative 9 objectives would generally increase opportunities for the formation of sandbars in the Plan Area.

- Restore 10,000 acres of seasonally inundated floodplain (Objective L2.11, associated with CM5).
- Enhance 20 miles of channel margin habitat (Objective L2.12, associated with CM6),
- Restore 5,000 acres of riparian habitat, with at least 3,000 acres occurring on restored seasonally inundated floodplain. (VFRNC1.1, associated with CM7).

These measures would improve shoreline conditions by creating benches along levees, shallow habitat along margins and in floodplains, and increasing shoreline vegetation, all of which would likely contribute to the formation of sandbars along Delta river channels where these measures would be implemented. Increasing the structural diversity of Delta river channel margins and floodplains would create opportunities for sand to be deposited and for sandbars to subsequently form. As explained below, potential impacts on Sacramento and Antioch Dunes anthicid beetles would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Impact BIO-41: Loss or Conversion of Habitat for and Direct Mortality of Sacramento and Antioch Dunes Anthicid Beetles

Implementation of Alternative 9 conservation measures could affect Sacramento and Antioch Dunes anthicid beetles and their habitat. As mentioned above, the extent of this habitat in the study area is unknown but it is assumed that sand bars likely occur along to some degree along the Sacramento and San Joaquin Rivers and that some islands in the Delta may contain sandy dredge spoil piles. A review of Google Earth imagery of the north Delta did identify three general areas that appear to have accumulations of sandy soils (with some vegetation), possibly from dredge disposal, are Decker Island, the western portion of Bradford Island, and the southwestern tip of Grand Island. A review of Google Earth imagery of the south Delta did identify sandbar habitat along the San Joaquin River from the southern end of the Plan Area downstream to an area just west of Lathrop. An additional area along Paradise Cut was identified just north of I-5. Conservation measures that could result in impacts on Sacramento and Antioch Dunes anthicid beetles are tidal habitat restoration (CM4), floodplain restoration (CM5), and channel margin enhancement (CM6). In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate habitat for Sacramento and Antioch Dunes anthicid beetles. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM4 Tidal Natural Communities Restoration*: Tidal natural communities restoration could impact the areas of sandy soils identified from aerial photographs on Decker Island, the western portion of Bradford Island, and on the southwestern tip of Grand Island because these areas fall within the West Delta Restoration Opportunity Area (ROA). The West Delta ROA has been identified in the BDCP (BDCP Chapter 3, *Conservation Strategy*, Section 3.4.4) as providing opportunities for creating subtidal aquatic and tidal marsh habitats. The methods and techniques identified in the BDCP that may be used for tidal restoration include the recontouring of lands so that they have elevations suitable for the establishment of marsh plains and the eventual breaching of levees. There are three CNDDB records of Sacramento anthicid beetle (just north of Rio Vista, one just south of Rio Vista along the west shore of the Sacramento River, and one on Grand Island) and one CNDDB record of Antioch Dunes anthicid beetle (just north of Rio Vista) that fall within the West Delta ROA (California Department of Fish and Wildlife 2013). Tidal restoration actions in the West Delta ROA may eliminate potential habitat and impact occupied habitat of both Sacramento and Antioch Dunes anthicid beetles.

- *CM5 Seasonally Inundated Floodplain Restoration*: Seasonally inundated floodplain restoration could impact areas with sandbars that were identified in a review of aerial photographs. The sandbars identified along the San Joaquin River and Paradise Cut are within the conceptual corridors (Corridors 1a, 1b, 2a, and 4) identified in Figure 3.4-20 of the BDCP. There are four CNDDB records for Sacramento anthicid beetle in the conceptual corridor along the San Joaquin River (California Department of Fish and Wildlife 2013). Floodplain restoration actions in these conceptual corridors could impact potential habitat for both these species and occupied habitat of Sacramento anthicid beetle.

- *CM6 Channel Margin Enhancement*: Channel margin enhancement could result in impacts on 20 miles of channel margin that could contain sandbars.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

The BDCP could result in substantial affects to Sacramento and Antioch Dunes anthicid beetles because all of the habitat identifiable from aerial photo review falls within either the West Delta ROA, which is being considered for tidal restoration (CM4), or within three of the conceptual corridors being considered for floodplain restoration (CM5). Furthermore, all seven of the records for Sacramento anthicid beetle within the study area fall within areas being considered for restoration (CM4 and CM5), which represent over half of the extant records for this species range wide (7 of 13), and the only extant record for Antioch Dunes anthicid beetle, which represent one of five extant records range wide, falls within the West Delta ROA that is just north of Rio Vista. These occurrences could be affected by restoration if these areas are chosen as restoration projects. However, over the term of the BDCP, implementation of conservation components would likely benefit Sacramento and Antioch Dunes anthicid beetles. CM5, CM6, and CM7 would generally contribute to the formation of sandbar habitat in the Plan Area. These measures would improve shoreline conditions by creating benches along levees (CM6), creating shallow margin and floodplain habitat (CM5), and increasing shoreline vegetation (CM7), all of which would likely contribute to the formation of sandbars along Delta river channels where these measures would be implemented. Increasing the structural diversity of Delta river channel margins would create areas of slow water that would allow for sand to be deposited and for sandbars to subsequently form. Other factors relevant to effects on Sacramento and Antioch Dunes anthicid beetle include:

- The actual extent of suitable and occupied habitat for these species in the plan is unknown.
- The sandbar habitat occupied by Sacramento anthicid beetle along the San Joaquin River would likely not be directly impacted where floodplain restoration occurs because the physical disturbance would be to adjacent levees and agricultural areas. Though these actions would change hydrologic conditions that could overtime remove the existing sandbars, the expanded floodplain would create conditions suitable for the formation of new and possibly larger sandbars.
- Floodplain restoration would be phased over a period of 30 years so that not all sandbar habitat within these areas would be affected at once. Furthermore, as floodplain restoration is being implemented new sandbar habitat would likely be forming prior and/or concurrent with future floodplain restoration projects that may affect sandbar habitat on the San Joaquin River and/or Paradise Cut.

NEPA Effects: The potential impacts on Sacramento and Antioch Dunes anthicid beetles associated with Alternative 9 as a whole would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of other conservation actions. However, with implementation of restoration associated with CM5, CM6, and CM7, which would be phased throughout the time period when the impacts would be occurring, the effects of Alternative 9 as a whole on Sacramento and Antioch Dunes anthicid beetles would not be adverse under NEPA.

CEQA Conclusion: Alternative 9 would impact Sacramento and Antioch Dunes anthicid beetles' habitat and could impact seven occurrences of Sacramento anthicid beetle and one occurrence of Antioch Dunes anthicid beetle. However, over the term of the BDCP, implementation of conservation components would likely benefit Sacramento and Antioch Dunes anthicid beetles. BDCP conservation components, particularly conservation measures CM5, CM6, and CM7, would generally contribute to the formation of sandbar habitat in the Plan Area. Floodplain restoration (CM5) would be phased over a period of 30 years so that not all sandbar habitat within these areas would be affected at once. Furthermore, as floodplain restoration is being implemented new sandbar habitat would likely be forming prior and/or concurrent with future floodplain restoration projects that may affect sandbar habitat on the San Joaquin River and/or Paradise Cut.

Considering that floodplain (CM5), channel margin enhancement (CM6), and riparian restoration (CM7) would contribute to the replacement of and possible expansion of sandbar habitat in the Delta and be phased throughout the time period when the impacts would be occurring, the implementation of Alternative 9 as a whole would not result in a substantial adverse effect though habitat modification and would not substantially reduce the number or restrict the range of these species. Therefore, the alternative would have a less-than-significant impact on Sacramento and Antioch Dunes anthicid beetles.

Delta Green Ground Beetle

This section describes the effects of Alternative 9 on delta green ground beetle. Suitable habitat in the study area would be vernal pool complexes and annual grasslands in the general Jepson Prairie area. The construction, and operations and maintenance of the water conveyance facilities under Alternative 9 would not affect delta green ground beetle because the facilities and construction area are outside the known range of the species. Implementation of Alternative 9 could affect delta green ground beetle through the protection of grasslands and vernal pool complex (CM3) in the vicinity of Jepson Prairie and the subsequent implementation of habitat enhancement and management actions and recreational trail construction (CM11) in these areas. In addition, tidal natural communities restoration (CM4) and vernal pool and alkali seasonal wetland complex restoration (CM9) could result in potential impacts on delta green ground beetle and its habitat. Full implementation of Alternative 9 would likely result in beneficial effects on delta green ground beetle through the following conservation actions.

- Protect 2,000 acres of grassland in CZ 1 (Objective GNC1.1, associated with CM3).
- Protect 600 acres of vernal pool complex in CZs 1, 8, and 11 (Objective VPNC1.1, associated with CM3).
- Restore up to 67 acres of vernal pool complex in CZs 1, 8, and/or 11 (Objective VPNC1.2, associated with CM9).

These areas could contain currently occupied habitat for delta green ground beetle and/or create conditions suitable for eventual range expansion. As explained below, potential impacts on delta green ground beetle would be adverse for NEPA purposes and would be significant for CEQA purposes. Mitigation Measure BIO-42, *Avoid Impacts on Delta Green Ground Beetle and its Habitat*, would reduce the effects under NEPA and reduce the impacts to a less-than-significant level under CEQA.

Impact BIO-42: Loss or Conversion of Habitat for and Direct Mortality of Delta Green Ground Beetle

Alternative 9 conservation measures could result in the conversion of habitat and/or direct mortality to delta green ground beetle. Conservation measures that could affect delta green ground beetle are tidal natural communities habitat restoration (CM4), vernal pool and alkali seasonal wetland complex restoration (CM9), and habitat enhancement and management activities (CM11) in CZ 1. CZ 1 is the only portion of the Plan Area that contains occupied and potential habitat for delta green ground beetle. The range of the delta green ground beetle is currently believed to be generally bound by Travis Air Force Base to the west, Highway 113 to the east, Hay Road to the north, and Creed Road to the south (Arnold and Kavanaugh 2007; U.S. Fish and Wildlife Service 2009a). Further discussion of this potential effect is provided below, and NEPA and CEQA conclusions follow.

- *CM4 Tidal Natural Communities Restoration:* Tidal restoration in the Cache Slough ROA could result in the loss of delta green ground beetle habitat if restoration is planned in areas known to be or potentially occupied by the species. CM4 identifies 5,000 acres of freshwater tidal natural communities restoration in the Cache Slough ROA and Lindsey Slough and Calhoun Cut have been identified as areas suitable for restoration. Lindsey Slough is just east of Jepson Prairie and Calhoun Cut, which is off of Lindsey Slough (see Figure 12-1), goes into the general Jepson Prairie area and is adjacent to areas of potential habitat for delta green ground beetle. The tidal restoration methods and techniques identified in CM4 (see BDCP Chapter 3, Section 3.4.4.3.3) includes excavating channels; modifying ditches, cuts, and levees to encourage tidal circulation; and scalping higher elevation areas to create marsh plains. These disturbances could affect delta green ground beetle through habitat modification, either directly or indirectly through hydrologic modifications, and/or result in direct mortality to the species. No CNDDB records for delta green ground beetle are intersected by the hypothetical tidal restoration footprints being used by the BDCP.

- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: Vernal pool restoration may occur in CZ 1 and could result in disturbance to delta green ground beetle habitat if restoration is planned in areas known to be or potentially occupied by the species. These restoration activities would most likely take place in areas that were historically vernal pool complexes that have since been highly degraded, but which are suitable for vernal pool restoration. These areas would not likely provide habitat for delta green ground beetle. However, if these activities do take place in suitable habitat, then disturbances could result in direct mortality of the species. Nevertheless, restoration ultimately would expand habitat available to the species.
- *CM11 Natural Communities Enhancement and Management*: As described in *CM3 Natural Communities Protection and Restoration*, up to 2,000 acres of grasslands would be protected in CZ 1 and a portion of the 600 acres of protection and possibly some of the up to 10 wetted acres of vernal pool restoration could also occur in CZ 1. Potential effects from CM11 could include direct mortality to larvae and adults from the implementation of grassland management techniques, which may include livestock grazing, prescribed burning, and mowing. In addition to these grassland and vernal pool complex management actions, CM11 also includes guidelines and techniques for invasive plant control, which may include manual control (hand-pulling and digging), mechanical control (large equipment), and chemical control, though some of these methods would be restricted in areas where rare plants occur or in critical habitat for vernal pool species. The creation of new recreation trails as part of CM11 would result in impacts on 15.5 acres of grasslands within CZ 1, which could affect delta green ground beetle if present.

NEPA Effects: The protection of 2,000 acres of grassland in CZ 1 (CM3) and the protection of 600 acres of vernal pool complex and up 10 wetted acres of vernal pool complex restoration, some of which could occur in CZ 1 (CM3 and CM9) could benefit delta green ground beetle if these areas occur within the range of the species. Tidal natural communities restoration (CM4), vernal pool and alkali seasonal wetland complex restoration (CM9), and recreational trail construction and subsequent enhancement and management actions (CM11) could impact delta green ground beetle. The management of these grasslands and vernal pool complexes according to *CM11 Natural Communities Enhancement and Management* and the construction of recreational trails in CZ 1 has a potential to affect this species. AMM37 would ensure that new trails in vernal pool complexes be sited at least 250 feet from wetland features, or closer if site-specific information indicates that local watershed surrounding a vernal pools is not adversely affected. Direct mortality and/or the affects to delta green ground beetle habitat would be an adverse effect under NEPA. Implementation of Mitigation Measure BIO-42, *Avoid Impacts on Delta Green Ground Beetle and its Habitat*, would reduce this effect.

CEQA Conclusion: The implementation of grassland and vernal pool complex protection (CM3), tidal natural communities restoration (CM4), vernal pool and alkali seasonal wetland complex restoration (CM9), and recreational trail construction and subsequent enhancement and management actions (CM11) could impact delta green ground beetle. Tidal restoration projects around Calhoun Cut and possible Lindsey Slough could affect habitat and result in direct mortality to the species from excavating channels; modifying ditches, cuts, and levees to encourage tidal circulation; and scalping higher elevation areas to create marsh plains. Potential impacts from CM11 could include direct mortality to larvae and adults resulting from the implementation of recreation trail construction in 15.5 acres of grassland in CZ 1 and from grassland management techniques, which may include livestock grazing, prescribed burning, and mowing. AMM37 would ensure that new trails in vernal pool complexes be sited at least 250 feet from wetland features, or closer if site-specific information indicates that local watershed surrounding a vernal pools is not adversely affected. CM11 also includes guidelines and techniques for invasive plant control, which may include manual control (hand-pulling and digging), mechanical control (large equipment), and chemical control, though some of these methods would be restricted in areas where rare plants occur and in critical habitat for vernal pool species. These actions could result in adverse effects through habitat modification and a possible reduction in the number of the species or restrict its range, and therefore result in significant impacts on delta green ground beetle. Implementation of Mitigation Measure BIO-42 would reduce these potential impacts on a less-than-significant level.

Mitigation Measure BIO-42: Avoid Impacts on Delta Green Ground Beetle and its Habitat

As part of the design and development of management plans for conservation areas in the area of Jepson Prairie, BDCP proponents will implement the following measures to avoid effects on delta green ground beetle.

- If habitat restoration or protection is planned for the lands adjacent to Calhoun Cut and non-cultivated lands on the western side of Lindsey Slough, these area will be evaluated by a USFWS approved biologist for potential delta green ground beetle habitat (large playa pools, or other similar aquatic features, with low growing vegetation or bare soils around the perimeter). The biologist will have previous experience with identifying suitable habitat requirements for delta green ground beetle.
- Any suitable habitat identified by the biologist (with previous experience with delta green ground beetle) within the species current range will be considered potentially occupied and all ground disturbing covered activities in these areas will be avoided, which for the Plan Area is generally the area west of State Route 113.
- Any other areas identified as suitable habitat outside of the current range of the species will be surveyed by a biologist with previous experience in surveying for and identifying delta green ground beetle. No ground disturbing covered activities will occur in areas identified as occupied by delta green ground beetle.
- Based on the results of the habitat evaluations and surveys, site-specific restoration and management plans will be developed so that they don’t conflict with the recovery goals for delta green ground beetle in the USFWS’s 2005 Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (U.S. Fish and Wildlife Service 2005). Plans will include measures to protect and manage for delta green ground beetle so that they continue to support existing populations or allow for future colonization.

Callippe Silverspot Butterfly

This section describes the effects of Alternative 9 on callippe silverspot butterfly. Suitable habitats are typically in areas influenced by coastal fog with hilltops that support the specie’s host-plant, Johnny jump-ups. Preferred nectar flowers used by adults include thistles, blessed milk thistle, and coyote wild mint. Other native nectar sources include hairy false goldeneaster, coast buckwheat, mourning bride, and California buckeye. The construction, and operations and maintenance of the water conveyance facilities under Alternative 9 would not result in impacts on callippe silverspot butterfly or its habitat. If Cordelia Hills and Potrero Hills are identified for grassland protection opportunities as part of *CM3 Natural Communities Protection and Restoration* and the subsequent implementation of *CM11 Natural Communities Enhancement and Management,* could affect callippe silverspot butterfly. Callippe silverspot butterfly has been documented in the western most portion of the Plan Area (CZ 11) in the Cordelia Hills (Solano County Water Agency 2009). Potential habitat for the species (grassy hills with *Viola pedunculata*) is present in the Potrero Hills, but it has not been observed there (EDAW 2005, California Department of Fish and Wildlife 2013). Though CZ 11 has been identified as potential area for grassland restoration in *CM8 Grassland Natural Community Restoration,* the primary goal there is to restore small patches of grassland to connect to Jepson Prairie and/or the restoration of upland grasses adjacent to tidal brackish emergent wetland in Suisun Marsh, both of which would not be areas suitable for Callippe silverspot butterfly. The full implementation of Alternative 9 would protect up to 2,000 acres of grassland in CZ 11 (Objective GNC1.1, associated with CM3), some of which may contain habitat for Callippe silverspot butterfly. Any potential effects on callippe silverspot would be avoided and minimized through the implementation of Mitigation Measure BIO-43, *Avoid and Minimize Loss of Callippe Silverspot Butterfly Habitat*. As explained below, potential impacts on callippe silverspot would be adverse for NEPA purposes and would be significant for CEQA purposes. Mitigation Measure BIO-43 would reduce the effects under NEPA and reduce the impacts on less-than significant under CEQA.

NA = not applicable

Impact BIO-43: Loss or Conversion of Habitat for and Direct Mortality of Callippe Silverspot Butterfly

Alternative 9 conservation measures could result in the conversion of habitat for and direct mortality of callippe silverspot butterfly. Only one conservation measure was identified as potentially affecting callippe silverspot butterfly, *CM11 Natural Communities Enhancement and Management*, which could result in the disturbance of callippe silverspot butterfly habitat if such areas are acquired as part of grassland protection under *CM3 Natural Communities Protection and Restoration*. Further discussion of this potential effect is provided below and NEPA and CEQA conclusions follow.

CM11 Natural Communities Enhancement and Management: As described in *CM3 Natural Communities Protection and Restoration*, up to 2,000 acres of grasslands would be protected in CZ 11. If areas chosen for protection include Cordelia Hills or Potrero Hills, where there is known and potential habitat, respectively, then grassland enhancement and management actions could affect the callippe silverspot butterfly. Potential effects from CM11 could include the loss of larval host and nectar sources and direct mortality to larvae and adults from the installation of artificial nesting burrows and structures and the implementation of grassland management techniques, which may include livestock grazing, prescribed burning, and mowing. In addition to these grassland management actions, CM11 also includes guidelines and techniques for invasive plant control, which may include manual control (hand-pulling and digging), mechanical control (large equipment), and chemical control. Several of the preferred nectar sources are thistles, some of which have been identified by the California Invasive Plant Council as having limited to moderate ecological impacts (California Invasive Plant Council 2006).

NEPA Effects: The protection of 2,000 acres of grassland within CZ 11 could benefit callippe silverspot butterfly if these protected areas include occupied and potential habitat on the hill tops in Cordelia Hills and Potrero Hills. The management of these grasslands according to CM11 Natural Communities Enhancement and Management has potential to adversely affect this species. Direct mortality and/or the removal of larval host plants and nectar sources for adults would be an adverse effect under NEPA. Implementation of Mitigation Measure BIO-43, *Avoid and Minimize Loss of Callippe Silverspot Butterfly Habitat*, would ensure the effect is not adverse.

CEQA Conclusion: If grasslands within the Cordelia Hills and Potrero Hills are protected as part of *CM3 Natural Communities Protection and Restoration* then the subsequent management of these grasslands according to *CM11 Natural Communities Enhancement and Management* has affect this species. Potential impacts from CM11 could include the loss of larval host and nectar sources and direct mortality to larvae and adults resulting from the installation of artificial nesting burrows and structures and the implementation of grassland management techniques, which may include livestock grazing, prescribed burning, and mowing. In addition to these grassland management actions, CM11 also includes guidelines and techniques for invasive plant control, which may include manual control (hand-pulling and digging), mechanical control (large equipment), and chemical control, which could result in direct and indirect effects on larval host plants and nectar plants. These actions could result in adverse effects through habitat modification and a possible reduction in the number of the species or restrict its range and would therefore result in significant impact on the species under CEQA. However, over the term of BDCP callippe silverspot butterfly could benefit from the protection of occupied and potential habitat for the species with the implementation of Mitigation Measure BIO-43, which would avoid and minimize effects from management actions and thus reduce the potential impact to a less-than-significant level.

Mitigation Measure BIO-43: Avoid and Minimize Loss of Callippe Silverspot Butterfly Habitat

As part of the development of site-specific management plans on protected grasslands in the Cordelia Hills and/or Potrero Hills, BDCP proponents will implement the following measures to avoid and minimize the loss of callippe silverspot habitat.

- Hilltops in Cordelia Hills and Potrero Hills will be surveyed for callippe silverspot larval host plants (Johnny jump-ups) by a biologist familiar with identifying this plant species. These surveys should occur during the plant's blooming period (typically early January through April)
- If larval host plants are present, then presence/absence surveys for callippe silverspot butterfly larvae will be conducted according to the most recent USFWS approved survey methods by a biologist with previous experience in surveying for and identifying callippe larvae and/or signs of larval presence. These surveys should be conducted prior to the adult flight season, which usually starts in mid-May.
- If larvae are detected then no further surveys are necessary. If larvae are not detected then surveys for adults will be conducted by a biologist familiar with surveying for and identifying callippe silverspot. Surveys typically start in mid-May and continue weekly for 8 to 10 weeks.
- If callippe silverspot butterflies are detected, then the site-specific management plans will be written to include measures to protect and manage for larval host plants and nectar sources so that they continue to support existing populations and/or allow for future colonization. Mapping of both larval host plants and nectar sources will be incorporated into the management plans.

California Red-Legged Frog

Modeled California red-legged frog habitat in the study area is restricted to freshwater aquatic and grassland habitat, and immediately adjacent cultivated lands along the study area's southwestern edge in CZ 7, CZ 8, CZ 9, and CZ 11. Pools in perennial and seasonal streams and stock ponds provide potential aquatic habitat for this species. While stock ponds are underrepresented as a modeled habitat, none is expected to be affected by BDCP actions. Construction and restoration associated with Alternative 9 conservation measures would result in permanent losses of California red-legged frog modeled habitat as indicated in Table 12-9-20. Factors considered in assessing the value of affected habitat for the California red-legged frog, to the extent that information is available, are presence of limiting habitat (aquatic breeding habitat), known occurrences and clusters of occurrences, proximity of the affected habitat to existing protected lands, and the overall degraded or fragmented nature of the habitat. The study area represents the extreme eastern edge of the species' coastal range, and species' occurrences are reported only from CZ 8 and CZ 11. Full implementation of Alternative 9 would also include the following biological objectives over the term of the BDCP to benefit the California red-legged frog (BDCP Chapter 3, *Conservation Strategy*).

- Increase native species diversity and relative cover of native plant species, and reduce the introduction and proliferation of nonnative species (Objective L2.6, associated with CM11, CM13, and CM20).
- Protect 8,000 acres of grassland (Objective GNC1.1, associated with CM3).

- Protect stock ponds and other aquatic features within protected grasslands to provide aquatic breeding habitat for native amphibians and aquatic reptiles (Objective GNC1.3, associated with CM3)
- Increase burrow availability for burrow-dependent species (Objective GNC2.3, associated with CM11).
- Maintain and enhance aquatic features in grasslands to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding for covered amphibian and aquatic reptile species (Objective GNC2.5, associated with CM11).

As explained below, with the restoration and protection of these amounts of habitat, in addition to implementation of AMMs, impacts on California red-legged frog would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-44: Loss or Conversion of Habitat for and Direct Mortality of California Red-Legged Frog

Alternative 9 conservation measure CM11 would result in the permanent loss of 24 acres of modeled upland habitat for t California red-legged frog. There are no California red-legged frog occurrences that overlap with the Plan footprint. Construction activities associated recreational facilities, including operation of construction equipment, could result in temporary effects on, as well as injury and mortality of, California red-legged frogs. In addition, natural enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate California red-legged frog habitat including injury and mortality of California red-legged frogs. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- *CM11 Natural Communities Enhancement and Management*: Based on the recreation assumptions described in BDCP Chapter 3, Section 3.4.11, an estimated 24 acres of upland cover and dispersal habitat for the California red-legged frog would be removed as a result of constructing trails and associated recreational facilities. Passive recreation in the reserve system could result in trampling and disturbance of egg masses in water bodies, degradation of water quality through erosion and sedimentation, and trampling of sites adjacent to upland habitat used for cover and movement. However, *AMM37 Recreation* requires protection of water bodies from recreational activities and requires trail setbacks from wetlands. With these restrictions, recreation-related effects on California red-legged frog are expected to be minimal.

  Activities associated with natural communities enhancement and management in protected California red-legged frog habitat, such as ground disturbance or herbicide use to control nonnative vegetation, could result in local adverse habitat effects on, and injury or mortality of, California red-legged frogs. These effects would be avoided and minimized with implementation of the AMMs discussed below. Herbicides would only be used in California red-legged frog habitat in accordance with the written recommendation of a licensed, registered pest control advisor and in conformance with label precautions and federal, state, and local regulations in a manner that avoids or minimizes harm to the California red-legged frog.

- Critical habitat: Several conservation measures would be implemented in California red-legged frog habitat and designated critical habitat in CZ 8 and CZ 11. Approximately 2,460 acres of designated critical habitat for the California red-legged frog overlaps with the study area along the western edge of CZ 11 in critical habitat unit SOL-1. An additional 862 acres of designated critical habitat is also present along the western edge of CZ 8 in critical habitat unit ALA-2. Conservation actions to protect and enhance grassland habitat for covered species, including California red-legged frog, in CZ 8 could include acquisition and enhancement of designated critical habitat for the California red-legged frog and California tiger salamander. Any habitat enhancement actions for these species in designated critical habitat are expected to enhance the value of any affected designated critical habitat for conservation of California red-legged frog. These actions would result in an overall benefit to California red-legged frog within the study area through protection and management of grasslands with associated intermittent stream habitat and through restoration of vernal pool complex habitat and its associated grassland habitat.

- Operations and maintenance: Ongoing water conveyance facilities operation and maintenance is expected to have little if any adverse effect on the California red-legged frog. Postconstruction operation and maintenance of the above-ground water conveyance facilities could result in ongoing but periodic postconstruction disturbances that could affect California red-legged frog use of the surrounding habitat. Operation of maintenance equipment, including vehicle use along transmission corridors in CZ 8, could also result in injury or mortality of California red-legged frogs if present in work sites. Implementation conservation actions and implementation of AMM1–AMM6, AMM10, AMM14, and AMM37 would reduce these effects.

- Injury and direct mortality: Construction activities associated with t vernal pool complex restoration, and habitat and management enhancement-related activities, including operation of construction equipment, could result in injury or mortality of California red-legged frogs. Breeding, foraging, dispersal, and overwintering behavior may be altered during construction activities, resulting in injury or mortality of California red-legged frog. Frogs occupying burrows could be trapped and crushed during ground-disturbing activities. Degradation and loss of estivation habitat is also anticipated to result from the removal of vegetative cover and collapsing of burrows. Injury or mortality would be avoided and minimized through implementation of seasonal constraints and preconstruction surveys in suitable habitat, collapsing unoccupied burrows, and relocating frogs outside of the construction area as described in AMM1–AMM6, AMM10, AMM14, and AMM37.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA.

Alternative 9 would permanently remove 8 acres of upland terrestrial cover habitat for California red-legged frog. The effects would result from construction of recreational facilities (CM11).

Typical NEPA project-level mitigation ratios for those natural communities that would be affected and that are identified in the biological goals and objectives for California's red-legged frog in Chapter 3 of the BDCP would be 2:1 for protection of grassland habitats. Using these ratios would indicate that 16 acres of grassland should be protected for California red-legged frog to mitigate the near-term losses.

The BDCP has committed to near-term protection of up to 2,000 acres grassland in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). Protection of at least 1,000 acres of grassland in CZ 8, west of Byron Highway, would benefit California red-legged frog by providing habitat in the portion of the Plan Area with the highest long-term conservation value for the species based on known species occurrences and large, contiguous habitat areas (Objective GNC1.1). Consistent with Objective GNC1.3, ponds and other aquatic features within the grasslands would be protected to provide aquatic habitat for this species, and surrounding grassland would provide dispersal and aestivation habitat which would compensate for the loss of 1 acre of aquatic habitat. In addition, aquatic features in grasslands would be maintained and enhanced to provide suitable inundation depth and duration to support breeding habitat for covered amphibians (Objective GNC2.5).

These conservation actions would occur in the same timeframe as the construction losses, thereby avoiding adverse effects of habitat loss on California red-legged frog. These Plan objectives represent performance standards for considering the effectiveness of CM3 protection and restoration actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives for California red-legged frog satisfy the typical mitigation that would be applied to the project-level effects of CM1, as well as mitigate the near-term effects of the other conservation measures.

The plan also contains commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM14 California Red-Legged Frog, and AMM37 Recreation*. These AMMs include elements that avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS, *Avoidance and Minimization Measures*.

Late Long-Term Timeframe

The habitat model indicates that the study area supports approximately 159 acres of aquatic 7,766 acres of upland habitat for California red-legged frog.

Alternative 9 as a whole would result in the permanent loss of 24 acres of upland habitat for California red-legged frog for the term of the plan (less than 1% of the total upland habitat in the study area). Most of the California red-legged frog upland habitat that would be removed consists of naturalized grassland or cultivated land in a highly disturbed or modified setting on lands immediately adjacent to Clifton Court Forebay. The removed upland cover and dispersal habitat is within 0.5 mile of a cluster of known California red-legged frog occurrences to the west. However, this habitat consists mostly of cultivated lands and small patches of grasslands, and past and current surveys in this area have not found any evidence that this habitat is being used (Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*).

The BDCP has committed to long-term protection of 8,000 acres grassland in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). Protection of at least 1,000 acres of grassland in CZ 8 west of Byron Highway would benefit the California red-legged frog by providing habitat in the portion of the study area with the highest long-term conservation value for the species based on known species occurrences and large, contiguous habitat areas (Objective GNC1.1). Consistent with Objective GNC1.3, ponds and other aquatic features in the grasslands would also be protected to provide aquatic habitat for this species, and the surrounding grassland would provide dispersal and aestivation habitat. Aquatic features in the protected grasslands in CZ 8 would be maintained and enhanced to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding California red-legged frogs (Objective GNC2.5). Additionally, livestock exclusion from streams and ponds and other measures would be implemented as described in CM11 to promote growth of aquatic vegetation with appropriate cover characteristics favorable to California red-legged frogs. Lands protected in CZ 8 would connect with lands protected under the *East Contra Costa County HCP/NCCP* and the extensive Los Vaqueros Watershed lands, including grassland areas supporting this species. This objective would ensure that California red-legged frog upland and associated aquatic habitats would be protected and enhanced in the largest possible patch sizes adjacent to occupied habitat within and adjacent to the Plan Area.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of tidal freshwater emergent wetland, grassland, valley/foothill riparian, and vernal pool complex that could overlap with the species model, would result in the restoration of 16 acres of aquatic and 351 acres of upland modeled habitat for California red-legged frog. In addition, protection of managed wetland, grassland, valley/foothill riparian, and vernal pool complex could overlap with the species model and would result in the protection of 3 acres of aquatic and 1,047 acres of upland California red-legged frog modeled habitat.

NEPA Effects: In the near-term, the loss of California red-legged frog habitat under Alternative 9 would be not be adverse because the BDCP has committed to protecting and restoring the acreage required to meet the typical mitigation ratios described above. In the late long-term, the losses of California red-legged frog aquatic and upland habitat associated with Alternative 9, in the absence of other conservation actions, would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality. However, with habitat protection and restoration associated with the conservation components, guided by landscape-scale goals and objectives and by AMM1–AMM6, AMM10, AMM14, and AMM37, the effects of Alternative 9 as a whole on California red-legged frog would not be adverse.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the impacts of construction would be less than significant under CEQA.

Alternative 9 would permanently remove 8 acres of upland terrestrial cover habitat for California red-legged frog. The effects would result from construction of recreational facilities (CM11).

Typical CEQA project-level mitigation ratios for those natural communities that would be affected and that are identified in the biological goals and objectives for California's red-legged frog in Chapter 3 of the BDCP would be 2:1 for protection of grassland habitats. Using these ratios would indicate that 16 acres of grassland should be protected for California red-legged frog to mitigate the near-term losses.

The BDCP has committed to near-term protection of up to 2,000 acres grassland in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). Protection of at least 1,000 acres of grassland in CZ 8, west of Byron Highway, would benefit California red-legged frog by providing habitat in the portion of the Plan Area with the highest long-term conservation value for the species based on known species occurrences and large, contiguous habitat areas (Objective GNC1.1). Consistent with Objective GNC1.3, ponds and other aquatic features within the grasslands would be protected to provide aquatic habitat for this species, and surrounding grassland would provide dispersal and aestivation habitat which would compensate for the loss of 1 acre of aquatic habitat. In addition, aquatic features in grasslands would be maintained and enhanced to provide suitable inundation depth and duration to support breeding habitat for covered amphibians (Objective GNC2.5).

These conservation actions would occur in the same timeframe as the construction losses, thereby avoiding adverse effects of habitat loss on California red-legged frog. These Plan objectives represent performance standards for considering the effectiveness of CM3 protection and restoration actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives for California red-legged frog satisfy the typical mitigation that would be applied to the project-level effects of CM1, as well as mitigate the near-term effects of the other conservation measures.

The BDCP also contains commitments to implement AMM1–AMM6, AMM10, AMM14, and AMM37. These AMMs include elements that avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 on California red-legged frog would be less than significant under CEQA, because the number of acres required to meet the typical ratios described above would be only 16 acres of upland communities protected.

Late Long-Term Timeframe

The habitat model indicates that the study area supports approximately 159 acres of aquatic 7,766 acres of upland habitat for California red-legged frog. Alternative 9 as a whole would result in the permanent loss of 24 acres of upland habitat for California red-legged frog for the term of the plan (less than 1% of the total upland habitat in the study area). Most of the California red-legged frog upland habitat that would be removed consists of naturalized grassland or cultivated land in a highly disturbed or modified setting on lands immediately adjacent to Clifton Court Forebay. The removed upland cover and dispersal habitat is within 0.5 mile of a cluster of known California red-legged frog occurrences to the west. However, this habitat consists mostly of cultivated lands and small patches of grasslands, and past and current surveys in this area have not found any evidence that this habitat is being used (Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*).

The BDCP has committed to long-term protection of 8,000 acres grassland in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). Protection of at least 1,000 acres of grassland in CZ 8 west of Byron Highway would benefit the California red-legged frog by providing habitat in the portion of the study area with the highest long-term conservation value for the species based on known species occurrences and large, contiguous habitat areas (Objective GNC1.1). Consistent with Objective GNC1.3, ponds and other aquatic features in the grasslands would also be protected to provide aquatic habitat for this species, and the surrounding grassland would provide dispersal and aestivation habitat. Aquatic features in the protected grasslands in CZ 8 would be maintained and enhanced to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding California red-legged frogs (Objective GNC2.5). Additionally, livestock exclusion from streams and ponds and other measures would be implemented as described in CM11 to promote growth of aquatic vegetation with appropriate cover characteristics favorable to California red-legged frogs. Lands protected in CZ 8 would connect with lands protected under the *East Contra Costa County HCP/NCCP* and the extensive Los Vaqueros Watershed lands, including grassland areas supporting this species. This objective would ensure that California red-legged frog upland and associated aquatic habitats would be protected and enhanced in the largest possible patch sizes adjacent to occupied habitat within and adjacent to the Plan Area.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of tidal freshwater emergent wetland, grassland, valley/foothill riparian, and vernal pool complex that could overlap with the species model, would result in the restoration of 16 acres of aquatic and 351 acres of upland modeled habitat for California red-legged frog. In addition, protection of managed wetland, grassland, valley/foothill riparian, and vernal pool complex could overlap with the species model and would result in the protection of 3 acres of aquatic and 1,047 acres of upland California red-legged frog modeled habitat.

In the absence of other conservation actions, the losses of California red-legged frog aquatic and upland habitat associated with Alternative 9 would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality. However, with habitat protection and restoration associated with the conservation components, guided by landscape-scale goals and objectives and by AMM1–AMM6, AMM10, AMM14, and AMM37, the effects of Alternative 9 would have a less-than-significant impact on California red-legged frog.

Impact BIO-45: Indirect Effects of Plan Implementation on California Red-Legged Frog

Noise and visual disturbance including aritifical nighttime lighting outside the project footprint but within 500 feet of construction activities are indirect effects that could temporarily affect the use of California red-legged frog habitat, all of which is upland cover and dispersal habitat. The areas to be affected are near Clifton Court Forebay, and no California red-legged frogs were detected during recent surveys conducted in this area (Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*).

Maintenance and refueling of heavy equipment could result in the inadvertent release of sediment and hazardous substances into species habitat. Increased sedimentation could reduce the suitability of California red-legged frog habitat downstream of the construction area by filling in pools and smothering eggs. Accidental spills of toxic fluids also could result in the subsequent loss of California red-legged frog if these materials enter the aquatic system. Hydrocarbon and heavy metal pollutants associated with roadside runoff also have the potential to enter the aquatic system, affecting water quality and California red-legged frog.

NEPA Effects: Implementation of AMM1–AMM6, AMM10, AMM14, and AMM37 as part of implementing Alternative 9 would avoid the potential for substantial adverse effects on California red-legged frogs, either indirectly or through habitat modifications. These AMMs would also avoid and minimize effects that could substantially reduce the number of California red-legged frogs, or restrict the species' range. Therefore, the indirect effects of Alternative 9 would not have an adverse effect on California red-legged frog.

CEQA Conclusion: Indirect effects from conservation measure operations and maintenance, as well as construction-related noise and visual disturbances including aritifical nighttime lighting, could impact California red-legged frog in aquatic and upland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could impact California red-legged frog or its prey. The inadvertent discharge of sediment or excessive dust adjacent to California red-legged frog habitat could also have a negative impact on the species or its prey. With implementation of AMM1–AMM6, AMM10, AMM14, and AMM37, construction, operation, and maintenance under Alternative 9 would avoid the potential for substantial adverse effects on California red-legged frog, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of California red-legged frogs. The indirect effects of Alternative 9 would have a less-than-significant impact on California red-legged frogs.

California Tiger Salamander

Modeled California tiger salamander habitat in the study area contains two habitat types: terrestrial cover and aestivation habitat, and aquatic breeding habitat and is restricted to CZ 1, CZ 2, CZ 4, CZ 5, CZ 7, CZ 8, and CZ 11 (Figure 12-14). Modeled terrestrial cover and aestivation habitat contains all grassland types and alkali seasonal wetland with a minimum patch size of 100 acres and within a geographic area defined by species records and areas most likely to support the species. Patches of grassland that were below the 100-acre minimum patch size but were contiguous with grasslands outside of the study area boundary were included. Modeled aquatic breeding habitat for the California tiger salamander includes vernal pools and seasonal and perennial ponds.

Factors considered in assessing the value of affected habitat for California tiger salamander, to the extent that information is available, include presence of limiting habitat (aquatic breeding habitat), known occurrences and clusters of occurrences, proximity of the affected habitat to existing protected lands, and the overall degraded or fragmented nature of the habitat. While conservation measures implemented in other CZs could have potential effects on California tiger salamander, those activities in CZ 8 and CZ 11 are considered to have a proportionately larger effect due to their closer proximity to known occurrences of the species.

Alternative 9 is expected to result in the temporary, permanent, and periodic removal of upland habitat that California tiger salamander uses for cover and dispersal (Table 12-9-21). Potential aquatic habitat for this species would not be affected. While stock ponds are underrepresented as a modeled habitat, none is expected to be affected by BDCP actions. Full implementation of Alternative 9 would also include the following biological objectives over the term of the BDCP to benefit the California tiger salamander (BDCP Chapter 3, *Conservation Strategy*).

- Increase the size and connectivity of the reserve system by acquiring lands adjacent to and between existing conservation lands (Objective L1.6, associated with CM3).
- Increase native species diversity and relative cover of native plant species, and reduce the introduction and proliferation of nonnative species (Objective L2.6, associated with CM11).
- Protect and improve habitat linkages that allow terrestrial covered and other native species to move between protected habitats within and adjacent to the Plan Area (Objective L3.1, associated with CM3, CM8, and CM11).
- Protect 150 acres of alkali seasonal wetland in CZ 1, CZ 8, and/or CZ 11 among a mosaic of protected grasslands and vernal pool complex (Objective ASWNC1.1, associated with CM3).
- Provide appropriate seasonal flooding characteristics for supporting and sustaining alkali seasonal wetland species (Objective ASWNC2.1, associated with CM3 and CM11).
- Increase burrow availability for burrow-dependent species in grasslands surrounding alkali seasonal wetlands within restored and protected alkali seasonal wetland complex (Objective ASWNC2.3, associated with CM11).
- Protect 600 acres of existing vernal pool complex in CZ 1, CZ 8, and/or CZ 11, primarily in core vernal pool recovery areas identified in the *Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon* (U.S. Fish and Wildlife Service 2005) (Objective VPNC1.1, associated with CM3).

- Restore vernal pool complex in CZ 1, CZ 8, and/or CZ 11 to achieve no net loss of vernal pool acreage (up to 67 acres of vernal pool complex restoration, assuming that all anticipated impacts [10 wetted acres] occur and that the restored vernal pool complex has 15% density of vernal pools) (Objective VPNC1.2, associated with CM3 and CM9).
- Increase the size and connectivity of protected vernal pool complex within the Plan Area and increase connectivity with protected vernal pool complex adjacent to the Plan Area (Objective VPNC1.3, associated with CM3).
- Protect the range of inundation characteristics that are currently represented by vernal pools throughout the Plan Area (Objective VPNC1.4, associated with CM3).
- Protect 8,000 acres of grassland (Objective GNC1.1, associated with CM3).
- Restore 2,000 acres of grasslands to connect fragmented patches of protected (Objective GNC1.2, associated with CM3 and CM8).
- Protect stock ponds and other aquatic features within protected grasslands to provide aquatic breeding habitat for native amphibians and aquatic reptiles (Objective GNC1.3, associated with CM3).
- Increase burrow availability for burrow-dependent species (Objective GNC2.3, associated with CM11).
- Maintain and enhance aquatic features in grasslands to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding for covered amphibian and aquatic reptile species (Objective GNC2.5, associated with CM11).

As explained below, with the restoration or protection of these amounts of habitat, in addition to the implementation of AMMs, impacts on California tiger salamander would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-21. Changes in California Tiger Salamander Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent NT	Permanent LLT[c]	Temporary NT	Temporary LLT[c]	Periodic[d] CM2	Periodic[d] CM5

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-46: Loss or Conversion of Habitat for and Direct Mortality of California Tiger Salamander

Alternative 9 conservation measures would result in the permanent loss of up to 634 acres of modeled upland habitat for California tiger salamander (Table 12-9-21). There are no California tiger salamander occurrences that overlap with the Plan footprint. Conservation measures that would result in these losses are Fremont Weir/Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), construction of recreational facilities, and construction of a conservation fish hatchery (CM18). Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate California tiger salamander habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- *CM2 Yolo Bypass Fisheries Enhancement*: Improvements in the Yolo Bypass would result in the permanent removal of approximately 42 acres of terrestrial cover and aestivation habitat for the California tiger salamander in the late long-term. The modeled habitat in the Yolo Bypass is of low potential for California tiger salamander: There have been no observations of California tiger salamander in this area based on the results of a number of surveys for vernal pool invertebrates and plants, and the bypass lacks vernal pool complexes with large, deep pools or large grassland areas with stock ponds and similar aquatic features that hold water long enough to provide potential breeding habitat for this species.

- *CM4 Tidal Natural Communities Restoration*: This activity would result in the permanent removal of approximately 517 acres of terrestrial cover and aestivation habitat in the study area in the late long-term. Tidal restoration in the Cache Slough area would result in habitat loss along the edges of Lindsey Slough and Duck Slough, and adjacent to cultivated land along the eastern edge of a block of modeled habitat. The modeled aquatic breeding habitat nearby the hypothetical tidal restoration footprint is of relatively high value, consisting of vernal pool complex along Lindsey Slough within the Jepson Prairie area in and near open space. The Jepson Prairie area includes numerous California tiger salamander CNDDB recorded occurrences and overlaps with Critical Habitat Unit 2, Jepson Prairie Unit, for this species. However, the hypothetical tidal restoration footprint does not overlap with critical habitat or recorded occurrences in this area. The tidal restoration at Lindsey Slough would occur along the northeastern edge of the Jepson Prairie block of habitat and would not contribute to fragmentation. Because the estimates of habitat loss resulting from tidal inundation are based on projections of where restoration may occur, actual effects are expected to be lower because of the ability to select sites that minimize effects on California tiger salamander.

- *CM11 Natural Communities Enhancement and Management*: Based on the recreation assumptions described in BDCP Chapter 3, Section 3.4.11, an estimated 40 acres of terrestrial cover and aestivation habitat for the California tiger salamander would be removed as a result of constructing trails and associated recreational facilities. Passive recreation in the reserve system could result in trampling and disturbance of eggs and larvae in water bodies, degradation of water quality through erosion and sedimentation, and trampling of sites adjacent to upland habitat used for cover and movement. However, *AMM37 Recreation* requires protection of water bodies from recreational activities and requires trail setbacks from wetlands. With these restrictions, recreation related effects on California tiger salamander are expected to be minimal.

  Habitat enhancement- and management-related activities in protected California tiger salamander habitats would result in overall improvements to and maintenance of California tiger salamander habitat values over the term of the BDCP. At least 1,000 acres of grassland habitat and some unknown acres of vernal pool complex habitat in CZ 8 are expected to benefit the California tiger salamander through protection of existing upland cover and dispersal habitat from potential loss or degradation that otherwise could happen with future changes in existing land use. Activities associated with natural communities enhancement and management over the term of the BDCP in protected California tiger salamander habitat, such as ground disturbance or herbicide use to control nonnative vegetation, could result in local adverse habitat effects and injury or mortality of California tiger salamander and disturbance effects if individuals are present in work sites. Implementation of AMM1–AMM6, AMM10, AMM13, and AMM37 would reduce these effects. Herbicides would only be used in California tiger salamander habitat in accordance with the written recommendation of a licensed, registered Pest Control Advisor and in conformance with label precautions and federal, state, and local regulations in a manner that avoids or minimizes harm to the California tiger salamander.

- *CM18 Conservation Hatcheries*: This activity could result in the permanent removal of approximately 35 acres of terrestrial cover and aestivation habitat for California tiger salamander in the Yolo Bypass area (CZ 2). The specifications and operations of this facility have not been developed, although the facility is expected to be constructed near Rio Vista on cultivated lands in low-value habitat for the species.

- Critical habitat: Approximately 1,781 acres of designated Critical Habitat Unit 2, Jepson Prairie Unit, for California tiger salamander overlap the study area in CZ 1. While this area is located within the Cache Slough Complex, it is not expected to be affected by BDCP tidal habitat restoration actions. Tidal habitat would be restored approximately 2 miles east of SR 113, with some restoration taking place along the Barker and Lindsey Slough channels west to approximately SR 113 and a small amount (0.4 acre) taking place along the Lindsey Slough Channel west of SR 113 into Critical Habitat Unit 2.
- Operations and maintenance: Ongoing facilities operation and maintenance is expected to have little if any adverse effect on the California tiger salamander. Postconstruction operation and maintenance of the above-ground water conveyance facilities could result in ongoing but periodic disturbances that could affect California tiger salamander use of the surrounding habitat. Operation of maintenance equipment, including vehicle use along transmission corridors in CZ 8, could also result in injury or mortality of California tiger salamanders if present in work sites. These effects, however, would be minimized with implementation of the California tiger salamander measures described in AMM1–AMM6, AMM10, AMM13, and AMM37.
- Injury and direct mortality: Construction activities associated with the water conveyance facilities, vernal pool complex restoration, and habitat and management enhancement-related activities, including operation of construction equipment, could result in injury or mortality of California tiger salamanders. Foraging, dispersal, and overwintering behavior may be altered during construction activities, resulting in injury or mortality of California tiger salamander if the species is present. Salamanders occupying burrows could be trapped and crushed during ground-disturbing activities. Degradation and loss of estivation habitat is also anticipated to result from the removal of vegetative cover and collapsing of burrows. Injury or mortality would be avoided and minimized through implementation of seasonal constraints and preconstruction surveys in suitable habitat, collapsing unoccupied burrows, and relocating salamanders outside of the construction area as described in AMM1–AMM6, AMM10, AMM13, and AMM37.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA effects and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction effects would not be adverse under NEPA.

Alternative 9 would permanently remove approximately 292 acres of upland terrestrial cover habitat for California tiger salamander. There would be no effect on aquatic habitat. The effects would result from Yolo Bypass improvements (CM2, 42 acres), tidal habitat restoration (CM4, 203 acres), construction of recreational facilities (CM11, 12 acres), and construction of conservation hatcheries (CM18, 35 acres).

The typical NEPA project-level mitigation ratio of 2:1 for protected grassland habitats would indicate that 584 acres of grassland should be protected in the near-term for California tiger salamander to mitigate the near-term losses.

The BDCP has committed to near-term restoration of up to 1,140 acres of upland habitat (Objective GNC1.2) and 40 acres of aquatic habitat and to protection of at least 520 acres of aquatic habitat (Objective ASWNC1.1 and Objective VPNC1.1) and 2,000 acres of upland habitat (Objective GNC1.1). The landscape-scale goals and objectives would inform the near-term protection and restoration efforts. The natural community restoration and protection activities are expected to be concluded during the first 10 years of plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for NEPA purposes.

In addition, the plan contains commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM13 California Tiger Salamander*, and *AMM37 Recreation*. These AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Late Long-Term Timeframe

Based on the habitat model, the study area supports approximately 8,273 acres of aquatic and 29,459 acres of upland modeled habitat for California tiger salamander. Alternative 9 as a whole would result in the permanent loss of, and temporary effects on 634 acres of upland habitat for California tiger salamander for the term of the plan (less than 2% of the total upland habitat in the study area). The location of these losses is described above in the discussions of CM2, CM4, CM11, and CM18.

The BDCP has committed to long-term protection of 8,000 acres grassland in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). Protection of at least 1,000 acres of grassland in CZ 8 west of Byron Highway would benefit the California tiger salamander by providing habitat in the portion of the study area with the highest long-term conservation value for the species based on known species occurrences and large, contiguous habitat areas (Objective GNC1.1). Consistent with Objective GNC1.3, ponds and other aquatic features in the grasslands would also be protected to provide aquatic habitat for this species, and the surrounding grassland would provide dispersal and aestivation habitat. Aquatic features in the protected grasslands in CZ 8 would be maintained and enhanced to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding California tiger salamanders (Objective GNC2.5). Additionally, livestock exclusion from streams and ponds and other measures would be implemented as described in CM11 to promote growth of aquatic vegetation with appropriate cover characteristics favorable to California tiger salamanders. Lands protected in CZ 8 would connect with lands protected under the *East Contra Costa County HCP/NCCP* and the extensive Los Vaqueros Watershed lands, including grassland areas supporting this species. This objective would ensure that California tiger salamander upland and associated aquatic habitats would be protected and enhanced in the largest possible patch sizes adjacent to occupied habitat within and adjacent to the Plan Area.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of alkali seasonal wetland complex, vernal pool complex, and grassland that could overlap with the species model, would result in the restoration of 88 acres of aquatic and 598 acres of upland modeled habitat for California tiger salamander. In addition, protection of alkali seasonal wetland complex, vernal pool complex, and grassland that could overlap with the species model, would result in the protection of 750 acres of aquatic and 5,000 acres of upland California tiger salamander modeled habitat.

NEPA Effects: In the near-term, the loss of California tiger salamander habitat under Alternative 9 would be not be adverse because the BDCP has committed to protecting the acreage required to meet the typical mitigation ratios described above. In the late long-term, the losses of California tiger salamander upland habitat associated with Alternative 9, in the absence of other conservation actions, would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality. However, with habitat protection and restoration associated with the conservation components, guided by landscape-scale goals and objectives and by AMM1–AMM6, AMM10, AMM13, and AMM37, the effects of Alternative 9 as a whole on California tiger salamander would not be adverse.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the impacts of construction would be less than significant.

Alternative 9 would permanently remove approximately 292 acres of upland terrestrial cover habitat for California tiger salamander. There would be no effect on aquatic habitat. The effects would result from Yolo Bypass improvements (CM2, 42 acres), tidal habitat restoration (CM4, 203 acres), construction of recreational facilities (CM11, 12 acres), and construction of conservation hatcheries (CM18, 35 acres).

The typical CEQA project-level mitigation ratio of 2:1 for protected grassland habitats would indicate that 584 acres of grassland should be protected in the near-term for California tiger salamander to mitigate the near-term losses.

The BDCP has committed to near-term restoration of up to 1,140 acres of upland habitat (Objective GNC1.2) and 40 acres of aquatic habitat and to protection of at least 520 acres of aquatic habitat (Objective ASWNC1.1 and Objective VPNC1.1) and 2,000 acres of upland habitat (Objective GNC1.1). The landscape-scale goals and objectives would inform the near-term protection and restoration efforts. The natural community restoration and protection activities are expected to be concluded during the first 10 years of plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for CEQA purposes.

In addition, the plan contains commitments to implement AMM1–AMM6, AMM10, AMM13, and AMM37, which include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS. These commitments are more than sufficient to support the conclusion that the near-term impacts of Alternative 9 on California tiger salamander would be less than significant under CEQA, because the number of acres required to meet the typical ratios described above would be only 584 acres of upland communities protected.

Late Long-Term Timeframe

Based on the habitat model, the study area supports approximately 8,273 acres of aquatic and 29,459 acres of upland modeled habitat for California tiger salamander. Alternative 9 as a whole would result in the permanent loss of, and temporary effects on 634 acres of upland habitat for California tiger salamander for the term of the plan (less than 2% of the total upland habitat in the study area). The location of these losses is described above in the discussions of CM2, CM4, CM11, and CM18.

The BDCP has committed to long-term protection of 8,000 acres grassland in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). Protection of at least 1,000 acres of grassland in CZ 8 west of Byron Highway would benefit the California tiger salamander by providing habitat in the portion of the study area with the highest long-term conservation value for the species based on known species occurrences and large, contiguous habitat areas (Objective GNC1.1). Consistent with Objective GNC1.3, ponds and other aquatic features in the grasslands would also be protected to provide aquatic habitat for this species, and the surrounding grassland would provide dispersal and aestivation habitat. Aquatic features in the protected grasslands in CZ 8 would be maintained and enhanced to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding California tiger salamanders (Objective GNC2.5). Additionally, livestock exclusion from streams and ponds and other measures would be implemented as described in CM11 to promote growth of aquatic vegetation with appropriate cover characteristics favorable to California tiger salamanders. Lands protected in CZ 8 would connect with lands protected under the *East Contra Costa County HCP/NCCP* and the extensive Los Vaqueros Watershed lands, including grassland areas supporting this species. This objective would ensure that California tiger salamander upland and associated aquatic habitats would be protected and enhanced in the largest possible patch sizes adjacent to occupied habitat within and adjacent to the Plan Area.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of alkali seasonal wetland complex, vernal pool complex, and grassland that could overlap with the species model, would result in the restoration of 88 acres of aquatic and 598 acres of upland modeled habitat for California tiger salamander. In addition, protection of alkali seasonal wetland complex, vernal pool complex, and grassland that could overlap with the species model, would result in the protection of 750 acres of aquatic and 5,000 acres of upland California tiger salamander modeled habitat.

In the absence of other conservation actions, the losses of California tiger salamander upland habitat associated with Alternative 9 would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality. However, with habitat protection and restoration associated with the conservation components, guided by landscape-scale goals and objectives and by AMM1–AMM6, AMM10, AMM13, and AMM37, which would be in place throughout the construction phase, the impacts of Alternative 9 as a whole on California tiger salamander would not be significant under CEQA.

Impact BIO-47: Indirect Effects of Plan Implementation on California Tiger Salamander

Indirect effects could occur outside of the construction footprint but within 500 feet of California tiger salamander habitat. Activities associated with conservation component construction and ongoing habitat enhancement, as well as operation and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances with localized effects on California tiger salamander and its habitat, and temporary noise and visual disturbances, including aritifical night lighting at a worksite, over the term of the BDCP. Most of the areas indirectly affected are associated with the construction of Byron Forebay and its borrow and spoil areas in CZ 8.

Maintenance and refueling of heavy equipment could result in the inadvertent release of sediment and hazardous substances into species habitat. Increased sedimentation could reduce the suitability of California tiger salamander habitat downstream of the construction area by filling in pools and smothering eggs. Accidental spills of toxic fluids into the aquatic system could result in the subsequent loss of California tiger salamander habitat. Hydrocarbon and heavy metal pollutants associated with roadside runoff also have the potential to enter the aquatic system, affecting water quality and California tiger salamander.

***NEPA Effects*:** Implementation of AMM1–AMM6, AMM10, AMM13, and AMM37 under Alternative 9 would avoid or minimize the potential for substantial adverse effects on California tiger salamanders, either indirectly or through habitat modifications. These AMMs would also avoid and minimize effects that could substantially reduce the number of California tiger salamanders or restrict the species' range. Therefore, the indirect effects of Alternative 9 would not have an adverse effect on California tiger salamander.

CEQA Conclusion: Indirect effects from conservation measure operations and maintenance as well as construction-related noise and visual disturbances including aritifical night lighting at a worksite could impact California tiger salamander in aquatic and upland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could impact California tiger salamander or its prey. The inadvertent discharge of sediment or excessive dust adjacent to California tiger salamander habitat could also have a negative impact on the species or its prey. With implementation of AMM1–AMM6, AMM10, AMM13, and AMM37 as part of Alternative 9, the BDCP would avoid the potential for substantial adverse effects on California tiger salamander, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of California tiger salamanders. The indirect effects of Alternative 9 would have a less-than-significant impact on California tiger salamander.

Impact BIO-48: Periodic Effects of Inundation of California Tiger Salamander Habitat as a Result of Implementation of Conservation Components

CM2 Yolo Bypass Fisheries Enhancement is the only conservation measure expected to result in periodic inundation of California tiger salamander habitat. Periodic inundation of Yolo Bypass could affect from an estimated 191 acres of terrestrial habitat during a notch flow of 1,000 cfs, to an estimated 639 acres of terrestrial habitat during a notch flow of 4,000 cfs in CZ 1 (Table 12-9-21). This effect would only occur during an estimated maximum of 30% of years and in areas that are already inundated in more than half of all years; therefore, these areas are expected to provide only marginal terrestrial habitat for the California tiger salamander under existing conditions. No aquatic breeding habitat would be affected (Table 12-9-21). The modeled habitat in the Yolo Bypass in the vicinity of terrestrial habitat is of low value in that there are no California tiger salamander records in this area and the bypass lacks vernal pool complexes with large, deep pools, or large grassland areas with stock ponds and similar aquatic features that provide the habitat of highest value for this species. Therefore, the terrestrial habitat to be affected has a small likelihood of supporting California tiger salamanders, and Yolo Bypass operations are expected to have a minimal effect on the species, if any.

***NEPA Effects*:** The effects of periodic inundation from Alternative 9 would not have an adverse effect on California tiger salamander.

***CEQA Conclusion*:** Flooding of the Yolo Bypass from Fremont Weir operations would periodically increase the frequency and duration of inundation of 191–639 acres of terrestrial habitat for California tiger salamander. Because this area is considered low-value habitat and there are no California tiger salamander records in the area, and because of the lack of suitable breeding habitat in this area, the effects of periodic inundation of California tiger salamander habitat from Alternative 9 would have a less-than-significant impact**.**

Giant Garter Snake

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on the giant garter snake. The habitat model used to assess effects for the giant garter snake is based on aquatic habitat and upland habitat. Modeled aquatic habitat is composed of tidal perennial aquatic (except in Suisun Marsh), tidal freshwater perennial emergent wetland, nontidal freshwater emergent wetland, and nontidal perennial aquatic natural communities; rice fields; and artificial canals and ditches. Modeled upland habitat is composed of all nonwetland and nonaquatic natural communities within 200 feet of modeled aquatic habitat features (primarily grassland and cropland). The modeled upland habitat is ranked as high-, moderate-, or low-value based on giant garter snake associations between vegetation and cover types (U.S. Fish and Wildlife Service 2012) and historical and recent occurrence records (Hansen pers. comm. in Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*), and presence of features necessary to fulfill the species' life cycle requirements. Modeled habitat is expressed in acres for aquatic and upland habitats, and in miles for linear movement corridors in aquatic habitat. Other factors considered in assessing the value of affected habitat for the giant garter snake, to the extent that information is available, are proximity to conserved lands and recorded occurrences of the species, proximity to giant garter snake subpopulations (Yolo Basin/Willow Slough and Coldani Marsh-White Slough) in the study area that are identified in the draft recovery plan for this species (U.S. Fish and Wildlife Service 1999b), and contribution to connectivity between giant garter snake subpopulations.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of giant garter snake modeled habitat as indicated in Table 12-9-22. The majority of the losses would take place over an extended period of time as tidal marsh is restored in the study area. Full implementation of Alternative 9 would also include the following biological objectives over the term of the BDCP to benefit the giant garter snake (BDCP Chapter 3, *Conservation Strategy*).

- Increase native species diversity and relative cover of native plant species, and reduce the introduction and proliferation of nonnative species (Objective L2.6, associated with CM11).

- Within the 65,000 acres of tidal natural communities (L1.3), restore or create 24,000 acres of tidal freshwater emergent wetland in CZ 1, CZ 2, CZ 4, CZ 5, CZ 6, and/or CZ 7 (Objective TFEWNC1.1, associated with CM3 and CM4).
- Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities, with suitable habitat characteristics for giant garter snake and western pond turtle (Objective NFEW/NPANC1.1, associated with CM3 and CM10).
- Protect 48,625 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species (Objective CLNC1.1, associated with CM3 and CM11).
- Target cultivated land conservation to provide connectivity between other conservation lands (Objective CLNC1.2, associated with CM3).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3 and CM11).
- Of the at least 1,200 acres of nontidal marsh created under (Objective NFEW/NPANC1.1), create 600 acres of aquatic habitat giant garter snake aquatic habitat that is connected to the 1,500 acres of rice land or equivalent-value habitat described below in Objective GGS1.4 (Objective GGS1.1, associated with CM3, CM4, and CM10).
- Of the 8,000 acres of grassland protected under Objective GNC1.1 and 2,000 acres restored under Objective GNC1.2, create or protect 200 acres of high-value upland giant garter snake habitat adjacent to the at least 600 acres of nontidal perennial habitat being restored and/or created in CZ 4 and/or CZ 5 (Objective GGS1.2, associated with CM3 and CM8).
- Protect giant garter snakes on restored and protected nontidal marsh and adjacent uplands (Objectives GGS1.1 and GGS1.2) from incidental injury or mortality by establishing 200-foot buffers between protected giant garter snake habitat and roads (other than those roads primarily used to support adjacent cultivated lands and levees). Establish giant garter snake reserves at least 2,500 feet from urban areas or areas zoned for urban development (Objective GGS1.3, associated with CM3).
- Create connections from the White Slough population to other areas in the giant garter snake's historical range in the Stone Lakes vicinity by protecting, restoring, and/or creating at least 1,500 acres of rice land or equivalent-value habitat (e.g., perennial wetland) for the giant garter snake in CZ 4 and/or CZ 5. Any portion of the 1,500 acres may consist of tidal freshwater emergent wetland and may overlap with the 24,000 acres of tidally restored freshwater emergent wetland if it meets specific giant garter snake habitat criteria described in CM4. Up to 500 (33%) of the 1,500 acres may consist of suitable uplands adjacent to protected or restored aquatic habitat (Objective GGS1.4, associated with CM3 and CM4).
- Of the at least 1,200 acres of nontidal marsh created under Objective NFEW/NPANC1.1, create 600 acres of connected aquatic giant garter snake habitat outside the Yolo Bypass in CZ 2 (Objective GGS2.1, associated with CM3 and CM10).
- Of the 8,000 acres of grasslands protected under Objective GNC1.1 and the 2,000 acres restored under Objective GNC1.2, create or protect 200 acres of high-value upland habitat adjacent to the

600 acres of nontidal marsh created in CZ 2 outside of Yolo Bypass (GGS2.1) (Objective GGS2.2, associated with CM3 and CM8).

- To expand upon and buffer the newly restored/created nontidal perennial habitat in CZ 2, protect 700 acres of cultivated lands, with 500 acres consisting of rice land and the remainder consisting of compatible cultivated land that can support giant garter snakes. The cultivated lands may be a subset of lands protected for the cultivated lands natural community and other covered species (Objective GGS2.3, associated with CM3).
- Protect giant garter snakes on created nontidal marsh (Objective GGS2.1) and created or protected adjacent uplands (Objective GGS2.2) from incidental injury or mortality by establishing 200-foot buffers between protected giant garter snake habitat and roads, and establishing giant garter snake reserves at least 2,500 feet from urban areas or areas zoned for urban development (Objective GGS2.4, associated with CM3).
- Protect, restore, and/or create 2,740 acres of rice land or equivalent-value habitat (e.g., perennial wetland) for the giant garter snake in CZ 1, CZ 2, CZ 4, or CZ 5. Up to 500 acres may consist of tidal freshwater emergent wetland and may overlap with the at least 5,000 acres of tidally restored freshwater emergent wetland in the Cache Slough ROA if this portion meets giant garter snake habitat criteria specified in CM4. Up to 1,700 acres may consist of rice fields in the Yolo Bypass if this portion meets the criteria specified in CM3, *Reserve Design Requirements by Species*. Any remaining acreage would consist of rice land or equivalent-value habitat outside the Yolo Bypass. Up to 915 (33%) of the 2,740 acres may consist of suitable uplands adjacent to protected or restored aquatic habitat (Objective GGS3.1, associated with CM3, CM4, and CM10).

As explained below, with the restoration or protection of these amounts of habitat, in addition to the implementation of AMMs, impacts on giant garter snake would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-22. Changes in Giant Garter Snake Modeled Habitat Associated with Alternative 9[a]

Conservation Measure[b]	Habitat Type[c]	Permanent		Temporary		Periodic[e]

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] Aquatic acres represent tidal and nontidal habitat combined, and upland acres represent low-, moderate-, and high-value acreages combined.
[d] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[e] Periodic effects were estimated for the late long-term only. CM2 periodic impacts on upland habitats only are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-49: Loss or Conversion of Habitat for and Direct Mortality of Giant Garter Snake

Alternative 9 conservation measures would result in the permanent and temporary loss combined of up to 1,012 acres of modeled aquatic habitat (tidal and nontidal combined), up to 3,485 acres of modeled upland habitat, and up to 239 miles of channels providing aquatic movement habitat for the giant garter snake (Table 12-9-22). There is one giant garter snake occurrence that overlaps with the Plan footprint. Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Fremont Weir/Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), and construction of a conservation fish hatchery (CM18). Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate giant garter snake habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of Alternative 9 conveyance facilities would result in the permanent loss of approximately 364 acres of modeled giant garter snake habitat, composed of 210 acres of aquatic habitat and 154 acres of upland habitat (Table 12-9-22). The 364 acres of upland habitat that would be removed for the construction of the conveyance facilities consists of 23 acres of high-, 96 acres of moderate-, and 35 acres of low-value habitat. In addition, approximately 20 miles of channels providing giant garter snake movement habitat would be removed as a result of conveyance facilities construction. Development of the water conveyance facilities would also result in the temporary removal of up to 266 acres of giant garter snake aquatic habitat and up to 627 acres of adjacent upland habitat in areas near construction in CZ 5 and CZ 6 (see Table 12-9-22 and Terrestrial Biology Map Book). In addition, approximately 20 miles of channels providing giant garter snake movement habitat would be temporarily removed as a result of conveyance facilities construction.

  Most of the habitat that would be lost is located in the central Delta, in CZ 6, and CZ 8 south of Bacon Island. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Water facilities construction and operation is expected to have low to moderate potential for adverse effects on giant garter snake aquatic habitat on Mandeville Island because it is not located near or between subpopulations identified in the draft recovery plan However, giant garter snake occurrences were reported in 1992 in the vicinity of Snodgrass Slough just northeast of Locke in CZ 5 and in 1996 on the north side of Columbia Cut on the south side of Medford Island in CZ 6. There would be no effect from construction of CM1 near the CZ 6 occurrence. However, there would be both permanent (channel enlargement and connections) and temporary impacts on modeled giant garter snake habitat in Meadow Slough which is hydrologically connected to Snodgrass Slough and is less than 0.4 miles away from the giant garter snake occurrence.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction activity associated with fisheries improvements in the Yolo Bypass would result in the permanent and temporary removal of approximately 83 acres of aquatic habitat and 458 acres of upland habitat for the giant garter snake in the late long-term. The upland habitat that would be removed is composed of 336 acres of high-value, 121 acres of moderate-value, and 1 acre of low-value habitat. Approximately 14 miles (less than 1% of total miles in Plan Area) of channels providing giant garter snake habitat for movements would be removed as a result of Freemont Weir/Yolo Bypass Improvements. Most of this habitat removal would occur at the north end of the Yolo Bypass, near Fremont Weir. Construction is expected to have adverse effects on giant garter snake aquatic habitat in the Yolo Bypass area because it is near the Yolo Basin/Willow Slough subpopulation.

  In addition to habitat loss from construction related activities in Yolo Bypass, late season flooding in the bypass may result in loss of rice habitat (considered aquatic habitat for giant garter snake) by precluding the preparation and planting of rice fields. The methods for estimating loss of rice in the bypass and results are provided in BDCP Appendix 5.J, Attachment 5J.E, *Estimation of BDCP Impact on Giant Garter Snake Summer Foraging Habitat in the Yolo Bypass.* This analysis concludes that the estimated loss of rice is 1,662 acres which was considered to occur late long-term.

- *CM4 Tidal Natural Communities Restoration*: Tidal natural communities restoration would result in the permanent loss of approximately 395 acres of aquatic habitat and 2,123 acres of upland habitat for the giant garter snake to tidal marsh in the late long-term. The upland habitat affected by tidal inundation includes 594 acres of high-value, 1,375 acres of moderate-value, and 154 acres of low-value habitat. In addition, approximately 138 miles of channels providing giant garter snake movement habitat would be removed as a result of tidal natural communities restoration. Most of the effects of tidal natural communities restoration would occur in the Cache Slough and Yolo Bypass areas (CZ 1 and CZ 2). This aquatic habitat is of low to moderate value: it is in and near Category 1 open space but is not near any giant garter snake occurrences and is not near or between giant garter snake subpopulations identified in the draft recovery plan. Tidal natural communities restoration is expected to have little to no adverse effects on giant garter snake aquatic or upland habitat in the Cache Slough ROA. There are no giant garter snake occurrences in this area, which is already tidally influenced so it has limited value for the giant garter snake (giant garter snakes may occur in tidally muted areas but are not likely to use aquatic areas with a strong tidal influence).

- *CM5 Seasonally Inundated Floodplain Restoration*: Levee construction associated with floodplain restoration in the south Delta (CZ 7) would result in the permanent and temporary removal of approximately 60 acres of aquatic habitat and 89 acres of upland habitat for giant garter snake. The upland habitat to be removed is composed of 51 acres of moderate-value and 38 acres of low-value upland habitat. Approximately 2 miles of channels providing giant garter snake movement habitat would be removed as a result of floodplain restoration. Seasonally inundated floodplain restoration is expected to have little to no adverse effects on giant garter snake aquatic habitat because the site is not located near or between giant garter snake subpopulations identified in the draft recovery plan. As with CM4, the estimates of the effect of seasonal floodplain levee construction and inundation are based on projections of where restoration may occur. Actual effects are expected to be lower because sites would be selected to minimize effects on giant garter snake habitat.

- *CM11 Natural Communities Enhancement and Management*: Passive recreation in the reserve system could result in human disturbance of giant garter snakes basking in upland areas and compaction of upland burrow sites used for brumation. However, *AMM37 Recreation* requires setbacks for trails in giant garter snake habitat. With this measure in place, recreation-related effects on giant garter snake are expected to be minimal.

  A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in BDCP-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of giant garter snake habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available giant garter snake habitat and are expected to result in overall improvements to and maintenance of giant garter snake habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.

- *CM18 Conservation Hatcheries*: Construction for conservation hatcheries could result in the permanent removal of 35 acres of moderate-value upland habitat for the giant garter snake in the Yolo Bypass area (CZ 2).

- Operations and maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect giant garter snake use of the surrounding habitat in the Yolo Bypass, the Cache Slough area, and the north and south Delta (CZ 1, CZ 2, CZ 4, CZ 5, CZ 6, CZ 7, and CZ 8). Maintenance activities would include vegetation management, levee and structure repair, and regrading of roads and permanent work areas. These effects, however, would be reduced by AMMs and conservation actions as described below.

- Injury and direct mortality: Construction vehicle activity may cause injury or mortality of the giant garter snake. If snakes reside where activities take place (most likely in the vicinity of the two subpopulations: Yolo Basin/Willow Slough [CZ 2] and the Coldani Marsh-White Slough [CZ 4 and CZ 5]), the operation of equipment for land clearing, construction, conveyance facilities operation and maintenance, and habitat restoration, enhancement, and management could result in injury or mortality of giant garter snakes. This risk is highest from late fall through early spring, when the snakes are dormant. Increased vehicular traffic associated with BDCP actions could contribute to a higher incidence of road kill. However, preconstruction surveys would be implemented after the project planning phase and prior to any ground-disturbing activity. Any disturbance to suitable aquatic and upland sites in or near the project footprint would be avoided to the extent feasible, and the loss of aquatic habitat and grassland vegetation would be minimized through adjustments to project design, as practicable. Construction monitoring, and other measures would be implemented to avoid and minimize injury or mortality of this species during construction, as described in *AMM16 Giant Garter Snake*.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA.

Alternative 9 would permanently and temporarily remove 670 acres of aquatic habitat and 2,467 acres of upland habitat for giant garter snake in the study area during the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 476 acres of aquatic and 781 acres of upland habitat), Yolo Bypass fisheries improvements (CM2, 83 acres of aquatic and 458 acres of upland habitat), from tidal restoration (CM4, 111 acres of aquatic and 1,193 acres of upland habitat), and conservation hatcheries (CM18, 35 acres of upland habitat). The aquatic habitat losses would occur in tidal and nontidal wetland natural communities and rice fields. The upland habitat losses would occur in cropland and grassland communities. In addition, approximately 98 miles of irrigation and drainage channels providing giant garter snake movement habitat would be removed. The habitat model likely overestimates the relative value of irrigation and drainage canals in the vicinity of White Slough and south due to its proximity to records that likely represent single displaced snakes, not viable populations.

Typical NEPA project-level mitigation ratios for those natural communities that would be affected and that are identified in the biological goals and objectives for giant garter snake in Chapter 3 of the BDCP would be 1:1 for restoration and 1:1 for protection of aquatic habitats and 2:1 for protection of upland habitats. Using these ratios would indicate that 670 acres of aquatic habitat should be restored, 670 acres of aquatic habitat should be protected, and 4,934 acres of upland habitat should be protected for giant garter snake to mitigate the near-term losses.

The BDCP has committed to near-term restoration of up to 8,100 acres of aquatic habitat and up to 1,140 acres of upland habitat, and to protection of at least 16,900 acres of upland habitat. Lands to be protected and restored in the near-term specifically for the giant garter snake total 3,900 acres (400 acres nontidal marsh, 400 acres of grassland, 700 acres of cultivated lands including at least

500 acres of rice) in CZ 2, and acres of rice or habitat of equivalent value in CZ 2, CZ 4, and CZ 5. Additionally, 2,400 acres of rice or habitat equivalent (1,500 acres under Objective GGS1.4 and 900 acres under Objective GGS3.1) would be restored or protected to create connections from the Coldani Marsh/White Slough population to other areas in the giant garter snake historical range. Additionally, 900 of the 2,400 acres of rice land or habitat of equivalent value would be protected and restored for the giant garter snake to achieve a 1:1 ratio of habitat conserved to habitat affected (habitat affected includes uplands periodically flooded and rice lost due to late season flooding in Yolo Bypass as a result of CM2) (Objective GGS3.1). An unknown number of irrigation and drainage ditches located in cultivated lands and suitable for giant garter snake movement would be maintained and protected within the reserve system, which would include isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3).

These habitat protection and restoration measures would benefit the giant garter snake and the plan's species-specific biological goals and objectives would inform the near-term protection and restoration efforts. Protecting and expanding existing giant garter snake subpopulations, and providing connectivity between protected areas, is considered the most effective approach to giant garter snake conservation in the Plan Area. The Coldani Marsh/White Slough and Yolo Basin/Willow Slough subpopulations are the only known populations of giant garter snakes in the Plan Area and are identified as important for the recovery of the species in the draft recovery plan for the species (U.S. Fish and Wildlife Service 1999b). Implementation actions that target giant garter snake habitat would focus on these two important subpopulations.

The species-specific biological goals and objectives would inform the near-term protection and restoration efforts. The natural community restoration and protection activities are expected to be concluded during the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for NEPA purposes. These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be not be adverse under NEPA, because the number of acres required to meet the typical ratios described above would be only 670 acres of aquatic communities restored, 670 acres of aquatic communities protected, and 4,934 acres of upland communities protected.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM16 Giant Garter Snake,* and *AMM37 Recreation*. All of these AMMs include elements that avoid or minimize the risk of BDCP activities affecting habitats and species adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 31,281 acres of aquatic and 53,285 acres of upland habitat for giant garter snake. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 1,012 acres of aquatic habitat and 3,485 acres of upland habitat for giant garter snake during the term of the plan (3% of the total aquatic habitat and 6% of the total upland habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The BDCP has committed to protecting 8,000 acres of grassland and 48,625 acres of cultivated lands in the study area, and restoring 25,100 acres tidal and nontidal wetlands and 2,000 acres of grasslands in the study area. Lands to be protected and restored specifically for the giant garter snake total 6,540 acres (1,200 acres nontidal marsh, 400 acres of grassland, 700 acres of cultivated lands including at least 500 acres of rice) in CZ 2, and acres of rice or habitat of equivalent value in CZ 2, CZ 4, and CZ 5. Additionally, 4,240 acres of rice or habitat equivalent (1,500 acres under Objective GGS1.4 and 2,740 acres under Objective GGS3.1) would be restored or protected to create connections from the Coldani Marsh/White Slough population to other areas in the giant garter snake historical range. Additionally, the 2,740 acres of rice land or habitat of equivalent value would be protected and restored for the giant garter snake under Objective GGS3.1 to achieve a 1:1 ratio of habitat conserved to habitat affected (habitat affected includes uplands periodically flooded and rice lost due to late season flooding in Yolo Bypass as a result of CM2). In addition to the 6,540 acres of high-value habitat targeted specifically for giant garter snake, the protection and restoration of other natural communities is expected to provide additional restoration of 4,430 acres and protection of 3,733 acres of garter snake habitat.

Protection and management of cultivated lands (CM3 and CM11*)* would also benefit the giant garter snake by providing connectivity and maintaining irrigation and drainage channels that provide aquatic habitat for the snake. Assuming the length of canals and ditches providing giant garter snake movement habitat on the protected cultivated lands is proportional to the modeled habitat on cultivated lands in the Plan Area, the 48,625 acres of protected cultivated lands would support approximately 281 miles of movement habitat for the giant garter snake (2,784 miles multiplied by 0.101 [48,625 acres protected of 481,909 acres in Plan Area]).

Giant garter snake habitat would be restored and protected specifically, to conserve and expand the Coldani Marsh/White Slough and Yolo Basin/Willow Slough subpopulations of the giant garter snake. Protecting and expanding existing giant garter snake subpopulations, and providing connectivity between protected areas, is considered the most effective approach to giant garter snake conservation in the Plan Area. The Coldani Marsh/White Slough and Yolo Basin/Willow Slough subpopulations are the only known subpopulations of giant garter snakes in the Plan Area and are identified as important for the recovery of the species in the draft recovery plan for the species (U.S. Fish and Wildlife Service 1999b). Implementation actions that target giant garter snake habitat would focus on these two important subpopulations.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of managed wetland, nontidal freshwater perennial emergent wetland, nontidal perennial aquatic, tidal freshwater emergent wetland, alkali seasonal wetland, grassland, and vernal pool complex that could overlap with the species model, would result in the restoration of 3,450 acres of aquatic and 980 acres of upland modeled habitat for giant garter snake. In addition, protection of cultivated land, grassland, alkali seasonal wetland, and vernal pool complex could overlap with the species model and would result in the protection of 1,547 acres of aquatic and 2,185 acres of upland giant garter snake modeled habitat.

NEPA Effects: In the near-term, the loss of giant garter snake habitat under Alternative 9 would not be adverse because the BDCP has committed to protecting and restoring the acreage required to meet the typical mitigation ratios described above. In the late long-term, the losses of giant garter snake associated with Alternative 9, in the absence of other conservation actions, would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality. However, with habitat protection and restoration associated with the conservation components, guided by landscape-scale goals and objectives and AMM1–AMM7, AMM10, AMM16, and AMM37, the effects of Alternative 9 as a whole on giant garter snake would not be adverse.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA.

Alternative 9 would permanently and temporarily remove 670 acres of aquatic habitat and 2,467 acres of upland habitat for giant garter snake in the study area during the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 476 acres of aquatic and 781 acres of upland habitat), Yolo Bypass fisheries improvements (CM2, 83 acres of aquatic and 458 acres of upland habitat), from tidal restoration (CM4, 111 acres of aquatic and 1,193 acres of upland habitat), and conservation hatcheries (CM18, 35 acres of upland habitat). The aquatic habitat losses would occur in tidal and nontidal wetland natural communities and rice fields. The upland habitat losses would occur in cropland and grassland communities. In addition, approximately 98 miles of irrigation and drainage channels providing giant garter snake movement habitat would be removed. The habitat model likely overestimates the relative value of irrigation and drainage canals in the vicinity of White Slough and south due to its proximity to records that likely represent single displaced snakes, not viable populations.

Typical CEQA project-level mitigation ratios for those natural communities that would be affected and that are identified in the biological goals and objectives for giant garter snake in Chapter 3 of the BDCP would be 1:1 for restoration and 1:1 for protection of aquatic habitats and 2:1 for protection of upland habitats. Using these ratios would indicate that 670 acres of aquatic habitat should be restored, 670 acres of aquatic habitat should be protected, and 4,934 acres of upland habitat should be protected for giant garter snake to mitigate the near-term losses.

The BDCP has committed to near-term restoration of up to 8,100 acres of aquatic habitat and up to 1,140 acres of upland habitat, and to protection of at least 16,900 acres of upland habitat. Lands to be protected and restored in the near-term specifically for the giant garter snake total 3,900 acres (400 acres nontidal marsh, 400 acres of grassland, 700 acres of cultivated lands including at least 500 acres of rice) in CZ 2, and acres of rice or habitat of equivalent value in CZ 2, CZ 4, and CZ 5. Additionally, 2,400 acres of rice or habitat equivalent (1,500 acres under Objective GGS1.4 and 900 acres under Objective GGS3.1) would be restored or protected to create connections from the Coldani Marsh/White Slough population to other areas in the giant garter snake historical range. Additionally, 900 of the 2,400 acres of rice land or habitat of equivalent value would be protected and restored for the giant garter snake to achieve a 1:1 ratio of habitat conserved to habitat affected (habitat affected includes uplands periodically flooded and rice lost due to late season flooding in Yolo Bypass as a result of CM2) (Objective GGS3.1). An unknown number of irrigation and drainage ditches located in cultivated lands and suitable for giant garter snake movement would be maintained and protected within the reserve system, which would include isolated valley oak trees,

trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3).

These habitat protection and restoration measures would benefit the giant garter snake and the plan's species-specific biological goals and objectives would inform the near-term protection and restoration efforts. Protecting and expanding existing giant garter snake subpopulations, and providing connectivity between protected areas, is considered the most effective approach to giant garter snake conservation in the Plan Area. The Coldani Marsh/White Slough and Yolo Basin/Willow Slough subpopulations are the only known populations of giant garter snakes in the Plan Area and are identified as important for the recovery of the species in the draft recovery plan for the species (U.S. Fish and Wildlife Service 1999b). Implementation actions that target giant garter snake habitat would focus on these two important subpopulations.

The species-specific biological goals and objectives would inform the near-term protection and restoration efforts. The natural community restoration and protection activities are expected to be concluded during the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for CEQA purposes. These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be not be adverse under CEQA, because the number of acres required to meet the typical ratios described above would be only 670 acres of aquatic communities restored, 670 acres of aquatic communities protected, and 4,934 acres of upland communities protected.

The Plan also includes commitments to implement AMM1-AMM7, AMM10, AMM16, and AMM37. All of these AMMs include elements that avoid or minimize the risk of BDCP activities affecting habitats and species adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 31,281 acres of aquatic and 53,285 acres of upland habitat for giant garter snake. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 1,012 acres of aquatic habitat and 3,485 acres of upland habitat for giant garter snake during the term of the plan (3% of the total aquatic habitat and 6% of the total upland habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The BDCP has committed to protecting 8,000 acres of grassland and 48,625 acres of cultivated lands in the study area, and restoring 25,100 acres tidal and nontidal wetlands and 2,000 acres of grasslands in the study area. Lands to be protected and restored specifically for the giant garter snake total 6,540 acres (1,200 acres nontidal marsh, 400 acres of grassland, 700 acres of cultivated lands including at least 500 acres of rice) in CZ 2, and acres of rice or habitat of equivalent value in CZ 2, CZ 4, and CZ 5. Additionally, 4,240 acres of rice or habitat equivalent (1,500 acres under Objective GGS1.4 and 2,740 acres under Objective GGS3.1) would be restored or protected to create connections from the Coldani Marsh/White Slough population to other areas in the giant garter snake historical range. Additionally, the 2,740 acres of rice land or habitat of equivalent value under Objective GGS3.1 would be protected and restored for the giant garter snake to achieve a 1:1 ratio of habitat conserved to habitat affected (habitat affected includes uplands periodically flooded and rice lost due to late season flooding in Yolo Bypass as a result of CM2). In addition to the 6,540 acres of high-value habitat targeted specifically for giant garter snake, the protection and restoration of other natural communities is expected to provide additional restoration of 4,430 acres and protection of 3,733 acres of garter snake habitat.

Protection and management of cultivated lands (CM3 and CM11) would also benefit the giant garter snake by providing connectivity and maintaining irrigation and drainage channels that provide aquatic habitat for the snake. Assuming the length of canals and ditches providing giant garter snake movement habitat on the protected cultivated lands is proportional to the modeled habitat on cultivated lands in the Plan Area, the 48,625 acres of protected cultivated lands would support approximately 281 miles of movement habitat for the giant garter snake (2,784 miles multiplied by 0.101 [48,625 acres protected of 481,909 acres in Plan Area]).

Giant garter snake habitat would be restored and protected specifically, to conserve and expand the Coldani Marsh/White Slough and Yolo Basin/Willow Slough subpopulations of the giant garter snake. Protecting and expanding existing giant garter snake subpopulations, and providing connectivity between protected areas, is considered the most effective approach to giant garter snake conservation in the Plan Area. The Coldani Marsh/White Slough and Yolo Basin/Willow Slough subpopulations are the only known subpopulations of giant garter snakes in the Plan Area and are identified as important for the recovery of the species in the draft recovery plan for the species (U.S. Fish and Wildlife Service 1999b). Implementation actions that target giant garter snake habitat would focus on these two important subpopulations.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of managed wetland, nontidal freshwater perennial emergent wetland, nontidal perennial aquatic, tidal freshwater emergent wetland, alkali seasonal wetland, grassland, and vernal pool complex that could overlap with the species model, would result in the restoration of 3,450 acres of aquatic and 980 acres of upland modeled habitat for giant garter snake. In addition, protection of cultivated land, grassland, alkali seasonal wetland, and vernal pool complex could overlap with the species model and would result in the protection of 1,547 acres of aquatic and 2,185 acres of upland giant garter snake modeled habitat.

The BDCP also includes a number of AMM1–AMM7, AMM10, AMM16, and AMM37 directed at minimizing or avoiding potential impacts on adjacent habitats during construction and operation of the conservation measures. Considering the protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for habitats lost to construction and restoration activities, implementation of Alternative 9 as a whole would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the loss of giant garter snake habitat and potential mortality of snakes would have a less-than-significant impact on giant garter snake under CEQA.

Impact BIO-50: Indirect Effects of Plan Implementation on Giant Garter Snake

Construction activities outside the project footprint but within 200 feet of construction associated with water conveyance facilities, conservation components and ongoing habitat enhancement, as well as operation and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances with localized effects on giant garter snake habitat, and temporary noise and visual disturbances over the term of the BDCP. These potential effects would be minimized or avoided through AMM1–AMM7, AMM10, AMM16, and AMM37, which would be in effect throughout the plan's construction phase.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect giant garter snake or its aquatic prey. The inadvertent discharge of sediment or excessive dust adjacent to giant garter snake habitat could also have a negative effect on the species or its prey. AMM1–AMM6 would minimize the likelihood of such spills occurring and would ensure measures are in place to prevent runoff from the construction area and potential effects of sediment or dust on giant garter snake or its prey.

Covered activities have the potential to exacerbate bioaccumulation of mercury in covered species that feed on aquatic species, including giant garter snake. The operational impacts of new flows under CM1 were analyzed to assess potential effects on mercury concentration and bioavailability. Results indicated that changes in total mercury levels in water and fish tissues due to future operational conditions were insignificant (see BDCP Appendix 5.D, Tables 5D.4-3, 5D.4-4, and 5D.4-5).

Marsh (tidal and nontidal) and floodplain restoration also have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and floodplains. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury. Increased methylmercury associated with natural community and floodplain restoration may indirectly affect giant garter snake, which feeds on small fishes, tadpoles, and small frogs, especially introduced species, such as small bullfrogs (*Rana catesbeiana*) and their larvae, carp (*Cyprinus carpio*), and mosquitofish (*Gambusia affinis*). In general, the highest methylation rates are associated with high tidal marshes that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). Along with avoidance and minimization measures and adaptive management and monitoring, *CM12 Methylmercury Management* is expected to reduce the amount of methylmercury resulting from the restoration of natural communities and floodplains.

Extant populations of giant garter snake within the study area are known only from the upper Yolo Basin and at the Coldani Marsh/White Slough area. Davis et al. (2007) found mercury concentrations in fish at White Slough (and the Central Delta in general) to be relatively low compared to other areas of the Delta. No restoration activities involving flooding (and subsequent methylation of mercury) are planned within the known range of the Coldani Marsh/White Slough giant garter snake population. Effects on giant garter snake from increased methylmercury exposures is more likely in the Yolo Basin, where some of the highest concentrations of mercury and methylmercury have been documented (Foe et al. 2008). Effects from exposure to methylmercury may include decreased predator avoidance, reduced success in prey capture, difficulty in shedding, and reduced ability to move between shelter and foraging or thermoregulation areas (Wylie et al. 2009). Planned floodplain restoration activities in the Yolo Basin are expected to seasonally increase methylmercury production, although production would be minimized by *CM12 Methylmercury Mitigation*. Further, the periods of production and increased exposure to methylmercury do not overlap with giant garter snake seasonal activity periods. This seasonal trend should help to decrease risk to the giant garter snake, although snakes could prey on individuals that have been exposed to methylmercury during the previous season.

The potential mobilization or creation of methylmercury within the study area varies with site-specific conditions and would need to be assessed at the project level. Measures described in *CM12 Methylmercury Management* include provisions for project-specific Mercury Management Plans.

Along with avoidance and minimization measures and adaptive management and monitoring, CM12 is expected to reduce the effects of methylmercury resulting from BDCP natural communities and floodplain restoration on giant garter snake.

***NEPA Effects*:** Implementation of the AMMs listed above as part of implementing Alternative 9 would avoid the potential for substantial adverse effects on giant garter snakes, either indirectly or through habitat modifications. These AMMs would also avoid and minimize effects that could substantially reduce the number of giant garter snakes or restrict the species' range. Therefore, the indirect effects of Alternative 9 would not have an adverse effect on giant garter snake.

***CEQA Conclusion*:** Indirect effects from conservation measure operations and maintenance as well as construction-related noise and visual disturbances could impact giant garter snake in aquatic and upland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could impact giant garter snake or its prey. The inadvertent discharge of sediment or excessive dust adjacent to giant garter snake habitat could also have a negative impact on the species or its prey. With implementation of AMM1–AMM7, AMM10, AMM16, and AMM37 as part of Alternative 9 construction, operation and maintenance, the BDCP would avoid the potential for substantial adverse effects on giant garter snakes, either indirectly or through habitat modifications. Alternative 9 would not result in a substantial reduction in numbers or a restriction in the range of giant garter snakes. Therefore, the indirect effects of Alternative 9 would have a less-than-significant impact on giant garter snakes.

Giant garter snake could experience indirect effects from increased exposure to methylmercury as a result of tidal habitat restoration (CM4). With implementation of CM12, the potential indirect effects of methlymercury would not result in a substantial reduction in numbers or a restriction in the range of giant garter snakes, and, therefore, would have a less-than-significant impact on giant garter snakes.

Impact BIO-50a: Loss of Connectivity among Giant Garter Snakes in the Coldani Marsh/White Slough Subpopulation, Stone Lakes National Wildlife Refuge, and the Delta

Implementation of Alternative 9 would not introduce a substantial barrier to the movement among giant garter snakes in the Coldani Marsh/White Slough subpopulation, Stone Lakes National Wildlife Refuge, and the Delta in the study area.

***NEPA Effects*:** Alternative 9 would not adversely affect connectivity among giant garter snakes in the Coldani Marsh/White Slough subpopulation, Stone Lakes National Wildlife Refuge, and the Delta in the study area.

***CEQA Conclusion*:** Alternative 9 would have a less-than-significant impact on connectivity between giant garter snakes in the study area.

Impact BIO-51: Periodic Effects of Inundation of Giant Garter Snake Habitat as a Result of Implementation of Conservation Components

CM2 Yolo Bypass Fisheries Enhancement: The proposed changes in Fremont Weir operations would occur intermittently from as early as mid-November through as late as mid-May. The core operations would occur during the winter/spring period, which corresponds mostly with the giant garter snake's inactive season. During this time, snakes are overwintering underground. Giant garter snakes that occur in the bypass during the active season could overwinter in the bypass during the inactive season: these snakes may be vulnerable to inundation of the bypass and could be drowned or displaced from overwintering sites. However, most typically, Fremont Weir "notch" operations would occur on the shoulders of time periods in which the Sacramento River rises enough for Fremont Weir to overtop passively, without the proposed project. Project-associated inundation of areas that would not otherwise have been inundated is expected to occur in no more than 30% of all years, since Fremont Weir is expected to overtop the remaining estimated 70% of all years, and during those years notch operations would not typically affect the maximum extent of inundation that would have occurred Currently, in more than half of all years, an area greater than the area that would be inundated as a result of covered activities is already inundated during the snake's inactive season (Kirkland pers. comm.). Duration of inundation may also be an important factor determining effects on overwintering giant garter snakes. Radiotelemetry studies have revealed giant garter snakes surviving in burrows that had been inundated for 2 to 3 weeks, but it is unknown what duration of inundation the snakes can survive while overwintering in their burrows.

Appendix 5.J, *Effects on Natural Communities, Wildlife, and Plants,* provides the method used to estimate periodic inundation effects in the Yolo Bypass. Based on this method, periodic inundation could affect giant garter snakes overwintering in upland areas ranging from an estimated 582 acres of upland habitat during notch flow of 1,000 cfs to an estimated 1,402 acres during a 4,000-cfs notch flow. The 4,000-cfs notch flow would affect an estimated 888 acres of high-value habitat and 514 acres of moderate-value habitat.

As noted above under the discussion of habitat loss from construction-related activities in Yolo Bypass, late season flooding in the bypass may result in loss of rice habitat (considered aquatic habitat for giant garter snake) by precluding the preparation and planting of a maximum of 1,662 acres of rice fields (BDCP Appendix 5.J, Attachment 5J.E, *Estimation of BDCP Impact on Giant Garter Snake Summer Foraging Habitat in the Yolo Bypass*). This analysis concludes that the estimated loss of rice is 1,662 acres which was considered to occur late long-term. Restoration and protection of 2,740 acres of rice land or habitat of equivalent value for the giant garter snake would achieve a 1:1 ratio of habitat conserved to habitat affected (habitat affected includes uplands periodically flooded and rice lost due to late season flooding in Yolo Bypass as a result of CM2).

CM5 Seasonally Inundated Floodplain Restoration would periodically inundate 606 acres of upland habitat for the giant garter snake in the south Delta (CZ 7). The upland habitat to be inundated contains 432 acres of moderate-value and 174 acres of low-value habitat. The area between existing levees would be breached and the newly constructed setback levees would be inundated through seasonal flooding. The restored floodplain would include a range of elevations from low-lying areas that flood frequently (e.g., every 1 to 2 years) to high-elevation areas that flood infrequently (e.g., every 10 years or more). There are no records of giant garter snakes in the vicinity of where floodplain restoration is expected to occur.

Based on modeled habitat for the giant garter snake, the study area supports approximately 53,285 acres of upland habitat for giant garter snake. Approximately 2,008 acres of giant garter snake upland habitat (4% of total upland habitat in the study area) may be adversely affected by periodic flooding as a consequence of floodplain restoration and the operation of the Fremont Weir.

NEPA Effects: Periodic effects on upland habitat for giant garter snake associated with implementing Alternative 9 are not expected to result in substantial adverse effects on giant garter snakes, either directly or through habitat modifications, as it would not result in a substantial reduction in numbers or a restriction in the range of giant garter snakes. Therefore, Alternative 9 would not adversely affect the species.

CEQA Conclusion: Flooding of the Yolo Bypass from CM2 and creation of seasonally inundated floodplain in various parts of the study area (CM5) would periodically affect a total of approximately 2,008 acres of upland habitat for giant garter snake. The inundation could affect overwintering snakes. Project-associated inundation of areas that would not otherwise have been inundated is expected to occur in no more than 30% of all years, since Fremont Weir is expected to overtop the remaining estimated 70% of all years, and during those years notch operations would not typically affect the maximum extent of inundation. Currently, in more than half of all years, an area greater than the area that would be inundated as a result of covered activities is already inundated during the snake's inactive season (Kirkland pers. comm.). Therefore, increased inundation in the Yolo Bypass as a result of BDCP is expected to have a minimal effect on the Yolo Basin/Willow Slough subpopulation. Therefore, implementing Alternative 9, including AMM1–AMM7, AMM10, and AMM16, would not be expected to result in substantial adverse effects on giant garter snakes, either directly or through habitat modifications, because it would not result in a substantial reduction in numbers or a restriction in the range of giant garter snakes. Periodic effects of inundation under Alternative 9 would have a less-than-significant impact on the species.

Western Pond Turtle

The habitat model used to assess effects on the western pond turtle is based on aquatic and upland nesting and overwintering habitat. Further details regarding the habitat model, including assumptions on which the model is based, are provided in BDCP Appendix 2.A, Section 2A.30, *Western Pond Turtle.* The model quantified two types of upland nesting and overwintering habitat, including upland habitat in natural communities as well as upland in agricultural areas adjacent to aquatic habitats. Both of these upland habitat types are combined for this analysis. Factors considered in assessing the value of affected aquatic habitat are natural community type and availability of adjacent nesting and overwintering habitat. The highest value aquatic habitat types in the study area consist of nontidal freshwater perennial emergent wetlands and ponds adjacent to suitable nesting and overwintering habitat (Patterson pers. comm.). Less detail is provided on effects on dispersal habitat because, although dispersal habitat is important for maintaining and increasing distribution and genetic diversity, turtles have been known to travel over many different land cover types; therefore, this habitat type is not considered limiting. The value of dispersal habitat depends less on the habitat type itself than on the proximity of that habitat type to high-value aquatic and nesting and overwintering habitat.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of western pond turtle modeled habitat, as indicated in Table 12-9-23. The majority of these losses would take place over an extended period of time as tidal marsh is restored in the study area. Full implementation of Alternative 9 would also include the following biological objectives over the term of the BDCP to benefit the western pond turtle (BDCP Chapter 3, *Conservation Strategy*).

- Protect or restore 142,200 acres of high-value natural communities and covered species habitats (Objective L1.1, associated with CM3).
- Restore and protect 65,000 acres of tidal natural communities and transitional uplands to accommodate sea level rise. Minimum restoration targets for tidal natural communities in each ROA are 7,000 acres in Suisun Marsh ROA, 5,000 acres in Cache Slough ROA, 1,500 acres in Cosumnes/Mokelumne ROA, 2,100 acres in West Delta ROA, and 5,000 acres in South Delta ROA (Objective L1.3, associated with CM2, CM3, and CM4).

- Within the 65,000 acres of tidal natural communities and transitional uplands (Objective L1.3), include sufficient transitional uplands along the fringes of restored brackish and freshwater tidal emergent wetlands to accommodate up to 3 feet of sea level rise where possible and allow for the future upslope establishment of tidal emergent wetland communities (Objective L1.7, associated with CM3, CM4, and CM8).
- Allow floods to promote fluvial processes, such that bare mineral soils are available for natural recolonization of vegetation, desirable natural community vegetation is regenerated, and structural diversity is promoted, or implement management actions that mimic those natural disturbances (Objective L2.1, associated with CM3, CM5, and CM11).
- Allow lateral river channel migration (Objective L2.2, associated with CM3 and CM5).
- Within the 65,000 acres of tidal natural communities (L1.3), restore or create 24,000 acres of tidal freshwater emergent wetland in CZ 1, CZ 2, CZ 4, CZ 5, CZ 6, and/or CZ 7 (Objective TFEWNC1.1, associated with CM3 and CM4).
- Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities, with suitable habitat characteristics for giant garter snake and western pond turtle (Objective NFEW/NPANC1.1, associated with CM3 and CM10).
- Protect and enhance 8,100 acres of managed wetland, 1,500 acres of which are in the Grizzly Island Marsh Complex (Objective MWNC1.1, associated with CM3 and CM11).
- Protect 8,000 acres of grassland (Objective GNC1.1, associated with CM3).
- Protect stock ponds and other aquatic features within protected grasslands to provide aquatic breeding habitat for native amphibians and aquatic reptiles (Objective GNC1.3, associated with CM3).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3 and CM11).

As explained below, with the restoration and protection of these amounts of habitat, in addition to implementation of AMMs, impacts on western pond turtle would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-23. Changes in Western Pond Turtle Modeled Habitat Associated with Alternative 9[a]

Conservation Measure[b]	Habitat Type	Permanent NT	Permanent LLT[c]	Temporary NT	Temporary LLT[c]	Periodic[d] CM2	Periodic[d] CM5

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

[e] Upland acres represent upland nesting and overwintering habitat acreages combined for both natural communities and agricultural lands adjacent to aquatic habitats.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-52: Loss or Conversion of Habitat for and Direct Mortality of Western Pond Turtle

Alternative 9 conservation measures would result in the permanent and temporary loss of up to 1,311 acres of aquatic habitat and 1,397 acres of upland nesting and overwintering habitat (Table 12-9-23). There are no western pond turtle occurrences that overlap with the CM1 footprint (Figure 12-16). Activities that would result in the temporary and permanent loss of western pond turtle modeled habitat are conveyance facilities and transmission line construction, and establishment and use of RTM, borrow, and spoils areas (CM1), Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), seasonally inundated floodplain restoration (CM5), and riparian restoration (CM7). Habitat enhancement and management activities (CM11), such as ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate western pond turtle habitat. The activity accounting for most (80%) of the habitat loss or conversion would be *CM4 Tidal Natural Communities Restoration*. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of Alternative 9 conveyance facilities would result in the permanent loss of approximately 685 acres of aquatic habitat and 59 acres of upland nesting and overwintering habitat for the western pond turtle in the study area (Table 12-9-23). Development of the water conveyance facilities would also result in the temporary removal of up to 468 acres of aquatic habitat and 174 acres of nesting and overwintering habitat for the western pond turtle in the study area (see Table 12-9-23). Approximately 1 mile of channels providing western pond turtle movement habitat would be removed and 8 miles would be temporarily disturbed. There are no western pond turtle occurrences that overlap with the CM1 footprint but these are numerous occurrences scattered throughout the Delta. The majority of the permanent loss of aquatic habitat and nesting and overwintering habitat would be near Clifton Court Forebay in CZ 8. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. The aquatic habitat in the Clifton Court Forebay area is considered to be of reasonably high-value because it consists of agricultural ditches in or near known species occurrences. The nesting and overwintering and dispersal habitat that would be lost consists primarily of cultivated lands with some small portion of ruderal grassland habitat. Except for remnant, uncultivated patches, the cultivated lands are not suitable for nesting and overwintering unless left fallow. Construction of the water conveyance facilities would also affect dispersal habitat, which is primarily cultivated lands. While there are western pond turtle occurrences scattered throughout CZ 3, CZ 4, CZ 5, and CZ 6, this effect is widely dispersed because of the long, linear nature of the pipeline footprint.
- *CM2 Yolo Bypass Fisheries Enhancement*: Improvements in the Yolo Bypass would result in the permanent and temporary removal of approximately 60 acres of aquatic habitat and 249 acres of upland nesting and overwintering habitat for the western pond turtle. Approximately 4 miles of channels providing western pond turtle movement habitat would be permanently or temporarily removed as a result of Yolo Bypass improvements. Although there are no CNDDB occurrences for western pond turtle in the Yolo Bypass, the species is known to be present in the Yolo Bypass Wildlife Area (California Department of Fish and Wildlife 2013).
- *CM4 Tidal Natural Communities Restoration*: Tidal natural communities restoration would result in the conversion of approximately 45 acres of aquatic habitat and 872 acres of upland nesting and overwintering habitat for western pond turtle to tidal marsh. Approximately 106 miles of channels providing western pond turtle movement habitat would be removed as a result of restoration. Tidal habitat restoration is expected to change existing salinity and flow conditions rather than lead to complete loss of aquatic habitat. Restoration of tidal flow where habitat consists of the calm waters of managed freshwater ponds and wetlands could have an adverse effect on the western pond turtle. Tidal restoration outside Suisun Marsh is likely to create suitable, slow-moving freshwater slough and marsh habitat.

  Although the aquatic habitat model includes all tidal perennial aquatic, tidal brackish emergent wetland, and managed wetland as habitat, most of the Suisun Marsh pond turtle observations have been in the interior drainage ditches or near water control structures not hydrologically connected to Suisun Marsh. While the model does not include an aquatic class type called *drainage ditches* and therefore an effect on this habitat type cannot be calculated, it is likely that this general type of habitat accounts for a very small portion of the total modeled aquatic effects; almost certainly less than 5%, or less than 287 acres of the modeled aquatic habitat affected by tidal restoration. The suitable nesting and overwintering habitat that would be affected in the interior of Suisun Marsh is limited, because the levees likely function as the primary nesting and overwintering habitat. The nesting and overwintering habitat of highest value to be affected is on the fringe of the marsh where the aquatic habitat is adjacent to undeveloped grassland habitat.

The habitat affected in the interior Delta (West Delta and South Delta) is of low value, consisting of levees and intensively farmed cultivated lands, while the Cache Slough and Cosumnes-Mokelumne ROAs are less intensively farmed and have higher-value habitat for the turtle. Because the estimates of the effect of tidal inundation are based on projections of where restoration may occur, actual effects are expected to be lower because sites would be selected to minimize effects on western pond turtle habitat (see AMM17 in Appendix 3B, *Environmental Commitments, AMMs, and CMs*).

- *CM5 Seasonally Inundated Floodplain Restoration*: Levee construction associated with floodplain restoration in the south Delta (CZ 7) would result in the permanent and temporary removal of approximately 53 acres of aquatic habitat and 33 acres of upland habitat for western pond turtle. Approximately 3 miles of channels providing western pond turtle movement habitat would be removed as a result of floodplain restoration. Although there are no CNDDB occurrences for pond turtles in the areas where floodplain restoration is likely to occur, the species is known to occur along the San Joaquin River to the south in the San Joaquin River National Wildlife Refuge. As with CM4, the estimates of the effect of seasonal floodplain levee construction and inundation are based on projections of where restoration may occur. Actual effects are expected to be lower because sites would be selected to minimize effects on western pond turtle habitat.
- *CM7 Riparian Natural Community Restoration*: Riparian restoration that is part of tidal natural communities restoration in CZ 1 and CZ 2, would result in the permanent removal of 10 acres of upland nesting and overwintering habitat for western pond turtle.
- *CM11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in BDCP protected habitats may result in localized ground disturbances that could temporarily remove small amounts of western pond turtle habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor adverse effects on available western pond turtle habitat and are expected to result in overall improvements to and maintenance of western pond turtle habitat values over the term of the BDCP. In addition, effects would be avoided and minimized by the AMMs listed below.

  Management of the 6,600 acres of managed wetlands to be protected for waterfowl and shorebirds is not expected to result in overall adverse effects for the western pond turtle. Management actions that would improve wetland quality and diversity on managed wetlands include control and eradication of invasive plants; maintenance of a diversity of vegetation types and elevations, including upland areas to provide flood refugia; water management and leaching to reduce salinity; and enhancement of water management infrastructure (improvements to enhance drainage capacity, levee maintenance). These management actions could benefit the western pond turtle. The 6,600 acres of protected managed wetlands would be monitored and adaptively managed to ensure that management options are implemented to avoid adverse effects on the western pond turtle.
- Operations and maintenance: Ongoing maintenance of BDCP facilities is expected to have little if any adverse effect on the western pond turtle. Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect western pond turtle use where there is

suitable habitat in the study area. Maintenance activities would include vegetation management, levee and structure repair, and regrading of roads and permanent work areas. These effects, however, would be minimized by AMMs and conservation actions described below.

- Injury and direct mortality: Construction vehicle activity may cause injury to or mortality of western pond turtles. If turtles reside where conservation measures are implemented (most likely in the vicinity of aquatic habitats in the study area), the operation of equipment for land clearing, construction, conveyance facilities operation and maintenance, and habitat restoration, enhancement, and management could result in injury or mortality of western pond turtles. However, to avoid injury or mortality, preconstruction surveys would be conducted in suitable aquatic or upland habitat for the western pond turtle, and turtles found would be relocated outside the construction areas, as required by the AMMs listed below.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA.

Alternative 9 would temporarily and permanently remove 1,258 acres of aquatic habitat and 766 acres of upland nesting and overwintering habitat for western pond turtle in the near-term. These effects would result from water conveyance facilities construction (CM1, 1,153 acres of aquatic and 233 acres of upland habitats), Yolo Bypass improvements (CM2, 60 acres of aquatic and 249 acres of upland habitats), tidal habitat restoration (CM4, 45 acres of aquatic and 280 acres of upland habitats), and riparian restoration (CM7, 4 acres of upland habitat).

Typical project-level mitigation ratios for those natural communities that would be affected and that are identified in the biological goals and objectives for western pond turtle in Chapter 3 of the BDCP would be 1:1 for restoration and 1:1 for protection of aquatic habitats and 2:1 for protection of upland habitats. Using these ratios would indicate that 1,258 acres of aquatic habitat should be restored, 1,258 acres of aquatic habitat should be protected, and 1,532 acres of upland habitat should be protected for western pond turtle to mitigate the near-term losses.

The conservation strategy for western pond turtle involves restoration and protection of aquatic and adjacent upland habitat, and establishment of an interconnected reserve system that provides for western pond turtle dispersal. The habitat protection and restoration needs for this species are addressed at the landscape and natural community levels. The BDCP has committed to near-term restoration and creation of up to 24,350 acres of aquatic habitat (Objective L1.1, Objective L1.3, Objective NFEW/NPANC1.1, and Objective MWNC1.1) and up to 2,000 acres of upland habitat (Objective GNC1.1). In addition, the protection and management of existing managed wetland habitat in Suisun Marsh may increase the value of aquatic habitat. The most beneficial restoration would occur in freshwater emergent wetland consisting of slow-moving slough and marsh adjacent to protected, undisturbed grassland. Additionally, basking platforms would be installed as needed in restored freshwater marsh to benefit the western pond turtle.

The natural community restoration and protection activities would be concluded in the first 10 years of Plan implementation, which is close enough in time to the impacts of construction to constitute adequate mitigation. Because the number of acres required to meet the typical ratios described above would be only 1,258 acres of aquatic communities protected, 1,258 acres restored, and 1,532 acres of upland communities protected, the 24,350 acres of aquatic and 2,000 acres of upland habitats restored or created in the near-term Plan goals, and the additional detail in the biological goals for western pond turtle, are more than sufficient to support the conclusion that the near-term impacts of habitat loss and direct mortality under Alternative 9 on western pond turtles would not be adverse.

The plan also contains commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM17 Western Pond Turtle*. These AMMs include elements that would avoid or minimize the risk of affecting habitats and species adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 81,666 acres of aquatic and 28,864 acres of upland habitat for western pond turtle. Alternative 9 would remove 1,311 acres of aquatic habitat and 1,397 acres of upland habitat for western pond turtle in the late long-term timeframe.

Implementation of Alternative 9 as a whole would increase the extent and distribution of high-value aquatic and upland nesting and overwintering habitat for western pond turtle in the study area. While the extent of dispersal habitat is expected to be reduced by approximately 9%, this habitat is abundant in the study area (composed primarily of cultivated lands), is not believed to be a factor limiting the turtle, and would be replaced with higher-value habitats for western pond turtle.

The conservation strategy for western pond turtle involves restoration and protection of aquatic and adjacent upland habitat, and establishment of an interconnected reserve system that provides for western pond turtle dispersal. The habitat protection and restoration needs for this species are addressed at the landscape and natural community levels. The BDCP has committed to late long-term restoration and creation of up to 74,300 acres of aquatic habitat (Objective L1.1, Objective L1.3, Objective NFEW/NPANC1.1, MWNC1.1) and up to 8,000 acres of upland habitat (Objective GNC1.1). In addition, the protection and management of existing managed wetland habitat in Suisun Marsh may increase the value of aquatic habitat. The most beneficial restoration would occur in freshwater emergent wetland consisting of slow-moving slough and marsh adjacent to protected, undisturbed grassland. Aquatic features (e.g., ditches and ponds) and adjacent uplands that are preserved and managed as part of the 45,405 acres of protected cultivated lands described above for giant garter snake are also expected to benefit the species. Additionally, basking platforms would be installed as needed in restored freshwater marsh to benefit the western pond turtle.

Riparian and floodplain restoration would potentially increase the quantity and value of aquatic and nesting and overwintering habitat. Where the floodplain is widened and restored, this would allow oxbows and slow-moving side channels to form, providing suitable aquatic habitat for this species (Bury and Germano 2008; Ernst and Lovich 2009). Where riparian vegetation is restored adjacent to slower-moving channels, sloughs, and ponds, downed trees can provide important basking habitat and cover habitat for turtles. Riparian restoration in those more interior portions of Old and Middle Rivers that would be managed for riparian brush rabbit habitat have potential to benefit resident western pond turtles as riparian-adjacent grassland is an important habitat characteristic for the rabbit.

The study area represents only a small portion of the range of the western pond turtle in California (which includes most all the Pacific drainages) and southern Oregon. Effects from permanent and temporary loss or conversion of habitat for the western pond turtle, and other effects described above, are not expected to result in an adverse effect on the long-term survival and recovery of western pond turtle because for the following reasons.

- The study area represents a small portion of the species' entire range.
- Only 1% of the habitat in the study area would be removed or converted.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of managed wetland, nontidal freshwater perennial emergent wetland, nontidal perennial aquatic, tidal brackish emergent wetland, tidal freshwater emergent wetland, grassland, valley foothill riparian, that could overlap with the species model, would result in the restoration of 29,738 acres of aquatic and 1,421 acres of upland modeled habitat for western pond turtle. In addition, protection of cultivated land, managed wetland, grassland, and valley/foothill riparian could overlap with the species model and would result in the protection of 1,281 acres of aquatic and 4,993 acres of upland western pond turtle modeled habitat.

NEPA Effects: In the near-term, the loss of western pond turtle habitat under Alternative 9 would not be adverse because the BDCP has committed to protecting and restoring the acreage required to meet the typical mitigation ratios described above. In the late long-term, the losses of western pond turtle habitat associated with Alternative 9, in the absence of other conservation actions, would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality. However, with habitat protection and restoration associated with the conservation components, guided by landscape-scale goals and objectives and by AMM1–AMM6, AMM10, and AMM17, the effects of Alternative 9 as a whole on western pond turtle would not be adverse.

CEQA Conclusion:

Near-Term Timeframe

Because *CM1 Water Facilities and Operation* construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the impacts of construction would be less than significant under CEQA.

Alternative 9 would temporarily and permanently remove 1,258 acres of aquatic habitat and 766 acres of upland nesting and overwintering habitat for western pond turtle in the near-term. These effects would result from water conveyance facilities construction (CM1, 1,153 acres of aquatic and 233 acres of upland habitats), Yolo Bypass improvements (CM2, 60 acres of aquatic and 249 acres of upland habitats), tidal habitat restoration (CM4, 45 acres of aquatic and 280 acres of upland habitats), and riparian restoration (CM7, 4 acres of upland habitat).

Typical CEQA project-level mitigation ratios for those natural communities that would be affected and that are identified in the biological goals and objectives for western pond turtle in Chapter 3 of the BDCP would be 1:1 for restoration and 1:1 for protection of aquatic habitats and 2:1 for protection of upland habitats. Using these ratios would indicate that 1,258 acres of aquatic habitat should be restored, 1,258 acres of aquatic habitat should be protected, and 1,532 acres of upland habitat should be protected for western pond turtle to mitigate the near-term losses.

The conservation strategy for western pond turtle involves restoration and protection of aquatic and adjacent upland habitat, and establishment of an interconnected reserve system that provides for western pond turtle dispersal. The habitat protection and restoration needs for this species are addressed at the landscape and natural community levels. The BDCP has committed to near-term restoration and creation of up to 24,350 acres of aquatic habitat (Objective L1.1, Objective L1.3, Objective NFEW/NPANC1.1, and Objective MWNC1.1) and up to 2,000 acres of upland habitat (Objective GNC1.1). In addition, the protection and management of existing managed wetland habitat in Suisun Marsh may increase the value of aquatic habitat. The most beneficial restoration would occur in freshwater emergent wetland consisting of slow-moving slough and marsh adjacent to protected, undisturbed grassland. Additionally, basking platforms would be installed as needed in restored freshwater marsh to benefit the western pond turtle.

The natural community restoration and protection activities would be concluded in the first 10 years of Plan implementation, which is close enough in time to the impacts of construction to constitute adequate mitigation for CEQA purposes. Because the number of acres required to meet the typical ratios described above would be only 1,258 acres of aquatic communities protected, 1,258 acres of aquatic communities restored and 1,532 acres of upland communities protected, the 24,350 acres of aquatic and 2,000 acres of upland habitats restored or created in the near-term Plan goals, and the additional detail in the biological goals for western pond turtle, are more than sufficient to support the conclusion that the near-term impacts of habitat loss and direct mortality under Alternative 9 on western pond turtles would be less than significant.

In addition, the plan also contains commitments to implement AMM1–6, AMM10, and AMM17, which include elements that would avoid or minimize the risk of directly and indirectly affecting habitats and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 81,666 acres of aquatic and 28,864 acres of upland habitat for western pond turtle. Alternative 9 would remove 1,311 acres of aquatic habitat and 1,397 acres of upland habitat for western pond turtle in the late long-term timeframe.

Implementation of Alternative 9 as a whole would increase the extent and distribution of high-value aquatic and upland nesting and overwintering habitat for western pond turtle in the study area. While the extent of dispersal habitat is expected to be reduced by approximately 1%, this habitat is abundant in the study area (composed primarily of cultivated lands), is not believed to be a factor limiting the turtle, and would be replaced with higher-value habitats for western pond turtle.

The conservation strategy for western pond turtle involves restoration and protection of aquatic and adjacent upland habitat, and establishment of an interconnected reserve system that provides for western pond turtle dispersal. The habitat protection and restoration needs for this species are addressed at the landscape and natural community levels. The BDCP has committed to late long-term restoration and creation of up to 74,300 acres of aquatic habitat (Objective L1.1, Objective L1.3, Objective NFEW/NPANC1.1, MWNC1.1) and up to 8,000 acres of upland habitat (Objective GNC1.1). In addition, the protection and management of existing managed wetland habitat in Suisun Marsh may increase the value of aquatic habitat. The most beneficial restoration would occur in freshwater emergent wetland consisting of slow-moving slough and marsh adjacent to protected, undisturbed grassland. Aquatic features (e.g., ditches and ponds) and adjacent uplands that are preserved and managed as part of the 45,405 acres of protected cultivated lands described above for giant garter snake are also expected to benefit the species. Additionally, basking platforms would be installed as needed in restored freshwater marsh to benefit the western pond turtle.

Riparian and floodplain restoration would potentially increase the quantity and value of aquatic and nesting and overwintering habitat. Where the floodplain is widened and restored, this would allow oxbows and slow-moving side channels to form, providing suitable aquatic habitat for this species (Bury and Germano 2008; Ernst and Lovich 2009). Where riparian vegetation is restored adjacent to slower-moving channels, sloughs, and ponds, downed trees can provide important basking habitat and cover habitat for turtles. Riparian restoration in those more interior portions of Old and Middle Rivers that would be managed for riparian brush rabbit habitat have potential to benefit resident western pond turtles as riparian-adjacent grassland is an important habitat characteristic for the rabbit.

The study area represents only a small portion of the range of the western pond turtle in California (which includes most all the Pacific drainages) and southern Oregon. Effects from permanent and temporary loss or conversion of habitat for the western pond turtle, and other effects described above, are not expected to result in an adverse effect on the long-term survival and recovery of western pond turtle because for the following reasons.

- The study area represents a small portion of the species' entire range.
- Only 1% of the habitat in the study area would be removed or converted.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of managed wetland, nontidal freshwater perennial emergent wetland, nontidal perennial aquatic, tidal brackish emergent wetland, tidal freshwater emergent wetland, grassland, valley foothill riparian, that could overlap with the species model, would result in the restoration of 29,738 acres of aquatic and 1,421 acres of upland modeled habitat for western pond turtle. In addition, protection of cultivated land, managed wetland, grassland, and valley/foothill riparian could overlap with the species model and would result in the protection of 1,281 acres of aquatic and 4,993 acres of upland western pond turtle modeled habitat.

The loss of western pond turtle habitat associated with Alternative 9 as a whole would represent an adverse effect as a result of habitat modification of a special-status species and the potential for direct mortality of turtles. However, considering the habitat restoration and protection associated with the conservation components, guided by landscape-scale goals and objectives and AMM1–AMM6, AMM10, and AMM17, which would be in place throughout the construction phase, the loss of habitat and potential mortality would not have an adverse effect on western pond turtle. Therefore, the loss of western pond turtle habitat and potential mortality of turtles from Alternative 9 would have a less-than-significant impact on western pond turtle.

Impact BIO-53: Indirect Effects of Plan Implementation on Western Pond Turtle

Indirect effects on western pond turtle within 200 feet of construction activities could temporarily affect the use of aquatic habitat and upland nesting, overwintering, and dispersal habitat for the western pond turtle. Construction activities outside the construction footprint but within 200 feet of water conveyance facilities, conservation components and ongoing habitat enhancement, as well as operation and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances with localized impacts on western pond turtle habitat, and temporary noise and visual disturbances over the term of the BDCP. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect western pond turtle or its aquatic prey. The inadvertent discharge of sediment or excessive dust adjacent to western pond turtle aquatic habitat could also have a negative effect on the species or its prey. AMM1–AMM6, and AMM10 would minimize the likelihood of such spills and would ensure measures are in place to prevent runoff from the construction area and potential effects of sediment or dust on western pond turtle or its prey.

Water operations would affect salinity gradients in Suisun Marsh. This effect mechanism cannot be disaggregated from tidal natural community restoration in Suisun Marsh. It is expected that the salinity of water in Suisun Marsh would generally increase as a result of water operations and operation of salinity control gates to mimic a more natural water flow. Results of modeling for full implementation of the BDCP show salinity to double by the late long-term compared with current conditions during late fall and winter months. Changes in salinity would not be uniform across Suisun Marsh, as salinity would likely be more pronounced in some tidal channels and sloughs than others, and most of the salinity increase would occur during the fall and winter. Western pond turtles are primarily a freshwater species, although they can also be found in brackish marsh, and could respond negatively to increased salinity in Suisun Marsh. However, most of the Suisun Marsh pond turtle observations have been in the interior drainage ditches or near water control structures not connected to tidal channels and sloughs in Suisun Marsh which is where increases in salinity would occur. Therefore, the potential effects associated with changes in salinity are not expected to adversely affect western pond turtles.

NEPA Effects: With implementation of AMM1–AMM6, AMM10, and AMM17 as part of Alternative 9, the BDCP would avoid the potential for substantial adverse effects on western pond turtles, either directly or through habitat modifications. These AMMs would also avoid and minimize effects that could substantially reduce the number of western pond turtles or restrict the species range. Therefore, the indirect effects of Alternative 9 would not have an adverse effect on western pond turtle.

CEQA Conclusion: Indirect effects resulting from conservation measure operations and maintenance as well as construction-related noise and visual disturbances could impact western pond turtle in aquatic and upland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could affect western pond turtle or its prey. The inadvertent discharge of sediment or excessive dust adjacent to western pond turtle habitat could also have a negative effect on the species or its prey. Changes in water salinity would have a less-than-significant impact on western pond turtles because most of the salinity increases would occur in areas not used extensively by western pond turtles. With implementation of AMM1–AMM6, AMM10, AMM17, and AMM37 as part of Alternative 9 construction, operation, and maintenance, the BDCP would avoid the potential for substantial adverse effects on western pond turtles, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of western pond turtles. The indirect effects of Alternative 9 would have a less-than-significant impact on western pond turtles.

Impact BIO-54: Periodic Effects of Inundation of Western Pond Turtle Habitat as a Result of Implementation of Conservation Components

CM2 Yolo Bypass Fisheries Enhancement would result in periodic inundation that could affect western pond turtle and its upland habitat. Appendix 5.J, *Effects on Natural Communities, Wildlife, and Plants* provides the method used to estimate periodic inundation effects in the Yolo Bypass. Based on this method, periodic inundation could affect from an estimated 283 acres of habitat during 1,000 cfs notch flow to an estimated 798 acres of habitat during 4,000 cfs notch flow (Table 12-4-23). This effect would occur during an estimated maximum of 30% of years, in areas that are already inundated in more than half of all years; therefore, these areas are expected to provide only marginal overwintering habitat for the western pond turtle under Existing Conditions. Furthermore, Yolo Bypass inundation is not expected to affect nesting western pond turtles because operations would not occur during the nesting season (approximately May through October). Therefore, Yolo Bypass operations are expect to have a minimal effect, if any, on western pond turtles in the Yolo Bypass.

CM5 Seasonally Inundated Floodplain Restoration would periodically inundate 331 acres of upland habitat for the western pond turtle in the south Delta (CZ 7). Seasonal flooding in restored floodplains is not expected to adversely affect aquatic and dispersal habitat, because these habitat functions are expected to remain in the seasonally inundated floodplains. Floodplains are not expected to be inundated during the nesting season; however, turtle hatchlings may overwinter in the nest and could be affected by flooding. Restored floodplains would transition for areas that flood frequently (e.g., every 1 to 2 years) to areas that flood infrequently (e.g., every 10 years or more); adverse effects on turtle hatchlings are most likely at the lower elevations of the restored floodplain, where frequent flooding occurs.

NEPA Effects: Periodic effects on upland habitat for western pond turtle from CM2 and CM5 associated with implementing Alternative 9 are not expected to result in substantial adverse effects either directly or through habitat modifications because there would not be a substantial reduction in numbers or a restriction in the range of western pond turtles. Therefore, Alternative 9 would not adversely affect the species.

CEQA Conclusion: Flooding of the Yolo Bypass and creation of seasonally inundated floodplain in various parts of the study area would periodically affect a total of up to 283–798 acres from CM2 and approximately 331 acres from CM5 of upland habitat for western pond turtle. These acreages represent only 1% of the total upland western pond turtle habitat in the study area. Most of the increase in inundation would occur in the winter and early spring months, when western pond turtles may be in the water or overwintering and occupying upland habitats. Therefore, implementing Alternative 9, including AMM1–AMM6, AMM10, and AMM17, would not be expected to result in substantial adverse effects on western pond turtle, either directly or through habitat modifications, because it would not result in a substantial reduction in numbers or a restriction in the range of western pond turtles. Periodic effects of inundation under Alternative 9 would have a less-than-significant impact on the species.

Silvery Legless Lizard, San Joaquin Coachwhip, and Blainville's Horned Lizard

This section describes the effects of Alternative 9 on the silvery legless lizard, San Joaquin coachwhip, and Blainville's horned lizard (special-status reptiles). The habitat types used to assess effects on silvery legless lizard are limited to inland sand dunes near Antioch (CZ 9 and CZ 10), which would not be affected by construction or restoration activities. This species is not discussed any further.

The habitat types used to assess effects on the San Joaquin coachwhip are alkali seasonal wetland complex, grassland, and inland dune scrub west of Byron Highway (CZ 7)and west of Old River and West Canal (CZ 8). The habitat types used to assess effects on the Blainville's horned lizard are the same as those for the coachwhip in CZ 7 and CZ 8. There is also potential habitat for the horned lizard to occur in grassland habitat around Stone Lake (CZ 4) Although the expected range for San Joaquin coachwhip and Blainville's horned lizard extends into the study area, there are no records for either of these species within the study area (California Department of Fish and Wildlife 2013). In addition, historic museum records show that Blainville's horned lizard occurrences could have been extirpated within the study area (Jennings and Hayes 1994).

Alternative 9 is expected to result in the temporary and permanent removal of habitat that special-status reptiles uses for cover and dispersal (Table 12-9-24). BDCP actions that could affect this habitat are limited to construction and maintenance of the water conveyance facilities in the vicinity of Clifton Court Forebay, and grassland restoration, protection and management. Full implementation of Alternative 9 would also include the following biological objectives over the term of the BDCP that would also benefit special-status reptiles (BDCP Chapter 3, *Conservation Strategy*).

- Increase the size and connectivity of the reserve system by acquiring lands adjacent to and between existing conservation lands (Objective L1.6, associated with CM3).
- Increase native species diversity and relative cover of native plant species, and reduce the introduction and proliferation of nonnative species (Objective L2.6, associated with CM11).
- Protect and improve habitat linkages that allow native terrestrial species to move between protected habitats within and adjacent to the Plan Area (Objective L3.1, associated with CM3, CM8, and CM11).
- Protect 8,000 acres of grassland (Objective GNC1.1, associated with CM3).
- Restore 2,000 acres of grasslands to connect fragmented patches of protected grassland (Objective GNC1.2, associated with CM3 and CM8).

As explained below, with the restoration or protection of these amounts of habitat, in addition to implementation of AMMs, impacts on special-status reptiles would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-24. Changes in Special-Status Reptile Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[e]	
		NT	LLT[d]	NT	LLT[d]	CM2	CM5
CM1	Grassland[c]	20	20	10	10	NA	NA
Total Impacts CM1		**20**	**20**	**10**	**10**	**NA**	**NA**
CM2–CM18	Grassland[c]	0	0	O	0	0	0
Total Impacts CM2–CM18		**0**	**0**	**0**	**0**	**0**	**0**
TOTAL IMPACTS		**20**	**20**	**10**	**10**	**0**	**0**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] Grassland impacts include alkali seasonal wetland complex, grassland, and inland dune scrub habitats.

[d] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[e] Periodic effects were estimated for the late long-term only.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-55: Loss or Conversion of Habitat for and Direct Mortality of Special-Status Reptiles

Alternative 9 conservation measures would result in the permanent and temporary loss of 30 acres of potential habitat for special-status reptiles (Table 12-9-24). Water conveyance facilities and transmission line construction, including establishment and use of RTM, borrow, and spoils areas, (CM1) would cause the loss of special-status reptile habitat. In addition, habitat enhancement and management activities (CM11), such as ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects for special-status reptiles. In addition to habitat loss and conversion, construction activities, such as grading, the movement of construction vehicles or heavy equipment, and the installation of water conveyance facilities components and new transmission lines, may result in the direct mortality, injury, or harassment of special-status reptiles, including the potential crushing of individuals and disruption of essential behaviors. Construction of access roads could fragment suitable habitat, impede upland movements in some areas, and increase the risk of road mortality. Construction activities related to conservation components could have similar affects. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Development of the conveyance facilities would result in the permanent loss of approximately 20 acres of habitat for special-status reptiles in the vicinity of Clifton Court Forebay. Construction-related effects would temporarily disturb 10 acres of suitable habitat for special-status reptiles in the study area.

- *CM11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in *CM11* that are designed to enhance wildlife values in BDCP-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of special-status reptile habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor adverse effects on available special-status reptile habitat and are expected to result in overall improvements to and maintenance of species habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be reduced through implementation of Mitigation Measure BIO-55 *Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs*.
- Operations and maintenance: Ongoing facilities operation and maintenance is expected to have little if any adverse effect on special-status reptiles. Postconstruction operation and maintenance of the above-ground water conveyance facilities could result in ongoing but periodic disturbances that could affect special-status reptiles' use of suitable habitat in the study area. These effects, however, would be minimized with implementation of Mitigation Measure BIO-55.
- Injury and direct mortality: Construction vehicles may cause injury to or mortality of special-status reptiles. The operation of equipment for land clearing, construction, operation and maintenance, and restoration, enhancement, and management activities could result in injury or mortality. This risk is highest from late fall through early spring, when special-status reptiles are not as active. However, the risk of crushing Blainville's horned lizard would not necessarily be lower during the active season, because the species uses crypsis to hide from predators and would be hard to spot from a moving vehicle. Seasonal risk reduction may be more appropriate for the coachwhip, but there is still a risk of crushing the horned lizard during the active season. In addition, both species would not be active under conditions of extreme temperatures and could be taking cover in burrows or crevices or under structures such as rocks or logs (Morey 2000). They could also burrow beneath the soil and be crushed by vehicles. *P. blainvillii* may only be active during the early morning and evening hours in the summer (Morey 2000). Increased vehicular traffic associated with BDCP actions could contribute to a higher incidence of road kill. However, conducting construction during the late-spring through early fall periods when feasible, and when temperatures are 67–100 degrees F, and implementation of Mitigation Measure BIO-55 would avoid and minimize injury or mortality of special-status reptiles during construction.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction effects would not be adverse under NEPA.

Alternative 9 would remove 30 acres of grassland habitat for special-status reptiles. The typical NEPA mitigation ratio (2:1 for protection) for this natural community would indicate that 60 acres should be protected in the near-term to offset CM1 losses.

The BDCP has committed to near-term restoration of 1,140 acres of grassland (CM8) and protection of up to 2,000 acres of grassland in the Plan Area (CM3). These conservation actions are all associated with CM3 and CM8 and would occur in the same timeframe as CM1 construction and early restoration losses, thereby avoiding adverse effects on special-status reptiles.

Considering the BDCP conservation strategy and the implementation of Mitigation Measure BIO-55. to avoid and minimize injury or mortality of special-status reptiles during construction, the permanent and temporary loss of special-status reptile habitat and the potential mortality of either species from Alternative 9 would not be an adverse effect.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of 30 acres of habitat for special-status reptiles over the life of the plan.

Effects of water conveyance facilities construction would be offset through the plan's long-term commitment to protect 8,000 acres of grassland, and grassland associated with alkali seasonal wetlands and vernal pool complexes, and to restore 2,000 acres of grassland in the Plan Area. Grassland protection would focus in particular on acquiring the largest remaining contiguous patches of unprotected grassland habitat, which are located south of SR 4 in CZ 8 (Objective GNC1.1). This area connects to more than 620 acres of existing habitat that is protected under the East Contra Costa County HCP/NCCP.

Other effects would be reduced through implementation of Mitigation Measure BIO-55, *Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs*. The plan as a whole is expected to benefit special-status reptiles that could be present by protecting potential habitat from loss or degradation that otherwise could occur with future changes in existing land use. To the extent that grassland habitat is restored in CZ 8, restoration would replace unsuitable special-status reptile habitat, such as cultivated land, with high-value cover, foraging, and dispersal habitat. The overall effect would be beneficial because the plan would result in a net increase in acreage of grassland habitat in the study area.

BDCP's commitment to protect the largest remaining contiguous habitat patches (including grasslands and the grassland component of alkali seasonal wetland and vernal pool complexes) in CZ 8 would sufficiently offset the adverse effects resulting from water conveyance facilities construction.

***NEPA Effects*:** In the near-term and late long-term, the loss of special-status reptile habitat under Alternative 9 would be not be adverse because the BDCP has committed to protecting the acreage required to meet the typical mitigation ratios described above and because of the implementation of Mitigation Measure BIO-55.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction effects would be less than significant under CEQA.

Alternative 9 would remove 30 acres of grassland habitat for special-status reptiles. The typical CEQA mitigation ratio (2:1 for protection) for this natural community would indicate that 60 acres should be protected in the near-term to offset CM1 losses.

The BDCP has committed to near-term restoration of 1,140 acres of grassland (CM8) and protection of up to 2,000 acres of grassland in the Plan Area (CM3). These conservation actions are all associated with CM3 and CM8 and would occur in the same timeframe as CM1 construction and early restoration losses, thereby avoiding adverse effects on special-status reptiles.

The natural community restoration and protection activities are expected to be concluded during the first 10 years of Plan implementation, which would be close enough to the timing of construction impacts to constitute mitigation for CEQA purposes. Considering the BDCP conservation strategy and the implementation of Mitigation Measure BIO-55, the permanent and temporary loss of special-status reptile habitat and the potential mortality of either species would be a less-than-significant impact under CEQA.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of 30 acres of habitat for special-status reptiles over the life of the plan. Effects of water conveyance facilities construction would be offset through the plan's long-term commitment to protect up to 8,000 acres of grassland, and grassland associated with alkali seasonal wetlands and vernal pool complexes, and to restore 2,000 acres of grassland in the Plan Area (Objective GNC1.1 and Objective GNC1.2). Grassland protection would focus in particular on acquiring the largest remaining contiguous patches of unprotected grassland habitat, which are located south of SR 4 in CZ 8 (Objective GNC1.1). This area connects to more than 620 acres of existing habitat that is protected under the East Contra Costa County HCP/NCCP.

Other effects would be reduced through implementation of Mitigation Measure BIO-55, *Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs*. The plan as a whole is expected to benefit special-status reptiles that could be present by protecting potential habitat from loss or degradation that otherwise could occur with future changes in existing land use. To the extent that grassland habitat is restored in CZ 8, restoration would replace unsuitable special-status reptile habitat, such as cultivated land, with high-value cover, foraging, and dispersal habitat. The overall effect would be beneficial because the plan would result in a net increase in acreage of grassland habitat in the Plan Area.

BDCP's commitment to protect the largest remaining contiguous habitat patches (including grasslands and the grassland component of alkali seasonal wetland and vernal pool complexes) in CZ 8 would sufficiently offset the adverse effects resulting from water conveyance facilities construction. Considering the BDCP conservation strategy and the implementation of Mitigation Measure BIO-55, the permanent and temporary loss of special-status reptile habitat and the potential mortality of either species under Alternative 9 would not result in a significant impact under CEQA.

Mitigation Measure BIO-55: Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs

DWR will retain a qualified biologist to conduct a habitat assessment in construction and restoration areas that are relatively undisturbed or have a moderate to high potential to support noncovered special-status reptiles (Blainville's horned lizard and San Joaquin coachwhip) in CZ

4, CZ 7, and CZ 8. The qualified biologist will survey for noncovered special-status reptiles in areas of suitable habitat concurrent with the preconstruction surveys for covered species in CZ 4, CZ 7, and CZ 8. If special-status reptiles are found in work areas, the biologist will first attempt to allow these species to move out of the work area on their own but if conditions do not allow this, individuals will be captured by the biologist and relocated to the nearest suitable habitat outside of the work area as determined in consultation with CDFW. To the extent feasible, work in areas of suitable habitat for Blainville's hornzed lizard and San Joaquin coachwhip should not be conducted during periods of cold and hot temperatures (below 67 degrees F and above 100 degrees F), because both species would be relatively inactive during these periods and could be taking cover in loose soil, in burrows or crevices, or under structures such as rocks or logs (Morey 2000). This would reduce the impact of being crushed by vehicles and equipment.

In addition, *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities*, will be implemented for all noncovered special-status reptiles adversely affected by the BDCP to avoid, minimize, or compensate for impacts.

Impact BIO-56: Indirect Effects of Plan Implementation on Special-Status Reptile Species

Construction activities associated with water conveyance facilities, conservation components and ongoing habitat enhancement, as well as operations and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances and noise with localized effects on special-status reptiles and their habitat over the term of the BDCP. In addition, construction activities could indirectly affect special-status reptiles if construction resulted in the introduction of invasive weeds that create vegetative cover that is too dense for the species to navigate. Construction vehicles and equipment can transport in their tires and various parts under the vehicles invasive weed seeds and vegetative parts from other regions to construction sites, resulting in habitat degradation. These potential effects would be reduced through implementation of *AMM10 Restoration of Temporarily Affected Natural Communities.* Water conveyance facilities operations and maintenance activities would include vegetation and weed control, ground squirrel control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. While maintenance activities are not expected to remove special-status reptile habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in injury or mortality of individual special-status reptiles, if present.

***NEPA Effects*:** Implementation of the Mitigation Measure BIO-55, *Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs* would avoid the potential for substantial adverse effects on these species, either indirectly or through habitat modifications. The mitigation measures would also avoid and minimize effects that could substantially reduce the number of special-status reptiles, or restrict either species' range. Therefore, with implementation of Mitigation Measure BIO-55, the indirect effects of Alternative 9 on special-status reptiles would not be adverse under NEPA.

***CEQA Conclusion*:** Indirect effects from conservation measure operations and maintenance as well as construction-related noise and visual disturbances could impact special-status reptiles. In addition, construction activities could indirectly affect special-status reptiles if construction resulted in the introduction of invasive weeds that create vegetative cover that is too dense for the species to navigate. Water conveyance facilities operations and maintenance activities, such as vegetation and weed control, and road maintenance, are not expected to remove special-status reptile habitat, but operation of equipment could disturb small areas of vegetation around maintained structures and could result in injury or mortality of individual special-status reptiles, if present.

With implementation of Mitigation Measure BIO-55 as part of Alternative 9 construction, operation, and maintenance, the BDCP would avoid the potential for significant effects on special-status reptile species, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of either species. With implementation of Mitigation Measure BIO-55, the indirect effects of Alternative 9 would have a less-than-significant impact on special-status reptiles.

Mitigation Measure BIO-55: Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs

See description of Mitigation Measure BIO-55 under Impact BIO-55.

California Black Rail

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on the California black rail. The habitat model used to assess effects for the California black rail is based on primary breeding habitat and secondary habitat. Primary (breeding) habitat for this species within the Delta includes all *Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acre (essentially instream islands of the San Joaquin River and its tributaries and White Slough Wildlife Area). In Suisun Marsh, primary habitat includes all *Schoenoplectus* and *Typha*-dominated, and *Salicornia*-dominated patches greater than 0.55 acre, with the exception that all low marsh habitats dominated by *Schoenoplectus acutus* and *S. californicus* and all managed wetlands, in general, are considered secondary habitat with lesser ecological value. Upland transitional zones, providing refugia during high tides, within 150 feet of the tidal wetland edge were also included as secondary habitat. Secondary habitats generally provide only a few ecological functions such as foraging (low marsh and managed wetlands) or extreme high tide refuge (upland transition zones), while primary habitats provide multiple functions, including breeding, effective predator cover, and valuable foraging opportunities.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of California black rail modeled habitat as indicated in Table 12-9-25. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit the California black rail (BDCP Chapter 3 Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 6,000 acres of tidal brackish emergent wetland in CZ 11, including at least 1,500 acres of middle and high marsh (Objectives TBEWNC1.1 and TBEWNC1.2, associated with CM4).
- Restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1, associated with CM4).
- Protect and enhance at least 8,100 acres of managed wetland, at least 1,500 acres of which are in the Grizzly Island Marsh Complex (Objective MWNC1.1, associated with CM3).
- Create 1,700 acres of black rail habitat between restored tidal freshwater emergent wetlands and transitional uplands to provide upland refugia (Objective CBR1.1, associated with CM4).

- Create topographic heterogeneity in restored tidal brackish and freshwater emergent wetlands (Objectives TBEWNC1.4 and TFEWNC2.2, associated with CM4).
- Limit perennial pepperweed to no more than 10% cover in the tidal brackish emergent wetland natural community within the reserve system (Objective TBEWNC2.1, associated with CM11).

As explained below, with the restoration and protection of these amounts of habitat, in addition to natural community enhancement and management commitments (including *CM12 Methylmercury Management*) and implementation of AMM1–AMM7, *AMM38 California Black Rail*, and *AMM27 Selenium Management*, impacts on the California black rail would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-57: Loss or Conversion of Habitat for and Direct Mortality of California Black Rail

Alternative 9 conservation measures would result in the combined permanent loss or conversion and temporary loss of up to 395 acres of modeled primary habitat, and up to 3,044 acres of modeled secondary habitat for California black rail (Table 12-9-25). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1) and tidal habitat restoration (CM4). Habitat enhancement and management activities (CM11) activities, which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate California black rail habitat. Each of these individual activities is described below. A summary statement of the combined NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 311 acres of modeled California black rail primary habitat, (15 acres of permanent loss, 296 acres of temporary loss)y habitat, Table 12-9-25). Activities that would permanently impact black rail habitat consist of instream island channel dredging. Permanent losses of habitat would occur from the dredging of Victoria Canal. Although the channel dredging in Middle River would avoid the majority of the instream islands, small portions of these islands would be permanently affected by this activity. Temporary disturbances of California black rail habitat would primarily occur from dredging activities in Middle River, which would cause temporary disturbances from dredging equipment use, turbidity, and other temporary effects. The CM1 permanent construction footprint overlaps with 16 California black rail occurrences in Middle River. Three of these occurrences overlap with the channel dredging footprint, and 13 occurrences are located in temporary dredging work areas. *AMM38 California Black Rail* would minimize potential effects of construction on nesting California black rail. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations.
- *CM2 Yolo Bypass Fisheries Enhancement*: Construction or channel modification from fish passage improvements associated with the Yolo Bypass would result in the permanent removal of approximately 5 acres of primary California black rail habitat in CZ 2. There are no occurrences of California black rail that intersect with the CM1 footprint. The loss is expected to occur during the first 10 years of Alternative 9 implementation.
- *CM4 Tidal Natural Communities Restoration*: California black rail modeled habitat would be affected by tidal marsh restoration. Some California black rail modeled habitat would be permanently lost such that it no longer serves as habitat, while other modeled habitat would change value through conversion from one habitat type to another. Tidal habitat restoration site preparation and inundation would result in the permanent loss of 79 acres of primary habitat and 3,044 acres of secondary habitat for California black rail. Of the 79 acres of primary habitat lost, an estimated 76 acres would be converted to low marsh, or secondary habitat, for the species due to increased water elevations.

  The majority of the effects of tidal natural communities restoration would occur in Suisun Marsh (CZ 11). Much of the natural wetland habitat that would be removed occurs in isolated patches and would be replaced by larger continuous areas of tidal wetlands that are expected to support higher habitat functions for the rail than the impacted wetlands. As described in the BDCP, restoration of up to 24,000 acres of tidal freshwater emergent wetland in the Delta and at least 6,000 acres of tidal brackish emergent wetland natural communities in CZ 11 by the late long-term would benefit California black rail. The primary habitat for the species in the Delta consists of inchannel islands, which are in areas that are most vulnerable to the effects of sea level rise in the study area. Tidal restoration under CM4 would ensure that land is protected adjacent to current habitat in the delta with the consideration of sea level rise. Tidal restoration projects would include an ecotone between wetlands and transitional uplands which would provide upland refugia for the species.

  The tidal natural communities restoration would be phased through the course of the BDCP restoration program to allow for recovery of some areas before the initiation of restoration actions in other areas. However, California black rails have a greater use of mature tidal marshes and, therefore, it would be years before the newly restored marshes provided suitable habitat for the species. In the long-term, tidal natural communities restoration is expected to have little to no adverse effects on California black rail habitat because the habitat removed would be replaced by a greater acreage of high-value tidal wetland and, thus, is expected to provide a benefit for California black rail.

- *CM11 Natural Communities Enhancement and Management:* A variety of habitat management actions contained in *CM11 Natural Communities Enhancement and Management* that are designed to enhance wildlife values in restored and protected tidal wetland habitats may result in localized ground disturbances that could temporarily remove small amounts of California black rail habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, are expected to have minor adverse effects on available California black rail habitat and are expected to result in overall improvements and maintenance of California black rail habitat values over the term of the BDCP. Noise and visual disturbances during implementation of habitat management actions could also result in temporary disturbances that affect California black rail use of the surrounding habitat. These effects cannot be quantified, but would be avoided and minimized by the AMMs listed below. Additional actions under CM11 include the control of nonnative predators to reduce nest predation as needed.
- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect California black rail use of the surrounding habitat in Suisun and the central Delta. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and conservation actions as described below.
- Injury and Direct Mortality: Construction vehicle activity may cause injury or mortality to California black rail. If rails are present adjacent to covered activities, the operation of equipment for land clearing, construction, conveyance facilities operation and maintenance, and habitat restoration, enhancement, and management could result in injury or mortality of California black rail. Increased vehicular traffic associated with BDCP actions could contribute to a higher incidence of road kill. However, conducting construction outside of the breeding season where feasible (reducing the risk of impacting active nests), construction monitoring, and other measures would be implemented to avoid and minimize injury or mortality of the species during construction, as required by AMM1–AMM7 and *AMM38 California Black Rail*.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. With Alternative 9 implementation, there would be a loss of 1,373 acres of modeled habitat for California black rail in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 311 acres of primary habitat), and implementing other conservation measures (*CM2 Yolo Bypass*

Fisheries Enhancement and *CM4 Tidal Natural Communities Restoration*—76 acres of primary habitat, 986 acres of secondary habitat).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities that would be affected and that are identified in the biological goals and objectives for California black rail in Chapter 3 of the BDCP would be 1:1 for restoration/creation of wetland natural communities such as tidal freshwater emergent wetland, tidal brackish emergent wetland, and managed wetland. Using this ratio would indicate that 311 acres of tidal natural communities should be restored/created to compensate for the CM1 losses of California black rail habitat. The near-term effects of other conservation actions would remove 1,062 acres of tidal natural communities, therefore requiring 1,062 acres of tidal natural communities restoration using the same typical NEPA and CEQA ratio (1:1 for restoration).

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal brackish emergent wetland, 8,850 acres of tidal freshwater emergent wetland, and 4,800 acres of managed wetland in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are all associated with CM4 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on California black rail. The tidal brackish emergent wetland would be restored in CZ 11 among the Western Suisun/Hill Slough Marsh Complex, the Suisun Slough/Cutoff Slough Marsh Complex, and the Nurse Slough/Denverton Marsh complex (Objective TBEWNC1.1 in BDCP Chapter 3, *Conservation Strategy*) and the tidal freshwater emergent wetland would be restored in CZ 1, CZ 2, CZ 4, CZ 5, CZ 6, and/or CZ 7 (Objective TFEWNC1.1). In addition, tidal brackish and tidal freshwater emergent wetlands would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objectives TBEWNC1.4 and TFEWNC2.2). Portions of the 4,800 acres of managed wetland protected and enhanced in CZ 11 would benefit the California black rail through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). These Plan objectives represent performance standards for considering the effectiveness of CM4 restoration actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives for California black rail satisfy the typical mitigation that would be applied to the project-level effects of CM1, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM38 California Black Rail*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The study area supports approximately 7,467 acres of primary and 17,915 acres of secondary habitat for California black rail. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 395 acres of primary habitat and 3,044 acres of secondary habitat for

California black rail during the term of the Plan (2% of the total primary habitat in the study area and 17% of the total secondary habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM4 Tidal Natural Communities Restoration* to restore or create at least 6,000 acres of tidal brackish emergent wetland in CZ 11 (Objective TBEWNC1.1) and at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1). These tidal wetlands would be restored as a mosaic of large, interconnected and biologically diverse patches, and at least 1,500 acres of restored marsh would consist of middle-and high-marsh vegetation with dense, tall stands of pickleweed and bulrush cover serving as primary habitat for California black rail in Suisun Marsh (Objective TBEWNC1.1). In the Delta, at least 1,700 acres of upland refugia for California black rail would be created between the restored tidal freshwater emergent wetlands and transitional uplands to provide cover from predators (Objectives TBEWNC1.4, TFEWNC2.2, and CBR1.1). Portions of the 8,100 acres of managed wetland protected and enhanced in CZ 11 as part of *CM3 Natural Communities Protection and Restoration* would benefit the California black rail through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). Additional pressures on the species such as loss of habitat from invasive species and mortality from nest predators would also be addressed through the BDCP. Perennial pepperweed, which outcompetes suitable nesting habitat for California black rail (such as pickleweed) would be reduced to no more than 10% cover in the tidal brackish emergent wetland natural community within CZ 11 (TBEWNC2.1). In addition, nonnative predators would be controlled to reduce nest predation if necessary through *CM11 Natural Communities Enhancement and Management*.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above would result in the restoration of 3,579 acres of primary habitat and 12,115 acres of secondary habitat for California black rail and the protection of 275 acres of secondary habitat for the species.

NEPA Effects: The loss of California black rail habitat and potential direct mortality of this special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. However, with habitat protection and restoration associated with CM4, guided by the biological objectives for the species and by *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM38 California Black Rail*, which would be in place throughout the construction period, the effects of Alternative 9 as a whole on California black rail would not be adverse under NEPA.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. With Alternative 9 implementation, there would be a loss of 1,373 acres of modeled habitat for California black rail in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 311 acres of primary habitat), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement* and *CM4 Tidal Natural Communities Restoration*—76 acres of primary habitat, 986 acres of secondary habitat).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities that would be affected and that are identified in the biological goals and objectives for California black rail in Chapter 3 of the BDCP would be 1:1 for restoration/creation of wetland natural communities such as tidal freshwater emergent wetland, tidal brackish emergent wetland, and managed wetland. Using this ratio would indicate that 311 acres of tidal natural communities should be restored/created to compensate for the CM1 losses of California black rail habitat. The near-term effects of other conservation actions would remove 1,062 acres of tidal natural communities, therefore requiring 1,062 acres of tidal natural communities restoration using the same typical NEPA and CEQA ratio (1:1 for restoration).

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal brackish emergent wetland, 8,850 acres of tidal freshwater emergent wetland, and 4,800 acres of managed wetland in the Plan Area (Table 3-4 in Chapter 3). These conservation actions are all associated with CM4 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on California black rail. The tidal brackish emergent wetland would be restored in CZ 11 among the Western Suisun/Hill Slough Marsh Complex, the Suisun Slough/Cutoff Slough Marsh Complex, and the Nurse Slough/Denverton Marsh complex (Objective TBEWNC1.1) and the tidal freshwater emergent wetland would be restored in CZ 1, CZ 2, CZ 4, CZ 5, CZ 6, and/or CZ 7 (Objective TFEWNC1.1). In addition, tidal brackish and tidal freshwater emergent wetlands would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objectives TBEWNC1.4 and TFEWNC2.2). Portions of the 4,800 acres of managed wetland protected and enhanced in CZ 11 would benefit the California black rail through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). These Plan objectives represent performance standards for considering the effectiveness of CM4 restoration actions.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM38 California Black Rail*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

The natural community restoration and protection activities would be concluded in the first 10 years of Alternative 9 implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for CEQA purposes. In addition, *AMM38 California Black Rail* and AMM1–AMM7 would avoid and minimize potential impacts on the species from construction-related habitat loss and noise and disturbance. Because the number of acres required to meet the typical mitigation ratio described above would be only 3,608 acres of restored/created tidal natural communities, the 10,850 acres of tidal brackish and tidal freshwater emergent wetland restoration and the 4,100 acres of managed wetland protection and enhancement contained in the near-term Plan goals, and the additional detail in the biological objectives for California black rail, are more than sufficient to support the conclusion that the near-term impacts of habitat loss and direct mortality under Alternative 9 would be less than significant under CEQA.

Late Long-Term Timeframe

The study area supports approximately 7,467 acres of primary and 17,915 acres of secondary habitat for California black rail. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 395 acres of primary habitat and 3,044 acres of secondary habitat for California black rail during the term of the Plan (2% of the total primary habitat in the study area and 17% of the total secondary habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM4 Tidal Natural Communities Restoration* to restore or create at least 6,000 acres of tidal brackish emergent wetland in CZ 11 (Objective TBEWNC1.1) and at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (TFEWNC1.1). These tidal wetlands would be restored as a mosaic of large, interconnected and biologically diverse patches and much of the restored marsh would consist of middle-and high-marsh vegetation with dense, tall stands of pickleweed and bulrush cover, serving as primary habitat for California black rail in Suisun Marsh (Objective TBEWNC1.1). In the Delta, at least 1,700 acres of upland refugia for California black rail would be created between the restored tidal freshwater emergent wetlands and transitional uplands to provide cover from predators (Objectives TBEWNC1.4, TFEWNC2.2, and CBR1.1). Portions of the 8,100 acres of managed wetland protected and enhanced in CZ 11 as part of *CM3 Natural Communities Protection and Restoration* would benefit the California black rail through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). Additional pressures on the species such as loss of habitat from invasive species and mortality from nest predators would also be addressed through the BDCP. Perennial pepperweed, which outcompetes suitable nesting habitat for California black rail (such as pickleweed) would be reduced to no more than 10% cover in the tidal brackish emergent wetland natural community within CZ 11 (Objective TBEWNC2.1). In addition, nonnative predators would be controlled to reduce nest predation if necessary through *CM11 Natural Communities Enhancement and Management*.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM38 California Black Rail*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above would result in the restoration of 3,579 acres of primary habitat and 12,115 acres of secondary habitat for California black rail and the protection of 275 acres of secondary habitat for the species.

Considering these protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for habitats lost to construction and restoration activities, loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the alternative would have a less-than-significant impact on California black rail.

Impact BIO-58: Effects on California Black Rail Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of California black rail. A variety of rail species are known to suffer mortality from transmission line collision, likely associated with migration and flights between foraging areas (Eddleman et al 1994). Due to their wing shape and body size, rails have low to moderate flight maneuverability (Bevanger 1998), increasing susceptibility to collision mortality. However, there are relatively few records of California black rail collisions with overhead wires. California black rails exhibit daytime site fidelity and a lack of long-distance night migration, two factors which are associated with low collision risk in avian species (Eddleman et al. 1994). California black rail movements in the study area are likely short, seasonal, and at low altitudes, typically less than 16 feet (5 meters) (Eddleman et al 1994). However, although the species may have low to moderate flight maneuverability, the bird's behavior (e.g., sedentary, nonmigratory, ground-nesting and foraging, solitary, no flocking, secretive) reduces potential exposure to overheard wires and vulnerability to collision mortality (BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). For example, Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. As described in *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters, which would eliminate any potential for mortality of California black rail individuals from powerline collisions.

Transmission line poles and towers also provide perching substrate for raptors, which are predators on California black rail. Although there is potential for transmission lines constructed in the Delta to increase perching opportunities for raptors and result in increased predation pressure on local black rails, little is currently known about the seasonal movements of black rails or the potential for increased predation on rails near power poles. Therefore, because of the limited area over which poles would be installed relative to the amount of California black rail habitat in the Delta, it is assumed that the increase risk of predation on California black rail from an increase in raptor perching opportunities would be negligible.

***NEPA Effects*:** The construction and presence of new transmission lines would not represent an adverse effect because the risk of bird strike is considered to be minimal based on the species' flight behaviors. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines and select existing powerlines, which would minimize the risk of bird strike for California black rails in the Delta. The increased risk of predation on California black rail from an increase in raptor perching opportunities would be negligible because of the limited area over which poles would be installed relative to the amount of California black rail habitat in the Delta. Therefore, the construction and operation of new transmission lines would not result in an adverse effect on California black rail.

CEQA Conclusion: The construction and presence of new transmission lines would have a less-than-significant impact on California black rail because the risk of bird strike is considered to be minimal based on the species' flight behaviors. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would minimize the risk of bird strike for California black rails in the Delta. The increased risk of predation on California black rail from an increase in raptor perching opportunities would be negligible because of the limited area over which poles would be installed relative to the amount of California black rail habitat in the Delta. Therefore, the construction and operation of new transmission lines under Alternative 9 would result in a less-than-significant impact on California black rail.

Impact BIO-59: Indirect Effects of Plan Implementation on California Black Rail

Indirect Construction-Related Effects: Both primary and secondary habitat for California black rail within the vicinity of proposed construction areas could be indirectly affected by construction activities. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 500 feet from the construction edge. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect California black rail. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect California black rail in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to California black rail habitat could also affect the species.

If construction occurs during the nesting season, these indirect effects could result in the loss or abandonment of nests, and mortality of any eggs and/or nestlings. However, there is a commitment in AMM38 that preconstruction surveys of potential breeding habitat would be conducted within 700 feet of project activities, and a 500-foot no-disturbance buffer would be established around any territorial call-centers during the breeding season (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). In addition, construction would be avoided altogether if breeding territories cannot be accurately delimited.

Salinity: Water operations under Operational Scenario A would have an effect on salinity gradients in Suisun Marsh. These effects cannot be disaggregated from tidal habitat restoration, which would also cause changes in salinity gradients. It is expected that the salinity of water in Suisun Marsh would generally increase as a result of water operations and operations of salinity-control gates to mimic a more natural water flow. This would likely encourage the establishment of tidal wetland plant communities tolerant of more brackish environments, which should be beneficial to California black rail because its historical natural Suisun Marsh habitat was brackish tidal marsh.

Methylmercury Exposure: The modeled primary habitat for California black rail includes tidal brackish emergent wetland and tidal freshwater emergent wetland in Suisun Marsh and the Delta west of Sherman Island, and instream islands and White Slough Wildlife Area in the central Delta. Black rails typically occur in the high marsh zone near the upper limit of tidal flooding in salt and brackish habitats. Low marsh, managed wetlands, and the upland fringe are considered secondary habitat. California black rails are a top predator in the benthic food chain; they nest and forage in dense vegetation and prey on isopods, insects and arthropods from the surface of mud and vegetation They also consume insects and seeds from bulrushes (*Schoenoplectus* spp.) and cattails (*Typha* spp.) (Eddleman et al. 1994).

Largemouth bass was used as a surrogate species for analysis (see Appendix 11F, *Substantive BDCP Revisions*). Results of the quantitative modeling of mercury effects on largemouth bass as a surrogate species would overestimate the effects on black rail. Organisms feeding within pelagic-based (algal) foodwebs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic foodwebs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009). Modeled effects of mercury concentrations from changes in water operations under CM1 on largemouth bass did not differ substantially from existing conditions; therefore, results also indicate that black rail mercury tissue concentrations would not measurably increase as a result of CM1 implementation.

Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, Alternative 9 restoration activities that create newly inundated areas could increase bioavailability of mercury. In general, the highest methylation rates are associated with high tidal marshes (primary black rail habitat) that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008); however, the majority of the overlap between restoration areas and black rail habitat is within Suisun Marsh, where conversion of managed wetlands to tidal wetlands is expected to result in an overall reduction in mercury methylation. Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury. Given that some species have elevated mercury tissue levels pre-BDCP, these low level increases could result in some level of effects. CM 12 would be implemented to address this risk of low level increases in methylmercury that could add to the current elevated tissue concentrations.

Due to the complex and very site-specific factors that determine if mercury becomes mobilized into the foodweb, *CM12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. CM12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This conservation measure would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by

interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including California black rail. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4, CM5) would lead to adverse effects on California black rail.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on California black rail from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects**:** Noise and visual disturbances related to construction-related activities from conservation measures could disturb California black rail habitat adjacent to work sites. Potential effects of noise and visual disturbances on California black rail would be minimized with *AMM38 California Black Rail*. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of spills from occurring and ensure that measures were in place to prevent runoff from the construction area and to avoid negative effects of dust on the species. Implementation of Operational Scenario A, including operation of salinity-control gates, and tidal habitat restoration are expected to increase water salinity in Suisun Marsh, which would be expected to establish tidal marsh similar to historic conditions.

Changes in water operations under CM1 would not be expected to result in increased mercury bioavailability or exposures to Delta foodwebs. Restoration actions that would create high and low tidal marsh, which is black rail habitat, could provide biogeochemical conditions for methylation of mercury in the newly inundated soils. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the planned ROA's do not overlap with the areas of highest mercury concentrations, which are in the in Yolo Bypass. Also, the conversion of managed wetlands to tidal wetlands in Suisun Marsh would be expected to reduce the overall production of methylmercury, resulting in a net benefit to species. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

Tidal habitat restoration could result in increased exposure of California black rail to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

CEQA Conclusion: Noise and visual disturbances related to construction-related activities and other conservation measures could disturb primary and secondary California black rail habitat adjacent to work sites. *AMM38 California Black Rail* would avoid and minimize impacts on California black rail from noise and visual disturbance. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect California black rail in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to California black rail habitat could also affect the species. These impacts on California black rail would be less than significant with the incorporation of AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, into the BDCP. Implementation of Operational Scenario A, including operation of salinity-control gates, and tidal habitat restoration are expected to increase water salinity in Suisun Marsh. These salinity gradient changes should have a beneficial impact on California black rail through the establishment of tidal marsh similar to historic conditions.

Tidal habitat restoration is unlikely to have a significant impact on California black rail through increased exposure to methylmercury, as rails currently reside in tidal marshes where elevated methylmercury levels exist. However, it is unknown what concentrations of methylmercury are harmful to the species. Site-specific restoration plans in addition to monitoring and adaptive management, described in *CM12 Methylmercury Management,* would address the uncertainty of methylmercury levels in restored tidal marsh. Tidal habitat restoration could result in increased exposure of California black rail to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Therefore, the indirect effects of Alternative 9 implementation would have a less-than-significant impact on California black rail.

Tidal habitat restoration could result in increased exposure of California black rail to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. With implementation of AMM27, potential for increased selenium exposure would result in no adverse effect on the species.

Changes in water operations under CM1 would not be expected to result in increased mercury bioavailability or exposures to Delta foodwebs. Restoration Actions that would create high and low tidal marsh, which is Black Rail habitat, could provide biogeochemical conditions for methylation of mercury in the newly inundated soils. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the planned ROA's do not overlap with the areas of highest mercury concentrations, which are in the in Yolo Bypass. Also, the conversion of managed wetlands to tidal wetlands in Suisun Marsh would be expected to reduce the overall production of methylmercury, resulting in a net benefit to species. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

With these measures in place, indirect effects of plan implementation would not result in a substantial adverse effect on the species through habitat modification or potential mortality of a special-status species. Therefore, the indirect effects of Alternative 9 implementation would have a less-than-significant impact on California black rail. No mitigation would be required.

Impact BIO-60: Fragmentation of California Black Rail Habitat as a Result of Conservation Component Implementation

Restoration activities may temporarily fragment existing wetlands in Suisun Marsh and could create temporary barriers to California black rail movements. Grading, filling, contouring and other initial ground-disturbing activities could remove habitat along movement corridors used by individuals and potentially temporarily reduce access to adjacent habitat areas. The temporary adverse effects of fragmentation of tidal brackish emergent wetland habitat for California black rail or restoration activities resulting in barriers to movement would be minimized through sequencing of *CM4 Tidal Natural Community Restoration* activities. The tidal natural communities restoration would be phased through the course of the BDCP restoration program to allow for recovery of some areas before restoration actions are initiated in other areas. In addition, *AMM38 California Black Rail* would avoid and minimize effects on California black rail.

***NEPA Effects*:** The fragmentation of existing wetlands and creation of temporary barriers to movement would not represent an adverse effect on California black rail as a result of habitat modification of a special-status species because *CM4 Tidal Natural Communities Restoration* would be phased to allow for the recovery of some areas before restoration actions are initiated in other areas. In addition, *AMM38 California Black Rail* would avoid and minimize effects on California black rail.

CEQA Conclusion: The fragmentation of existing wetlands and creation of temporary barriers to movement would represent a less-than-significant impact on California black rail as a result of habitat modification of a special-status species because *CM4 Tidal Natural Communities Restoration* would be phased to allow for the recovery of some areas before restoration actions are initiated in other areas. In addition, *AMM38 California Black Rail* would avoid and minimize impacts on California black rail.

Impact BIO-61: Periodic Effects of Inundation of California Black Rail Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from *CM2 Yolo Bypass Fisheries Enhancement* would not result in the periodic inundation of modeled habitat for California black rail. There are no records for California black rails in the Yolo Bypass, although the species is highly secretive and the extent to which the area has been surveyed for California black rails is unknown. Therefore, there is potential for the species to occur in the Yolo Bypass. In addition, rails may occur in the bypass after restoration activities are completed. However, periodic inundation would not result in permanent habitat loss and would not prevent use of the bypass by current or future rail populations.

Based on hypothetical floodplain restoration for *CM5 Seasonally Inundated Floodplain Restoration*, construction of setback levees could result in increased magnitude, frequency and duration of periodic inundation by up to 6 acres of modeled California black rail habitat in CZ 7. The risk of changes in inundation frequency, magnitude, and duration through CM2 and CM5 affecting California black rail are considered to be low, and would not be expected to result in adverse effects on the species.

NEPA Effects: Periodic inundation under *CM2 Yolo Bypass Fisheries Enhancement* and *CM5 Seasonally Inundated Floodplain Restoration* would not represent an adverse effect on California black rail as a result of habitat modification of a special-status species because periodic inundation would not result in permanent habitat loss and would not prevent use of the bypass by current or future rail populations. The risk of changes in inundation frequency and duration through CM2 and CM5 affecting California black rail is considered to be low.

CEQA Conclusion: Periodic inundation under *CM2 Yolo Bypass Fisheries Enhancement* and *CM5 Seasonally Inundated Floodplain Restoration* would represent a less-than-significant impact on California black rail because periodic inundation would not result in permanent habitat loss and would not prevent use of the bypass by current or future rail populations. The risk of changes in inundation frequency and duration as a result of CM2 and CM5 affecting California black rail is considered to be low.

California Clapper Rail

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on California clapper rail. California clapper rail habitat includes mostly middle marsh habitat with select emergent wetland plant alliances. Secondary habitats generally provide only a few ecological functions such as foraging (low marsh) or high-tide refuge (upland transition zones), while primary habitats provide multiple functions including breeding, effective predator cover, and forage. Further details regarding the habitat model, including assumptions on which the model is based, are provided in BDCP Appendix 2.A, *Covered Species Accounts*.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of California clapper rail modeled habitat as indicated in Table 12-9-26. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit the California clapper rail (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 6,000 acres of tidal brackish emergent wetland in CZ 11 including at least 1,500 acres of middle and high marsh (Objectives TBEWNC1.1 and TBEWNC1.2, associated with CM4).

As explained below, with the restoration and protection of these amounts of habitat, in addition to natural community enhancement and management commitments (including *CM12 Methylmercury Management*) and implementation of AMM1–AMM7, *AMM19 California Clapper Rail*, and *AMM27 Selenium Management*, impacts on the California clapper rail would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-26. Changes to California Clapper Rail Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	Primary	0	0	0	0	NA	NA
	Secondary	0	0	0	0	NA	NA

	Secondary	50	50	0	0	0	0
Total Impacts CM2–CM18		**76**	**77**	**0**	**0**	**0**	**0**
TOTAL IMPACTS		**76**	**77**	**0**	**0**	**0**	**0**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-62: Loss or Conversion of Habitat for and Direct Mortality of California Clapper Rail

Alternative 9 conservation measures would result in the total loss or conversion of up to 77 acres of modeled clapper rail habitat consisting of 27 acres of primary habitat and 50 acres of secondary habitat (Table 12-9-26). The conservation measure that would result in these losses is tidal natural communities restoration (CM4). Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could also result in local adverse habitat effects. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM4 Tidal Natural Communities Restoration*: Site preparation and inundation would convert approximately 77 acres of modeled California clapper rail habitat (27 acres of primary habitat, 50 acres of secondary habitat), the majority of which would occur in CZ 11. The tidal marsh restoration action would not result in the permanent loss of any California clapper rail habitat in the study area. However, approximately 27 acres of primary habitat would be converted to secondary low marsh habitat and 50 acres of secondary habitat would be converted to middle or high marsh. Full implementation of CM4 would restore or create at least 6,000 acres of tidal brackish emergent wetland in CZ 11. Tidal wetlands would be restored as a mosaic of large, interconnected, and biologically diverse patches that supported a natural gradient extending from subtidal to the upland fringe. Much of the restored tidal brackish emergent wetland would meet the primary habitat requirements of the California clapper rail, including development of mid- and high-marsh vegetation with dense, tall stands of pickleweed cover. Restoration would be sequenced and spaced in a manner that minimizes any temporary, initial loss of habitat and habitat fragmentation.

- *CM11 Natural Communities Enhancement and Management*: Because the entire California clapper rail population is restricted to the San Francisco Bay Area estuary, BDCP enhancement and restoration actions would be expected to benefit the species by creating the potential for extending its abundance and distribution in Suisun Marsh. Occupied California clapper rail habitat would be monitored to determine if there is a need for predator control actions. If implemented, nonnative predators would be controlled as needed to reduce nest predation and to help maintain species abundance. A variety of habitat management actions included in *CM11 Natural Communities Enhancement and Management* that are designed to enhance wildlife values in restored and protected tidal wetland habitats could result in localized ground disturbances that could temporarily remove small amounts of California clapper rail habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available California clapper rail habitat. These potential effects are currently not quantifiable, but would be minimized with implementation *AMM19 California Clapper Rail* (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*).

- Operations and Maintenance: Postconstruction operation and maintenance of the restoration infrastructure could result in ongoing but periodic disturbances that could affect California clapper rail use of the surrounding habitat in Suisun. Maintenance activities could include vegetation management, and levee repair. These effects, however, would be reduced by AMMs and conservation actions as described below.

- Injury and Direct Mortality: Construction vehicle activity may cause injury or mortality to California black rail. If rails are present adjacent to covered activities, the operation of equipment for land clearing, and habitat restoration, enhancement, and management could result in injury or mortality of California clapper rail. Operation of construction equipment could result in injury or mortality of California clapper rails. Risk would be greatest to eggs and nestlings susceptible to land clearing activities, nest abandonment, or increased exposure to the elements or to predators. Injury to adults and fledged juveniles is less likely as these individuals are expected to avoid contact with construction equipment. However, nest sites would be avoided during the nesting season as required by AMM1–AMM7 and *AMM19 California Clapper Rail*.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. There would be no impacts resulting from the construction of the water conveyance facilities (CM1). However, there would be a loss of 76 acres of modeled habitat for California clapper rail in the study area in the near-term. These effects would result from implementing *CM4 Tidal Natural Communities Restoration* (26 acres of primary and 50 acres of secondary habitat).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected by CM4 and that are identified in the biological goals and objectives for California clapper rail in Chapter 3 of the BDCP would be 1:1 for restoration/creation of tidal brackish emergent habitat. Using this ratio would indicate that 76 acres of tidal brackish emergent wetland should be restored/created to compensate for the CM4 losses of California clapper rail habitat.

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal brackish emergent wetland in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM4 and would occur in the same timeframe as the early restoration losses, thereby avoiding adverse effects on California clapper rail. The tidal brackish emergent wetland would be restored in CZ 11 among the Western Suisun/Hill Slough Marsh Complex, the Suisun Slough/Cutoff Slough Marsh Complex, and the Nurse Slough/Denverton Marsh complex (Objective TBEWNC1.1) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objectives TBEWNC1.4). These biological goals and objectives would inform the near-term restoration efforts and represent performance standards for considering the effectiveness of restoration actions. These Plan objectives represent performance standards for considering the effectiveness of CM4 restoration actions. The acres of restoration contained in the near-term Plan goals satisfy the typical mitigation that would be applied to the near-term effects of tidal restoration.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM19 California Clapper Rail*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The habitat model indicates that the study area supports approximately 296 acres of primary and 6,420 acres of secondary habitat for California clapper rail. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 27 acres of primary habitat and 50 acres of secondary habitat for California clapper rail during the term of the Plan (9% of the total primary habitat in the study area and less than 1% of the total secondary habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes a commitments through *CM4 Tidal Natural Communities Restoration* to restore or create at least 6,000 acres of tidal brackish emergent wetlands for California clapper rail in Suisun

Marsh in CZ 11 (Objective TBEWNC1.1). These tidal wetlands would be restored as a mosaic of large, interconnected and biologically diverse patches and at least 1,500 acres of the restored marsh would consist of middle-and high-marsh vegetation, serving as primary habitat for California clapper rail in Suisun Marsh (Objectives TBEWNC1.1 and TBEWNC1.2). Additional pressures on the species such as loss of habitat from invasive species and mortality from nest predators would also be addressed through the BDCP. Perennial pepperweed, which outcompetes suitable clapper rail habitat (such as pickleweed) would be reduced to no more than 10% cover in the tidal brackish emergent wetland natural community within CZ 11 (Objective TBEWNC2.1). In addition, nonnative predators would be controlled to reduce nest predation if necessary through *CM11 Natural Communities Enhancement and Management*.

The BDCP's beneficial effects analysis (BDCP Chapter 5, *Effects Analysis*) estimates that the restoration and protection actions discussed above, would result in the restoration of 1,500 acres of primary habitat and 4,500 acres of secondary habitat for California clapper rail.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM19 California Clapper Rail*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

NEPA Effects: In the absence of other conservation actions, the loss of California clapper rail habitat associated with Alternative 9 would represent an adverse effect as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection and restoration associated with CM4, guided by biological goals and objectives and by *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM19 California Clapper Rail*, which would be in place throughout the construction period, the effects of Alternative 9 as a whole on California clapper rail would not be adverse under NEPA.

***CEQA Conclusion*:**

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. There would be no impacts resulting from the construction of the water conveyance facilities (CM1). However, there would be a loss of 76 acres of modeled habitat for California clapper rail in the study area in the near-term from the implementation of *CM4 Tidal Natural Communities Restoration* (26 acres of primary and 50 acres of secondary habitat).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected by CM4 and that are identified in the biological goals and objectives for California clapper rail in

Chapter 3 of the BDCP would be 1:1 for restoration/creation of tidal brackish emergent habitat. Using this ratio would indicate that 76 acres of tidal brackish emergent wetland should be restored/created to mitigate the CM4 losses of California clapper rail habitat.

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal brackish emergent wetland in the study area. These conservation actions are associated with CM4 and would occur in the same timeframe as the early restoration losses, thereby avoiding adverse effects on California clapper rail. The tidal brackish emergent wetland would be restored in CZ 11 among the Western Suisun/Hill Slough Marsh Complex, the Suisun Slough/Cutoff Slough Marsh Complex, and the Nurse Slough/Denverton Marsh complex (Objective TBEWNC1.1) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objectives TBEWNC1.4).

These biological goals and objectives would inform the near-term restoration efforts and represent performance standards for considering the effectiveness of restoration actions. These Plan objectives represent performance standards for considering the effectiveness of CM4 restoration actions.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM19 California Clapper Rail*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

The natural community restoration and protection activities would be concluded in the first 10 years of Plan implementation, which is close enough in time to the occurrence of restoration impacts to constitute adequate mitigation for CEQA purposes. In addition, *AMM19 California Clapper Rail* and AMM1–AMM7 would avoid and minimize potential impacts on the species from construction-related habitat loss and noise and disturbance. Because the number of acres required to meet the typical mitigation ratio described above would be only 76 acres of restored tidal natural communities, the 2,000 acres of tidal brackish emergent wetland restoration contained in the near-term Plan goals, and the additional detail in the biological objectives for California clapper rail, are more than sufficient to support the conclusion that the near-term impacts of habitat loss and direct mortality under Alternative 9 would be less than significant under CEQA.

Late Long-Term Timeframe

The habitat model indicates that the study area supports approximately 296 acres of primary and 6,420 acres of secondary habitat for California clapper rail. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 27 acres of primary habitat and 8 acres of secondary habitat for California clapper rail during the term of the Plan (9% of the total primary habitat in the study area and less than 1% of the total secondary habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes a commitment to restore or create at least 6,000 acres of tidal brackish emergent wetlands for California clapper rail in Suisun Marsh in CZ 11 (Objective TBEWNC1.1). These tidal wetlands would be restored as a mosaic of large, interconnected and biologically diverse patches and much of the restored marsh would consist of middle-and high-marsh vegetation with dense, tall stands of pickleweed, serving as primary habitat for clapper rail in Suisun Marsh (Objective TBEWNC1.1). Additional pressures on the species such as loss of habitat from invasive species and mortality from nest predators would also be addressed through the BDCP. Perennial pepperweed, which outcompetes suitable clapper rail habitat (such as pickleweed) would be reduced to no more than 10% cover in the tidal brackish emergent wetland natural community within CZ 11 (Objective TBEWNC2.1). In addition, nonnative predators would be controlled to reduce nest predation if necessary through *CM11 Natural Communities Enhancement and Management*.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, would result in the restoration of 1,500 acres of primary habitat and 4,500 acres of secondary habitat for California clapper rail.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM19 California Clapper Rail*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Considering Alternative 9's protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for habitats lost to construction and restoration activities, loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of California clapper rail. Therefore, the alternative would have a less-than-significant impact on California clapper rail.

Impact BIO-63: Indirect Effects of Plan Implementation on California Clapper Rail

Indirect Construction-Related Effects: California clapper rail habitat within the vicinity of proposed restoration areas could be indirectly affected by construction activities. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 500 feet from the construction edge. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect California clapper rail. The use of mechanical equipment during construction-related restoration activities could cause the accidental release of petroleum or other contaminants that could affect California clapper rail in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to California clapper habitat could also affect the species. If construction occurs during the nesting season, these indirect effects could result in the loss or abandonment of nests, and mortality of any eggs and/or nestlings. However, there is a commitment in *AMM19 California Clapper Rail* that preconstruction surveys of potential breeding habitat would be conducted within 500 feet of project activities, and a 500-foot no-disturbance buffer would be established around any territorial call-centers during the breeding season (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). In addition, construction would be avoided altogether if breeding territories cannot be accurately delimited.

Preconstruction surveys conducted under *AMM19 California Clapper Rail* would ensure construction-related noise and visual disturbances would not have an adverse effect on California clapper rail. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring and ensure measures were in place to prevent runoff from the construction area and to avoid negative effects of dust on the species. Therefore, with the implementation of AMM1–AMM7 and *AMM19 California Clapper Rail*, there would be no adverse effect on California clapper rail.

Salinity: Water operations under Operational Scenario A would have an effect on salinity gradients in Suisun Marsh. These effects cannot be disaggregated from tidal habitat restoration, which would also cause changes in salinity gradients. It is expected that the salinity of water in Suisun Marsh would generally increase as a result of water operations and operations of salinity-control gates to mimic a more natural water flow. This would likely encourage the establishment of tidal wetland plant communities tolerant of more brackish environments, which would be beneficial to California clapper rail because its historical natural Suisun Marsh habitat was brackish tidal marsh.

Methylmercury Exposure: California clapper rail modeled habitat includes primarily middle marsh habitat with select emergent wetland plant alliances in Suisun Marsh. High marsh is also used if it is of high value, and low marsh provides foraging habitat for the species. California clapper rails are a top predator in the benthic food chain; they forage by probing their beaks into the mud (Zembal and Fancher 1988) and prey primarily on mussels, spiders, seeds and hulls of cordgrass, and insects (Eddleman and Conway 1998).

Largemouth bass was used as a surrogate species for analysis (see Appendix 11F, *Substantive BDCP Revisions*). Results of the quantitative modeling of mercury effects on largemouth bass as a surrogate species would overestimate the effects on California clapper rail. Organisms feeding within pelagic-based (algal) foodwebs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic foodwebs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009).

Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, Alternative 9 restoration activities that create newly inundated areas could increase bioavailability of mercury. Concentrations of methylmercury known to be toxic to bird embryos have been found in the eggs of San Francisco Bay clapper rails (Schwarzbach and Adelsbach 2003); however, currently, it is unknown how much of the sediment-derived methylmercury enters the food chain in Suisun Marsh or what tissue concentrations are actually harmful to the California clapper rail. In general, the highest methylation rates are associated with high tidal marshes that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). In Suisun Marsh, the conversion of managed wetlands to tidal wetlands is expected to result in an overall reduction in mercury methylation. Due to the complex and very site-specific factors that determine if mercury becomes mobilized into the foodweb, *CM12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. CM12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This conservation measure would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability.
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009), and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including California clapper rail. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and, therefore, increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 9 restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations are analyzed in Chapter 8, *Water Quality*, which concludes that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on California clapper rail.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on California clapper rail from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium*

Management, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Noise and visual disturbances related to construction-related activities from conservation measures could disturb California clapper rail habitat adjacent to work sites. Potential effects of noise and visual disturbances on California clapper rail would be minimized with *AMM19 California Clapper Rail*. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of spills from occurring and ensure that measures were in place to prevent runoff from the construction area and to avoid negative effects of dust on the species.

Implementation of Operational Scenario A, including operation of salinity-control gates, and tidal habitat restoration are expected to increase water salinity in Suisun Marsh, which would be expected to establish tidal marsh similar to historic conditions. Tidal habitat restoration could result in increased exposure of California clapper rail to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Restoration actions that would create tidal marsh could provide biogeochemical conditions for methylation of mercury in the newly inundated soils. There is potential for increased exposure of the California clapper rail foodweb to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the conversion of managed wetlands to tidal wetlands in Suisun Marsh would be expected to reduce the overall production of methylmercury, resulting in a net benefit to species. Implementation of CM12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

The indirect effects associated with noise and visual disturbances, potential spills of hazardous material, changes in salinity, and increased exposure to selenium from Alternative 9 implementation would not have an adverse effect on California clapper rail.

CEQA Conclusion: Noise and visual disturbances related to construction-related activities from the conservation measures could disturb approximately 542 acres of California clapper rail habitat adjacent to work sites. *AMM19 California Clapper Rail* would avoid and minimize impacts on California clapper rail from noise and visual disturbance. The use of mechanical equipment during restoration activities could cause the accidental release of petroleum or other contaminants or the inadvertent discharge of sediment or excessive dust adjacent to California clapper rail habitat could also affect the species. These impacts on California clapper rail would be less than significant with the incorporation of AMM1–AMM7 into the BDCP. Implementation of Operational Scenario A, including operation of salinity-control gates, and tidal habitat restoration are expected to increase water salinity in Suisun Marsh. These salinity gradient changes should have a beneficial impact on

California clapper rail through the establishment of tidal marsh similar to historic conditions. Tidal habitat restoration could result in increased exposure of California clapper rail to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management,* which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Restoration actions that would create tidal marsh could provide biogeochemical conditions for methylation of mercury in the newly inundated soils. There is potential for increased exposure of the California clapper rail foodweb to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the conversion of managed wetlands to tidal wetlands in Suisun Marsh would be expected to reduce the overall production of methylmercury, resulting in a net benefit to species. Implementation of CM12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

With these measures in place, indirect effects of plan implementation would not result in a substantial adverse effect on the species through habitat modification or potential mortality of a special-status species. Therefore, the indirect effects of Alternative 9 implementation would have a less-than-significant impact on California clapper rail.

Impact BIO-64: Effects on California Clapper Rail Associated with Electrical Transmission Facilities

Isolated patches of suitable California clapper rail habitat may occur in the Plan Area as far east as (but not including) Sherman Island. Home range and territory of the California clapper rail is not known, but in locations outside of California, clapper rail territory ranges 0.3 acre to 8 acres (0.1 to 3.2 hectares) (Rush et al. 2012), indicating that known occurrences are not likely to intersect with the proposed lines (BDCP Attachment 5J.C*, Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). The location of the current population and suitable habitat for the species make collision with the proposed transmission lines highly unlikely.

NEPA Effects: The construction and presence of new transmission lines would not have an adverse effect on California clapper rail because the location of the current population and suitable habitat for the species would make collision with the proposed transmission lines highly unlikely.

CEQA Conclusion: The construction and presence of new transmission lines would have a less-than-significant impact on California clapper rail because the location of the current population and suitable habitat for the species would make collision with the proposed transmission lines highly unlikely.

Impact BIO-65: Fragmentation of California Clapper Rail Habitat as a Result of Conservation Component Implementation

Restoration activities may temporarily fragment existing wetlands in Suisun Marsh and could create temporary barriers to movements of California clapper rail. Grading, filling, contouring and other initial ground-disturbing activities could remove habitat along movement corridors used by individuals and, thus, temporarily reduce access to adjacent habitat areas. The temporary adverse effects of fragmentation of tidal brackish emergent wetland habitat for California clapper rail or restoration activities resulting in barriers to movement would be minimized through sequencing of restoration activities to minimize effects of temporary habitat loss. In addition, *AMM19 California Clapper Rail* would avoid and minimize effects on California clapper rail.

NEPA Effects: The fragmentation of existing wetlands and creation of temporary barriers to movement would not represent an adverse effect on California clapper rail as a result of special-status species habitat modification because *CM4 Tidal Natural Communities Restoration* would be phased to allow for the recovery of some areas before restoration actions are initiated in other areas. In addition, *AMM19 California Clapper Rail* would avoid and minimize effects on California clapper rail.

***CEQA Conclusion*:** The fragmentation of existing wetlands and creation of temporary barriers to movement would represent a less-than-significant impact on California clapper rail as a result of habitat modification of a special status species because Tidal Natural Communities Restoration (CM4) would be phased to allow for the recovery of some areas before initiating restoration actions in other areas. In addition, In addition, *AMM19 California Clapper Rail* would avoid and minimize effects on California clapper rail.

California Least Tern

This section describe the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components on California least tern. California least tern modeled habitat identifies foraging habitat as all tidal perennial aquatic natural community in the study area. Breeding habitat is not included in the model because most of the natural shoreline in the study area that historically provided nesting sites has been modified or removed.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of California least tern modeled habitat as indicated in Table 12-9-27. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit California least tern (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore and protect at least 65,000 acres of tidal natural communities and transitional uplands to accommodate sea level rise (Objective L1.3, associated with CM4).
- Within the 65,000 acres of tidal natural communities and transitional uplands, restore or create tidal perennial aquatic natural community as necessary when creating tidal emergent wetland (Objective TPANC1.1, associated with CM4).
- Control invasive aquatic vegetation that adversely affects native fish habitat (Objective TPANC2.1, associated with CM13).

Least terns currently nest on artificial fill adjacent to tidal perennial aquatic habitat in the vicinity of Suisun Marsh and the west Delta, and additional nesting could occur at the edge of tidal perennial waters whenever disturbed or artificial sites mimic habitat conditions sought for nesting (i.e., sandy or gravelly substrates with sparse vegetation).

As explained below, with the restoration and protection of tidal perennial aquatic foraging habitat, in addition to natural community enhancement and management commitments (including CM12 *Methylmercury Management*) and implementation of AMM1–AMM7, *AMM27 Selenium Management*, and mitigation to avoid impacts on terns should they nest in the study area, impacts on the

California least tern would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-27. Changes in California Least Tern Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent NT	Permanent LLT[c]	Temporary NT	Temporary LLT[c]	Periodic[d] CM2	Periodic[d] CM5

Total Impacts CM2–CM18		**38**	**46**	**11**	**16**	**NA**	**NA**
TOTAL IMPACTS		**713**	**721**	**356**	**361**	**NA**	**NA**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-66: Loss or Conversion of Habitat for and Direct Mortality of California Least Tern

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 1,082 acres of modeled foraging habitat for California least tern, consisting of 721 acres of permanent loss and 361 acres of temporary loss (Table 12-9-27). The conservation measures that would result in these losses are construction of water conveyance facilities and operation (CM1), Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), and floodplain restoration (CM5). The majority of the permanent and temporary losses would occur during the first 10 years of BDCP implementation, as water conveyance facilities are constructed and habitat restoration is initiated. The majority of the permanent and temporary losses would occur during the first 10 years of BDCP implementation, as water conveyance facilities are constructed and habitat restoration is initiated. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could also result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate California least tern foraging habitat. Each of these individual activities is described below. A summary statement of the combined impacts, NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 1,020 acres of modeled California least tern aquatic foraging habitat (Table 12-9-27). Of the 1,020 acres of modeled habitat that would be removed for the construction of the conveyance facilities, 345 acres would be a temporary loss. Permanent impacts on California least tern foraging habitat would include canal Construction, dredging for channel enlargement, and operable barrier construction. However, impacts would not permanently remove the waterways, but would permanently modify the channel bottoms and eliminate any associated aquatic vegetation. The temporary effects on California least tern foraging habitat would occur primarily along the channels of the Middle River and Victoria Canal, where temporary work areas would be needed to support channel dredging operations. Several smaller temporary impact areas would occur where barge operations areas would be developed. The CM1 footprint does not overlap with any California least tern occurrences. Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized,* (described below) would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address potential effects on terns were they to nest in the vicinity of the construction footprint. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of Yolo Bypass fisheries enhancement would result in the permanent loss of 8 acres and the temporary loss of 11 acres of modeled aquatic foraging habitat for California least tern in CZ 2. Activities from Fremont and Sacramento Weir improvements, Putah Creek realignment, and Lisbon Weir modification could involve excavation and grading in tidal perennial aquatic areas to improve passage of fish through the bypasses. The loss is expected to occur during the first 10 years of Alternative 9 implementation.
- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration actions would result in the permanent loss of 36 acres of modeled aquatic foraging habitat for California least tern. An estimated 65,000 acres of tidal wetlands would be restored during tidal habitat restoration, consistent with BDCP Objective L1.3. Of these acres, an estimated 27,000 acres of tidal perennial aquatic would be restored, based on modeling conducted by ESAPWA (refer to Table 5 in BDCP Appendix 3.B, *BDCP Tidal Habitat Evolution Assessment*). This restoration is consistent with BDCP Objective TPANC1.1. Tidal perennial aquatic restoration would be expected to substantially increase the primary productivity of fish, increasing the prey base for California least tern. Approximately 3,400 acres of the restoration would happen during the first 10 years of BDCP implementation, which would coincide with the timeframe of water conveyance facilities construction. The remaining restoration would be phased over the following 30 years. Some of the restoration would occur in the lower Yolo Bypass, but restoration would also be spread among the Suisun Marsh, South Delta, Cosumnes/Mokelumne and West Delta ROAs.
- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain would result in the permanent loss of 2 acres and the temporary loss of 5 acres of modeled aquatic foraging habitat for California least tern. This activity is scheduled to start following construction of water conveyance facilities, which is expected to take 10 years. Specific locations for the floodplain restoration have not been identified, but it is expected that much of the activity would occur in the south Delta along the major rivers.
- *CM11 Natural Communities Enhancement and Management*: Noise and visual disturbances during implementation of habitat management actions could result in temporary disturbances that affect California least tern use of the surrounding habitat. These effects cannot be quantified, but are expected to be minimal because few management activities would be implemented in aquatic habitat and because terns are not expected to nest on protected lands.

Surveys would be conducted prior to ground disturbance in any areas that have suitable nesting substrate for California least tern (flat, unvegetated areas near aquatic foraging habitat) and injury mortality and noise and visual disturbance of nesting terns would be avoided and minimized by the AMMs and Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized*, described below.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic postconstruction disturbances, localized impacts on California least tern foraging habitat, and temporary noise and disturbances over the term of the BDCP. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas which could be adjacent to California least tern foraging habitat. These effects, however, would be reduced by AMMs listed below.
- Injury and Direct Mortality: California least terns currently nest in the vicinity of potential restoration sites in Suisun Marsh and west Delta area (CZ 10 and CZ 11). New nesting colonies could establish if suitable nesting habitat is created during restoration activities (e.g., placement of unvegetated fill to raise surface elevations prior to breaching levees during restoration efforts). If nesting occurs where covered activities are undertaken, the operation of equipment for land clearing, construction, conveyance facilities operation and maintenance, and habitat restoration, enhancement, and management could result in injury or mortality of California least tern. Risk of injury or disturbance would be greatest to eggs and nestlings susceptible to land-clearing activities, abandonment of nests and nesting colonies, or increased exposure to the elements or to predators. Injury to adults or fledged juveniles is less likely as these individuals would be expected to avoid contact with construction equipment. However, injury or mortality would be avoided through planning and preconstruction surveys to identify nesting colonies, the design of projects to avoid locations with least tern colonies, and the provision for 500-foot buffers as required by Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized*.

The following paragraph summarizes the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. With Alternative 9 implementation, there would be a loss of 1,069 acres of modeled foraging habitat for California least tern in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,020 acres), and implementing other conservation measures (Yolo Bypass fisheries improvements [CM2], and tidal habitat restoration [CM4] - 49 acres). All modeled foraging habitat impacts would occur in tidal perennial aquatic natural communities.

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected by CM1 would be 1:1 for restoration/creation of tidal perennial aquatic habitat. Using this ratio would indicate that 1,069 acres of the tidal perennial aquatic natural community should be restored/created to compensate for the CM1 losses of California least tern foraging habitat. The near-term effects of other conservation actions would remove 49 acres of tidal perennial aquatic habitat, and therefore require 49 acres of tidal perennial aquatic natural community restoration using the same typical NEPA and CEQA ratio (1:1 for restoration).

The BDCP has committed to near-term goals of restoring 19,150 acres of tidal natural communities in the Plan Area through *CM4 Tidal Natural Communities Restoration* (Table 3-4 in Chapter 3, *Description of Alternatives*).This conservation action would result in the creation of approximately 3,400 acres of high quality tidal perennial aquatic natural community, based on modeling conducted by ESAPWA (refer to Table 5 in BDCP Appendix 3.B, *BDCP Tidal Habitat Evolution Assessment*) (Tidal perennial aquatic) restoration would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects on California least tern from loss of foraging habitat.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3, Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats at or adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

The California least tern is not a species that is covered under the BDCP. Although nesting by California least tern is not expected to occur, restoration sites could attract individuals wherever disturbed or artificial sites mimic habitat conditions sought for nesting (i.e., sandy or gravelly substrates with sparse vegetation). If nesting were to occur, construction activities could have an adverse effect on California least tern. Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall be Avoided and Indirect Effects on Colonies Will be Minimized*, would be available to address this adverse effect on nesting California least terns.

Late Long-Term Timeframe

The habitat model indicates that the study area supports approximately 86,263 acres of foraging habitat for California least tern. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 1,082 acres of foraging habitat during the term of the Plan (1% of the total habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM4 Tidal Natural Communities Restoration* would restore an estimated 27,000 acres of high quality tidal perennial aquatic natural community would be restored (estimated from Table 5 in BDCP Appendix 3.B, *BDCP Tidal Habitat Evolution Assessment*). The restoration would occur over a wide region of the study area, including within the Suisun Marsh, Cosumnes/Mokelumne, Cache Creek, and South Delta ROAs (see Figure 12-1).

NEPA Effects: The loss of California least tern foraging habitat and potential direct mortality associated with Alternative 9 would represent an adverse effect in the absence of other conservation actions. Although nesting by California least tern is not expected to occur, restoration sites could attract individuals wherever disturbed or artificial sites mimic habitat conditions sought for nesting (i.e., sandy or gravelly substrates with sparse vegetation). If nesting were to occur, construction activities could have an adverse effect on California least tern. Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall be Avoided and Indirect Effects on Colonies will be Minimized*, would be available to address this adverse effect on nesting California least terns. With habitat restoration associated with CM4 and guided by *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan*, which would be in place throughout the construction period, the effects of Alternative 9 as a whole on California least tern would not be adverse under NEPA.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. With Alternative 9 implementation, there would be a loss of 1,069 acres of modeled foraging habitat for California least tern in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,020 acres), and implementing other conservation measures (Yolo Bypass fisheries improvements [CM2], and tidal habitat restoration [CM4] - 49 acres). All modeled foraging habitat impacts would occur in tidal perennial aquatic natural communities.

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected by CM1 would be 1:1 for restoration/creation of tidal perennial aquatic habitat. Using this ratio would indicate that 1,069 acres of the tidal perennial aquatic natural community should be restored/created to compensate for the CM1 losses of California least tern foraging habitat. The near-term effects of other conservation actions would remove 49 acres of tidal perennial aquatic habitat, and therefore require 49 acres of tidal perennial aquatic natural community restoration using the same typical NEPA and CEQA ratio (1:1 for restoration).

The BDCP has committed to near-term goals of restoring 19,150 acres of tidal natural communities in the Plan Area through *CM4 Tidal Natural Communities Restoration* (Table 3-4 in Chapter 3). Modeling conducted by ESA PWA indicates that this conservation action would result in the creation of approximately 3,400 acres of high-value tidal perennial aquatic natural community (refer to Table 5 in BDCP Appendix 3.B, *BDCP Tidal Habitat Evolution Assessment*). Tidal perennial aquatic restoration would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects on California least tern.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM*2 *Construction Best Management Practices and Monitoring*, *AMM3, Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats at or adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Although nesting by California least tern is not expected to occur, restoration sites could attract individuals wherever disturbed or artificial sites mimic habitat conditions sought for nesting (i.e., sandy or gravelly substrates with sparse vegetation). If nesting were to occur, construction activities could have an adverse effect on California least tern. Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall be Avoided and Indirect Effects on Colonies will be Minimized*, would reduce the impact on nesting California least terns to a less-than-significant level.

The natural community restoration and protection activities would be concluded in the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for CEQA purposes. In addition, AMM1–AMM7 and Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall be Avoided and Indirect Effects on Colonies will be Minimized*, would avoid and minimize potential impacts on the species from construction-related habitat loss and noise and disturbance. Because the number of acres required to meet the typical mitigation ratio described above would be only 2,309 acres of restored tidal perennial aquatic habitat, the 3,400 acres of tidal perennial aquatic restoration estimated in the near-term, are more than sufficient to support the conclusion that the near-term impacts of habitat loss and direct mortality under Alternative 9 would be less than significant under CEQA.

Late Long-Term Timeframe

The habitat model indicates that the study area supports approximately 86,263 acres of foraging habitat for California least tern. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 1,082 acres of foraging habitat during the term of the Plan (1% of the total habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM4 Tidal Natural Communities Restoration* to restore an estimated 27,000 acres of high-value tidal perennial aquatic natural community (estimated from Table 5 in BDCP Appendix 3.B, *BDCP Tidal Habitat Evolution Assessment*). The restoration would occur over a wide region of the study area, including within the Suisun Marsh, Cosumnes/Mokelumne, Cache Creek, and South Delta ROAs (see Figure 12-1).

In the absence of other conservation actions, the loss of California least tern foraging habitat and potential direct mortality associated with Alternative 9 would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality. Although nesting by California least tern is not expected to occur, restoration sites could attract individuals wherever disturbed or artificial sites mimic habitat conditions sought for nesting (i.e., sandy or gravelly substrates with sparse vegetation). If nesting were to occur, construction activities could have a significant impact on California least tern. The loss of California least tern foraging habitat and potential direct mortality associated with Alternative 9 would represent a significant impact in the absence of other conservation actions. However, with habitat restoration associated with CM4, and guided by *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and with implementation of Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized*, the loss of habitat or mortality under this alternative would have a less-than-significant impact on California least tern.

Mitigation Measure BIO-66: California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized

If suitable nesting habitat for California least tern (flat unvegetated areas near aquatic foraging habitat) is identified during planning level surveys, DWR will ensure that a qualified biologist with experience observing the species and its nests conducts at least three preconstruction surveys for this species during the nesting season. DWR will design projects to avoid the loss of California least tern nesting colonies. No construction will take place within 500 feet of California least tern nests during the nesting season (April 15 to August 15 or as determined through surveys). Only inspection, maintenance, research, or monitoring activities may be performed during the least tern breeding season in areas within or adjacent to least tern breeding habitat with USFWS and CDFW approval under the supervision of a qualified biologist.

Impact BIO-67: Indirect Effects of Plan Implementation on California Least Tern

Indirect Construction- and Operation-Related Effects: Indirect effects associated with construction that could affect California least tern include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 500 feet from the construction edge. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect California least tern. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect California least tern or their prey species in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to foraging habitat could also affect the species. Noise and visual disturbance is not expected to have an adverse effect on California least tern foraging behavior. As described in Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized*, if least tern nests were found during planning or preconstruction surveys, no construction would take place within 500 feet of active nests. In addition, AMM1–AMM7, including construction best management practices, would minimize the likelihood of spills from occurring or excessive dust being created during construction. Should a spill occur, implementation of these AMMs would greatly reduce the likelihood of individuals being affected.

Methylmercury Exposure: Covered activities have the potential to exacerbate the bioaccumulation of mercury in the California least tern. The operational impacts of new flows under CM1 were analyzed using a DSM-2 based model to assess potential effects on mercury concentration and bioavailability. Largemouth bass were used as a surrogate species for this analysis and results would be expected to be similar or lower for the California least tern. Results indicated that changes in total mercury levels in water and large mouth bass tissues were insignificant (see BDCP Appendix 5.D, Tables 5D.4-3, 5D.4-4, and 5D.4-5).

Marsh (tidal and nontidal) and floodplain restoration also have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury. Increased methylmercury associated with natural community and floodplain restoration may indirectly affect California least tern, via uptake through consumption of prey (as described in BDCP Appendix 5.D, *Contaminants*).

Schwarzbach and Adelsbach (2003) investigated mercury exposure in 15 species of birds inhabiting the Bay-Delta ecosystem. Among the species studied, the highest concentrations of mercury were found in the eggs of piscivorous birds (terns and cormorants) that bioaccumulate mercury from their fish prey. The very highest concentrations were found in Caspian and Forster's terns, especially those inhabiting South San Francisco Bay. Based on three California least tern eggs collected from Alameda Naval Air Station in the San Francisco Central Bay, concentrations in California least tern eggs were a third (0.3 ppm) those of the eggs of the other two terns. Because of the small sample size, there is a high degree of uncertainty regarding the levels of mercury that may be present in California least tern eggs. If the mercury levels measured at Alameda Naval Air Station are representative of the population in the San Francisco Bay, they would not be expected to result in adverse effects on tern hatchlings. Hatching and fledging success were not reduced in common tern eggs in Germany with mercury concentrations of 6.7 ppm (Hothem and Powell 2000).

Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury. Given that some species have elevated mercury tissue levels pre-BDCP, these low level increases could result in some level of effects. CM12, described below, will be implemented to address this risk of low level increases in methylmercury which could add to the current elevated tissue concentrations.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including California least tern. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on California least tern.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on California least tern from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Noise and visual disturbances within 500 feet of construction-related activities from the CMs could disturb California least tern foraging habitat adjacent to work sites. Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized*, would be available to address this potential adverse effect. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of spills from occurring and ensure that measures were in place to prevent runoff from the construction area and to avoid negative effects of dust on the species. Tidal habitat restoration could result in increased exposure of California least tern to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Changes in water operations under CM1 would not be expected to result in increased mercury bioavailability or exposures to Delta foodwebs. Tidal habitat restoration could result in increased exposure of California least tern to methylmercury. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, it is unknown what concentrations of methylmercury are harmful to the species, and the potential for increased exposure varies substantially within the study area. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

CEQA Conclusion: Noise and visual disturbances within 500 feet of construction-related activities from the CMs could disturb California least tern foraging habitat adjacent to work sites. Implementation of Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized*, would avoid this potential adverse effect.

AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of spills from occurring and ensure that measures were in place to prevent runoff from the construction area and to avoid negative effects of dust on the species.

Tidal habitat restoration could result in increased exposure of California least tern to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Changes in water operations under CM1 would not be expected to result in increased mercury bioavailability or exposures to Delta foodwebs. Tidal habitat restoration could result in increased exposure of California least tern to methylmercury. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, it is unknown what concentrations of methylmercury are harmful to the species, and the potential for increased exposure varies substantially within the study area. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

With AMM1-7, AMM12, AMM27, and CM12 in place, in addition to the implementation of Mitigation Measure BIO-66, the indirect effects of plan implementation would not result in a substantial adverse effect on the species through habitat modification or potential mortality of a special-status species. Therefore, the indirect effects of Alternative 9 implementation would have a less-than-significant impact on California least tern.

Mitigation Measure BIO-66, California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized

See Mitigation Measure BIO-66 under Impact BIO-66.

Impact BIO-68: Effects on California Least Tern Associated with Electrical Transmission Facilities

The risk of mortality of California least tern from the construction of new transmission lines is considered to be minimal based on tern flight behaviors and its unlikely use of habitats near the transmission line corridors. Terns exhibit low wing loading and high aspect-ratio wings and as a result can maneuver relatively quickly around an obstacle such as a transmission line. Their wing structure and design allows for rapid flight and quick, evasive actions (see BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new project transmission lines would be fitted with flight diverters. Bird flight diverters would make transmission lines highly visible to California least terns and would substantially reduce the potential for powerline collisions.

NEPA Effects: The construction and presence of new transmission lines would not represent an adverse effect on California least tern as a result of direct mortality of a special-status species because they are uncommon in the vicinity of proposed transmission lines and because the probability of bird-powerline strikes is highly unlikely due to tern flight behaviors. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. With implementation of *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines would not result in an adverse effect on California least tern.

CEQA Conclusion: The construction and presence of new transmission lines would represent a less-than-significant impact on California least tern as a result of direct mortality of a special-status species because they are uncommon in the vicinity of proposed transmission lines and because the probability of bird-powerline strikes is highly unlikely due to tern flight behaviors. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. With implementation of *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines would result in a less-than-significant impact on California least tern.

Greater Sandhill Crane

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on greater sandhill crane. Greater sandhill cranes in the Plan Area are almost entirely dependent on privately owned agricultural lands for foraging. Long-term sustainability of the species is thus dependent on providing a matrix of compatible crop types that afford suitable foraging habitat and maintaining compatible agricultural practices, while sustaining and increasing the extent of other essential habitat elements such as night roosting habitat. The habitat model for greater sandhill crane includes “roosting and foraging” and “foraging” habitat. These habitat types include certain agricultural types, specific grassland types, irrigated pastures and hay crops, managed seasonal wetland, and other natural seasonal wetland. Roosting and foraging habitat includes known, traditional roost sites that also provide foraging habitat (BDCP Appendix 2.A, *Covered Species Accounts*). Both temporary and permanent roost sites were identified for greater Sandhill crane. Permanent roosting and foraging sites are those used regularly, year after year, while temporary roosting and foraging sites are those used in some years. Factors included in assessing the value of affected habitat for the greater sandhill crane includes the relative habitat value of specific crop or land cover types, and proximity to known roost sites. Foraging habitat for greater sandhill crane included crop types and natural communities up to 4 miles from known roost sites, within the boundary of the winter crane use area (BDCP Appendix 2A).

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of foraging and roosting habitat for greater sandhill crane as indicated in Table 12-9-28. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit the greater sandhill crane (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect at least 7,300 acres of high- to very high-value habitat for greater sandhill crane, with at least 80% maintained in very high-value types in any given year. This protected habitat would be within 2 miles of known roosting sites in CZs 3, 4, 5, and/or 6. Selection of protected habitat locations would consider sea level rise and local seasonal flood events, greater sandhill crane population levels, and the location of foraging habitat loss. Patch size of protected cultivated lands will be at least 160 acres (Objective GSHC1.1, associated with CM3).

- To create additional high-value greater sandhill crane winter foraging habitat, 10% of the habitat protected under Objective GSHC1.1 would involve acquiring low-value habitat or nonhabitat areas and converting them to high- or very high-value habitat. Habitat would be created within 2 miles of known roosting sites in CZs 3, 4, 5, and/or 6. Selection of protected habitat locations would consider sea level rise and local seasonal flood events, greater sandhill crane population levels, and the location of foraging habitat loss (Objective GSHC1.2, associated with CM3).
- Create at least 320 acres of managed wetlands in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6, with consideration of sea level rise and local seasonal flood events. The wetlands would be located within 2 miles of existing permanent roost sites and protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of 2:1 upland to wetland to provide buffers around the wetlands (Objective GSHC1.3, associated with CM3).
- Create at least two 90-acre wetland complexes within the Stone Lakes NWR project boundary. The complexes would be no more than 2 miles apart and would help provide connectivity between the Stone Lakes and Cosumnes greater sandhill crane populations. Each complex would consist of at least three wetlands totaling at least 90 acres of greater sandhill crane roosting habitat, and would be protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of at least 2:1 uplands to wetlands (i.e., two sites with at least 90 acres of wetlands each). One of the 90-acre wetland complexes may be replaced by 180 acres of cultivated lands (e.g., cornfields) that would be flooded following harvest to support roosting cranes and provide highest-value foraging habitat, provided such substitution is consistent with the long-term conservation goals of Stone Lakes NWR for greater sandhill crane (Objective GSHC1.4, associated with CM10).
- Create an additional 95 acres of roosting habitat within 2 miles of existing permanent roost sites. The habitat would consist of active cornfields that are flooded following harvest to support roosting cranes and that provide highest-value foraging habitat. Individual fields would be at least 40 acres and locations may be shifted throughout the Greater Sandhill Crane Winter Use Area, but would be sited with consideration of the location of roosting habitat loss and would be in place prior to roosting habitat loss (Objective GSCH1.5, associated with CM3).
- Protect at least 48,625 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species (Objective CLNC1.1, associated with CM3).
- Target cultivated land conservation to provide connectivity between other conservation lands (Objective CLNC1.2, associated with CM3).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the reserve system, including water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).

As explained below, with the restoration and protection of these amounts of habitat, in addition to natural community enhancement and management commitments (including *CM12 Methylmercury Management*) and implementation of AMM1–AMM7, *AMM20 Greater Sandhill Crane*, *AMM27*

*Selenium Managemen*t, and *AMM30 Transmission Line Design and Alignment Guidelines*, impacts on the greater sandhill crane would be less than significant for CEQA purposes.

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-69: Loss or Conversion of Habitat for and Direct Mortality of Greater Sandhill Crane

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 66 acres of modeled roosting and foraging habitat for greater sandhill crane (41 acres of permanent loss and 25 acres of temporary loss) and 4,956 acres of foraging habitat for greater sandhill crane (4,404 of permanent loss, 552 acres of temporary loss, Table 12-9-28). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Tidal Natural Communities Restoration (CM4), Grassland Natural Community Restoration (CM8), Nontidal Marsh Natural Community Restoration (CM10), and Natural Communities Enhancement and Management

(CM11). The majority of habitat loss would result from water conveyance facility construction and conversion of habitat to tidal natural communities through CM4. Habitat enhancement and management activities through CM11, which include ground disturbance or removal of nonnative vegetation, could also result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate greater sandhill crane modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts, NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities as they are currently designed would result in the permanent loss of up to 37 acres of modeled greater sandhill crane foraging habitat. Foraging habitat that would be permanently impacted by CM1 would consist of 1 acre of very high-value, 0 acres of high-value, and 9 acres of medium-value foraging habitat (Table 12-9-29). Permanent loss of foraging habitat would result from intake and fish screen construction, channel enlargement, and transmission line construction in CZ 4, 5, and 6. Fish barrier construction would permanently impact foraging habitat in CZ 6 on Bradford Island, Bacon Island, north of Woodward Island, and between Mandeville and Bradford Island. In addition, 25 acres of temporary roosting and foraging habitat, and 552 acres of foraging habitat would be temporarily removed (Table 12-9-28). Temporary habitat loss would primarily result from potential borrow and spoil areas (367 acres) and work areas for the above construction activities. The temporarily removed habitat would consist primarily of cultivated lands and it would be restored within 1 year following construction. However, it would not necessarily be restored to its original topography and it could be restored as grasslands in the place of cultivated lands.

  The temporary roosting and foraging habitat that would be temporarily impacted is located on the east side of Bradford Island. The temporary roost site would be impacted by a concrete batch plant, an operable barrier work area, and a borrow and spoil area. The implementation of *AMM20 Greater Sandhill Crane* would require that all CM1 activities be designed to avoid direct loss of crane roost sites. Avoidance of crane roost sites would be accomplished either by siting activities outside of identified roost sites or by relocating the roost site if it consisted of cultivated lands (roost sites consisting of wetlands would not be subject to re-location). Relocated roost sites would be established prior to construction activities affecting the original roost site (as described for *AMM20 Greater Sandhill Crane* in Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Therefore there would be no loss of crane roosting and foraging habitat as a result of water conveyance facility construction once the facilities were fully designed. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations.

Table 12-9-29. Total Amount of Greater Sandhill Crane Foraging Habitat Affected under Alternative 9

Foraging Habitat Value Class	Land Cover Type	Acres Affected by CM1 permanent (temporary)	Acres Affected by CM2–CM18 permanent (temporary)
Very high	Corn, rice	1 (51)	1,155 (0)
High	Wheat, managed wetlands,	0 (8)	489 (0)
Medium	Alfalfa and alfalfa mixtures, irrigated mixed pasture, irrigated native pasture, irrigated pasture, irrigated other pasture, grain and hay crops, miscellaneous grain and hay, mixed grain and hay, nonirrigated mixed grain and hay, other grain crops, sudan, miscellaneous grasses, grassland, alkali seasonal wetlands, vernal pool complex	9 (348)	1,403 (0)
Low	Other irrigated crops, idle cropland, blueberries, asparagus, clover, cropped within the last 3 years, grain sorghum, green beans, miscellaneous truck, miscellaneous field, new lands being prepped for crop production, nonirrigated mixed pasture, nonirrigated native pasture, onions, garlic, peppers, potatoes, safflower, sugar beets, tomatoes (processing), melons squash and cucumbers all types, artichokes, beans (dry), native vegetation	27 (145)	1,320 (0)
Total		**37 (552)**	**4,367**

- *CM4 Tidal Natural Communities Restoration*: Based on the hypothetical tidal restoration footprint, this activity would result in the permanent loss or conversion of approximately 2,754 acres of greater sandhill crane habitat, consisting of 41 acres of temporary roosting and foraging habitat and 2,713 acres of foraging habitat. Loss of foraging habitat from CM4 would consist of 716 acres of very high-value, 304 acres of high value, 873acres of medium-value, and 821 acres of low-value foraging habitat This loss would occur in the Cosumnes-Mokelume River and West Delta ROAs. Tidal wetland restoration in CZ 4 could occur between the high crane use areas of the central Delta and the Cosumnes River Preserve. However, the conversion of grasslands and cultivated lands to tidal wetlands would not prohibit crane movement or reduce use of these areas. In CZ 5, loss of modeled habitat would occur along the western edge of the greater sandhill crane winter use area and therefore would not result in fragmentation of traditional crane habitats. Therefore fragmentation of habitat from tidal restoration activities would be expected to be minimal. Approximately 1,951 acres of foraging habitat would be impacted within the first 10 years of Alternative 9 implementation.
- *CM8 Grassland Natural Community Restoration*: Approximately 300 acres of cultivated lands that provide foraging habitat for greater sandhill crane would be converted to grassland by the late long-term timeframe. No roosting/foraging habitat would be impacted by grassland restoration activities. The restored grasslands would continue to provide foraging habitat value for the greater sandhill crane. Approximately 257 acres would be impacted within the first 10 years of Plan implementation.

- *CM10 Nontidal Marsh Restoration:* Nontidal marsh restoration would result in the permanent conversion of approximately 1,350 acres of modeled foraging habitat for the greater sandhill crane. A portion of the restored nontidal marsh would be expected to continue to provide roosting and foraging habitat value for the greater sandhill crane. However, some of this restored marsh would be unsuitable as it would lack emergent vegetation and consist of open water that would be too deep to provide suitable roosting or foraging habitat. Approximately 567 acres of habitat would be converted to nontidal marsh within the first 10 years of Alternative 9 implementation.
- *CM11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. The potential for these activities to result in direct mortality of greater sandhill crane would be minimized with the implementation of *AMM20 Greater Sandhill Crane*. CM11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. If new ground disturbance was necessary, greater sandhill crane habitat would be avoided, with the exception of a permanent loss of 4 acres of grassland foraging habitat (1 acre of which would be impacted within the first 10 years of Alternative 9 implementation).
- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect greater sandhill crane use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, could be adverse as sandhill cranes are sensitive to disturbance. However, impacts would be reduced by AMMs, and conservation actions as described below.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of greater sandhill crane if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. Potential effects would be avoided and minimized with the implementation of *AMM20 Greater Sandhill Crane*. The potential for injury and direct mortality from electrical transmission facilities is discussed below under Impact BIO-70.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Based on current design footprints, Alternative 9 would remove 25 acres roosting and foraging habitat (temporary loss from CM1) in the study area in the near-term. In addition, 3,364 acres of foraging habitat would be removed or converted in the near-term (CM1, 589 acres; *CM4 Tidal Natural Communities Restoration*, *CM8 Grassland Natural Community Restoration*, and *CM11 Natural Communities Enhancement and Management*—2,776 acres). Of these near-term acres of foraging habitat impact, 2,352 acres would be moderate- to very high-value habitat (CM1, 417 acres, CM4-11, 1,935 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 and that are identified in the biological goals and objectives for greater sandhill crane in Chapter 3 of the BDCP would be 1:1 protection and 1:1 restoration for loss of roost sites and 1:1 protection of high- to very high-value foraging habitat for loss of moderate- to very high-value foraging habitat. Using these ratios would indicate that 25 acres of greater roosting habitat should be restored/created and 25 acres should be protected to compensate for the CM1 losses of greater sandhill crane roosting and foraging habitat. In addition, 417 acres of high- to very high-value foraging habitat should be protected to mitigate the CM1 losses of greater sandhill crane moderate- to very high-value foraging habitat. The near-term effects of other conservation actions would remove 1,935 acres of moderate- to very high-value foraging habitat, and therefore require 1,935 acres of protection of high- to very high-value foraging habitat using the same typical NEPA and CEQA ratios (1:1 restoration and 1:1 protection for the loss of roosting and foraging habitat; 1:1 protection for the loss of foraging habitat).

The implementation of *AMM20 Greater Sandhill Crane* would require that no greater sandhill crane roost sites were directly impacted by CM1 covered activities (including transmission lines and their associated footprints). Therefore there would be no loss of crane roosting and foraging habitat as a result of water conveyance facility construction once the facilities were fully designed, which would avoid the CM1 impact on 25 acres of roosting and foraging habitat once the project design is final. Indirect effects of construction-related noise and visual disturbance are discussed below under Impact BIO-71.

The BDCP has committed to near-term goals of creating 500 acres of managed wetlands and protecting 15,600 acres of cultivated lands in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3 and CM10 and would occur in the same timeframe as the construction and early restoration losses. Up to 95 acres of roosting habitat would be created within 2 miles of existing permanent roost sites (Objective GSHC1.5). These roosts would consist of active cornfields that are flooded following harvest to support roosting cranes and also provide the highest-value foraging habitat for the species. Individual fields would be at least 40 acres could shift locations throughout the Greater Sandhill Crane Winter Use Area, and would be in place prior to roosting habitat loss. Of the 500 acres of managed wetlands to be created for roosting habitat, 320 acres would be created in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6 (Objective GSHC1.3). Restoration sites would be identified with consideration of sea level rise and local seasonal flood events. These wetlands would be created within 2 miles of existing permanent roost sites and protected in association with other protected natural community types at a ratio of 2:1 upland to wetland habitat to provide buffers that will protect cranes from the types of disturbances that would otherwise result from adjacent roads and developed areas (e.g., roads, noise, visual disturbance, lighting). The remaining 180 acres of crane roosting habitat would be constructed within the Stone Lakes NWR project boundary (BDCP Chapter 3, Figure 3.3-6) and would be designed to provide connectivity between the Stone Lakes and Cosumnes greater sandhill crane populations (Objective GSHC1.4). The large patch sizes of these wetland complexes would provide additional conservation to address the threats of vineyard conversion, urbanization to the east, and sea level rise to the west of greater sandhill crane wintering habitat.

At least 15,600 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1). Mitigation Measure BIO-69a, *Compensate for the Loss of Medium- to Very High-Value Greater Sandhill Crane Foraging Habitat*, would be available to guide the near-term protection of cultivated lands to ensure that the near-term impacts of moderate- to very high-value habitat for greater sandhill crane were compensated for with appropriate crop types and natural communities.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The study area supports approximately 23,919 acres of roosting and foraging habitat and 164,676 acres of foraging habitat for greater sandhill crane. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 66 acres of roosting and foraging habitat (less than 1% of the total habitat in the study area) and 4,956 acres of foraging habitat (3% of the total habitat in the study area) for the greater sandhill crane during the term of the Plan. The foraging habitat lost by the late long-term timeframe would consist of 3,464 acres of medium- to very high-value foraging habitat. The locations of these losses are described above in the analyses of individual conservation measures. The implementation of *AMM20 Greater Sandhill Crane* would require that no roost sites were directly affected by water conveyance facilities including transmission lines and associated footprints. In addition, temporarily removed habitat would be restored within 1 year following construction. However, it would not necessarily be restored to its original topography and it could result in the conversion of cultivated lands to grasslands.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration* and *CM10 Nontidal Marsh Restoration Restoration* to restore or create at least 595 acres of greater Sandhill crane roost habitat (Objectives GSHC1.3, GSHC1.4, and GSHC1.5) and to protect at least 7,300 acres of high- to very high-value foraging habitat for greater Sandhill crane (Objective GSHC1.1).

Of the 500 acres of managed wetlands to be created for roosting habitat, 320 acres would be created in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6 (Objective GSHC1.3). Restoration sites would be identified with consideration of sea level rise and local seasonal flood events. These wetlands would be created within 2 miles of existing permanent roost sites and protected in association with other protected natural community types at a ratio of 2:1 upland to wetland habitat to provide buffers that will protect cranes from the types of disturbances that would otherwise result from adjacent roads and developed areas (e.g., roads, noise, visual disturbance, lighting). The remaining 180 acres of crane roosting habitat would be constructed within the Stone Lakes NWRproject boundary (BDCP Chapter 3, Figure 3.3-6) and would be designed to provide connectivity between the Stone Lakes and Cosumnes greater sandhill crane populations (Objective GSHC1.4). These wetlands would consist of two 90-acre wetland complexes each consisting of at least three wetlands and would be no more than 2 miles apart. One of the 90-acre wetland complexes created under this objective could be replaced by 180 acres of cultivated lands (e.g., cornfields) that are flooded following harvest to support roosting cranes and provide highest-value foraging habitat, provided such substitution is consistent with the long-term conservation goals of Stone Lakes National Wildlife Refuge for greater sandhill crane. The large patch sizes of these wetland complexes would provide additional conservation to address the threats of vineyard conversion, urbanization to the east, and sea level rise to the west of greater sandhill crane wintering habitat.

To compensate for near-term impacts on crane roosting and foraging habitat, 95 acres of roosting habitat would be created within 2 miles of existing permanent roost sites (Objective GSHC1.5). These roosts would consist of active cornfields that are flooded following harvest to support roosting cranes and also provide the highest-value foraging habitat for the species. Individual fields would be at least 40 acres could shift locations throughout the Greater Sandhill Crane Winter Use Area, but would be sited with consideration of the location of roosting habitat loss and would be in place prior to roosting habitat loss.

The BDCP has committed to protecting 7,300 acres of high- to very high-value greater sandhill crane foraging habitat by the late long-term timeframe with at least 80% maintained in very-high value types in any given year (Objective GSHC1.1). To create additional high-value foraging habitat in the study area, 10% of these acres of protected foraging habitat would result from the conversion of low-value or nonhabitat areas to high- or very high-value habitat (Objective GSHC1.2). These acres of protected foraging habitat would be located within 2 miles of known roosting sites in CZs 3, 4, 5, and/or 6 and would consider sea level rise and local seasonal flood events, greater Sandhill crane population levels, and the location of foraging habitat loss. The patch size of these protected lands would be at least 160 acres (Objectives GSHC1.1 and GSHC1.2). Because agricultural habitat values change over time based largely on economically driven agricultural practices, protecting crane habitat would provide enhanced stability to agricultural habitat value within the crane use area that does not currently exist.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

***CEQA Conclusion*:**

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the impacts of construction would be less than significant. Based on current design footprints, Alternative 9 would remove 25 acres roosting and foraging habitat (temporary loss from CM1) in the study area in the near-term. In addition, 3,364 acres of foraging habitat would be removed or converted in the near-term (CM1, 589 acres; *CM4 Tidal Natural Communities Restoration*, *CM8 Grassland Natural Community Restoration*, and *CM11 Natural Communities Enhancement and Management*—2,776 acres). Of these near-term acres of foraging habitat impact, 2,352 acres would be moderate- to very high-value habitat (CM1, 417 acres, CM4-11, 1,935 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 and that are identified in the biological goals and objectives for greater sandhill crane in Chapter 3 of the BDCP would be 1:1 protection and 1:1 restoration for loss of roost sites and 1:1 protection of high- to very high-value foraging habitat for loss of moderate- to very high-value foraging habitat. Using these ratios would indicate that 25 acres of greater roosting habitat should be restored/created and 25 acres should be protected to compensate for the CM1 losses of greater sandhill crane roosting and foraging habitat. In addition, 417 acres of high- to very high-value foraging habitat should be protected to mitigate the CM1 losses of greater sandhill crane moderate- to very high-value foraging habitat. The near-term effects of other conservation actions would remove 1,935 acres of moderate- to very high-value foraging habitat, and therefore require 1,935 acres of protection of high- to very high-value foraging habitat using the same typical NEPA and CEQA ratios (1:1 restoration and 1:1 protection for the loss of roosting and foraging habitat; 1:1 protection for the loss of foraging habitat).

The implementation of *AMM20 Greater Sandhill Crane* would require that no greater sandhill crane roost sites were directly impacted by CM1 covered activities (including transmission lines and their associated footprints). Therefore there would be no loss of crane roosting and foraging habitat as a result of water conveyance facility construction once the facilities were fully designed, which would avoid the CM1 impact on 25 acres of roosting and foraging habitat once the project design is final. Indirect effects of construction-related noise and visual disturbance are discussed below under Impact BIO-71.

The BDCP has committed to near-term goals of creating 500 acres of managed wetlands and protecting 15,600 acres of cultivated lands in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3 and CM10 and would occur in the same timeframe as the construction and early restoration losses. Up to 95 acres of roosting habitat would be created within 2 miles of existing permanent roost sites (Objective GSHC1.5). These roosts would consist of active cornfields that are flooded following harvest to support roosting cranes and also provide the highest-value foraging habitat for the species. Individual fields would be at least 40 acres could shift locations throughout the Greater Sandhill Crane Winter Use Area, and would be in place prior to roosting habitat loss. Of the 500 acres of managed wetlands to be created for roosting habitat, 320 acres would be created in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6 (Objective GSHC1.3). Restoration sites would be identified with consideration of sea level rise and local seasonal flood events. These wetlands would be created within 2 miles of existing permanent roost sites and protected in association with other protected natural community types at a ratio of 2:1 upland to wetland habitat to provide buffers that will protect cranes from the types of disturbances that would otherwise result from adjacent roads and developed areas (e.g., roads, noise, visual disturbance, lighting). The remaining 180 acres of crane roosting habitat would be constructed within the Stone Lakes National Wildlife Refuge project boundary (BDCP Chapter 3, Figure 3.3-6) and would be designed to provide connectivity between the Stone Lakes and Cosumnes greater sandhill crane populations (Objective GSHC1.4). The large patch sizes of these wetland complexes would provide additional conservation to address the threats of vineyard conversion, urbanization to the east, and sea level rise to the west of greater sandhill crane wintering habitat.

At least 15,600 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1). Mitigation Measure BIO-69a would be available to guide the near-term protection of cultivated lands to ensure that the near-term impacts of moderate- to very high-value habitat for greater sandhill crane were compensated for with appropriate crop types and natural communities.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The study area supports approximately 23,919 acres of roosting and foraging habitat and 164,676 acres of foraging habitat for greater sandhill crane. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 66 acres of roosting and foraging habitat (less than 1% of the total habitat in the study area) and 4,956 acres of foraging habitat (3% of the total habitat in the study area) for the greater sandhill crane during the term of the Plan. The foraging habitat lost by the late long-term timeframe would consist of 3,464 acres of medium- to very high-value foraging habitat. The locations of these losses are described above in the analyses of individual conservation measures. The implementation of *AMM20 Greater Sandhill Crane* would require that no roost sites were directly affected by water conveyance facilities including transmission lines and associated footprints. In addition, temporarily removed habitat would be restored within 1 year following construction. However, it would not necessarily be restored to its original topography and it could result in the conversion of cultivated lands to grasslands.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration* and *CM10 Nontidal Marsh Restoration Restoration* to restore or create at least 595 acres of greater Sandhill crane roost habitat (Objectives GSHC1.3, GSHC1.4, and GSHC1.5) and to protect at least 7,300 acres of high- to very high-value foraging habitat for greater Sandhill crane (Objective GSHC1.1).

Of the 500 acres of managed wetlands to be created for roosting habitat, 320 acres would be created in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6 (Objective GSHC1.3). Restoration sites would be identified with consideration of sea level rise and local seasonal flood events. These wetlands would be created within 2 miles of existing permanent roost sites and protected in association with other protected natural community types at a ratio of 2:1 upland to wetland habitat to provide buffers that will protect cranes from the types of disturbances that would otherwise result from adjacent roads and developed areas (e.g., roads, noise, visual disturbance, lighting). The remaining 180 acres of crane roosting habitat would be constructed within the Stone Lakes NWRproject boundary (BDCP Chapter 3, Figure 3.3-6) and would be designed to provide connectivity between the Stone Lakes and Cosumnes greater sandhill crane populations (Objective GSHC1.4). These wetlands would consist of two 90-acre wetland complexes each consisting of at least three wetlands and would be no more than 2 miles apart. One of the 90-acre wetland complexes created under this objective could be replaced by 180 acres of cultivated lands (e.g., cornfields) that are flooded following harvest to support roosting cranes and provide highest-value foraging habitat, provided such substitution is consistent with the long-term conservation goals of Stone Lakes National Wildlife Refuge for greater sandhill crane. The large patch sizes of these wetland complexes would provide additional conservation to address the threats of vineyard conversion, urbanization to the east, and sea level rise to the west of greater sandhill crane wintering habitat.

To compensate for near-term impacts on crane roosting and foraging habitat, 95 acres of roosting habitat would be created within 2 miles of existing permanent roost sites (Objective GSHC1.5). These roosts would consist of active cornfields that are flooded following harvest to support roosting cranes and also provide the highest-value foraging habitat for the species. Individual fields would be at least 40 acres could shift locations throughout the Greater Sandhill Crane Winter Use Area, but would be sited with consideration of the location of roosting habitat loss and would be in place prior to roosting habitat loss.

The BDCP has committed to protecting 7,300 acres of high- to very high-value greater sandhill crane foraging habitat by the late long-term timeframe with at least 80% maintained in very-high value types in any given year (Objective GSHC1.1). To create additional high-value foraging habitat in the study area, 10% of these acres of protected foraging habitat would result from the conversion of low-value or nonhabitat areas to high- or very high-value habitat (Objective GSHC1.2). These acres of protected foraging habitat would be located within 2 miles of known roosting sites in CZs 3, 4, 5, and/or 6 and would consider sea level rise and local seasonal flood events, greater Sandhill crane population levels, and the location of foraging habitat loss. The patch size of these protected lands would be at least 160 acres (Objectives GSHC1.1 and GSHC1.2). Because agricultural habitat values change over time based largely on economically driven agricultural practices, protecting crane habitat would provide enhanced stability to agricultural habitat value within the crane use area that does not currently exist.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Considering Alternative 9's protection and restoration provisions, in addition to Mitigation Measure BIO-69a, which would compensate for the loss of medium- to very high-value foraging habitat at a ratio of 1:1 prior to or concurrent with impacts, loss of habitat and direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the alternative would have a less-than-significant impact on greater sandhill crane.

Mitigation Measure BIO-69a: Compensate for the loss of Medium to Very High-Value Greater Sandhill Crane Foraging Habitat

DWR will compensate for the loss of greater sandhill crane medium- to very high-value foraging habitat at a ratio of 1:1 by protecting or managing high- to very high-value habitat in the Plan Area. Compensation must occur prior to or concurrent within the impacts to minimize the effects of habitat loss. The crop types and natural communities that are included in foraging habitat value categories are listed in Table 12-9-29. Foraging habitat conservation must occur within the greater sandhill crane winter use area and the location of protected habitat or conservation easements must be preapproved by the USFWS and CDFW.

Impact BIO-70: Effects on Greater Sandhill Crane Associated with Electrical Transmission Facilities

Greater sandhill cranes are susceptible to collision with power lines and other structures during periods of inclement weather and low visibility (Avian Power Line Interaction Committee 1994, Brown and Drewien 1995, Manville 2005). There are extensive existing transmission and distribution lines in the sandhill crane winter use area. These include a network of distribution lines that are between 11- and 22-kV. In addition, there are two 115-kV lines that cross the study area, one that overlaps with the greater sandhill crane winter use area between Antioch and I-5 east of Hood, and one that crosses the northern tip of the crane winter use area north of Clarksburg. There are 69-kv lines within the study area that parallel Twin Cities Road, Herzog Road, Lambert Road, and the Southern Pacific Dredge Cut in the vicinity of Stone Lakes NWR. At the south end of the winter use area, there are three 230-kV transmission lines that follow I-5, and then cut southwest through Holt, and two 500-kV lines cross the southwestern corner of the winter use area. This existing network of power lines in the study currently poses a collision and electrocution risk for sandhill cranes, because they cross over or surround sandhill crane roost sites in the study area.

Both permanent and temporary electrical transmission lines would be constructed to supply construction and operational power to Alternative 9 facilities. The potential for birdstrikes could also be exacerbated by construction-related effects, especially in low-visibility conditions. The potential mortality of greater sandhill crane in the area of the proposed transmission lines under Alternative 9 was estimated using collision mortality rates by Brown and Drewien (1995) and an estimate of potential crossings along the proposed lines (methods are described in BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*). This analysis concluded that mortality risk could be substantially reduced by marking new transmission lines to increase their visibility to sandhill cranes.

Typically, higher-voltage (230-kV) lines vary in height from 90 to 110 feet, while subtransmission (69-kV) lines vary from 50 to 70 feet (Avian Power Line Interaction Committee 2006). The Alternative 9 alignment would primarily use existing transmission and distribution lines and would require the installation of approximately 42 miles of transmission line (3 miles of 60-kV line, 38 miles of 12-kV line, and 0.5 miles of 480-V line). These lines would occur in the vicinity of Walnut Grove and adjacent to fish screen and operable barrier structures throughout the CM1 footprint. Temporary lines would be removed after construction of the water conveyance facilities, within 10 years.

AMM30 Transmission Line Design and Alignment Guidelines would require design features for the transmission line alignment, such as co-locating transmission lines when it would minimize effects on sandhill cranes, to avoid impacts on sensitive habitats to the maximum extent feasible. After the

Draft EIR/EIS was issued in December 2013, additional avoidance features were added to *AMM20 Greater Sandhill Crane*. *AMM20 Greater Sandhill Crane* requires that Alternative 9 meet the performance standard of no mortality of greater sandhill crane associated with the new facilities. This would be achieved by implementing one or any combination of the following: 1) siting new transmission lines in lower bird strike risk zones; 2) removing, relocating or undergrounding existing lines where feasible; 3) using natural gas generators in lieu of installing transmission lines in high-risk zones of the greater sandhill crane winter use area; 4) undergrounding new lines in high-risk zones of the greater sandhill crane winter use area; 5) permanently installing flight diverters on existing lines over lengths equal to or greater than the length of the new transmission lines in the crane winter use area; 6) for areas outside of the Stone Lakes NWR project boundary, shifting locations of flooded areas that provide crane roosts to lower risk areas. These measures are described in detail in *AMM20 Greater Sandhill Crane* in Appendix 3B, *Environmental Commitments, AMMs, and CMs*.

The implementation of the measures (described above) under *AMM20 Greater Sandhill Crane* would substantially reduce the potential for crane collisions with transmission lines. Potential measures that would eliminate this risk include using natural gas generators in lieu of transmission lines or undergrounding new lines in high-risk zones in the greater sandhill crane winter use area. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality, including for sandhill cranes (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new transmission lines would be fitted with flight diverters. The installation of flight diverters on existing permanent lines would be prioritized in the highest risk zones for greater sandhill crane (as described in BDCP Appendix 5.J, Appendix 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*) and diverters would be installed in a configuration that research indicates would reduce bird strike risk by at least 60%. The length of existing line to be fitted with bird strike diverters will be equal to the length of new transmission lines constructed as a result of the project, in an area with the same or higher greater sandhill crane strike risk to provide a net benefit to the species. For optimum results, the recommended spacing distance for bird flight diverters is 15 to 16.5 feet (4.5 to 5 meters) (Avian Power Line Interaction Committee 1994). Placing diverters on existing lines would be expected to reduce existing mortality in the Plan Area and therefore result in a net benefit to the greater sandhill crane population because these flight diverters would be maintained in perpetuity.

NEPA Conclusion: Sandhill cranes are known to be susceptible to collision with overhead wires. The existing network of power lines in the study area currently poses a risk for sandhill cranes. The current proposed transmission line alignment under Alternative 9 is not fully designed, and line locations are not final. *AMM30 Transmission Line Design and Alignment Guidelines* would require design features for the transmission line alignment, such as co-locating transmission lines when it would minimize effects on sandhill cranes, to avoid impacts on sensitive habitats to the maximum extent feasible. The implementation of *AMM20 Greater Sandhill Crane* would require that the final transmission line alignment avoid crane roost sites and achieve the performance standard of no mortality of greater sandhill crane associated with the new facilities. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. With incorporation of *AMM30 Transmission Line Design and Alignment Guidelines* and one or a combination of the measures to greatly reduce the risk of bird strike described in *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines under Alternative 9 would not result in an adverse effect on greater sandhill crane.

CEQA Conclusion: Sandhill cranes are known to be susceptible to collision with overhead wires. The existing network of power lines in the study area currently poses a risk for sandhill cranes. The current proposed transmission line alignment under Alternative 9 is not fully designed, and line locations are not final. *AMM30 Transmission Line Design and Alignment Guidelines* would require design features for the transmission line alignment, such as co-locating transmission lines when it would minimize effects on sandhill cranes, to avoid impacts on sensitive habitats to the maximum extent feasible. The implementation of *AMM20 Greater Sandhill Crane* would require that the final transmission line alignment avoid crane roost sites and achieve the performance standard of no mortality of greater sandhill crane associated with the new facilities. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. With incorporation of *AMM30 Transmission Line Design and Alignment Guidelines* and one or a combination of the measures to greatly reduce the risk of bird strike described in *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines under Alternative 9 would have a less-than-significant impact on greater sandhill crane.

Impact BIO-71: Indirect Effects of Plan Implementation on Greater Sandhill Crane

Indirect Construction- and Operation-Related Effects: Sandhill cranes are sensitive to disturbance. Noise and visual disturbances from the construction of water conveyance facilities and other conservation measures could reduce greater sandhill crane use of modeled habitat adjacent to work areas. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet of the construction edge. Furthermore, maintenance of the aboveground water conveyance facilities could result in ongoing but periodic postconstruction noise and visual disturbances that could affect greater sandhill crane use of surrounding habitat. These effects could result from periodic vehicle use along the conveyance corridor, inspection and maintenance of aboveground facilities, and similar activities. These potential effects would be minimized with implementation of *AMM20 Greater Sandhill Crane* described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*.

The BDCP includes an analysis of the indirect effects of noise and visual disturbance that would result from the construction of the Alternative 4 water conveyance facilities on greater sandhill crane (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*). The same methods were employed to addresses the potential noise effects on cranes from Alternative 9 and to determine that as much as 1,217–5,108 acres of crane habitat could potentially be affected by general construction noise above baseline level (50–60 dBA). This would include 44 – 157 acres of temporary crane roosting habitat and 1,173 – 4,951 acres of crane foraging habitat. In addition, 0-40 acres of permanent crane roosting habitat, 38 – 688 acres of temporary crane roosting habitat, and 1,392 – 7,699 acres of crane foraging habitat could be affected by noise from pile driving that would be above baseline level (50–60dBA, Table 12-9-30). The analysis was conducted based on the assumption that there would be direct line-of-sight from sandhill crane habitat areas to the construction site, and, therefore, provides a worst-case estimate of effects. In many areas the existing levees would partially or completely block the line-of-sight and would function as effective noise barriers, substantially reducing noise transmission. However, there is insufficient data to assess the effects that increased noise levels would have on sandhill crane behavior.

Table 12-9-30. Greater Sandhill Crane Habitat Affected by General Construction and Pile Driving Noise Under Alternative 9 (acres)

	General Construction		Pile Driving	
Habitat Type	Above 60 dBA	Above 50 dBA	Above 60 dBA	Above 50 dBA
Permanent Roosting	0	0	0	40
Temporary Roosting	44	157	38	688
Foraging	1,173	4,951	1,392	7,699
Total Habitat	**1,217**	**5,108**	**1,430**	**8,426**

Evening and nighttime construction activities would require the use of extremely bright lights. Nighttime construction could also result in headlights flashing into roost sites when construction vehicles are turning onto or off of construction access routes. Proposed surge towers would require the use of safety lights that would alert low-flying aircraft to the presence of these structures because of their height. Little data is available on the effects of impact of artificial lighting on roosting birds. Direct light from automobile headlights has been observed to cause roosting cranes to flush and it is thought that they may avoid roosting in areas where lighting is bright (BDCP Chapter 5, *Effects Analysis*). If the birds were to roost in a brightly lit site, they may be vulnerable to sleep-wake cycle shifts and reproductive cycle shifts. Potential risks of visual impacts from lighting include a reduction in the cranes' quality of nocturnal rest, and effects on their sense of photo-period which might cause them to shift their physiology towards earlier migration and breeding (BDCP Chapter 5, *Effects Analysis*). Effects such as these could prove detrimental to the cranes' overall fitness and reproductive success (which could in turn have population-level impacts). A change in photo-period interpretation could also cause cranes to fly out earlier from roost sites to forage and might increase their risk of power line collisions if they were to leave roosts before dawn (BDCP Chapter 5, *Effects Analysis*).

The effects of noise and visual disturbance on greater sandhill crane would be minimized through the implementation of *AMM20 Greater Sandhill Crane* (Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Activities within 0.75 mile of crane roosting habitat would reduce construction noise during night time hours (from one hour before sunset to one hour after sunrise) such that construction noise levels do not exceed 50 dBA L_{eq} (1 hour) at the nearest temporary or permanent roosts during periods when the roost sites are available (flooded). In addition, the area of crane foraging habitat that would be affected during the day (from one hour after sunrise to one hour before sunset) by construction noise exceeding 50 dBA L_{eq} (1 hour) would also be minimized. Unavoidable noise related effects would be compensated for by the enhancement of 0.1 acre of foraging habitat for every acre indirectly affected within the 50 dBA L_{eq} (1 hour) construction noise contour. With these measures in place, indirect effects of noise and visual disturbance from construction activities are not expected to reduce the greater sandhill crane population in the study area.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect greater sandhill crane in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to greater sandhill crane habitat could also affect the species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills and ensure that measures were in place to prevent runoff from the construction area and negative effects of dust on foraging habitat.

Methylmercury Exposure: Largemouth bass was used as a surrogate species for analysis (Appendix 11F, *Substantive BDCP Revisions*). Results of the quantitative modeling of mercury effects on largemouth bass as a surrogate species would overestimate the effects on greater sandhill crane. Organisms feeding within pelagic-based (algal) foodwebs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic foodwebs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009). Therefore, potential indirect effects of increased mercury exposure is likely low for greater sandhill crane because they primarily forage on cultivated crops. Modeled effects of mercury concentrations from changes in water operations under CM1 on largemouth bass did not differ substantially from existing conditions; therefore, results also indicate that greater sandhill crane tissue concentrations would not measurably increase as a result of CM1 implementation.

Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury. Increased methylmercury associated with natural community and floodplain restoration may indirectly affect greater sandhill crane via uptake in lower trophic levels (see Appendix 5.D, *Contaminants*, of the BDCP). Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury. Given that some species have elevated mercury tissue levels pre-BDCP, these low level increases could result in some level of effects.

Due to the complex and very site-specific factors that determine if mercury becomes mobilized into the foodweb, *CM12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. CM12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This conservation measure would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including greater sandhill crane. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy,* for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4–CM5) would lead to adverse effects on greater sandhill crane.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on greater sandhill crane from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Crane habitat could potentially be affected by general construction noise above baseline level (50–60 dBA). Construction in certain areas would take place 7 days a week and 24 hours a day and evening and nighttime construction activities would require the use of extremely bright lights, which could adversely affect roosting cranes by impacting their sense of photo-period and by exposing them to predators. Effects of noise and visual disturbance could substantially alter the suitability of habitat for greater sandhill crane. *AMM20 Greater Sandhill Crane* would include requirements (described above) to minimize the effects of noise and visual disturbance on greater sandhill cranes and to mitigate effects on habitat.

Tidal habitat restoration could result in increased exposure of greater sandhill crane to selenium which could result in the potential mortality of a special-status species. This effect would be addressed through the implementation of *AMM27 Selenium Management,* which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of greater sandhill crane to methylmercury. The potential indirect effects of increased mercury exposure is likely low for greater sandhill crane because they primarily forage on cultivated crops. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

CEQA Conclusion: Crane habitat could potentially be affected by general construction noise and pile driving above baseline level (50–60 dBA). Construction in certain areas would take place 7 days a week and 24 hours a day and evening and nighttime construction activities would require the use of extremely bright lights, which could adversely affect roosting cranes by impacting their sense of photo-period and by exposing them to predators. Effects of noise and visual disturbance could substantially alter the suitability of habitat for greater sandhill crane. This would be a significant impact. *AMM20 Greater Sandhill Crane* would include requirements (described above) to minimize the effects of noise and visual disturbance on greater sandhill cranes and to mitigate effects on habitat.

Tidal habitat restoration could result in increased exposure of greater sandhill crane to selenium which could result in the potential mortality of a special-status species. This would be a significant impact. This effect would be addressed through the implementation of *AMM27 Selenium Management,* which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Methylmercury tissue concentrations in greater sandhill cranes would not be expected to measurably increase as a result of water operations under CM1 compared to the No Action Alternative. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of greater sandhill crane to methylmercury. This would be a significant impact. The potential indirect effects of increased mercury exposure is likely low for greater sandhill crane because they primarily forage on cultivated crops. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

With AMM1–AMM7, AMM20, AMM27, and CM12 in place, the indirect effects of plan implementation under Alternative 9 would not substantially reduce the number or restrict the range of greater sandhill cranes. Therefore, the indirect effects of Alternative 9 implementation would have a less-than-significant impact on greater sandhill crane.

Lesser Sandhill Crane

Lesser sandhill cranes in the Plan Area are almost entirely dependent on privately owned agricultural lands for foraging. Long-term sustainability of the lesser sandhill crane is thus dependent on providing a matrix of compatible crop types that afford suitable foraging habitat and maintaining compatible agricultural practices, while sustaining and increasing the extent of other essential habitat elements such as night roosting habitat. The habitat model for lesser sandhill crane identifies “roosting and foraging” and “foraging” habitat. These habitat types include suitable foraging and roosting habitat in the study area as certain agricultural types, specific grassland types, irrigated pastures and hay crops, managed seasonal wetland, and other natural seasonal wetland. Roosting and foraging habitat consists of traditional roost sites that are known to be used by sandhill cranes (both greater and lesser) and that provide foraging habitat. Detail regarding the roosting and foraging modeled habitat for both subspecies of sandhill crane is included in BDCP Appendix 2.A *Covered Species Accounts.* Both temporary and permanent roost sites were identified for sandhill cranes. Permanent roosting and foraging sites are those used regularly, year after year, while temporary roosting and foraging sites are those used in some years. The assessment of the loss of foraging habitat for the lesser sandhill crane considers the relative habitat value of specific crop or land cover types. Although both the greater and the lesser sandhill crane use similar crop or land cover types, these provide different values of foraging habitat for the two subspecies based on proportional use of these habitats. Lesser sandhill cranes are less traditional than greater sandhill cranes and are more likely to move between different roost site complexes and different wintering regions (Ivey pers. comm.) The wintering range is ten times larger than the greater sandhill crane and their average foraging flight radius from roost sites is twice that of greater sandhill cranes. Because of this higher mobility, lesser sandhill cranes are more flexible in their use of foraging areas than the greater sandhill crane.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of foraging and roosting habitat for lesser sandhill crane as indicated in Table 12-9-31. Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP that would benefit the lesser sandhill crane (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect at least 7,300 acres of high- to very high-value habitat for greater sandhill crane, with at least 80% maintained in very high-value types in any given year. Habitat would be protected within 2 miles of known roosting sites in CZs 3, 4, 5, and/or 6. The selection of protected habitat locations would consider sea level rise and local seasonal flood events, greater sandhill crane population levels, and the location of foraging habitat loss. Patch size of protected cultivated lands would be at least 160 acres (Objective GSHC1.1, associated with CM3).

- To create additional high-value greater sandhill crane winter foraging habitat, 10% of the habitat protected under Objective GSHC1.1 would involve acquiring low-value habitat or nonhabitat areas and converting it to high- or very high-value habitat. Habitat would be created within 2 miles of known roosting sites in CZs 3, 4, 5, and/or 6. The selection of areas in which habitat would be created would consider sea level rise and local seasonal flood events, greater sandhill crane population levels, and the location of foraging habitat loss (Objective GSHC1.2, associated with CM3).

- Create at least 320 acres of managed wetlands in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6, with consideration of sea level rise and local seasonal flood events. The wetlands would be located within 2 miles of existing permanent roost sites and protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of 2:1 upland to wetland to provide buffers around the wetlands (Objective GSHC1.3, associated with CM3).

- Create at least two 90-acre wetland complexes within the Stone Lakes NWR project boundary. The complexes would be no more than 2 miles apart and would help provide connectivity between the Stone Lakes and Cosumnes greater sandhill crane populations. Each complex would consist of at least three wetlands totaling at least 90 acres of greater sandhill crane roosting habitat, and would be protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of at least 2:1 uplands to wetlands (i.e., two sites with at least 90 acres of wetlands each). One of the 90-acre wetland complexes may be replaced by 180 acres of cultivated lands (e.g., cornfields) that are flooded following harvest to support roosting cranes and provide highest-value foraging habitat, provided such substitution is consistent with the long-term conservation goals of Stone Lakes NWR for greater sandhill crane. (Objective GSHC1.4, associated with CM10).

- Create an additional 95 acres of roosting habitat within 2 miles of existing permanent roost sites. The habitat would consist of active cornfields that are flooded following harvest to support roosting cranes and that provide highest-value foraging habitat. Individual fields would be at least 40 acres and can shift locations throughout the Greater Sandhill Crane Winter Use Area, but would be sited with consideration of the location of roosting habitat loss and would be in place prior to roosting habitat loss (Objective GSCH1.5, associated with CM3).
- Target cultivated land conservation to provide connectivity between other conservation lands (Objective CLNC1.2, associated with CM3).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the reserve system, including, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).

As explained below, with the restoration and protection of these amounts of habitat, in addition to natural community enhancement and management commitments (including *CM12 Methylmercury Management*) and implementation of AMM1–AMM7, *AMM20 Greater Sandhill Crane*, *AMM27 Selenium Management*, and *AMM30 Transmission Line Design and Alignment Guidelines*, impacts on the lesser sandhill crane would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-72: Loss or Conversion of Habitat for and Direct Mortality of Lesser Sandhill Crane

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 66 acres of modeled roosting and foraging habitat (41 acres of permanent loss and 25 acres of temporary loss) and 13,779 acres of foraging habitat (12,175 acres of permanent loss and 1,604 acres of temporary loss) for lesser sandhill crane Table 12-9-31). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass Fisheries Improvements (CM2), Tidal Natural Communities Restoration (CM4), Grassland Natural Community Restoration (CM8), Nontidal Marsh Natural Community Restoration (CM10), and Natural Communities Enhancement and Management (CM11). The majority of habitat loss would result from water conveyance facility construction and conversion of habitat to tidal natural communities through CM4. Habitat enhancement and management activities through CM11, which include ground disturbance or removal of nonnative vegetation, could also result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate lesser sandhill crane modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts, NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of Alternative 9 conveyance facilities as they are currently designed would result in the permanent loss of up to 44 acres of lesser sandhill crane foraging habitat. Foraging habitat that would be permanently impacted by CM1 would consist of 9 acre of very high-value, 2 acres of high-value, and 29 acres of medium-value foraging habitat (Table 12-9-32). Permanent loss of foraging habitat would result from intake and fish screen construction, channel enlargement, and transmission line construction in CZ 4, 5, and 6. Fish barrier construction would permanently impact foraging habitat in CZ 6 on Bradford Island, Bacon Island, north of Woodward Island, and between Mandeville and Bradford Island. In addition, 25 acres of temporary roosting and foraging habitat, and 1,600 acres of foraging habitat would be temporarily removed (Table 12-9-31). Temporary habitat loss would primarily result from potential borrow and spoil areas (1,278 acres) and work areas for the above construction activities. The temporarily removed habitat would consist primarily of cultivated lands and it would be restored within 1 year following construction. However, it would not necessarily be restored to its original topography and it could be restored as grasslands in the place of cultivated lands.

  The temporary roosting and foraging habitat that would be temporarily impacted is located on the east side of Bradford Island. The temporary roost site would be impacted by a concrete batch plant, an operable barrier work area, and a borrow and spoil area. The implementation of *AMM20 Greater Sandhill Crane* would require that all CM1 activities be designed to avoid direct loss of crane roost sites. Avoidance of crane roost sites would be accomplished either by siting activities outside of identified roost sites or by relocating the roost site if it consisted of cultivated lands (roost sites consisting of wetlands would not be subject to re-location). Relocated roost sites would be established prior to construction activities affecting the original roost site (as described for *AMM20 Greater Sandhill Crane* in Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Therefore there would be no loss of crane roosting and foraging habitat as a result of water conveyance facility construction once the facilities were fully designed. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations.

Table 12-9-32. Total Amount of Lesser Sandhill Crane Foraging Habitat Affected under Alternative 9

Foraging Habitat Value Class	Land Cover Type	CM1 Permanent (Temporary)	CM2–CM18 Permanent (Temporary)
Very high	Corn, alfalfa and alfalfa mixtures	9 (1,095)	4,083 (0)
High	Mixed pasture, native pasture, other pasture, irrigated pasture, native vegetation, rice	2 (29)	2,058 (0)
Medium	Grain and hay crops, miscellaneous grain and hay, mixed grain and hay, non-irrigated mixed grain and hay, other grain crops, miscellaneous grasses, grassland, wheat, other grain crops, managed wetlands	29 (235)	2,220 (2)
Low	Other irrigated crops, idle cropland, blueberries, asparagus, clover, cropped within the last 3 years, grain sorghum, green beans, miscellaneous truck, miscellaneous field, new lands being prepped for crop production, nonirrigated mixed pasture, nonirrigated native pasture, onions, garlic, peppers, potatoes, safflower, sudan, sugar beets, tomatoes (processing), melons squash and cucumbers all types, artichokes, beans (dry)	4 (241)	3,745 (2)
None	Vineyards, orchards	0 (0)	23 (0)

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction under CM2 would result in a permanent loss of 267 acres and a temporary loss of 2 acres of lesser sandhill crane foraging habitat in CZ 2. Lesser sandhill crane use in this area is less common than in the central Delta. Construction impacts from CM2 would occur within the first 10 years of Alternative 9 implementation.
- *CM4 Tidal Natural Communities Restoration*: Based on the hypothetical tidal restoration footprint, this activity would result in the permanent loss or conversion of approximately 10,248 acres of lesser sandhill crane habitat, consisting of 41 acres of temporary roosting and foraging habitat and 10,207 acres of foraging habitat. Loss of foraging habitat from CM4 would consist of 3,642 acres of very high-value, 1,529 acres of high value, 2,040 acres of medium-value, and 2,983 acres of low-value foraging habitat (Table 12-9-32). Habitat loss would primarily occur in the Cosumnes-Mokelume River and West Delta ROAs. Tidal wetland restoration in CZ 4 could occur between the high crane use areas of the central Delta and the Cosumnes River Preserve. However, the conversion of grasslands and cultivated lands to tidal wetlands would not prohibit crane movement or reduce use of these areas. Lesser sandhill cranes are less traditional than greater sandhill cranes and would be more adaptable to changes in land use. Approximately 2,516 acres of foraging habitat would be removed within the first 10 years of Alternative 9 implementation.
- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees would result in the loss of 2 acres of low-value lesser sandhill crane foraging habitat (1 acre of permanent loss, 1 acres of temporary loss). This impact would occur after the first 10 years of Alternative 9 implementation.
- *CM8 Grassland Natural Community Restoration*: Approximately 300 acres of cultivated lands (foraging habitat) would be converted to grassland. No roosting/foraging habitat would be

impacted by grassland restoration activities. The restored grasslands would continue to provide foraging habitat value for the lesser sandhill crane. Approximately 257 acres would be impacted within the first 10 years of Alternative 9 implementation.

- *CM10 Nontidal Marsh Restoration*: Nontidal marsh restoration would result in the permanent conversion of approximately 1,350 acres of modeled foraging habitat for the lesser sandhill crane. A portion of the restored nontidal marsh would be expected to continue to provide roosting and foraging habitat value for the lesser sandhill crane. However, some of this restored marsh would be unsuitable as it would lack emergent vegetation and consist of open water that would be too deep to provide suitable roosting or foraging habitat. Approximately 567 acres of habitat would be converted to nontidal marsh within the first 10 years of Alternative 9 implementation.

- *CM11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in *CM11* that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. The potential for these activities to result in direct mortality of lesser sandhill crane would be minimized with the implementation of *AMM20 Greater Sandhill Crane*. CM11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. If new ground disturbance was necessary, sandhill crane habitat would be avoided, with the exception of a permanent loss of 4 acres of grassland foraging habitat (1 acre of which would be impacted within the first 10 years of Plan implementation).

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect lesser sandhill crane use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, could be adverse as sandhill cranes are sensitive to disturbance. However, impacts would be reduced by AMMs, and conservation actions as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of lesser sandhill crane if they were present in the study area, because they would be expected to avoid contact with construction and other equipment. Potential effects would be avoided and minimized with the implementation of *AMM20 Greater Sandhill Crane*. Injury and mortality from electrical transmission facilities are described below under Impact BIO-73.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Based on current design footprints, Alternative 9 would remove 25 acres roosting and foraging habitat (temporary loss from CM1) in the study area in the near-term. In addition, 5,257 acres of foraging habitat would be removed or converted in the near-term (CM1, 1,664 acres; *CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration*, *CM8 Grassland Natural Community Restoration*, and *CM11 Natural Communities Enhancement and Management*—3,612 acres). Of these near-term acres of foraging habitat impacted, 3,906 acres would be medium- to very high-value habitat (CM1, 1,339 acres, CM2-11, 2,507 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 protection and 1:1 restoration for loss of roost sites and 1:1 protection for loss of foraging habitat. Using these ratios would indicate that 25 acres of lesser sandhill crane roosting habitat should be restored/created and 25 acres should be protected to compensate for the CM1 losses of lesser sandhill crane roosting and foraging habitat. In addition, 1,339 acres of high- to very high-value foraging habitat should be protected to mitigate the CM1 losses of lesser sandhill crane medium- to very high-value foraging habitat. The near-term effects of other conservation actions would remove 2,507 acres of medium- to very high-value foraging habitat, and therefore require 2,507 acres of protection of high- to very high-value foraging habitat using the same typical NEPA and CEQA ratios (1:1 restoration and 1:1 protection for the loss of roosting and foraging habitat; 1:1 protection for the loss of foraging habitat).

The implementation of *AMM20 Greater Sandhill Crane* would require that no sandhill crane roost sites were directly impacted by CM1 covered activities (including transmission lines and their associated footprints). Therefore there would be no loss of crane roosting and foraging habitat as a result of water conveyance facility construction once the facilities were fully designed, which would avoid the CM1 impact on 411 acres of roosting and foraging habitat once the project design is final. Indirect effects of construction-related noise and visual disturbance are discussed below under Impact BIO-74.

The BDCP has committed to near-term goals of creating 500 acres of managed wetlands and protecting 15,600 acres of cultivated lands in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3 and CM10 and would occur in the same timeframe as the construction and early restoration losses.

The BDCP also includes the following objectives for the greater sandhill crane which would also benefit the lesser sandhill crane, as they utilize similar habitats and face similar threats within their winter use areas.

Up to 95 acres of roosting habitat would be created within 2 miles of existing permanent roost sites (Objective GSHC1.5). These roosts would consist of active cornfields that are flooded following harvest to support roosting cranes and also provide the highest-value foraging habitat for the species. Individual fields would be at least 40 acres could shift locations throughout the Greater Sandhill Crane Winter Use Area, but would be sited with consideration of the location of roosting habitat loss and would be in place prior to roosting habitat loss. Of the 500 acres of managed wetlands to be created for roosting habitat, 320 acres would be created in minimum patch sizes of

40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6 (Objective GSHC1.3). Restoration sites would be identified with consideration of sea level rise and local seasonal flood events. These wetlands would be created within 2 miles of existing permanent roost sites and protected in association with other protected natural community types at a ratio of 2:1 upland to wetland habitat to provide buffers that will protect cranes from the types of disturbances that would otherwise result from adjacent roads and developed areas (e.g., roads, noise, visual disturbance, lighting). The remaining 180 acres of crane roosting habitat would be constructed within the Stone Lakes National Wildlife Refuge project boundary (BDCP Chapter 3, Figure 3.3-6) and would be designed to provide connectivity between the Stone Lakes and Cosumnes greater sandhill crane populations (Objective GSHC1.4). The large patch sizes of these wetland complexes would provide additional conservation to address the threats of vineyard conversion, urbanization to the east, and sea level rise to the west of greater sandhill crane wintering habitat.

At least 15,600 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1). Mitigation Measure BIO-72, *Compensate for the Loss of Medium- to Very High-Value Lesser Sandhill Crane Foraging Habitat*, would be available to guide the near-term protection of cultivated lands to ensure that the nearterm impacts of medium- to very high-value foraging habitat for lesser sandhill crane were compensated for with appropriate crop types and natural communities.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The study area supports approximately 23,919 acres of roosting and foraging habitat and 240,475 acres of foraging habitat for lesser sandhill crane. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 66 acres of roosting and foraging habitat (less than 1% of the total habitat in the study area) and 13,779 acres of foraging habitat (6% of the total habitat in the study area) for the lesser sandhill crane during the term of the Plan. The foraging habitat lost by the late long-term timeframe would consist of 9,762 acres of medium- to very high-value foraging habitat. The locations of these losses are described above in the analyses of individual conservation measures. The implementation of *AMM20 Greater Sandhill Crane* would require that no roost sites were directly affected by water conveyance facilities including transmission lines and associated footprints. In addition, temporarily removed habitat would be restored within 1 year following construction. However, it would not necessarily be restored to its original topography and it could result in the conversion of cultivated lands to grasslands.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration* and *CM10 Nontidal Marsh Restoration Restoration* to restore or create at least 595 acres of greater Sandhill crane roost habitat (Objectives GSHC1.3, GSHC1.4, and GSHC1.5) and to protect at least 7,300 acres of high- to very high-value foraging habitat for greater Sandhill crane (Objective

GSHC1.1). These croptypes would also provide high- to very high-value habitat for the lesser sandhill crane.

The BDCP also includes the following objectives for the greater sandhill crane which would also benefit the lesser sandhill crane, as they utilize similar habitats and face similar threats within their winter use areas.

Of the 500 acres of managed wetlands to be created for roosting habitat, 320 acres would be created in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6 (Objective GSHC1.3). Restoration sites would be identified with consideration of sea level rise and local seasonal flood events. These wetlands would be created within 2 miles of existing permanent roost sites and protected in association with other protected natural community types at a ratio of 2:1 upland to wetland habitat to provide buffers that will protect cranes from the types of disturbances that would otherwise result from adjacent roads and developed areas (e.g., roads, noise, visual disturbance, lighting). The remaining 180 acres of crane roosting habitat would be constructed within the Stone Lakes National Wildlife Refuge project boundary (BDCP Chapter 3, Figure 3.3-6) and would be designed to provide connectivity between the Stone Lakes and Cosumnes greater sandhill crane populations (Objective GSHC1.4). These wetlands would consist of two 90-acre wetland complexes each consisting of at least three wetlands and would be no more than 2 miles apart. The large patch sizes of these wetland complexes would provide additional conservation to address the threats of vineyard conversion, urbanization to the east, and sea level rise to the west of greater sandhill crane wintering habitat. Approximately 95 acres of roosting habitat would be created within 2 miles of existing permanent roost sites (Objective GSHC1.5). These roosts would consist of active cornfields that are flooded following harvest to support roosting cranes and also provide the highest-value foraging habitat for the species. Individual fields would be at least 40 acres could shift locations throughout the Greater Sandhill Crane Winter Use Area, but would be sited with consideration of the location of roosting habitat loss and would be in place prior to roosting habitat loss.

The BDCP has committed to protecting 7,300 acres of high- to very high-value greater sandhill crane foraging habitat by the late long-term timeframe with at least 80% maintained in very-high value types in any given year (Objective GSHC1.1). These acres of protected foraging habitat would be located within 2 miles of known roosting sites in CZs 3, 4, 5, and/or 6 and would consider sea level rise and local seasonal flood events, greater Sandhill crane population levels, and the location of foraging habitat loss. The patch size of these protected lands would be at least 160 acres (Objectives GSHC1.1 and GSHC1.2). Because agricultural habitat values change over time based largely on economically driven agricultural practices, protecting crane habitat would provide enhanced stability to agricultural habitat value within the crane use area that does not currently exist. Although lesser sandhill cranes are less traditional in their use of roost sites in the Delta, these objectives for the greater sandhill crane would also benefit the lesser sandhill crane.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

NEPA Effects: The loss of lesser sandhill crane habitat and potential for direct mortality of this special status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. However, with habitat protection and restoration associated with *CM3 Natural Communities Protection and Restoration* and *CM10 Nontidal Marsh Restoration*, guided by biological goals and objectives for the species and by AMM1–AMM7*, AMM20 Greater Sandhill Crane*, which would be in place throughout the construction period, and Mitigation Measure BIO-72, which would be available to compensate for loss of medium- to very high-value foraging habitat, the effects of habitat loss and potential mortality on lesser sandhill crane would not be adverse under NEPA.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Based on current design footprints, Alternative 9 would remove 25 acres roosting and foraging habitat (temporary loss from CM1) in the study area in the near-term. In addition, 5,257 acres of foraging habitat would be removed or converted in the near-term (CM1, 1,664 acres; *CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration*, *CM8 Grassland Natural Community Restoration*, and *CM11 Natural Communities Enhancement and Management*—3,612 acres). Of these near-term acres of foraging habitat impacted, 3,906 acres would be medium- to very high-value habitat (CM1, 1,339 acres, CM2-11, 2,507 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 protection and 1:1 restoration for loss of roost sites and 1:1 protection for loss of foraging habitat. Using these ratios would indicate that 25 acres of lesser sandhill crane roosting habitat should be restored/created and 25 acres should be protected to compensate for the CM1 losses of lesser sandhill crane roosting and foraging habitat. In addition, 1,339 acres of high- to very high-value foraging habitat should be protected to mitigate the CM1 losses of lesser sandhill crane medium- to very high-value foraging habitat. The near-term effects of other conservation actions would remove 2,507 acres of medium- to very high-value foraging habitat, and therefore require 2,507 acres of protection of high- to very high-value foraging habitat using the same typical NEPA and CEQA ratios (1:1 restoration and 1:1 protection for the loss of roosting and foraging habitat; 1:1 protection for the loss of foraging habitat).

The implementation of *AMM20 Greater Sandhill Crane* would require that no sandhill crane roost sites were directly impacted by CM1 covered activities (including transmission lines and their associated footprints). Therefore there would be no loss of crane roosting and foraging habitat as a result of water conveyance facility construction once the facilities were fully designed, which would avoid the CM1 impact on 411 acres of roosting and foraging habitat once the project design is final. Indirect effects of construction-related noise and visual disturbance are discussed below under Impact BIO-74.

The BDCP has committed to near-term goals of creating 500 acres of managed wetlands and protecting 15,600 acres of cultivated lands in the Plan Area (Table 3-4 in Chapter 3). These conservation actions are associated with CM3 and CM10 and would occur in the same timeframe as the construction and early restoration losses.

The BDCP also includes the following objectives for the greater sandhill crane which would also benefit the lesser sandhill crane, as they utilize similar habitats and face similar threats within their winter use areas.

Up to 95 acres of roosting habitat would be created within 2 miles of existing permanent roost sites (Objective GSHC1.5). These roosts would consist of active cornfields that are flooded following harvest to support roosting cranes and also provide the highest-value foraging habitat for the species. Individual fields would be at least 40 acres could shift locations throughout the Greater Sandhill Crane Winter Use Area, but would be sited with consideration of the location of roosting habitat loss and would be in place prior to roosting habitat loss. Of the 500 acres of managed wetlands to be created for roosting habitat, 320 acres would be created in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6 (Objective GSHC1.3). Restoration sites would be identified with consideration of sea level rise and local seasonal flood events. These wetlands would be created within 2 miles of existing permanent roost sites and protected in association with other protected natural community types at a ratio of 2:1 upland to wetland habitat to provide buffers that will protect cranes from the types of disturbances that would otherwise result from adjacent roads and developed areas (e.g., roads, noise, visual disturbance, lighting). The remaining 180 acres of crane roosting habitat would be constructed within the Stone Lakes National Wildlife Refuge project boundary (BDCP Chapter 3, Figure 3.3-6) and would be designed to provide connectivity between the Stone Lakes and Cosumnes greater sandhill crane populations (Objective GSHC1.4). The large patch sizes of these wetland complexes would provide additional conservation to address the threats of vineyard conversion, urbanization to the east, and sea level rise to the west of greater sandhill crane wintering habitat.

At least 15,600 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1). Mitigation Measure BIO-72 would be available to guide the near-term protection of cultivated lands to ensure that the nearterm impacts of medium- to very high-value foraging habitat for lesser sandhill crane were compensated for with appropriate crop types and natural communities.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The study area supports approximately 23,919 acres of roosting and foraging habitat and 240,475 acres of foraging habitat for lesser sandhill crane. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 66 acres of roosting and foraging habitat (less than 1% of the total habitat in the study area) and 13,779 acres of foraging habitat (6% of the total habitat in the study area) for the lesser sandhill crane during the term of the Plan. The foraging habitat lost by the late long-term timeframe would consist of 9,762 acres of medium- to very high-value foraging habitat. The locations of these losses are described above in the analyses of individual conservation measures. The implementation of *AMM20 Greater Sandhill Crane* would require that no roost sites

were directly affected by water conveyance facilities including transmission lines and associated footprints. In addition, temporarily removed habitat would be restored within 1 year following construction. However, it would not necessarily be restored to its original topography and it could result in the conversion of cultivated lands to grasslands.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration* and *CM10 Nontidal Marsh Restoration Restoration* to restore or create at least 595 acres of greater Sandhill crane roost habitat (Objectives GSHC1.3, GSHC1.4, and GSHC1.5) and to protect at least 7,300 acres of high- to very high-value foraging habitat for greater Sandhill crane (Objective GSHC1.1). These croptypes would also provide high- to very high-value habitat for the lesser sandhill crane.

The BDCP also includes the following objectives for the greater sandhill crane which would also benefit the lesser sandhill crane, as they utilize similar habitats and face similar threats within their winter use areas.

Of the 500 acres of managed wetlands to be created for roosting habitat, 320 acres would be created in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6 (Objective GSHC1.3). Restoration sites would be identified with consideration of sea level rise and local seasonal flood events. These wetlands would be created within 2 miles of existing permanent roost sites and protected in association with other protected natural community types at a ratio of 2:1 upland to wetland habitat to provide buffers that will protect cranes from the types of disturbances that would otherwise result from adjacent roads and developed areas (e.g., roads, noise, visual disturbance, lighting). The remaining 180 acres of crane roosting habitat would be constructed within the Stone Lakes National Wildlife Refuge project boundary (BDCP Chapter 3, Figure 3.3-6) and would be designed to provide connectivity between the Stone Lakes and Cosumnes greater sandhill crane populations (Objective GSHC1.4). These wetlands would consist of two 90-acre wetland complexes each consisting of at least three wetlands and would be no more than 2 miles apart. The large patch sizes of these wetland complexes would provide additional conservation to address the threats of vineyard conversion, urbanization to the east, and sea level rise to the west of greater sandhill crane wintering habitat. Approximately 95 acres of roosting habitat would be created within 2 miles of existing permanent roost sites (Objective GSHC1.5). These roosts would consist of active cornfields that are flooded following harvest to support roosting cranes and also provide the highest-value foraging habitat for the species. Individual fields would be at least 40 acres could shift locations throughout the Greater Sandhill Crane Winter Use Area, but would be sited with consideration of the location of roosting habitat loss and would be in place prior to roosting habitat loss.

The BDCP has committed to protecting 7,300 acres of high- to very high-value greater sandhill crane foraging habitat by the late long-term timeframe with at least 80% maintained in very-high value types in any given year (Objective GSHC1.1). These acres of protected foraging habitat would be located within 2 miles of known roosting sites in CZs 3, 4, 5, and/or 6 and would consider sea level rise and local seasonal flood events, greater Sandhill crane population levels, and the location of foraging habitat loss. The patch size of these protected lands would be at least 160 acres (Objectives GSHC1.1 and GSHC1.2). Because agricultural habitat values change over time based largely on economically driven agricultural practices, protecting crane habitat would provide enhanced stability to agricultural habitat value within the crane use area that does not currently exist. Although lesser sandhill cranes are less traditional in their use of roost sites in the Delta, these objectives for the greater sandhill crane would also benefit the lesser sandhill crane.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Considering Alternative 9's protection and restoration provisions, in addition to Mitigation Measure BIO-72, which would compensate for the loss of medium- to very high-value foraging habitat at a ratio of 1:1, loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the alternative would have a less-than-significant impact on lesser sandhill crane.

Mitigation Measure BIO-72: Compensate for the loss of Medium- to Very High-Value Lesser Sandhill Crane Foraging Habitat

DWR must compensate for the loss of lesser sandhill crane medium- to very high-value foraging habitat at a ratio of 1:1 by protecting or managing high- to very high-value habitat in the Plan Area. Compensation must occur prior to or concurrent with the impacts to minimize the effects of habitat loss. The crop types and natural communities that are included in foraging value categories are listed in Table 12-9-32. Foraging habitat conservation must occur within 10 kilometers of traditional sandhill crane roost sites and the location of protected habitat or conservation easements must be preapproved by CDFW.

Impact BIO-73: Effects on Lesser Sandhill Crane Associated with Electrical Transmission Facilities

Sandhill cranes are susceptible to collision with power lines and other structures during periods of inclement weather and low visibility (Avian Power Line Interaction Committee 1994, Brown and Drewien 1995, Manville 2005). There are extensive existing transmission and distribution lines in the sandhill crane winter use area. These include a network of distribution lines that are between 11- and 22-kV. In addition, there are two 115-kV lines that cross the study area, one that overlaps with the greater sandhill crane winter use area between Antioch and I-5 east of Hood, and one that crosses the northern tip of the crane winter use area north of Clarksburg. There are 69-kv lines within the study area that parallel Twin Cities Road, Herzog Road, Lambert Road, and the Southern Pacific Dredge Cut in the vicinity of Stone Lakes NWR. At the south end of the winter use area, there are three 230-kV transmission lines that follow I-5, and then cut southwest through Holt, and two 500-kV lines cross the southwestern corner of the winter use area. This existing network of power lines in the study currently poses a collision and electrocution risk for sandhill cranes, because they cross over or surround sandhill crane roost sites in the study area.

Both permanent and temporary electrical transmission lines would be constructed to supply construction and operational power to Alternative 9 facilities. The potential mortality of greater sandhill crane in the area of the proposed transmission lines under Alternative 9 was estimated using collision mortality rates by Brown and Drewien (1995) and an estimate of potential crossings along the proposed lines (methods are described in BDCP Appendix 5.J, Attachment 5J.C, *Analysis of*

Potential Bird Collisions at Proposed BDCP Powerlines). This analysis concluded that mortality risk could be substantially reduced by marking new transmission lines to increase their visibility to sandhill cranes. Lesser sandhill cranes use the same roost sites as greater sandhill cranes. However, their numbers fluctuate greatly over the season as they are more mobile and use a broader landscape than greater sandhill cranes. Mortality risk would be similarly reduced for lesser sandhill cranes by marking new transmission lines.

Typically, higher-voltage (230- kV) lines vary in height from 90 to 110 feet, while subtransmission (69-kV) lines vary from 50 to 70 feet (Avian Power Line Interaction Committee 2006). The Alternative 9 alignment would primarily use existing transmission and distribution lines and would require the installation of approximately 42 miles of transmission line (3 miles of 60-kV line, 38 miles of 12-kV line, and 0.5 miles of 480-V line). These lines would occur in the vicinity of Walnut Grove and adjacent to fish screen and operable barrier structures throughout the CM1 footprint. Temporary lines would be removed after construction of the water conveyance facilities, within 10 years.

AMM30 Transmission Line Design and Alignment Guidelines would require design features for the transmission line alignment, such as co-locating transmission lines when it would minimize effects on sandhill cranes, to avoid impacts on sensitive habitats to the maximum extent feasible. After the Draft EIR/EIS was issued in December 2013, additional avoidance features were added to *AMM20 Greater Sandhill Crane*. *AMM20 Greater Sandhill Crane* requires that Alternative 9 meet the performance standard of no mortality of greater sandhill crane associated with the new facilities. This would be achieved by implementing one or any combination of the following: 1) siting new transmission lines in lower bird strike risk zones; 2) removing, relocating or undergrounding existing lines where feasible; 3) using natural gas generators in lieu of installing transmission lines in high-risk zones of the greater sandhill crane winter use area; 4) undergrounding new lines in high-risk zones of the greater sandhill crane winter use area; 5) permanently installing flight diverters on existing lines over lengths equal to or greater than the length of the new transmission lines in the crane winter use area; 6) for areas outside of the Stone Lakes NWR project boundary, shifting locations of flooded areas that provide crane roosts to lower risk areas. These measures are described in detail in *AMM20 Greater Sandhill Crane* in Appendix 3B, *Environmental Commitments, AMMs, and CMs*.

The implementation of the measures described above under *AMM20 Greater Sandhill Crane* would substantially reduce the potential for lesser sandhill crane collisions with transmission lines. Potential measures that would eliminate this risk include using natural gas generators in lieu of transmission lines or undergrounding new lines in high-risk zones in the greater sandhill crane winter use area. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality, including for sandhill cranes (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new transmission lines would be fitted with flight diverters. The installation of flight diverters on existing permanent lines would be prioritized in the highest risk zones for greater sandhill crane (as described in BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*) and diverters would be installed in a configuration that research indicates would reduce bird strike risk by at least 60%. The length of existing line to be fitted with bird strike diverters would be equal to the length of new transmission lines constructed as a result of the project, in an area with the same or higher greater sandhill crane strike risk to provide a net benefit to the species. For optimum results, the recommended spacing distance for bird flight diverters is 15 to 16.5 feet (4.5 to 5 meters) (Avian Power Line Interaction

Committee 1994). Placing diverters on existing lines would be expected to reduce existing lesser and greater sandhill crane mortality in the Plan Area and therefore result in a net benefit to the lesser sandhill crane population because these flight diverters would be maintained in perpetuity.

***NEPA Effects*:** Sandhill cranes are known to be susceptible to collision with overhead wires. The existing network of power lines in the study area currently poses a risk for sandhill cranes. The current proposed transmission line alignment under Alternative 9 is not fully designed, and line locations are not final. The implementation of *AMM20 Greater Sandhill Crane* would require that the final transmission line alignment avoid crane roost sites and achieve the performance standard of no mortality of greater sandhill crane associated with the new facilities, which would also benefit the lesser sandhill crane. *AMM30 Transmission Line Design and Alignment Guidelines* would require design features for the transmission line alignment, such as co-locating transmission lines when it would minimize effects on sandhill cranes, to avoid impacts on sensitive habitats to the maximum extent feasible. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. With incorporation of *AMM30 Transmission Line Design and Alignment Guidelines* and one or a combination of the measures to greatly reduce the risk of bird strike described in *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines under Alternative 9 would not result in an adverse effect on lesser sandhill crane.

***CEQA Conclusion*:** Sandhill cranes are known to be susceptible to collision with overhead wires. The existing network of power lines in the study area currently poses a risk for sandhill cranes. The current proposed transmission line alignment under Alternative 9 is not fully designed, and line locations are not final. The implementation of *AMM20 Greater Sandhill Crane* would require that the final transmission line alignment avoid crane roost sites and achieve the performance standard of no mortality of greater sandhill crane associated with the new facilities, which would also benefit lesser sandhill crane. *AMM30 Transmission Line Design and Alignment Guidelines* would require design features for the transmission line alignment, such as co-locating transmission lines when it would minimize effects on sandhill cranes, to avoid impacts on sensitive habitats to the maximum extent feasible. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. With incorporation of *AMM30 Transmission Line Design and Alignment Guidelines* and one or a combination of the measures to greatly reduce the risk of bird strike described in *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines under Alternative 9 would have a less-than-significant impact on lesser sandhill crane.

Impact BIO-74: Indirect Effects of Plan Implementation on Lesser Sandhill Crane

Indirect Construction- and Operation-Related Effects: Sandhill cranes are sensitive to disturbance. Noise and visual disturbances from the construction of water conveyance facilities and other conservation measures could reduce lesser sandhill crane use of modeled habitat adjacent to work areas. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet of the construction edge. Furthermore, maintenance of the aboveground water conveyance facilities could result in ongoing but periodic postconstruction noise and visual disturbances that could affect lesser sandhill crane use of surrounding habitat. These effects could result from periodic vehicle use along the conveyance corridor, inspection and maintenance of aboveground facilities, and similar activities. These potential effects would be minimized with implementation of *AMM20 Greater Sandhill Crane* described in Appendix 3B, *Environmental Commitments, AMMs, and CMs*.

The BDCP includes an analysis of the indirect effects of noise and visual disturbance that would result from the construction of the Alternative 4 water conveyance facilities on greater sandhill crane (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*). The same methods were employed to addresses the potential noise effects on cranes from Alternative 9 and to determine that as much as 1,217–5,108 acres of crane habitat could potentially be affected by general construction noise above baseline level (50–60 dBA). This would include 44–157 acres of temporary crane roosting habitat and 1,173–4,951 acres of crane foraging habitat. In addition, 0–40 acres of permanent crane roosting habitat, 38–688 acres of temporary crane roosting habitat, and 1,392–7,699 acres of crane foraging habitat could be affected by noise from pile driving that would be above baseline level (50–60dBA, Table 12-9-30 under Impact BIO-71).

The analysis was conducted based on the assumption that there would be direct line-of-sight from sandhill crane habitat areas to the construction site, and, therefore, provides a worst-case estimate of effects. In many areas the existing levees would partially or completely block the line-of-sight and would function as effective noise barriers, substantially reducing noise transmission. However, there is insufficient data to assess the effects that increased noise levels would have on sandhill crane behavior. Similar acreages of lesser sandhill crane habitat would be expected to be indirectly affected. However, lesser sandhill cranes are less traditional in their winter roost sites and may be more likely to travel away from disturbed areas to roost and forage in more suitable habitat.

Evening and nighttime construction activities would require the use of extremely bright lights. Nighttime construction could also result in headlights flashing into roost sites when construction vehicles are turning onto or off of construction access routes. Proposed surge towers would require the use of safety lights that would alert low-flying aircraft to the presence of these structures because of their height. Little data is available on the effects of impact of artificial lighting on roosting birds. Direct light from automobile headlights has been observed to cause roosting cranes to flush and it is thought that they may avoid roosting in areas where lighting is bright (BDCP Chapter 5, *Effects Analysis*). If the birds were to roost in a brightly lit site, they may be vulnerable to sleep-wake cycle shifts and reproductive cycle shifts. Potential risks of visual impacts from lighting include a reduction in the cranes' quality of nocturnal rest, and effects on their "sense of photo-period which might cause them to shift their physiology towards earlier migration and breeding." (BDCP Chapter 5, *Effects Analysis*). Effects such as these could prove detrimental to the cranes' overall fitness and reproductive success (which could in turn have population-level impacts). A change in photo-period interpretation could also cause cranes to fly out earlier from roost sites to forage and might increase their risk of power line collisions if they were to leave roosts before dawn (BDCP Chapter 5, *Effects Analysis*).

The effects of noise and visual disturbance on lesser sandhill crane would be minimized through the implementation of AMM20 (Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Activities within 0.75 mile of crane roosting habitat would reduce construction noise during night time hours (from one hour before sunset to one hour after sunrise) such that construction noise levels do not exceed 50 dBA L_{eq} (1 hour) at the nearest temporary or permanent roosts during periods when the roost sites are available (flooded). In addition, the area of crane foraging habitat that would be affected during the day (from one hour after sunrise to one hour before sunset) by construction noise exceeding 50 dBA L_{eq} (1 hour) would also be minimized. Unavoidable noise related effects would be compensated for by the enhancement of 0.1 acre of foraging habitat for every acre indirectly affected within the 50 dBA L_{eq} (1 hour) construction noise contour. With these measures in place, indirect effects of noise and visual disturbance from construction activities are not expected to reduce the lesser sandhill crane population in the study area.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect lesser sandhill cranes in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to lesser sandhill crane habitat could also affect the subspecies. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills and ensure that measures were in place to prevent runoff from the construction area and negative effects of dust on foraging habitat.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in lesser sandhill cranes. Largemouth bass was used as a surrogate species for analysis (Appendix 11F, *Substantive BDCP Revisions*). Results of the quantitative modeling of mercury effects on largemouth bass as a surrogate species would overestimate the effects on lesser sandhill crane as they primarily forage on cultivated crops and invertebrates. Organisms feeding within pelagic-based (algal) foodwebs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic foodwebs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009). Modeled effects of mercury concentrations from changes in water operations under CM1 on largemouth bass did not differ substantially from existing conditions; therefore, results also indicate that lesser sandhill crane tissue concentrations would not measurably increase as a result of CM1 implementation.

Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury. Increased methylmercury associated with natural community and floodplain restoration may indirectly affect lesser sandhill crane via uptake in lower trophic levels (see BDCP Appendix 5.D, *Contaminants*). Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury. Given that some species have elevated mercury tissue levels pre-BDCP, these low level increases could result in some level of effects.

Due to the complex and very site-specific factors that determine if mercury becomes mobilized into the foodweb, *CM12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. CM12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This conservation measure would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.

Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including the lesser sandhill crane. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy,* for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on lesser sandhill crane.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on lesser sandhill crane from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management* (BDCP Appendix 3.C, *Avoidance and Minimization Measures*) which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Crane habitat could potentially be affected by general construction noise and pile driving above baseline level (50–60 dBA). However, lesser sandhill cranes are less traditional in their winter roost sites than greater sandhill cranes and may be more likely to travel away from disturbed areas to roost in more suitable habitat. Construction in certain areas would take place 7 days a week and 24 hours a day and evening and nighttime construction activities would require the use of extremely bright lights, which could adversely affect roosting cranes by impacting their sense of photo-period and by exposing them to predators.

Effects of noise and visual disturbance could substantially alter the suitability of habitat for lesser sandhill crane. *AMM20 Greater Sandhill Crane* would include requirements (described above) to minimize the effects of noise and visual disturbance on sandhill cranes and to mitigate effects on habitat.

Tidal habitat restoration could result in increased exposure of lesser sandhill crane to selenium which could result in the mortality of a special-status species. This effect would be addressed through the implementation of *AMM27 Selenium Management,* which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of lesser sandhill crane to methylmercury. The potential indirect effects of increased mercury exposure is likely low for lesser sandhill crane because they primarily forage on cultivated crops and associated invertebrates. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

CEQA Conclusion: Crane habitat could potentially be affected by general construction noise and pile driving above baseline level (50–60 dBA). However, lesser sandhill cranes are less traditional in their winter roost sites and may be more likely to travel away from disturbed areas to roost in more suitable habitat. Construction in certain areas would take place 7 days a week and 24 hours a day and evening and nighttime construction activities would require the use of extremely bright lights, which could adversely affect roosting cranes by impacting their sense of photo-period and by exposing them to predators.

Effects of noise and visual disturbance could substantially alter the suitability of habitat for lesser sandhill crane. This would be a significant impact. With *AMM20 Greater Sandhill Crane* in place, which would include requirements (described above) to minimize the effects of noise and visual disturbance on sandhill cranes and to mitigate effects on habitat, there would not be an adverse effect on lesser sandhill crane.

Tidal habitat restoration could result in increased exposure of lesser sandhill crane to selenium which could result in the potential mortality of a special-status species. This would be a significant impact. This effect would be addressed through the implementation of A*MM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Methylmercury tissue concentrations in lesser sandhill crane would not be expected to measurably increase as a result of water operations under CM1 compared to the No Action Alternative. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of lesser sandhill crane to methylmercury. This would be a significant impact. The potential indirect effects of increased mercury exposure is likely low for lesser sandhill crane because they primarily forage on cultivated crops and associated invertebrates. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on lesser sandhill crane.

With AMM1–AMM7, AMM20, AMM27, and CM12 in place, the indirect effects of plan implementation under Alternative 9 would not substantially reduce the number or restrict the range of lesser sandhill cranes. Therefore, the indirect effects of Alternative 9 implementation would have a less-than-significant impact on lesser sandhill crane.

Least Bell's Vireo and Yellow Warbler

Least Bell's vireo and yellow warbler modeled habitat identifies suitable nesting and migratory habitat as those plant alliances from the valley/foothill riparian modeled habitat that contain a dense shrub component, including all willow-dominated alliances.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of least Bell's vireo and yellow warbler modeled habitat as indicated in Table 12-9-33. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit least Bell's vireo and yellow warbler (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 5,000 acres of valley/foothill riparian natural community with at least 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM7).
- Protect at least 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM7).
- Maintain and enhance structural heterogeneity (Objective VFRNC2.1, associated with CM7).
- Maintain at least 1,000 acres of early- to mid-successional vegetation (Objective VFRNC2.2, associated with CM7).
- Maintain at least 500 acres of mature riparian forest in CZ 4 or CZ 7 (Objective VFRNC2.3, associated with CM3 and CM7).
- Maintain the at least 500 acres of mature riparian forest (Objective VFRNC2.3) intermixed with a portion of the early- to mid-successional riparian vegetation (Objective VFRNC2.2) in large blocks with a minimum patch size of 50 acres and minimum width of 330 feet (Objective VFRNC2.4, associated with CM3 and CM7).

As explained below, with the restoration and protection of these amounts of habitat, in addition to natural community enhancement and management commitments and implementation of AMM1–AMM7, *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, and Mitigation Measure BIO-75, impacts on least Bell's vireo and yellow warbler would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-33. Changes in Least Bell's Vireo and Yellow Warbler Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent NT	Permanent LLT[c]	Temporary NT	Temporary LLT[c]	Periodic[d] CM2	Periodic[d] CM5
CM1	Migratory and breeding	49	49	233	233	NA	NA
Total Impacts CM1		**49**	**49**	**233**	**233**	**NA**	**NA**
CM2–CM18	Migratory and breeding	382	656	88	109	48–85	148
Total Impacts CM2–CM18		**382**	**656**	**88**	**109**	**48–85**	**148**
TOTAL IMPACTS		**431**	**705**	**321**	**342**	**48–85**	**148**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-75: Loss or Conversion of Habitat for and Direct Mortality of Least Bell's Vireo and Yellow Warbler

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 1,047 acres of modeled habitat (705 acres of permanent loss, 342 acres of temporary loss) for least Bell's vireo and yellow warbler (Table 12-9-33). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Fremont Weir/Yolo Bypass fisheries improvements (CM2), tidal natural communities restoration (CM4), and seasonally inundated floodplain restoration (CM5). Habitat enhancement and management activities (CM11) which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate least Bell's vireo and yellow warbler habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 282 acres of modeled least Bell's vireo and yellow warbler habitat (Table 12-9-33). Of the 282 acres of modeled habitat that would be removed for the construction of the conveyance facilities, 49 acres would be a permanent loss and 233 acres would be a temporary loss of habitat. Most of the permanent loss would occur as wider and deeper channels are dredged in Middle River and Victoria Canal, and as operable barriers and new Sacramento River diversions are constructed in various waterways across the Delta. Temporary losses of riparian community would occur primarily along Middle River between Victoria Canal and Mildred Island, where large dredging work areas and operable barrier work areas would be placed. Some of this vegetation may be temporarily removed as dredging progresses, while other areas could remain in place but be temporarily affected by sedimentation and equipment movement associated with dredging.

Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities as described *in AMM10 Restoration of Temporarily Affected Natural Communities*. Although the effects are considered temporary, the restored riparian habitat would require at least four years for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. However, restored riparian vegetation can have the habitat structure to support breeding vireos within 3 to 5 years, particularly if the restored vegetation is adjacent to established riparian areas (Kus 2002), and similar habitat would be suitable for yellow warbler. The majority of the riparian vegetation to be temporarily removed is early- to mid-successional; therefore, the replaced riparian vegetation would be expected to have structural components comparable to the temporarily removed vegetation within the first 5 to 10 years after the initial restoration activities are complete. There are no occurrences of least Bell's vireo or yellow warbler that intersect with the CM1 footprint. However, this loss would have the potential to displace individuals, if present, and remove the functions and value of modeled habitat for nesting, protection, or foraging. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Impacts from CM1 would occur within the first 10 years of Alternative 9 implementation.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of Yolo Bypass fisheries enhancements would permanently remove approximately 83 acres and temporarily remove 88 acres of modeled least Bell's vireo and yellow warbler habitat in the Yolo Bypass in CZ 2. The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 545 acres of modeled least Bell's vireo and yellow warbler habitat.

- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain would permanently remove approximately 28 acres and temporarily remove 21 acres of modeled least Bell's vireo and yellow warbler habitat. Based on the riparian habitat restoration assumptions, a minimum of 3,000 acres of valley/foothill riparian habitat would be restored as a component of seasonally inundated floodplain restoration actions.

  The actual number of acres of valley/foothill riparian habitat that CM4 and CM5 would restore may differ from these estimates, depending on how closely the actual outcome of tidal habitat restoration approximates the assumed outcome. However, riparian restoration from CM4 and CM5 would increase the extent of least Bell's vireo and yellow warbler habitat within the study area once the restored riparian vegetation has developed habitat functions for these species.

- *CM6 Channel Margin Enhancement:* Channel margin habitat enhancement could result in removal of small amounts of valley/foothill riparian habitat along 20 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur along waterway margins where riparian habitat stringers exist, including levees and channel banks. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.

- *CM11 Natural Communities Enhancement and Management:* Habitat protection and management activities that could be implemented in protected least Bell's vireo and yellow warbler habitats are expected to maintain and improve the functions of the habitat over the term of the BDCP. Least Bell's vireo and yellow warbler would be expected to benefit from the increase in protected habitat, which would maintain conditions favorable for future species establishment in the study area. If least Bell's vireo and yellow warbler established breeding populations in restored riparian habitats in the study area, occupied habitat would be monitored to determine if there were a need to implement controls on brood parasites (brown-headed cowbird) or nest predators. If implemented, these actions would be expected to benefit the least Bell's vireo and yellow warbler by removing a potential stressor that could, if not addressed, adversely affect the stability of newly established populations.

  Habitat management- and enhancement-related activities could disturb least Bell's vireo and yellow warbler nests. If either species were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. The potential for these activities to result in direct mortality of least Bell's vireo or yellow warbler would be minimized with the implementation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect least Bell's vireo and yellow warbler use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and conservation actions as described below.

- Injury and Direct Mortality: Although least Bell's vireo nesting has not been confirmed in the study area, recent occurrences in the Yolo Bypass and at the San Joaquin River National Wildlife Refuge suggest that the reestablishment of a breeding population is a possibility over the duration of the BDCP. If present in the study area, construction -related activities would not be expected to result in direct mortality of least Bell's vireo or yellow warbler because adults and fledged young would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. These effects would be avoided and minimized with the implementation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo.* In addition, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would be available to address effects on nesting yellow warblers.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 752 acres of modeled habitat for least Bell's vireo and yellow warbler in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 282 acres of habitat), and implementing other conservation measures (Yolo Bypass fisheries improvements [CM2] tidal restoration [CM4], seasonally inundated floodplain restoration [CM5]—470 acres of habitat).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected and that are identified in the biological goals and objectives for least Bell's vireo in Chapter 3 of the BDCP would be 1:1 for restoration/creation and 1:1 protection of dense shrubby successional valley/foothill riparian habitat. Using these ratios would indicate that 282 acres of valley/foothill riparian habitat should be restored/created and 282 acres should be protected to compensate for the CM1 losses of least Bell's vireo and yellow warbler habitat. The near-term effects of other conservation actions would remove 470 acres of modeled habitat, and therefore require 470 acres of restoration and 470 acres of protection of dense shrubby valley/foothill riparian using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of the valley/foothill riparian natural community in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3 and CM7 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on least Bell's vireo and yellow warbler. The majority of the riparian restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2, BDCP Chapter 3, *Conservation Strategy*). This restoration would provide the large contiguous patches needed for suitable least Bell's vireo and yellow warbler breeding habitat. Goals and objectives in the Plan for riparian restoration also include the restoration, maintenance and enhancement of structural heterogeneity with adequate vertical and horizontal overlap among vegetation components and over adjacent riverine channels, freshwater emergent wetlands, and grasslands (Objective VFRNC2.1). These Plan objectives represent performance standards for considering the effectiveness of CM7 restoration and CM3 protection actions. The acres of protection contained in the near-term Plan goals and the additional detail in the biological objectives for least Bell's vireo satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1, as well as mitigate the near-term effects of the other conservation measures. The restored riparian habitat could require 5 years to several decades, for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. However, because the modeled habitat impacted largely consists of small patches of blackberry, willow, and riparian scrub, and because least Bell's vireo and yellow warbler are not known to be established breeders in the study area, BDCP actions would not be expected to have an adverse population-level effect on either species.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, *AMM10*

Restoration of Temporarily Affected Natural Communities, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. The yellow warbler is not a species that is covered under the BDCP. Although preconstruction surveys for least Bell's vireo may also detect yellow warblers (if they were to nest in the study area over the course of the BDCP), in order to have a less than adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that yellow warbler nests were detected and avoided. Mitigation Measure BIO-75 would be available to address adverse effects on nesting yellow warblers.

Late Long-Term Timeframe

The habitat model indicates that the study area supports approximately 14,850 acres of modeled habitat for least Bell's vireo and yellow warbler. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 1,047 acres of habitat for these species during the term of the Plan (7% of the total habitat in the study area). These losses would occur from the construction of the water conveyance facilities (CM1) and from *CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration*. The locations of these losses would be in fragmented riparian habitat throughout the study area.

The Plan includes conservation commitments through *CM7 Riparian Natural Community Restoration* and *CM3 Natural Communities Protection and Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian woodland. Of the 5,000 acres of restored riparian natural communities, a minimum of 3,000 acres of valley/foothill riparian would be restored within the seasonally inundated floodplain, and 1,000 acres would be managed as dense early to mid-successional riparian forest (Objectives VFRNC1.1 and VFRNC1.2). Goals and objectives in the Plan for riparian restoration also include the maintenance and enhancement of structural heterogeneity (Objective VFRNC2.1) which would provide suitable nesting and migratory habitat for the least Bell's vireo and yellow warbler.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 1,000 acres and the protection of 593 acres of habitat for the least Bell's vireo, which would also be suitable habitat for the yellow warbler.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities,* and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

NEPA Effects: The loss of least Bell's vireo and yellow warbler habitat and potential direct mortality of these special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. However, these species are not established breeders in the study area and impacts would likely be limited to loss of migratory habitat. In addition, with habitat protection and restoration associated with CM3 and CM7, guided by biological goals and objectives and by *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities,* and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, which would be in place during all project activities, the effects of habitat loss and potential mortality on least Bell's vireo, and the effect of habitat loss on yellow warbler under Alternative 9 would not be adverse. The yellow warbler is not a species that is covered under the BDCP and potential mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. Mitigation Measure BIO-75 would be available to address this effect.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the impacts of construction would be less than significant under CEQA. Alternative 9 would remove 752 acres of modeled habitat for least Bell's vireo and yellow warbler in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 282 acres of habitat), and implementing other conservation measures (Yolo Bypass fisheries improvements [CM2] tidal restoration [CM4], seasonally inundated floodplain restoration [CM5]—470 acres of habitat).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected and that are identified in the biological goals and objectives for least Bell's vireo in Chapter 3 of the BDCP would be 1:1 for restoration/creation and 1:1 protection of dense shrubby successional valley/foothill riparian habitat. Using these ratios would indicate that 282 acres of valley/foothill riparian habitat should be restored/created and 282 acres should be protected to compensate for the CM1 losses of least Bell's vireo and yellow warbler habitat. The near-term effects of other conservation actions would remove 470 acres of modeled habitat, and therefore require 470 acres of restoration and 470 acres of protection of dense shrubby valley/foothill riparian using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of the valley/foothill riparian natural community in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3 and CM7 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on least Bell's vireo and yellow warbler. The majority of the riparian restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2, BDCP Chapter 3, *Conservation Strategy*). This restoration would provide the large contiguous patches needed for suitable least Bell's vireo and yellow warbler breeding habitat. Goals and objectives in the Plan for riparian restoration also include the restoration, maintenance and enhancement of structural heterogeneity with adequate vertical and horizontal overlap among vegetation components and over adjacent riverine channels, freshwater emergent wetlands, and grasslands (Objective VFRNC2.1). These Plan objectives represent performance standards for considering the effectiveness of CM7 restoration and CM3 protection actions. biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions. The acres of protection contained in the near-term Plan goals and the additional detail in the biological objectives for least Bell's vireo satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1, as well as mitigate the near-term effects of the other conservation measures. The restored riparian habitat could require 5 years to several decades, for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. However, because the modeled habitat impacted largely consists of small patches of blackberry, willow, and riparian scrub, and because least Bell's vireo and yellow warbler are not known to be established breeders in the study area, BDCP actions would not be expected to have an adverse population-level effect on either species.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities,* and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. The yellow warbler is not a species that is covered under the BDCP. Although preconstruction surveys for least Bell's vireo may also detect yellow warblers (if they were to nest in the Plan Area over the course of the BDCP), in order to have a less than adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that yellow warbler nests are detected and avoided. Mitigation Measure BIO-75 would reduce the potential impact on nesting yellow warblers to a less-than-significant impact, should they become established in the Plan Area. Considering the conservation actions described above, and AMM1–AMM-7 AMM 22, and Mitigation Measure BIO-75, Alternative 9, over the term of the BDCP would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of either species. Therefore, Alternative 9 would have a less-than-significant impact on least Bell's vireo and yellow warbler.

Late Long-Term Timeframe

The habitat model indicates that the study area supports approximately 14,850 acres of modeled habitat for least Bell's vireo and yellow warbler. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 1,047 acres of habitat for these species during the term of the Plan (7% of the total habitat in the study area). These losses would occur from the construction of the water conveyance facilities (CM1) and from *CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration*. The locations of these losses would be in fragmented riparian habitat throughout the study area.

The Plan includes conservation commitments through *CM7 Riparian Natural Community Restoration* and *CM3 Natural Communities Protection and Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian woodland. Of the 5,000 acres of restored riparian natural communities, a minimum of 3,000 acres of valley/foothill riparian would be restored within the seasonally inundated floodplain, and 1,000 acres would be managed as dense early to mid-successional riparian forest (Objectives VFRNC1.1 and VFRNC1.2). Goals and objectives in the Plan for riparian restoration also include the maintenance and enhancement of structural heterogeneity (Objective VFRNC2.1) which would provide suitable nesting and migratory habitat for the least Bell's vireo and yellow warbler. The restored riparian habitat could require 5 years to several decades, for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. Therefore, there would be a time-lag before the restored habitat would benefit either species. However, neither species are established breeders in the study area and impacts would likely be limited to loss of migratory habitat for least Bell's vireo and yellow warbler.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 1,000 acres and the protection of 593 acres of habitat for the least Bell's vireo, which would also be suitable habitat for the yellow warbler.

The loss of least Bell's vireo and yellow warbler habitat and potential direct mortality of these special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. However, neither species is an established breeder in the study area and impacts would likely be limited to loss of migratory habitat for least Bell's vireo and yellow warbler. In addition, with habitat protection and restoration associated with CM3 and CM7, guided by biological goals and objectives and by *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, which would be in place during all project activities, the impact of habitat loss and potential mortality on least Bell's vireo and the effect of habitat loss on yellow warbler under Alternative 9 would be less than significant. The yellow warbler is not a species that is covered under the BDCP. Although preconstruction surveys for least Bell's vireo may also detect nesting yellow warblers, in order for the BDCP to have a less-than-significant impact on individuals, preconstruction surveys for noncovered avian species would be required to ensure that yellow warbler nests are detected and avoided. Implementation of Mitigation Measure BIO-75 would reduce this potential impact on nesting yellow warblers, if present in the study area, to a less-than-significant level.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

To reduce impacts on nesting birds, DWR will implement the measures listed below prior to construction and operations and maintenance activities.

- To the maximum extent feasible, vegetation removal and trimming will be scheduled during the nonbreeding season of birds (September 1–January 31). If vegetation removal cannot be removed in accordance with this timeframe, preconstruction/preactivity surveys for nesting birds and additional protective measures will be implemented as described below.

- A qualified wildlife biologists with knowledge of the relevant species will conduct nesting surveys before the start of construction. A minimum of three separate surveys will be conducted within 30 days prior to construction, with the last survey within 3 days prior to construction. Surveys will include a search of all suitable nesting habitat in the construction area. In addition, a 500-foot radius around the construction area, where accessible, will be surveyed for nesting raptors and species of special concern (except the Modesto song sparrow), and an area within 50 feet of construction will be surveyed for other non-special status nesting birds or other birds protected by the MBTA. If no active nests are detected during these surveys, no additional measures are required.
- If active nests are found in the survey area, no-disturbance buffers will be established around the nest sites to avoid disturbance or destruction of the nest site until the end of the breeding season (approximately September 1) or until a qualified wildlife biologist determines that the young have fledged and moved out of the project area (this date varies by species). A qualified wildlife biologist will monitor construction activities in the vicinity of the nests to ensure that construction activities do not affect nest success. The extent of the buffers will be determined by DWR biologists in consultation with USFWS and CDFW and will depend on the level of noise or construction disturbance, line-of-sight between the nest and the disturbance, ambient levels of noise and other disturbances, and other topographical or artificial barriers. Suitable buffer distances may vary between species.

Impact BIO-76: Fragmentation of Least Bell's Vireo and Yellow Warbler Habitat

Grading, filling, contouring, and other initial ground-disturbing operations may temporarily fragment modeled least Bell's vireo and yellow warbler habitat. This could temporarily reduce the affected habitat's extent and functions, including exposure to cowbird parasitism, a nest parasite of both species. Preconstruction surveys under *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* and Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would identify any nesting pairs and the potential for habitat fragmentation to affect either species. If a nesting pairs of either species were detected where fragmentation has occurred, nests would be monitored for edge effects or other effects caused by the disturbance. The habitat would be adaptively managed to avoid or minimize impacts (e.g., cowbird control) under CM11, which includes the control of nonnative predators through habitat manipulation techniques or trapping to reduce nest predation.

NEPA Effects: Because there are only two recent occurrences of least Bell's vireo within the Plan Area, and no occurrences of yellow warbler breeding in the Plan Area, habitat fragmentation resulting from ground-disturbing operations is not expected to affect either species. If nesting pairs of either species were detected where fragmentation has occurred, nests would be monitored for edge effects or other effects caused by the disturbance. The habitat would be adaptively managed to avoid or minimize impacts (e.g., cowbird control) under CM11. Therefore, habitat fragmentation as a result of Alternative 9 implementation would not have an adverse effect on least Bell's vireo or yellow warbler.

CEQA Conclusion: Because there are only two recent occurrences of least Bell's vireo within the Plan Area, and no occurrences of yellow warbler breeding in the Plan Area, habitat fragmentation resulting from ground-disturbing operations would not be expected to substantially modify habitat or result in the direct mortality of special status species. If nesting pairs of either species were detected where fragmentation has occurred, nests would be monitored for edge effects or other effects caused by the disturbance. The habitat would be adaptively managed to avoid or minimize impacts (e.g., cowbird control) under CM11. Therefore, habitat fragmentation as a result of Alternative 9 would have a less-than-significant impact on least Bell's vireo and yellow warbler.

Impact BIO-77: Effects on Least Bell's Vireo and Yellow Warbler Associated with Electrical Transmission Facilities

Both least Bell's vireo and yellow warbler typically occur in early to mid-successional riparian habitat, which is used to meet all of its life requisites. Least Bell's vireo are rarely observed in open habitats away from riparian vegetation. Neither species form flocks and individuals generally remain at or below the riparian canopy, below the height of proposed transmission lines (see BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*). The behavior and habitat requirements of least Bell's vireo and yellow warbler make collision with the proposed transmission lines unlikely. *AMM30 Transmission Line Design and Alignment Guidelines* would ensure that the transmission lines, poles, and towers are designed to avoid sensitive terrestrial habitats (including riparian) to the maximum extent feasible which would minimize the potential for collision. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). For example, Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. As described in *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters, which would substantially reduce any potential for mortality of least Bell's vireo or yellow warbler individuals from powerline collisions.

NEPA Effects: Installation and presence of new transmission lines would not result in an adverse effect on least Bell's vireo or yellow warbler because the probability of bird-powerline strikes is unlikely due to the behavior and habitat requirements of these species. Implementation of *AMM30 Transmission Line Design and Alignment Guidelines* would avoid impacts on riparian habitat to the maximum extent feasible, which would minimize the potential for collision. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would substantially reduce the risk of mortality from bird strike for least Bell's vireo and yellow warbler as a result of the project. Therefore, the construction and operation of new transmission lines would not result in an adverse effect on least Bell's vireo or yellow warbler.

CEQA Conclusion: Installation and presence of new transmission lines would result in a less-than-significant impact on least Bell's vireo or yellow warbler because the probability of bird-powerline strikes is unlikely due to the behavior and habitat requirements of these species. Implementation of *AMM30 Transmission Line Design and Alignment Guidelines* would avoid impacts on riparian habitat to the maximum extent feasible, which would minimize the potential for collision. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would substantially reduce the risk of mortality from bird strike for least Bell's vireo and yellow warbler as a result of the project. Therefore, the construction and operation of new transmission lines would result in a less-than-significant impact on least Bell's vireo or yellow warbler.

Impact BIO-78: Indirect Effects of Plan Implementation on Least Bell's Vireo and Yellow Warbler

Indirect Construction- and Operation-Related Effects: If least Bell's vireo or yellow warbler were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect least Bell's vireo or yellow warbler. *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would reduce the potential for adverse effects of construction-related activities on survival and productivity of nesting least Bell's vireo and a 500 foot no-disturbance buffer would be established around the active nest. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to reduce the potential for adverse effects of construction-related activities on nesting yellow warbler. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect least Bell's vireo and yellow warbler in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. *AMM2 Construction Best Management Practices and Monitoring* would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including the least Bell's vireo and yellow warbler. Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect least Bell's vireo and yellow warbler, via uptake in lower trophic levels (as described in BDCP Appendix 5.D, *Contaminants*).

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. *CM12 Methylmercury Management* contains provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on least Bell's vireo and yellow warbler.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009), and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including least Bell's vireo and yellow warbler. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and, therefore, increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 9 restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations are analyzed in Chapter 8, *Water Quality*, which concludes that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on least Bell's vireo and yellow warbler.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on least Bell's vireo and yellow warbler from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

***NEPA Effects*:** Impacts of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities on least Bell's vireo would not be adverse with the implementation of AMM1–AMM7, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo.* Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting yellow warblers.

The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of least Bell's vireo or yellow warbler to methylmercury, should they begin to nest in the study area. However, it is unknown what concentrations of methylmercury are harmful to these species. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in *CM12 Methylmercury Management*, would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential adverse effects of methylmercury on least Bell's vireo and yellow warbler.

Tidal habitat restoration could result in increased exposure of least Bell's vireo and yellow warbler to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

***CEQA Conclusion*:** Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would have a less-than-significant impact on least Bell's vireo and yellow warbler with the implementation of *AMM2 Construction Best Management Practices and Monitoring*, *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*.

The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of least Bell's vireo or yellow warbler to methylmercury, should they begin to nest in the study area. However, it is unknown what concentrations of methylmercury are harmful to these species. Sites-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in *CM12 Methylmercury Management*, would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential significant impacts on least Bell's vireo and yellow warbler.

Tidal habitat restoration could result in increased exposure of least Bell's vireo and yellow warbler to selenium. With implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats, the impact of potential increased selenium exposure would be less than significant.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-79: Periodic Effects of Inundation of Least Bell's Vireo and Yellow Warbler Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (CM2) would increase the frequency and duration of inundation of approximately 48–85 acres of modeled least Bell's vireo and yellow warbler habitat in CZ 2. No adverse effects of increased inundation frequency on least Bell's vireo, yellow warbler, or their habitat would be expected, because riparian vegetation supporting habitat has persisted under the existing Yolo Bypass flooding regime and changes to frequency and inundation would be within the tolerance of these vegetation types.

Based on hypothetical floodplain restoration for *CM5 Seasonally Inundated Floodplain Restoration*, construction of setback levees could result in periodic inundation of up to 148 acres of modeled least Bell's vireo and yellow warbler habitat in CZ 7. Inundation of restored floodplains would not be expected to affect least Bell's vireo, yellow warbler, or their habitat because the breeding period is outside the period when floodplains would likely be inundated. Additionally, periodic inundation of floodplains would be expected to restore a more natural flood regime in support of riparian vegetation types that support least Bell's vireo and yellow warbler habitat. The overall effect of seasonal inundation in existing riparian natural communities would be beneficial, because, historically, flooding was the main natural disturbance regulating ecological processes in riparian areas, and flooding promotes the germination and establishment of many native riparian plants.

NEPA Effects: Implementation of CM2 and CM5 would result in periodic inundation of 48–85 acres (CM2) and 148 acres (CM5) of modeled habitat for least Bell's vireo and yellow warbler. However, periodic inundation would not result in an adverse effect on least Bell's vireo or yellow warbler because inundation would occur primarily during the nonbreeding season and would promote a more natural flood regime in support of habitat for these species.

CEQA Conclusion: Implementation of CM2 and CM5 would result in periodic inundation of 48–85 acres (CM2) and 148 acres (CM5) of modeled habitat for least Bell's vireo and yellow warbler. However, periodic inundation would have a less-than-significant impact on least Bell's vireo or yellow warbler because inundation would occur during the nonbreeding season and would not be expected to adversely modify habitat or result in direct mortality of either species. Flooding promotes the germination and establishment of many native riparian plants. Therefore, the overall impact of seasonal inundation in existing riparian natural communities would be beneficial for least Bell's vireo and yellow warbler.

Suisun Song Sparrow and Saltmarsh Common Yellowthroat

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on Suisun song sparrow and saltmarsh common yellowthroat. The habitat model used to assess effects on Suisun song sparrow and saltmarsh common yellowthroat is based on primary breeding habitat and secondary habitat. Suisun song sparrow primary breeding habitat consists of all *Salicornia*-dominated tidal brackish emergent wetland and all *Typha*-, *Scirpus*-, and *Juncus*-dominated tidal freshwater emergent wetland in the Plan Area west of Sherman Island, with the exception that *Scirpus acutus* and *S. californicus* plant communities (low marsh) and all of the plant communities listed below that occur in managed wetlands were classified as secondary habitat. Upland transitional zones, providing refugia during high tides, within 150 feet of the wetland edge were also included as secondary habitat. Secondary habitats generally provide only a few ecological functions such as foraging (low marsh and managed wetlands) or extreme high tide refuge (upland transition zones), while primary habitats provide multiple functions, including breeding, effective predator cover, and valuable forage.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of Suisun song sparrow and saltmarsh common yellowthroat modeled habitat as indicated in Table 12-9-34. The majority of the losses would take place over an extended period of time as tidal marsh is restored in the study area. Full implementation of Alternative 9 also include the following conservation actions over the term of the BDCP to benefit the Suisun song sparrow and the saltmarsh common yellowthroat (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 6,000 acres of tidal brackish emergent wetland in CZ 11, including at least 1,500 acres of middle and high marsh (Objectives TBEWNC1.1, TBEWNC1.2).

- Protect and enhance at least 8,100 acres of managed wetland, at least 1,500 acres of which are in the Grizzly Island Marsh Complex (Objective MWNC1.1)
- Protect at least 200 feet of adjacent grasslands beyond the sea level rise accommodation area (Objective GNC1.4)

As explained below, with the restoration and protection of these amounts of habitat, in addition to natural community enhancement and management commitments (including *CM12 Methylmercury Management*) and implementation of AMM1–AMM7, *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, and mitigation to minimize potential effects, impacts on Suisun song sparrow and saltmarsh common yellowthroat would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-34. Changes in Suisun Song Sparrow Saltmarsh Common Yellowthroat Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5

LLT = late long-term
NA = not applicable

Impact BIO-80: Loss or Conversion of Habitat for and Direct Mortality of Suisun Song Sparrow and Saltmarsh Common Yellowthroat

Alternative 9 conservation measures would result in would result in the permanent loss of up to 3,688 acres of Suisun song sparrow and saltmarsh common yellowthroat habitat, which would include the conversion of 55 acres of primary habitat to secondary low marsh, and the conversion of 123 acres of secondary habitat to middle or high marsh (Table 12-9-34). The only conservation measure that would affect modeled habitat for Suisun song sparrow and saltmarsh common yellowthroat is *CM4 Tidal Natural Communities Restoration*. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could also result in local adverse habitat effects. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follows the individual conservation measure discussions.

- *CM4 Tidal Natural Communities Restoration*: Site preparation and inundation would permanently remove approximately 3,510 acres of modeled secondary Suisun song sparrow and saltmarsh common yellowthroat habitat from CZ 11 (Table 12-9-34). In addition, 55 acres of primary habitat would be converted to secondary low marsh, and 123 acres of secondary habitat would be converted to middle or high marsh. Most areas proposed for removal would be managed wetlands that serve as relatively marginal habitat for Suisun song sparrow and saltmarsh common yellowthroat, which primarily use brackish tidal wetlands. Approximately 2% of primary habitat for these species would be converted to foraging habitat. Full implementation of CM4 would restore or create at least 6,000 acres of tidal brackish emergent wetland natural community in CZ 11, which would be expected to support Suisun song sparrow and saltmarsh common yellowthroat habitat. It is expected that restoring tidal wetland communities that are self-sustaining and not reliant on ongoing management actions necessary to maintain the existing managed wetland habitats would better ensure the long-term viability of these populations. Furthermore, effects of tidal habitat restoration on sparrow and yellowthroat abundance and distribution would be monitored, and the restoration of tidal habitat would be sequenced and located in a manner that minimizes effects on occupied habitats until functional habitats were restored (see BDCP Chapter 3, Section 3.4.5, *CM4 Tidal Natural Communities Restoration*, and Section 3.6, *Adaptive Management and Monitoring Program*).

- *CM11 Natural Communities Enhancement and Management:* Control of nonnative Suisun song sparrow and saltmarsh common yellowthroat predators, if deemed necessary, would be expected to reduce predation loss of nests and, consequently, increase and maintain the abundance of Suisun song sparrow and saltmarsh common yellowthroat in restored tidal habitats over the term of the BDCP. Habitat management- and enhancement-related activities could disturb Suisun song sparrow or saltmarsh common yellowthroat nests if they are located near work sites. The potential for these activities to have an adverse effect on Suisun song sparrow would be avoided and minimized through *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. In addition, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these effects on saltmarsh common yellowthroat. A variety of *CM11 Natural Communities Enhancement and Management* habitat management actions that are designed to enhance wildlife values in restored and protected tidal wetland habitats may result in localized ground disturbances that could temporarily remove small amounts of Suisun song sparrow and saltmarsh common yellowthroat habitat in CZ 11. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, are expected to have minor adverse effects on available species' habitat.

- Operations and Maintenance: Postconstruction operation and maintenance of the restoration infrastructure could result in ongoing but periodic disturbances that could affect Suisun song sparrow and saltmarsh common yellowthroat use of the surrounding habitat in Suisun. Maintenance activities could include vegetation management, and levee repair. These effects, however, would be reduced by AMMs and conservation actions as described below.

- Construction-related activities could result in nest destruction or disturbance resulting in mortality of eggs and nestlings if restoration activities took place within the nesting period for these species. *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would minimize these potential effects on Suisun song sparrow. Mitigation

Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these effects on saltmarsh common yellowthroat. Grading, filling, contouring, and other initial ground-disturbing operations during restoration activities could temporarily fragment existing modeled tidal brackish emergent wetland habitat for Suisun song sparrow and saltmarsh common yellowthroat which could temporarily reduce the extent and functions of the affected habitat. These temporary effects would be minimized through sequencing of restoration activities and through *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* and Mitigation Measure BIO-75.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Under Alternative 9, there would be no impacts resulting from the construction of the water conveyance facilities (CM1). However, there would be a permanent loss of 1,040 acres of modeled secondary habitat for Suisun song sparrow and saltmarsh common yellowthroat in the study area in the near-term. In addition, 54 acres of primary habitat would be converted to secondary foraging habitat, and 58 acres of secondary habitat would be converted to mid to high marsh, which would provide primary nesting habitat for these species. Although there would be a temporal lag in these conversions, there would be no net loss of primary habitat in the near-term. These effects would result from implementing *CM4 Tidal Natural Communities Restoration* and would all occur in Suisun Marsh in CZ 11.

The typical NEPA and CEQA project-level mitigation ratio for those natural communities that would be affected and that are identified in the biological goals and objectives for Suisun song sparrow in Chapter 3 of the BDCP would be 1:1 for restoration/creation of tidal brackish emergent habitat. Using this ratio would indicate that 1,152 acres of tidal brackish emergent wetland should be restored/created to compensate for the near-term losses of Suisun song sparrow and saltmarsh common yellowthroat habitat.

The BDCP has committed to near-term goals of restoring 8,850 acres of tidal brackish emergent wetland and 4,800 acres of managed wetland in the Plan Area. These conservation actions are associated with CM4 and CM3 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on Suisun song sparrow and saltmarsh common yellowthroat. The tidal brackish emergent wetland would be restored in CZ 11 among the Western Suisun/Hill Slough Marsh Complex, the Suisun Slough/Cutoff Slough Marsh Complex, and the Nurse Slough/Denverton Marsh complex (Objective TBEWNC1.1, BDCP Chapter 3, *Conservation Strategy*) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TBEWNC1.4). Portions of the 4,800 acres of managed wetland would benefit both the Suisun song sparrow and the saltmarsh common yellowthroat through the enhancement of degraded areas to provide dense native vegetation, which is required for nesting sites, song perches, and refuge from predators. Tidal wetlands would be restored in a mosaic of large, interconnected and biologically diverse patches. Larger and more interconnected patches of suitable habitat would be expected to reduce the effects of habitat fragmentation that currently exist in Suisun marsh in CZ 11. Nonnative predators would be controlled as needed to reduce nest predation and to help maintain species abundance (CM11). Restoration would be sequenced over the term of the Plan and occur in a manner that would minimize any temporary, initial loss and fragmentation of habitat. The acres of restoration and protection contained in the near-term Plan goals, and the incorporation of the additional measures in the biological goals and objectives (BDCP Chapter 3) would be sufficient to mitigate the near-term effects of tidal restoration.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. The saltmarsh common yellowthroat is not a species that is covered under the BDCP. Although preconstruction surveys for Suisun song sparrow would likely also detect nesting saltmarsh common yellowthroat, in order to avoid adverse effects on individuals, preconstruction surveys for noncovered avian species would be required to ensure that saltmarsh common yellowthroat nests are detected and avoided. Mitigation Measure BIO-75 would be available to address the adverse effect of construction activities on nesting saltmarsh common yellowthroat.

Late Long-Term Timeframe

The habitat model indicates that the study area supports approximately 3,722 acres of primary and 23,986 acres of secondary habitat for Suisun song sparrow and saltmarsh common yellowthroat. Alternative 9 as a whole would result in the permanent loss of 3,688 acres of habitat (15% of the total habitat in the study area) from the implementation of *CM4 Tidal Natural Communities Restoration*. Within this habitat loss, 55 acres of primary habitat would be converted to secondary foraging habitat, and 123 acres of secondary habitat would be converted to primary habitat.

The Plan includes a commitment through *CM4 Tidal Natural Communities Restoration* to restore or create at least 6,000 acres of tidal brackish emergent wetland in CZ 11 (Objective TBEWNC1.1) These tidal wetlands would be restored as a mosaic of large, interconnected and biologically diverse patches, and at least 1,500 acres of restored marsh would consist of middle-and high-marsh vegetation with dense, tall stands of pickleweed and bulrush cover, serving as primary habitat for Suisun song sparrow and saltmarsh common yellowthroat (Objective TBEWNC1.2). In addition, grasslands adjacent to restored tidal brackish emergent wetlands would be protected or restored, to provide at least 200 feet of adjacent grasslands beyond the sea level rise accommodation. This adjacent upland habitat would provide high tide refugia during high tide events, after sea-level rise has converted the lower-level grasslands to tidal natural communities. Tidal wetlands would be restored in a mosaic of large, interconnected and biologically diverse patches. Larger and more interconnected patches of suitable habitat would be expected to reduce the effects of habitat fragmentation that currently exist in Suisun marsh in CZ 11. Nonnative predators would be controlled as needed to reduce nest predation and to help maintain species abundance (CM11). Restoration would be sequenced over the term of the Plan and occur in a manner that would minimize any temporary, initial loss and fragmentation of habitat.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 1,500 acres of primary habitat and 4,500 acres of secondary habitat in addition to the protection of 384 acres of secondary habitat for Suisun song sparrow, which would also benefit the saltmarsh common yellowthroat.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

NEPA Effects: The loss of Suisun song sparrow and saltmarsh common yellowthroat habitat and potential direct mortality of these special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. However, with habitat protection and restoration associated with CM4, with the management and enhancement actions (CM11), and with the incorporation of the additional measures in the biological goals and objectives, guided by AMM1–AMM7 and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, which would be in place throughout the construction period, the effects of habitat loss and potential mortality on Suisun song sparrow would not be adverse, and the effects of habitat loss and conversion on saltmarsh common yellowthroat would not be adverse under Alternative 9. The saltmarsh common yellowthroat is not a species that is covered under the BDCP. Although preconstruction surveys for Suisun song sparrow would likely also detect nesting saltmarsh common yellowthroat, in order for the BDCP to avoid adverse effects on individuals, preconstruction surveys for noncovered avian species would be required to ensure that saltmarsh common yellowthroat nests are detected and avoided. Mitigation Measure BIO-75 would be available to address this effect.

CEQA Conclusion:

Near-Term Timeframe

Under Alternative 9, there would be no impacts resulting from the construction of the water conveyance facilities (CM1). However, there would be a permanent loss of 1,040 acres of modeled secondary habitat for Suisun song sparrow and saltmarsh common yellowthroat in the study area in the near-term. In addition, 54 acres of primary habitat would be converted to secondary foraging habitat, and 123 acres of secondary habitat would be converted to mid to high marsh, which would provide primary nesting habitat for these species. Although there would be a temporal lag in these conversions, there would be no net loss of primary habitat in the near-term. These effects would result from implementing *CM4 Tidal Natural Communities Restoration* and would all occur in Suisun Marsh in CZ 11.

The typical NEPA and CEQA project-level mitigation ratio for those natural communities that would be affected and that are identified in the biological goals and objectives for Suisun song sparrow in Chapter 3 of the BDCP would be 1:1 for restoration/creation of tidal brackish emergent habitat. Using this ratio would indicate that 1,152 acres of tidal brackish emergent wetland should be restored/created to mitigate the near-term losses of Suisun song sparrow and saltmarsh common yellowthroat habitat.

The BDCP has committed to near-term goals of restoring 8,850 acres of tidal brackish emergent wetland and 4,800 acres of managed wetland in the Plan Area. These conservation actions are associated with CM4 and CM3 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on Suisun song sparrow and saltmarsh common yellowthroat. The tidal brackish emergent wetland would be restored in CZ 11 among the Western Suisun/Hill Slough Marsh Complex, the Suisun Slough/Cutoff Slough Marsh Complex, and the Nurse Slough/Denverton Marsh complex (Objective TBEWNC1.1, BDCP Chapter 3, *Conservation Strategy*) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TBEWNC1.4). Portions of the 4,800 acres of managed wetland would benefit both the Suisun song sparrow and the saltmarsh common yellowthroat through the enhancement of degraded areas to provide dense native vegetation, which is required for nesting sites, song perches, and refuge from predators. Tidal wetlands would be restored in a mosaic of large, interconnected and biologically diverse patches. Larger and more interconnected patches of suitable habitat would be expected to reduce the effects of habitat fragmentation that currently exist in Suisun marsh in CZ 11. Nonnative predators would be controlled as needed to reduce nest predation and to help maintain species abundance (CM11). Restoration would be sequenced over the term of the Plan and occur in a manner that would minimize any temporary, initial loss and fragmentation of habitat. The acres of restoration and protection contained in the near-term Plan goals, and the incorporation of the additional measures in the biological goals and objectives (BDCP Chapter 3) would be sufficient to mitigate the near-term effects of tidal restoration.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. The saltmarsh common yellowthroat is not a species that is covered under the BDCP. Although preconstruction surveys for Suisun song sparrow would likely also detect nesting saltmarsh common yellowthroat, in order to avoid adverse effects on individuals, preconstruction surveys for noncovered avian species would be required to ensure that saltmarsh common yellowthroat nests are detected and avoided. Implementation of Mitigation Measure BIO-75 would reduce the impact of construction activities on nesting saltmarsh common yellowthroat to a less-than-significant level.

Because the number of acres required to meet the typical mitigation ratio described above would be only 3,590 acres of restored/created tidal natural communities, the 6,000 acres of tidal brackish and tidal freshwater emergent wetland restoration and the 4,100 acres of managed wetland protection and enhancement contained in the near-term Plan goals, and the additional detail in the biological objectives for Suisun song sparrow, are more than sufficient to support the conclusion that the near-term impacts of habitat loss and direct mortality of Suisun song sparrow or saltmarsh common yellowthroat under Alternative 9 would be less than significant under CEQA.

Late Long-Term Timeframe

The habitat model indicates that the study area supports approximately 3,722 acres of primary and 23,986 acres of secondary habitat for Suisun song sparrow and saltmarsh common yellowthroat. Alternative 9 as a whole would result in the permanent loss of 3,688 acres of habitat (15% of the total habitat in the study area) from the implementation of *CM4 Tidal Natural Communities Restoration*. Within this habitat loss, 55 acres of primary habitat would be converted to secondary foraging habitat, and 123 acres of secondary habitat would be converted to primary habitat.

The Plan includes a commitment through *CM4 Tidal Natural Communities Restoration* to restore or create at least 6,000 acres of tidal brackish emergent wetland in CZ 11 (Objective TBEWNC1.1) These tidal wetlands would be restored as a mosaic of large, interconnected and biologically diverse patches, and at least 1,500 acres of restored marsh would consist of middle-and high-marsh vegetation with dense, tall stands of pickleweed and bulrush cover, serving as primary habitat for Suisun song sparrow and saltmarsh common yellowthroat (Objective TBEWNC1.2). In addition, grasslands adjacent to restored tidal brackish emergent wetlands would be protected or restored, to provide at least 200 feet of adjacent grasslands beyond the sea level rise accommodation. This adjacent upland habitat would provide high tide refugia during high tide events, after sea-level rise has converted the lower-level grasslands to tidal natural communities. Tidal wetlands would be restored in a mosaic of large, interconnected and biologically diverse patches. Larger and more interconnected patches of suitable habitat would be expected to reduce the effects of habitat fragmentation that currently exist in Suisun marsh in CZ 11. Nonnative predators would be controlled as needed to reduce nest predation and to help maintain species abundance (CM11). Restoration would be sequenced over the term of the Plan and occur in a manner that would minimize any temporary, initial loss and fragmentation of habitat.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 1,500 acres of primary habitat and 4,500 acres of secondary habitat in addition to the protection of 384 acres of secondary habitat for Suisun song sparrow, which would also benefit the saltmarsh common yellowthroat.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. The saltmarsh common yellowthroat is not a covered species under the BDCP. Although preconstruction surveys for Suisun song sparrow may detect nesting saltmarsh common yellowthroat, in order for the BDCP to have a less-than-significant impact on individuals, preconstruction surveys for noncovered avian species would be required to ensure that saltmarsh common yellowthroat nests are detected and avoided. Implementation of Mitigation Measure BIO-75 would reduce this potential impact on nesting saltmarsh common yellowthroat to a less-than-significant level.

Considering Alternative 9's restoration provisions, which would replace low-value secondary habitat with high-value tidal brackish emergent habitat, including both foraging and primary habitat, and provide upland refugia for Suisun song sparrow and saltmarsh common yellowthroat, the acreages of restoration would be sufficient to mitigate habitats lost to construction and restoration activities. Loss of habitat or direct mortality through implementation of Alternative 9, with the implementation of AMM1–AMM7, AMM22, and Mitigation Measure BIO-75, AMM1–AMM7 *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on Suisun song sparrow and saltmarsh common yellowthroat.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-81: Indirect Effects of Plan Implementation on Suisun Song Sparrow and Saltmarsh Common Yellowthroat

Indirect Construction-Related Effects: If Suisun song sparrow or saltmarsh common yellowthroat were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. Suisun song sparrow and saltmarsh common yellowthroat habitat adjacent to restoration work areas could be affected by such disturbances, which could temporarily result in diminished use of habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect either species. If construction occurred during the nesting season, these indirect effects could result in the loss or abandonment of nests and mortality of any eggs and/or nestlings. *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would avoid the potential for adverse effects of construction-related activities on survival and productivity of Suisun song sparrow and saltmarsh common yellowthroat by requiring preconstruction surveys and, if nests are present, the establishment of a no-disturbance buffer within 250 feet of a nest site. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect species in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on Suisun song sparrow and saltmarsh common yellowthroat. *AMM2 Construction Best Management Practices and Monitoring* would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and any adverse effects of dust on active nests.

Salinity: Water conveyance facilities operations would have an effect on salinity gradients in Suisun Marsh; however, these effects cannot be reasonably disaggregated from effects resulting from tidal habitat restoration. It is expected that the salinity of water in Suisun Marsh would generally increase as a result of water conveyance facilities operations and operations of salinity control gates to mimic a more natural water flow. This would likely encourage the establishment of tidal wetland plant communities tolerant of more saline environments, which should have a beneficial effect on Suisun song sparrow and saltmarsh common yellowthroat because their historical natural Suisun Marsh habitat is brackish tidal marsh. However, the degree to which salinity changes in all tidal channels and sloughs in and around Suisun Marsh would be highly variable.

Methylmercury Exposure: Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury. Although tidal habitat restoration might increase methylation of mercury export to other habitats, restoration is unlikely to significantly increase the exposure of Suisun song sparrow or saltmarsh common yellowthroat to methylmercury, as they currently reside in tidal marshes where elevated methylmercury levels exist. Robinson et al. (2011) found toxic levels of methylmercury levels in song sparrow populations from southern San Francisco Bay, although populations near Suisun Marsh (i.e., San Pablo and Simas Creeks) were much lower. The potential mobilization or creation of methylmercury within the study area varies with site-specific conditions and would need to be assessed at the project level. The Suisun Marsh Plan anticipates that restored tidal wetlands would generate less methylmercury than the existing managed wetlands to be restored (Bureau of Reclamation et al. 2010).

Due to the complex and very site-specific factors that determine if mercury becomes mobilized into the foodweb, *CM12 Methylmercury Management* (as revised in Appendix 11F, *Substantive BDCP Revisions*) is included to provide for site-specific evaluation for each restoration project. On a project-specific basis, where high potential for methylmercury production is identified that restoration design and adaptive management cannot fully address while also meeting restoration objectives, alternate restoration areas will be considered. CM12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This conservation measure would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009), and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including Suisun song sparrow and saltmarsh common yellowthroat. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and, therefore, increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 9 restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations are analyzed in Chapter 8, *Water Quality*, which concludes that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on Suisun song sparrow and saltmarsh common yellowthroat.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on Suisun song sparrow and saltmarsh common yellowthroat from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Noise and visual disturbances would not have an adverse effect on Suisun song sparrow with the implementation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects of noise and visual disturbance on saltmarsh common yellowthroat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of spills, and ensure that measures were in place to prevent runoff from the construction area and to avoid negative effects of dust on the species.

Implementation of Operational Scenario A, including operation of salinity-control gates, and tidal habitat restoration would be expected to increase water salinity in Suisun Marsh, which would be expected to establish tidal marsh similar to historic conditions. Tidal habitat restoration is unlikely to have a substantial impact on Suisun song sparrow and saltmarsh common yellowthroat through increased exposure to methylmercury, as these species currently reside in tidal marshes where elevated methylmercury levels exist. However, it is unknown what concentrations of methylmercury are harmful to the species and the potential for increased exposure varies substantially within the study area. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on Suisun song sparrow and saltmarsh common yellowthroat.

Tidal habitat restoration could result in increased exposure of Suisun song sparrow and saltmarsh common yellowthroat to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

CEQA Conclusion**:** Impacts of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would be less than significant with the implementation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and *AMM2 Construction Best Management Practices and Monitoring*.

Changes in salinity gradients would be expected to have a beneficial impact on Suisun song sparrow and saltmarsh common yellowthroat through the establishment of tidal marsh similar to historic conditions. The implementation of tidal natural communities restoration (CM4) is unlikely to significantly increase the exposure of Suisun song sparrow or saltmarsh common yellowthroat to methylmercury, as they currently reside in tidal marshes where elevated methylmercury levels exist. However, it is unknown what concentrations of methylmercury are harmful to these species. Implementation of CM12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on Suisun song sparrow and saltmarsh common yellowthroat.

Tidal habitat restoration could result in increased exposure of Suisun song sparrow and saltmarsh common yellowthroat to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

With these avoidance and minimization measures and Mitigation Measure BIO-75 in place, indirect effects of Alternative 9 implementation would have a less-than-significant impact on Suisun song sparrow and saltmarsh common yellowthroat.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-82: Effects on Suisun Song Sparrow and Saltmarsh Common Yellowthroat Associated with Electrical Transmission Facilities

The range of the Suisun song sparrow extends eastward into the Plan Area to approximately Kimball Island. There are several reported occurrences from Kimball Island, Browns Island, and in the Suisun Marsh in the western portion of the Plan Area. The easternmost range of the saltmarsh common yellowthroat also ends in Suisun Marsh. These species ranges, along with areas of suitable habitat, are far from the proposed transmission line routes (BDCP Appendix 5.J, Attachment 5J.C*, Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Location of the current populations, species ranges, and suitable habitat in the plan area make collision with the proposed transmission lines highly unlikely. Therefore the construction and presence of new transmission lines would not have an adverse effect on Suisun song sparrow and saltmarsh common yellowthroat.

***NEPA Effects*:** The construction and presence of new transmission lines would not have an adverse effect on Suisun song sparrow and saltmarsh common yellowthroat because the location of the current populations, species ranges, and suitable habitat for the species make collision with the proposed transmission lines highly unlikely.

***CEQA Conclusion*:** The construction and presence of new transmission lines would not be expected to have an adverse effect on Suisun song sparrow and saltmarsh common yellowthroat because the location of the current populations, species ranges, and suitable habitat for the species make collision with the proposed transmission lines highly unlikely. Therefore, the construction and presence of new transmission lines under Alternative 9 would have a less-than-significant impact on Suisun song sparrow and saltmarsh common yellowthroat

Swainson's Hawk

The habitat model used to assess impacts on Swainson's hawk includes plant alliances and land cover types associated with Swainson's hawk nesting and foraging habitat. Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of Swainson's hawk modeled habitat as indicated in Table 12-9-35. The majority of the losses would take place over an extended period of time as tidal marsh is restored in the study area. Although protection and restoration for the loss of nesting and foraging habitat would be initiated in the same timeframe as the losses, it would take years (for foraging habitat) and 1 or more decades (for nesting habitat) for restored habitats to replace the functions of habitat lost. This time lag between impacts and restoration of habitat function would be minimized through specific requirements of *AMM18 Swainson's Hawk*, including transplanting mature trees in the near-term time period. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit the Swainson's hawk (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 5,000 acres of valley/foothill riparian natural community, with at least 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM7)
- Protect at least 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).
- Plant and maintain native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SH2.1, associated with CM11).

- Establish 20- to 30- foot-wide hedgerows along fields and roadsides to promote prey populations throughout protected cultivated lands (Objective SH2.2, associated with CM3).
- Increase prey abundance and accessibility for grassland-foraging species (Objectives ASWNC2.4, VPNC2.5, and GNC2.4, associated with CM11).
- Conserve at least 1 acre of Swainson's hawk foraging habitat for each acre of lost foraging habitat (Objective SH1.1, associated with CM3).
- Protect at least 42,275 acres of cultivated lands as Swainson's hawk foraging habitat with at least 50% in very high-value habitat in CZs 2, 3, 4, 5, 7, 8, 9, and 11 (Objective SH1.2, associated with CM3).
- Of the 42,275 acres of cultivated lands protected as Swainson's hawk foraging habitat under Objective SH1.2, up to 1,500 acres can occur in CZs 5 and 6, and must have land surface elevations greater than −1 foot NAVD88 (Objective SH1.3, associated with CM3).
- Protect at least 10,750 acres of grassland, vernal pool, and alkali seasonal wetland as Swainson's hawk foraging habitat (Objective SH1.4, associated with CM3).
- Protect and enhance at least 8,100 acres of managed wetland, at least 1,500 acres of which are in the Grizzly Island Marsh Complex (Objective MWNC1.1, associated with CM3).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for the species and implementation of AMM1–AMM7 and *AMM18 Swainson's Hawk* to minimize potential effects, impacts on Swainson's hawk would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-35. Changes in Swainson's Hawk Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent NT	Permanent LLT[c]	Temporary NT	Temporary LLT[c]	Periodic[d] CM2	Periodic[d] CM5

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term

LLT = late long-term

NA = not applicable

Impact BIO-83: Loss or Conversion of Habitat for and Direct Mortality of Swainson's Hawk

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 53,516 modeled habitat (558 acres of nesting habitat and 52,958 acres of foraging habitat) for Swainson's hawk (Table 12-9-35). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), riparian restoration, (CM7), grassland restoration (CM8), vernal pool and wetland restoration (CM9), nontidal marsh restoration (CM10), and construction of conservation hatcheries (CM18). Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could affect Swainson's hawk modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of Alternative 9 water conveyance facilities would result in the combined permanent and temporary loss of up to 61 acres of Swainson's hawk nesting habitat (32 acres of permanent loss and 29 acres of temporary loss). In addition, 2,907 acres of foraging habitat would be removed (373 acres of permanent loss, 2,534 acres of temporary loss, Table 12-9-35). Activities that would impact modeled Swainson's hawk habitat include channel dredging, intakes, fish barriers, access roads, and construction of transmission lines. Permanent losses of nesting habitat would primarily consist of channel enlargement at the Sacramento River and Meadows Slough. Temporary losses would occur primarily along Middle River between Victoria Canal and Mildred Island, where large dredging work areas and operable barrier work areas would be placed. The riparian habitat in these areas is composed of very small patches or stringers bordering waterways, which include valley oak and scrub vegetation. Permanent impacts on foraging habitat would occur from the construction of the canals in CZ 8 east and south of Clifton Court Forebay and other conveyance structures in CZ 4, 5, 6, 7, and 8. Temporary impacts would primarily occur from borrow and spoil areas and temporary work areas. Impacts on foraging habitat would include the permanent loss of 1 acres and the temporary loss of 727 acres of very high-value alfalfa (Table 12-9-36). The CM1 permanent construction footprint overlaps with 3 Swainson's hawk occurrences. Canal construction overlaps with two occurrences and channel dredging, instream island dredging, and a potential spoil area overlap with one occurrence. Thirteen Swainson's hawk occurrences overlap with the temporary construction footprint for CM1. These impacts would consist of potential borrow and spoil areas (3 occurrences), access road work areas (8 occurrences), and work areas for dredging, a barge facility, and a siphon (one occurrence). *AMM18 Swainson's Hawk* would require preconstruction surveys and the establishment of a no-disturbance buffer and minimize potential effects of construction on nesting Swainson's hawks. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations.

Table 12-9-36. Acres of Impacted Swainson's Hawk Foraging Habitat by Value Classes

Foraging Habitat Value Class	Cultivated Land and Other Land Cover Types	CM1 Permanent (temporary)	CM2-18 permanent (temporary)
Very high	Alfalfa hay	114 (727)	13,898 (432)
Moderate	Irrigated pasture, other hay crops, tomatoes, grain crops (wheat, barley, oats), fallow fields	145 (225)	15,136 (477)
Low	Other irrigated field and truck crops, dry pasture, grasslands, alkali seasonal wetlands, vernal pool complex, sudan	87 (907)	10,535 (349)
Very low	Safflower, sunflower, corn, grain sorghum, managed wetlands	27 (674)	8,943 (281)

- *CM2 Yolo Bypass Fisheries Enhancement:* Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 133 acres of nesting habitat (79 acres of permanent loss, 54 acres of temporary loss) in the Yolo Bypass in CZ 2. In addition, 1,500 acres of foraging habitat would be removed (996 acres of permanent loss, 554 acres of temporary loss). Activities through CM2 could involve excavation and grading in valley/foothill riparian areas to improve passage of fish through the bypasses. Most of the riparian losses would occur at the north end of Yolo Bypass where major fish passage improvements are planned. Excavation to improve water movement in the Toe Drain and in the

Sacramento Weir would also remove Swainson's hawk habitat. The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 295 acres of Swainson's hawk nesting habitat and 37,359 acres of foraging habitat. The majority of the acres lost would consist of cultivated lands in CZs 1, 2, 4, 5, 6, and/or 7. Grassland losses would likely occur in the vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the upslope fringes of Suisun Marsh, and along narrow bands adjacent to waterways in the South Delta ROA. Tidal restoration would directly impact and fragment grassland just north of Rio Vista in and around French and Prospect Islands, and in an area south of Rio Vista around Threemile Slough. Losses of alkali seasonal wetland complex habitat would likely occur in the south end of the Yolo Bypass and on the northern fringes of Suisun Marsh. Impacts on foraging habitat from CM4 would consist of 10,757 acres of very high-value (alfalfa), 11,706 acres of moderate-value, and 7,973 acres of low-value habitat (See Table 12-9-36 for land cover types classified by habitat value). Because the species is highly mobile and wide-ranging, habitat fragmentation is not expected to reduce the use of remaining cultivated lands or preclude access to surrounding lands. However, the conversion of cultivated lands to tidal wetlands over fairly broad areas within the tidal restoration footprints could result in the removal or abandonment of nesting territories that occur within or adjacent to the restoration areas. Trees would not be actively removed but tree mortality would be expected over time as areas became tidally inundated. Depending on the extent and value of remaining habitat, this could reduce the local nesting population. There are at least 27 Swainson's hawk nest sites that overlap with the hypothetical restoration areas for CM4, suggesting that numerous nest sites could be directly affected by inundation from tidal restoration activities.

- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain and riparian restoration actions would remove approximately 69 acres of Swainson's hawk nesting habitat (38 acres of permanent loss, 31 acres of temporary loss) and 2,856 acres of foraging habitat (1,820 acres of permanent loss, 1,036 acres of temporary loss). These losses would be expected after the first 10 years of Alternative 9 implementation along the San Joaquin River and other major waterways in CZ 7.

- *CM7 Riparian Natural Community Restoration:* Riparian restoration would permanently remove approximately 953 acres of Swainson's hawk foraging habitat as part of tidal restoration and 3,991 acres as part of seasonal floodplain restoration through CM7. There are at least 27 Swainson's hawk nest sites that overlap with the hypothetical restoration areas for CM7.

- *CM8 Grassland Natural Community Restoration*: Restoration of grassland is expected to be implemented on agricultural lands and would result in the conversion of 1,849 acres of Swainson's hawk agricultural foraging habitat to grassland foraging habitat in CZs 1, 2, 4, 5, 7, 8, and 11. If agricultural lands supporting higher value foraging habitat than the restored grassland were removed, there would be a loss of Swainson's hawk foraging habitat value.

- *CM10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 1,440 acres of Swainson's hawk foraging habitat in CZ 2 and CZ 4. Small patches of riparian vegetation that support Swainson's hawk nesting habitat may develop along the margins of restored nontidal marsh if appropriate site conditions are present.

- *CM11 Natural Communities Enhancement and Management:* Habitat management- and enhancement-related activities could disturb Swainson's hawk nests if they were present near work sites. A variety of habitat management actions that are designed to enhance wildlife values in BDCP-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of Swainson's hawk habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available Swainson's hawk habitat and are expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below. CM11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. However, approximately 50 acres of Swainson's hawk grassland foraging habitat would be lost from the construction of trails and facilities.

- *CM18 Conservation Hatcheries*: Implementation of CM18 would remove up to 35 acres of Swainson's hawk foraging habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1. The loss is expected to occur during the first 10 years of Plan implementation.

  Permanent and temporary nesting habitat losses from the above conservation measures, would primarily consist of small, fragmented riparian stands. Temporarily affected nesting habitat would be restored as riparian habitat within 1 year following completion of construction activities. The restored riparian habitat would require 1 to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by Swainson's hawks. *AMM18 Swainson's Hawk* contains actions described below to reduce the effect of temporal loss of nesting habitat, including the transplanting of mature trees and planting of trees near high-value foraging habitat. The functions of cultivated lands and grassland communities that provide foraging habitat for Swainson's hawk are expected to be restored relatively quickly.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect Swainson's hawk use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7 and *AMM18 Swainson's Hawk* in addition to conservation actions as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged Swainson's hawk if they were present in the study area, because they would be expected to avoid contact with construction and other equipment. However, if Swainson's hawk were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could affect nests or lead to their abandonment, potentially resulting in mortality of eggs and nestlings. These effects would be avoided and minimized with the incorporation of *AMM18 Swainson's Hawk* into the BDCP.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effect of construction would not be adverse under NEPA. Alternative 9 would remove 367 acres (284 permanent, 83 temporary) of Swainson's hawk nesting habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 61 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration*, and *CM7 Riparian Natural Community Restoration*—306 acres). In addition, 12,314 acres of Swainson's hawk foraging habitat would be removed or converted in the near-term (CM1, 2,907 acres; *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—9,407 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected and those that are identified in the biological goals and objectives for Swainson's hawk in Chapter 3 of the BDCP would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for nesting habitat, and 1:1 protection for foraging habitat. Using these ratios would indicate that 61 acres of nesting habitat should be restored/created and 61 acres should be protected to compensate for the CM1 losses of Swainson's hawk nesting habitat. In addition, 2,907 acres of foraging habitat should be protected to mitigate the CM1 losses of Swainson's hawk foraging habitat. The near-term effects of other conservation actions would remove 306 acres of modeled nesting habitat, and therefore require 306 acres of restoration and 306 acres of protection of nesting habitat. Similarly, the near-term effects of other conservation actions would remove 9,407 acres of modeled foraging habitat, and therefore require 9,407 acres of protection of foraging habitat using the same typical NEPA and CEQA ratios (1:1 restoration and 1:1 protection for the loss of nesting habitat; 1:1 protection for the loss of foraging habitat).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of valley/foothill riparian natural community, protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, protecting 4,800 acres of managed wetland natural community, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM5, CM7, and CM8, and would occur in the same timeframe as the construction and early restoration losses.

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for the species. The distribution and abundance of potential Swainson's hawk nest trees would be

increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1). In addition, small but essential nesting habitat for Swainson's hawk associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide foraging habitat for Swainson's hawk and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) that dry during the spring would also serve as foraging habitat for Swainson's hawks as prey species recolonize the fields (Objective MWNC1.1). These biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions. At least 15,400 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1) A minimum of 87% of cultivated lands protected by the late long-term time period would be in very high- and high-value crop types for Swainson's hawk (Objective SH1.2). This biological objective provides an estimate for the proportion of cultivated lands protected in the near-term time period which would provide high-value habitat for Swainson's hawk. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on Swainson's hawk foraging habitat, as well as mitigate the near-term effects of the other conservation measures.

The 750 acres of protection and 800 acres of restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and other near-term impacts on Swainson's hawk nesting habitat. The 800 acres of restored riparian habitat would be initiated in the near-term to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by Swainson's hawks. This time lag between the removal and restoration of nesting habitat could have a substantial impact on Swainson's hawk in the near-term time period. Nesting habitat is limited throughout much of the Plan Area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active Swainson's hawk nests within the Plan Area until restored riparian habitat is sufficiently developed.

AMM18 Swainson's Hawk would implement a program to plant large mature trees, including transplanting trees scheduled for removal, to compensate for the temporal loss of Swainson's hawk nest sites, defined as a 125-acre area where more than 50% of suitable nest trees (20 feet or taller)

within the 125-acre block are removed. These mature trees would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least 5 trees (five gallon container size) would be planted within the BDCP reserve system for every tree removed by construction during the near-term period that was suitable for nesting by Swainson's hawks (20 feet or taller). A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Trees would be planted within the BDCP reserve system in areas that support high-value foraging habitat to increase nest sites, or within riparian plantings as a component of the riparian restoration (CM5, CM7) where they are in close proximity to suitable foraging habitat. Replacement trees that were incorporated into the riparian restoration would not be clustered in a single region of the study area, but would be distributed throughout the lands protected as foraging habitat for Swainson's hawk.

Swainson's hawk foraging habitat would be protected within 3 miles of a known Swainson's hawk nest tree and within 50 miles of the project footprint on land not subject to threat of seasonal flooding, construction disturbances, or other conditions that would reduce the foraging value of the land. With this program in place, Alternative 9 would not have a substantial adverse effect on Swainson's hawk in the near-term timeframe, either through direct mortality or through habitat modifications. Further details of AMM18 are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The study area supports approximately 9,796 acres of modeled nesting habitat and 477,879 acres of modeled foraging habitat for Swainson's hawk. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 558 acres of potential nesting habitat (6% of the potential nesting habitat in the study area) and 52,958 acres of foraging habitat (11% of the foraging habitat in the study area).

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration, and CM8 Grassland Natural Community Restoration,* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community, protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, protect 8,100 acres of managed wetland, and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3, *Description of Alternatives*).

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian

restoration would expand the patches of existing riparian forest in order to support nesting habitat for the species. The distribution and abundance of potential Swainson's hawk nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SH2.1). In addition, small but essential nesting habitat for Swainson's hawk associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide foraging habitat for Swainson's hawk and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SH2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) that dry during the spring would also serve as foraging habitat for Swainson's hawks as prey species recolonize the fields (Objective MWNC1.1). These biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions. Foraging habitat would be conserved at a ratio of 1:1 (Objective SH1.1) and at least 42,275 acres of cultivated lands that provide Swainson's hawk foraging habitat would be protected by the late long-term, 50% of which would be in very high-value habitat production in CZs 1–4, 7–9, and 11 (Objective SH1.2).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils*, and *AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

NEPA Effects: The loss of Swainson's hawk habitat and potential direct mortality of this special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection and restoration associated with CM3, CM5, CM7, CM8, CM9, and CM11, guided by biological goals and objectives and by AMM1–AMM7 and *AMM18 Swainson's Hawk*, which would be in place throughout the construction period, the effects of habitat loss and potential mortality on Swainson's hawk under Alternative 9 would not be adverse.

***CEQA Conclusion*:**

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effect of construction would be less than significant under CEQA. Alternative 9 would remove 367 acres (284 permanent, 83 temporary) of Swainson's hawk nesting habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 61 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration*, and *CM7 Riparian Natural Community Restoration*—306 acres). In addition, 12,314 acres of Swainson's hawk foraging habitat would be removed or converted in the near-term (CM1, 2,907 acres; *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—9,407 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected and those that are identified in the biological goals and objectives for Swainson's hawk in Chapter 3 of the BDCP would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for nesting habitat, and 1:1 protection for foraging habitat. Using these ratios would indicate that 61 acres of nesting habitat should be restored/created and 61 acres should be protected to compensate for the CM1 losses of Swainson's hawk nesting habitat. In addition, 2,907 acres of foraging habitat should be protected to mitigate the CM1 losses of Swainson's hawk foraging habitat. The near-term effects of other conservation actions would remove 306 acres of modeled nesting habitat, and therefore require 306 acres of restoration and 306 acres of protection of nesting habitat. Similarly, the near-term effects of other conservation actions would remove 9,407 acres of modeled foraging habitat, and therefore require 9,407 acres of protection of foraging habitat using the same typical NEPA and CEQA ratios (1:1 restoration and 1:1 protection for the loss of nesting habitat; 1:1 protection for the loss of foraging habitat).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of valley/foothill riparian natural community, protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, protecting 4,800 acres of managed wetland natural community, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM5, CM7, and CM8, and would occur in the same timeframe as the construction and early restoration losses.

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for the species. The distribution and abundance of potential Swainson's hawk nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1). In addition, small

but essential nesting habitat for Swainson's hawk associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide foraging habitat for Swainson's hawk and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) that dry during the spring would also serve as foraging habitat for Swainson's hawks as prey species recolonize the fields (Objective MWNC1.1). These biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions. At least 15,400 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1). A minimum of 87% of cultivated lands protected by the late long-term time period would be in very high- and high-value crop types for Swainson's hawk (Objective SH1.2). This biological objective provides an estimate for the proportion of cultivated lands protected in the near-term time period which would provide high-value habitat for Swainson's hawk. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on Swainson's hawk foraging habitat, as well as mitigate the near-term effects of the other conservation measures.

The 750 acres of protection and 800 acres of restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and other near-term impacts on Swainson's hawk nesting habitat. The 800 acres of restored riparian habitat would be initiated in the near-term to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by Swainson's hawks. This time lag between the removal and restoration of nesting habitat could have a substantial impact on Swainson's hawk in the near-term time period. Nesting habitat is limited throughout much of the Plan Area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active Swainson's hawk within the Plan Area until restored riparian habitat is sufficiently developed.

AMM18 Swainson's Hawk would implement a program to plant large mature trees, including transplanting trees scheduled for removal, to compensate for the temporal loss of Swainson's hawk nest sites, defined as a 125-acre area where more than 50% of suitable nest trees (20 feet or taller) within the 125-acre block are removed. These mature trees would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the BDCP reserve system for every tree removed by construction during the near-term period that was suitable for nesting by Swainson's hawks (20 feet or taller). A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Trees would be planted within the BDCP reserve system in areas that support high-value foraging habitat to increase nest sites, or within riparian plantings as a component of the riparian restoration (CM5, CM7) where they are in close proximity to suitable foraging habitat. Replacement trees that are incorporated into the riparian restoration would not be clustered in a single region of the Plan Area, but would be distributed throughout the lands protected as foraging habitat for Swainson's hawk.

Swainson's hawk foraging habitat would be protected within 3 miles of a known Swainson's hawk nest tree and within 50 miles of the project footprint on land not subject to threat of seasonal flooding, construction disturbances, or other conditions that would reduce the foraging value of the land. With this program in place, Alternative 9 would not have a substantial adverse effect on Swainson's hawk in the near-term timeframe, either through direct mortality or through habitat modifications. Further details of AMM18 are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The study area supports approximately 9,796 acres of modeled nesting habitat and 477,879 acres of modeled foraging habitat for Swainson's hawk. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 558 acres of potential nesting habitat (6% of the potential nesting habitat in the study area) and 52,958 acres of foraging habitat (11% of the foraging habitat in the study area).

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration,* and *CM8 Grassland Natural Community Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community, protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, protect 8,100 acres of managed wetland, and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3, *Description of Alternatives*).

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for the species. The distribution and abundance of potential Swainson's hawk nest trees would be

increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SH2.1). In addition, small but essential nesting habitat for Swainson's hawk associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide foraging habitat for Swainson's hawk and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SH2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) that dry during the spring would also serve as foraging habitat for Swainson's hawks as prey species recolonize the fields (Objective MWNC1.1). These biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions. Foraging habitat would be conserved at a ratio of 1:1 (Objective SH1.1) and at least 42,275 acres of cultivated lands that provide Swainson's hawk foraging habitat would be protected by the late long-term, 50% of which would be in very high-value habitat production in CZs 1–4, 7–9, and 11 (Objective SH1.2).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Considering Alternative 9's protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for the time lag of restoring riparian and foraging habitats lost to construction and restoration activities, and implementation of AMM1–AMM7 and *AMM18 Swainson's Hawk*, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on Swainson's hawk.

Impact BIO-84: Effects on Swainson's Hawk Associated with Electrical Transmission Facilities

New transmission lines would increase the risk that Swainson's hawks could be subject to power line strikes, which could result in injury or mortality of Swainson's hawks. This species would be at low risk of bird strike mortality based on factors assessed in the bird strike vulnerability analysis (BDCP Attachment 5J.C*, Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Factors analyzed include the height of the new transmission lines and the flight behavior of the species. The existing network of transmission lines in the Plan Area currently poses the same small risk for Swainson's hawk, and any incremental risk associated with the new power line corridors would also be expected to be low. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new project transmission lines would be fitted with flight diverters. Bird flight diverters would make transmission lines highly visible to Swainson's hawks and would further reduce any potential for powerline collisions.

***NEPA Effects*:** New transmission lines would minimally increase the risk for Swainson's hawk power line strikes. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. With implementation of *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines would not result in an adverse effect on Swainson's hawk.

***CEQA Conclusion*:** New transmission lines would minimally increase the risk for Swainson's hawk power line strikes. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. With implementation of *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines would result in a less-than-significant impact on Swainson's hawk.

Impact BIO-85: Indirect Effects of Plan Implementation on Swainson's Hawk

Noise and visual disturbances from the construction of water conveyance facilities and other conservation measures could reduce Swainson's hawk use of modeled habitat adjacent to work areas. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect Swainson's hawk. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect Swainson's hawk use of the surrounding habitat. These construction activities would include water conveyance construction, tidal restoration activities, floodplain restoration, and Fremont Weir/Yolo Bypass Enhancements. Swainson's hawks are seasonally abundant across much of the study area wherever adequate nest trees occur within a cultivated landscape that supports suitable foraging habitat. There would be a potential for noise and visual disturbances associated with BDCP actions to temporarily displace Swainson's hawks and temporarily reduce the use of suitable habitat adjacent to construction areas. These adverse effects would be minimized with the implementation of *AMM18 Swainson's Hawk*.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect Swainson's hawk foraging in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. *AMM2 Construction Best Management Practices and Monitoring* would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on habitat.

NEPA Effects: Noise and visual disturbances from the construction of water conveyance facilities could reduce Swainson's hawk use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect Swainson's hawk use of the surrounding habitat. The effects of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would not have an adverse effect on Swainson's hawk with the implementation of AMM1–AMM7, AMM10, and *AMM18 Swainson's Hawk.*

CEQA Conclusion: Noise and visual disturbances from the construction of water conveyance facilities could reduce Swainson's hawk use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect Swainson's hawk use of the surrounding habitat. The effects of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would result in a less-than-significant impact on Swainson's hawk with the implementation of AMM1–AMM7, AMM10, and *AMM18 Swainson's Hawk.*

Impact BIO-86: Periodic Effects of Inundation of Swainson's Hawk Nesting and Foraging Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on approximately 3,066–6,706 acres of modeled Swainson's hawk habitat (consisting of approximately 41–70 acres of nesting habitat and 3,025–6,635 acres of foraging habitat; Table 12-9-35). However, project-associated inundation of areas that would not otherwise have been inundated would be expected to occur in no more than 30% of all years, since Fremont Weir is expected to overtop the remaining estimated 70% of all years, and during those years notch operations would not typically affect the maximum extent of inundation. In more than half of all years under Existing Conditions, an area greater than the project-related inundation area already inundates in the bypass. Therefore, habitat conditions in the bypass would not be expected to change substantially as a result of Yolo Bypass operations. However, increased duration of inundation during years of Fremont Weir operation, may delay the period for which foraging habitat is available to Swainson's hawks by up to several weeks.

Based on hypothetical footprints, implementation of *CM5 Seasonally Inundated Floodplain Restoration*, could result in the periodic inundation of up to approximately 8,197 acres of modeled Swainson's hawk habitat (Table 12-9-35), consisting of 189 acres of nesting and 8,008 acres of foraging habitat. Floodplain restoration would be expected to restore a more natural flood regime and sustain riparian vegetation types that support regeneration of Swainson's hawk nesting habitat. The restored floodplains would transition from areas that flood frequently (e.g., every 1 to 2 years) to areas that flood infrequently (e.g., every 10 years or more). Foraging habitat that is inundated after Swainson's hawks arrive in the Central Valley in mid-March could result in a periodic loss of available foraging habitat due to the reduction in available prey. Inundated habitats would be expected to recover following draw-down and provide suitable foraging conditions until the following inundation period. Thus, this is considered a periodic and short term effect that is unlikely to affect Swainson's hawk distribution and abundance, or foraging use of the study area.

NEPA Effects: Increased periodic flooding would not be expected to cause any adverse effect on nest sites because trees in which nest sites are situated already withstand floods, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and nest sites are located above floodwaters. Although foraging habitat would be periodically unavailable to Swainson's hawk, inundated habitats are expected to recover following draw down. This would be considered a short-term effect that would not result in an adverse effect on Swainson's hawk.

CEQA Conclusion: Increased periodic flooding would not be expected to cause any adverse effect on nest sites because trees in which nest sites are situated already withstand floods, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and nest sites are located above floodwaters. Although foraging habitat would be periodically unavailable to Swainson's hawk, inundated habitats are expected to recover following draw down. This would be considered a short-term effect that would not have a significant impact on Swainson's hawk.

Tricolored Blackbird

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on tricolored blackbird. The habitat model used to assess effects on tricolored blackbird is based on breeding habitat and nonbreeding habitat. Although breeding colonies have been documented along the fringe of Suisun Marsh, in the Yolo Bypass and along the southwestern perimeter of the study area, breeding colonies are uncommon in the study area. Modeled breeding habitat includes bulrush/cattail wetlands and shrub communities that may provide suitable nesting substrate, and adjacent high-value foraging areas that occur within 5 miles of nesting colonies documented in the study area. The foraging component includes land cover types known to support abundant insect populations such as grasslands, pasturelands (including alfalfa), natural seasonal wetlands, and sunflower croplands. The Delta is recognized as a major wintering area for tricolored blackbird (Hamilton 2004, Beedy 2008). Modeled nonbreeding habitat includes emergent wetlands and shrub stands that provide suitable roosting habitat, as well as cultivated lands and noncultivated lands that provide foods sought by tricolored blackbirds during the winter. Outside of the breeding season, tricolored blackbirds are primarily granivores that forage opportunistically across the Plan Area in grasslands, pasturelands, croplands, dairies, and livestock feed lots. Factors considered in assessing the value of affected habitat for the tricolored blackbird, include patch size, suitability of vegetation, and proximity to recorded occurrences.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of tricolored blackbird modeled habitat as indicated in Table 12-9-37. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit the tricolored blackbird (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect and manage at least 50 acres of occupied or recently occupied (within the last 15 years) tricolored blackbird nesting habitat located within 5 miles of high-value foraging habitat in CZs 1, 2, 8, or 11. (Objective TRBL1.1).

- Protect at least 26,300 acres of moderate-, high-, or very high-value cultivated lands as nonbreeding foraging habitat, 50% of which is of high or very high value (Objective TRBL1.2).
- Protect at least 11,050 acres of high- to very high-value breeding-foraging habitat within 5 miles of occupied or recently occupied (within the last 15 years) tricolored blackbird nesting habitat in CZs 1, 2, 3, 4, 7, 8, or 11. At least 1,000 acres of this habitat would be within 5 miles of the nesting habitat protected under Objective TRBL1.1 (Objective TRBL1.3).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).
- Protect at least 8,000 acres of grassland, with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).
- Increase prey abundance and accessibility for grassland-foraging species (Objectives ASWNC2.4, VPNC2.5, and GNC2.4, associated with CM11).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species and implementation of AMM1–AMM7 and *AMM21 Tricolored Blackbird,* impacts on tricolored blackbird would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-37. Changes in Tricolored Blackbird Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]		Habitat Type	Permanent NT	Permanent LLT[c]	Temporary NT	Temporary LLT[c]	Periodic[d] CM2	Periodic[d] CM5

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-87: Loss or Conversion of Habitat for and Direct Mortality of Tricolored Blackbird

Alternative 9 conservation measures would result in the permanent and temporary loss combined of up to 12,872 acres of modeled breeding habitat and up to 29,289 acres of modeled nonbreeding for tricolored blackbird (Table 12-9-37). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), riparian restoration (CM7), grassland restoration (CM8), marsh restoration (CM10), and construction of conservation hatcheries (CM18). Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate tricolored blackbird habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the permanent loss of 293 acres of tricolored blackbird breeding habitat (8 acres nesting habitat, 230 acres of cultivated lands, and 55 acres of noncultivated lands suitable for foraging) and 122 acres of nonbreeding habitat (58 acres roosting habitat, 36 acres of cultivated lands, and 28 acres of noncultivated lands suitable for foraging; Table 12-9-37). In addition, CM1 would result in the temporary removal of 366 acres of breeding habitat (2 acres nesting habitat, 293 acres of cultivated lands, and 71 acres of noncultivated lands suitable for foraging) and 1,805 acres of nonbreeding habitat (198 acres roosting habitat, 1,334 acres of cultivated lands, and 273 acres of noncultivated lands suitable for foraging, Table 12-9-37). Habitat that would be lost is located in the central Delta, in CZs 4, 5, 6, 7, and 8. There are no occurrences of tricolored blackbird that overlap with the construction footprint for CM1. However, records exist throughout the study area. The implementation of *AMM21 Tricolored Blackbird* would require preconstruction surveys and the establishment of nodisturbance buffers and would minimize potential effects on nesting tricolored blackbirds (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Construction of CM1 would occur within the first 10 years of Alternative 9 implementation.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction activity associated with fisheries improvements in the Yolo Bypass would permanent loss of 595 acres of tricolored blackbird breeding habitat (13 acres nesting habitat, 477 acres of cultivated lands, and 105 acres of noncultivated lands suitable for foraging) and 8 acres of nonbreeding habitat (consisting entirely of roosting habitat). In addition, CM2 construction would result in the temporary removal of 314 acres of breeding habitat (75 acres nesting habitat, 84 acres of cultivated lands, and 155 acres of noncultivated lands suitable for foraging) and 54 acres of nonbreeding habitat (consisting entirely of cultivated lands). The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration*: Tidal natural communities restoration would result in the inundation of approximately 3,937 acres of tricolored blackbird breeding habitat (21 acres of nesting, 2,814 acres of cultivated lands, and 1,102 acres of noncultivated lands suitable for foraging) and 10,794 acres of nonbreeding habitat (1,633 acres of roosting, 18,489 acres of cultivated lands, and 672 acres of noncultivated lands suitable for foraging). An estimated 13,692 acres of the 28,424 acres to be permanently lost would be expected to convert to tidal emergent wetland communities that could provide nonbreeding season roosting habitat for tricolored blackbirds, depending on future vegetation density and composition. Conversion would result in the loss of an estimated 4,316 acres of tricolored blackbird breeding habitat (34 acres of nesting habitat; plus 3,635 acres of cultivated lands and 647 acres of noncultivated habitats suitable for foraging) and 9,375 acres of nonbreeding habitat (8,716 acres of cultivated lands and 659 acres of noncultivated habitats suitable for foraging). These habitat losses and conversions would occur in CZs 1, 2, 4, 5, 6, 7, 8, and 11. Although considered to be a permanent loss, due to the uncertainty of the quantity of restored suitable habitat, any areas that develop into riparian scrub-shrub could provide suitable nesting and roosting habitat for tricolored blackbird.

- *CM5 Seasonally Inundated Floodplain Restoration*: Levee construction and riparian restoration associated with floodplain restoration in the south Delta (CZ 7) would result in the permanent removal of up to 554 acres of tricolored blackbird breeding habitat (4 acres of nesting habitat, 503 acres of cultivated lands, and 47 acres of noncultivated habitats suitable for foraging) and 656 acres of nonbreeding habitat (1 acre of roosting habitat, 652 acres of cultivated lands, and 3 acres of noncultivated habitats suitable for foraging) in CZ 7. Patches of riparian scrub associated with the restoration of approximately 1,000 acres of valley/foothill riparian habitat managed as early- to mid-successional habitats (as a component of CM5) could provide suitable nesting, roosting or foraging habitat for tricolored blackbird once these restored habitats have developed habitat functions for the species.

- *CM8 Grassland Natural Communities Restoration*: Restoration of grassland would result in the permanent removal of 1,521 acres of tricolored breeding habitat and 210 acres of nonbreeding habitat. Grassland restoration would be implemented on cultivated lands and would therefore result in the conversion of tricolored blackbird cultivated foraging habitat to high-value grassland foraging habitat in CZs 2, 4, and 5.

- *CM10 Nontidal Marsh Restoration*: Marsh restoration activities would result in the permanent removal or conversion of approximately 568 acres of tricolored blackbird breeding habitat and 945 acres of nonbreeding habitat (all cultivated lands suitable for foraging). About two-thirds of the restored nontidal marsh would be open water, and the remainder would support emergent wetland vegetation that could provide low-value roosting habitat for tricolored blackbird depending on vegetation density and composition.

- *CM11 Natural Communities Enhancement and Management:* A variety of habitat management actions that are designed to enhance wildlife values in BDCP-protected habitats could result in localized ground disturbances that could temporarily remove small amounts of tricolored blackbird habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, would be expected to have minor effects on available tricolored blackbird habitat and are expected to result in overall improvements to and maintenance of tricolored blackbird habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below. CM11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). Trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. However, approximately 43.5 acres of breeding habitat and 6.5 acres of nonbreeding habitat (all grassland suitable for foraging) would be lost as a result of construction of trails and facilities. Impacts from recreational-related facilities that would occur within the first 10 years of Alternative 9 implementation would include a loss of 13 acres of breeding habitat.

- *CM18 Conservation Hatcheries*: Implementation of CM18 would remove up to 35 acres of tricolored blackbird grassland foraging habitat in CZ 1.
- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect tricolored blackbird use of the surrounding habitat in or adjacent to work areas. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and conservation actions as described below.
- Injury and Direct Mortality: Operation of construction equipment may cause injury to or mortality of tricolored blackbirds. Risk would be greatest to eggs and nestlings susceptible to land clearing activities, nest abandonment, or increased exposure to the elements or to predators. Injury to or mortality of adults and fledged juveniles would not be expected as individuals would be expected to avoid contact with construction equipment. Construction activities could temporarily fragment existing tricolored blackbird habitat during grading, filling, contouring, and other initial ground-disturbing operations that could temporarily reduce the extent and functions supported by the affected habitat. To the maximum extent practicable, construction activity will be avoided up to 1,300 feet, but not less than a minimum of 250 feet, from an active tricolored blackbird nesting colony. If monitoring determines an activity is adversely affecting a nesting colony, construction will be modified, as practicable, by either delaying construction until the colony site is abandoned or until the end of the breeding season, whichever occurs first, by temporarily relocating staging areas, or temporarily rerouting access to the construction site. Construction and restoration projects would also be designed, in consultation with CDFW, to avoid construction activity within at least 300 feet from occupied active tricolored blackbird roosting habitat. These measures to avoid injury or mortality of nesting and roosting tricolored blackbirds are described in *AMM21 Tricolored Blackbird* (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*).

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 3,290 acres of breeding habitat (98 acres of nesting, 2,264 acres of cultivated lands, and 985 acres of noncultivated lands suitable for foraging) and 6,757 acres of nonbreeding habitat (826 acres of roosting, 5,171 acres of cultivated lands, and 760 acres of noncultivated lands suitable for foraging) for tricolored blackbird in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 659 acres of breeding, 1,927 acres of nonbreeding), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain*

Restoration, CM7 Riparian Natural Community Restoration—2,688 acres of breeding, 4,830 acres of nonbreeding).

Typical NEPA and CEQA project-level mitigation ratios would be 1:1 for restoration/creation and 1:1 for protection for the loss of nesting and roosting wetland habitat, 2:1 protection for loss of noncultivated lands suitable for foraging (for the breeding and nonbreeding season), and 1:1 protection for the loss of cultivated lands.

Using these ratios would indicate that the compensation for loss or conversion of tricolored blackbird habitat from CM1 would require 10 acres of restoration and 10 acres of protection of nesting habitat, 256 acres of restoration and 256 acres of protection of roosting habitat, 854 acres of protection of noncultivated lands that provide foraging habitat, 523 acres of protection of cultivated lands suitable for foraging during the breeding season, and 1,370 acres of cultivated lands that provide foraging habitat during the nonbreeding season. The near-term effects of other conservation actions would remove or convert 88 acres of nesting habitat, 570 acres of roosting habitat, 619 acres of noncultivated lands suitable for foraging, 1,741 acres of cultivated lands that provide foraging habitat during the breeding season, and 3,801 acres of cultivated lands during the nonbreeding season. Compensation for these losses from other conservation measures would therefore require 88 acres of restoration and 88 acres of protection of nesting habitat, 570 acres of restoration and 570 acres of protection of roosting habitat, 1,238 acres of protection of noncultivated lands that provide foraging habitat, 1,741 acres of protection of cultivated lands suitable for foraging during the breeding season, and 3,801 acres of cultivated lands that provide foraging habitat during the nonbreeding season. using the same typical NEPA and CEQA ratios.

Total compensation for near-term loss or conversion of tricolored blackbird required using the typical ratios above would be 98 acres of restoration and 98 acres of protection for nesting habitat, 826 acres of restoration and 826 acres of protection for roosting habitat, 3,490 acres of protection of noncultivated foraging habitat, 2,264 acres of protection for cultivated lands that provide foraging habitat during the breeding season, and 5,171 acres of cultivated lands that provide foraging habitat during the nonbreeding season.

The BDCP has committed to near-term goals of protecting 25 acres and restoring protecting 750 acres and restoring 800 acres of valley/foothill riparian natural community, protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, protecting 4,800 acres of managed wetland natural community, protecting 15,400 acres of non-rice cultivated lands, protecting 900 acres of rice or rice equivalent habitat, restoring 8,850 acres of tidal freshwater emergent wetlands and 2,000 acres of tidal brackish emergent wetlands (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM4, CM5, CM7, and CM8 and would occur in the same timeframe as the construction and early restoration losses. Some proportion of these natural communities provide suitable habitat for tricolored blackbird as described below.

Nesting by tricolored blackbirds is currently limited by the availability of high-value breeding habitat, which is represented by suitable nesting substrate, such as cattail/bulrush emergent wetland, in close association with highly productive foraging areas that support abundant insect prey, such as grasslands, seasonal wetlands, pasturelands, alfalfa and other hay crops, and some croplands. The nesting habitat would be located within 5 miles of high-value foraging habitat in CZs 1, 2, 8, or 11 (see Table 12-9-38 for foraging habitat values) and would be actively managed to maintain actively growing stands of bulrush/cattail emergent vegetation through mechanical habitat manipulation, prescribed fire, or other measures described in *CM11 Natural Communities Enhancement and Management*. In addition to the actively managed nesting habitat, a portion of the 750 acres of protection and 800 acres of restoration of valley/foothill riparian natural community, and the restoration of 900 acres nontidal marsh would provide nesting habitat for tricolored blackbird. The Plan estimates that modeled nesting habitat in the Plan Area currently includes 8% of valley/foothill riparian and 22% of nontidal freshwater emergent marsh (BDCP Chapter 5, Section 5.6.12.2, *Beneficial Effects*). Assuming similar proportions of modeled habitat on conservation lands restored in the near-term, approximately 64 acres of valley foothill riparian and 198 acres of nontidal marsh restored would provide nesting habitat for tricolored blackbird.

The Plan estimates that modeled roosting habitat in the Plan Area currently includes 95% of tidal freshwater emergent wetland, 57% of brackish emergent wetland, 21% of valley/foothill riparian, 75% of nontidal marsh, and 15% of managed wetlands (BDCP Chapter 5, Section 5.6.12.2, *Beneficial Effects*). Assuming similar proportions of modeled habitat on conservation lands restored in the near-term, the restoration of approximately 8,408 acres of tidal freshwater emergent wetland, 1,140 acres of tidal brackish emergent wetland, 675 acres of nontidal marsh, and 168 acres of valley foothill riparian would provide 10,391 acres of nesting habitat for tricolored blackbird. An estimated 878 acres of roosting habitat would also be protected in the near-term time period (158 acres of valley/foothill riparian, 720 acres managed wetland).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) which would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities. The protection and restoration of grasslands, alkali seasonal wetlands, and vernal pool complexes would provide improved foraging opportunities for tricolored blackbirds during both the breeding and nonbreeding seasons. Proximity of nesting colonies to suitable foraging habitat contributes to high reproductive success in tricolored blackbirds. These natural communities are known to support large insect populations, a vital food resource for successful rearing and fledging of young. Those conservation lands that lie within a few miles of active nesting colonies would provide high-value foraging areas to support breeding tricolored blackbirds. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, further enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4).

Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,600 acres of potential foraging habitat for tricolored blackbird in the near-term (Objective CLNC1.1). Objective TRBL1.3 commits to protecting 11,050 acres (23% of the total cultivated lands commitment) of high- to very high-value breeding-foraging habitat by the late long-term. Assuming that lands would be protected proportional to the conservation objectives for covered species, approximately 3,588 acres of high- to very high-value breeding foraging habitat consisting of cultivated lands would be protected in the near-term. These lands would be protected within 5 miles of occupied or recently occupied tricolored blackbird nesting habitat in CZs 1, 2, 3, 4, 7, 8 or 11. In addition, Objective TRBL1.2 states that of the cultivated lands protected in the late long-term time period, 26,300 acres (54% of all cultivated lands protected) would be maintained in moderate – high, or very high-value cultivated lands, at least 50% of which would be high- to very high-value. Assuming proportional conservation in the near-term, an estimated 8,424 acres of cultivated lands that provide foraging habitat for tricolored blackbird would be protected in the near-term, 4,212 of which would be in high- to very high-value cultivated lands. Small but essential habitats for species including tricolored blackbird would also be protected that occur within the agricultural matrix. This would include the retention of wetlands, grassland patches, shrub stands, and herbaceous edge habitats, which could provide suitable nesting, foraging or roosting habitat for tricolored blackbird (Objective CLNC1.3).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

The acres of protection and restoration contained in the near-term Plan goals, in addition to the detailed habitat value goals that would be applied to near-term acres, are more than sufficient to satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and the near-term impacts from other conservation measures on nesting, roosting, and cultivated lands foraging habitat. The 3,660 acres of grassland protection in the near-term are 213 acres short of the 2:1 protection mitigation ratio. However, the acres of permanent impact would be compensated for by this acreage, and temporary impacts on grassland would be restored to preproject conditions (including revegetation with native vegetation if within 1 year of completion of construction) under *AMM2 Construction Best Management Practices and Monitoring*. With the enhancement of grasslands described above, and the restoration of temporary habitat impacts, this difference between impacted and conserved grassland acreages in the near-term time period would not result in an adverse effect on tricolored blackbird.

Table 12-9-38. Tricolored Blackbird Foraging Habitat Value Classes

Foraging Habitat Value Class	Agricultural Crop Type/Habitats	
	Breeding Season[a] Foraging Habitat	Nonbreeding Season Foraging Habitat
Very high	Native pasture, nonirrigated native pasture, annual grasslands, vernal pool grasslands, alkali grasslands	Livestock feed lots
High	Sunflower, alfalfa and mixed alfalfa, mixed pasture, induced high water table native pasture, nonirrigated mixed pasture, dairies	Corn, sunflower, millet, alfalfa and mixed alfalfa, mixed pasture, native pasture, induced high water table native pasture, nonirrigated native pasture, rice, dairies, annual grasslands, vernal pool grasslands, alkali grasslands
Moderate	Miscellaneous grass pasture, fallow lands cropped within 3 years, new lands prepped for crop production, livestock feed lots	Miscellaneous grass pasture, nonirrigated mixed pasture, fallow lands cropped within 3 years, new lands prepped for crop production
Low	Wheat, mixed grain and hay, farmsteads	Wheat, oats, mixed grain and hay, farmsteads
Marginal	Rice	None
None	All remaining crop types	All remaining crop types

[a] Generally March through August; occasional breeding in fall (September through November).

Late Long-Term Timeframe

Based on the habitat model, the study area approximately 164,947 acres of breeding and 259,093 acres of nonbreeding habitat for tricolored blackbird. The Delta is an important wintering area for the tricolored blackbird (Hamilton 2004, Beedy 2008). Although there is a large acreage of modeled breeding habitat available, the study area does not currently support many nesting tricolored blackbirds with the exception of a few occurrences on the fringes of the Suisun Marsh, in the Yolo Bypass, and along the southwestern perimeter of the study area (BDCP, Chapter 5, *Effects Analysis*). Alternative 9 as a whole would result in the permanent loss of and temporary effects on 12,872 acres of breeding habitat and 29,289 acres of nonbreeding habitat for tricolored blackbird during the term of the Plan (8% of the total breeding habitat in the study area and 11% of the total nonbreeding habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration, and CM8 Grassland Natural Community Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community, protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, protect 8,100 acres of managed wetland, and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3, *Description of Alternatives*).

Species-specific biological goals and objectives for tricolored blackbird commit to protecting or restoring at least 50 acres of occupied or recently occupied (within the last 15 years) tricolored blackbird nesting habitat located within 5 miles of high-value foraging habitat in CZs 1, 2, 8, or 11 (Objective TRBL1.1). Foraging habitat value classes for tricolored blackbird are found in Table 12-9-38. To ensure that natural community conservation benefits tricolored blackbird, the Plan further specifies that cultivated lands protected for tricolored blackbird retain residual wetland, grassland patches, shrub stands, and herbaceous edge habitats which may provide suitable nesting, foraging or roosting habitat for the species (Objective CLNC1.3). In addition, 26,300 acres of moderate-, high-, or very high-value cultivated lands would be conserved and managed as nonbreeding foraging habitat, 50% of which would be of high- or very high-value (Objective TRBL1.2). At least 11,050 acres of cultivated lands managed as high to very high breeding foraging habitat would be conserved within 5 miles of occupied or recently occupied (within the last 15 years) tricolored blackbird nesting habitat in CZs 1, 2, 3, 4, 7, 8, or 11 (Objective TRBL1.2). Most of the loss of breeding and nonbreeding habitat would be to cultivated lands that are abundant throughout the study area, so the loss is not expected to adversely affect the population in the study area.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the protection of an estimated 46,566 acres of tricolored blackbird habitat (16,476 acres breeding habitat and 31,090 acres nonbreeding habitat) and restoration of 31,001 acres of tricolored blackbird habitat (2,190 acres breeding habitat and 28,811 acres nonbreeding habitat).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

NEPA Effects: The losses of tricolored blackbird habitat and potential direct mortality of a special status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. However, with habitat protection and restoration associated with CM3, CM4, CM5, CM7, CM8, and CM11, guided by species-specific goals and objectives and by AMM1–AMM7 and *AMM21 Tricolored Blackbird*, which would be in place throughout the construction period, the effects of habitat loss or potential mortality 9on tricolored blackbird would not be adverse under Alternative 9.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Alternative 9 would remove 3,290 acres of breeding habitat (98 acres of nesting, 2,264 acres of cultivated lands, and 985 acres of noncultivated lands suitable for foraging) and 6,757 acres of nonbreeding habitat (826 acres of roosting, 5,171 acres of cultivated lands, and 760 acres of noncultivated lands suitable for foraging) for tricolored blackbird in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 659 acres of breeding, 1,927 acres of nonbreeding), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*, and *CM7 Riparian Natural Community Restoration*—2,688 acres of breeding, 4,830 acres of nonbreeding).

Typical NEPA and CEQA project-level mitigation ratios would be 1:1 for restoration/creation and 1:1 for protection for the loss of nesting and roosting wetland habitat, 2:1 protection for loss of noncultivated lands suitable for foraging (for the breeding and nonbreeding season), and 1:1 protection for the loss of cultivated lands.

Using these ratios would indicate that the compensation for loss or conversion of tricolored blackbird habitat from CM1 would require 10 acres of restoration and 10 acres of protection of nesting habitat, 256 acres of restoration and 256 acres of protection of roosting habitat, 854 acres of protection of noncultivated lands that provide foraging habitat, 523 acres of protection of cultivated lands suitable for foraging during the breeding season, and 1,370 acres of cultivated lands that provide foraging habitat during the nonbreeding season. The near-term effects of other conservation actions would remove or convert 88 acres of nesting habitat, 570 acres of roosting habitat, 619 acres of noncultivated lands suitable for foraging, 1,741 acres of cultivated lands that provide foraging habitat during the breeding season, and 3,801 acres of cultivated lands during the nonbreeding season. Compensation for these losses from other conservation measures would therefore require 88 acres of restoration and 88 acres of protection of nesting habitat, 570 acres of restoration and 570 acres of protection of roosting habitat, 1,238 acres of protection of noncultivated lands that provide foraging habitat, 1,741 acres of protection of cultivated lands suitable for foraging during the breeding season, and 3,801 acres of cultivated lands that provide foraging habitat during the nonbreeding season. using the same typical NEPA and CEQA ratios.

Total compensation for near-term loss or conversion of tricolored blackbird required using the typical ratios above would be 98 acres of restoration and 98 acres of protection for nesting habitat, 826 acres of restoration and 826 acres of protection for roosting habitat, 3,490 acres of protection of noncultivated foraging habitat, 2,264 acres of protection for cultivated lands that provide foraging habitat during the breeding season, and 5,171 acres of cultivated lands that provide foraging habitat during the nonbreeding season.

The BDCP has committed to near-term goals of protecting 25 acres and restoring protecting 750 acres and restoring 800 acres of valley/foothill riparian natural community, protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, protecting 4,800 acres of managed wetland natural community, protecting 15,400 acres of non-rice cultivated lands, protecting 900 acres of rice or rice equivalent habitat, restoring 8,850 acres of tidal freshwater emergent wetlands and 2,000 acres of tidal brackish emergent wetlands (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM4, CM5, CM7, and CM8 and would occur in the same timeframe as the construction and early restoration losses. Some proportion of these natural communities provide suitable habitat for tricolored blackbird as described below.

Nesting by tricolored blackbirds is currently limited by the availability of high-value breeding habitat, which is represented by suitable nesting substrate, such as cattail/bulrush emergent wetland, in close association with highly productive foraging areas that support abundant insect prey, such as grasslands, seasonal wetlands, pasturelands, alfalfa and other hay crops, and some croplands. The nesting habitat would be located within 5 miles of high-value foraging habitat in CZs 1, 2, 8, or 11 (see Table 12-9-38 for foraging habitat values) and would be actively managed to maintain actively growing stands of bulrush/cattail emergent vegetation through mechanical habitat manipulation, prescribed fire, or other measures described in *CM11 Natural Communities Enhancement and Management*. In addition to the actively managed nesting habitat, a portion of the 750 acres of protection and 800 acres of restoration of valley/foothill riparian natural community, and the restoration of 900 acres nontidal marsh would provide nesting habitat for tricolored blackbird. The Plan estimates that modeled nesting habitat in the Plan Area currently includes 8% of valley/foothill riparian and 22% of nontidal freshwater emergent marsh (BDCP Chapter 5, Section 5.6.12.2, *Beneficial Effects*). Assuming similar proportions of modeled habitat on conservation lands restored in the near-term, approximately 64 acres of valley foothill riparian and 198 acres of nontidal marsh restored would provide nesting habitat for tricolored blackbird.

The Plan estimates that modeled roosting habitat in the Plan Area currently includes 95% of tidal freshwater emergent wetland, 57% of brackish emergent wetland, 21% of valley/foothill riparian, 75% of nontidal marsh, and 15% of managed wetlands (BDCP Chapter 5, Section 5.6.12.2, *Beneficial Effects*). Assuming similar proportions of modeled habitat on conservation lands restored in the near-term, the restoration of approximately 8,408 acres of tidal freshwater emergent wetland, 1,140 acres of tidal brackish emergent wetland, 675 acres of nontidal marsh, and 168 acres of valley foothill riparian would provide 10,391 acres of nesting habitat for tricolored blackbird. An estimated 878 acres of roosting habitat would also be protected in the near-term time period (158 acres of valley/foothill riparian, 720 acres managed wetland).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) which would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities. The protection and restoration of grasslands, alkali seasonal wetlands, and vernal pool complexes would provide improved foraging opportunities for tricolored blackbirds during both the breeding and nonbreeding seasons. Proximity of nesting colonies to suitable foraging habitat contributes to high reproductive success in tricolored blackbirds. These natural communities are known to support large insect populations, a vital food resource for successful rearing and fledging of young. Those conservation lands that lie within a few miles of active nesting colonies would provide high-value foraging areas to support breeding tricolored blackbirds. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, further enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4).

Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,600 acres of potential foraging habitat for tricolored blackbird in the near-term (Objective CLNC1.1). Objective TRBL1.3 commits to protecting 11,050 acres (23% of the total cultivated lands commitment) of high- to very high-value breeding-foraging habitat by the late long-term. Assuming that lands would be protected proportional to the conservation objectives for covered species, approximately 3,588 acres of high- to very high-value breeding foraging habitat consisting of cultivated lands would be protected in the near-term. These lands would be protected within 5 miles of occupied or recently occupied tricolored blackbird nesting habitat in CZs 1, 2, 3, 4, 7, 8 or 11. In addition, Objective TRBL1.2 states that of the cultivated lands protected in the late long-term time period, 26,300 acres (54% of all cultivated lands protected) would be maintained in moderate – high, or very high-value cultivated lands, at least 50% of which would be high- to very high-value. Assuming proportional conservation in the near-term, an estimated 8,424 acres of cultivated lands that provide foraging habitat for tricolored blackbird would be protected in the near-term, 4,212 of which would be in high- to very high-value cultivated lands. Small but essential habitats for species including tricolored blackbird would also be protected that occur within the agricultural matrix. This would include the retention of wetlands, grassland patches, shrub stands, and herbaceous edge habitats, which could provide suitable nesting, foraging or roosting habitat for tricolored blackbird (Objective CLNC1.3).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

The acres of protection and restoration contained in the near-term Plan goals, in addition to the detailed habitat value goals that would be applied to near-term acres, are more than sufficient to satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and the near-term impacts from other conservation measures on nesting, roosting, and cultivated lands foraging habitat. The 3,660 acres of grassland protection in the near-term are 213 acres short of the 2:1 protection mitigation ratio. However, the acres of permanent impact would be compensated for by this acreage, and temporary impacts on grassland would be restored to preproject conditions (including revegetation with native vegetation if within 1 year of completion of construction) under *AMM2 Construction Best Management Practices and Monitoring*. With the enhancement of grasslands described above, and the restoration of temporary habitat impacts, this difference between impacted and conserved grassland acreages in the near-term time period would not result in a significant impact on tricolored blackbird.

Late Long-Term Timeframe

Based on the habitat model, the study area approximately 164,947 acres of breeding and 259,093 acres of nonbreeding habitat for tricolored blackbird. The Delta is an important wintering area for the tricolored blackbird (Hamilton 2004, Beedy 2008). Although there is a large acreage of modeled breeding habitat available, the study area does not currently support many nesting tricolored blackbirds with the exception of a few occurrences on the fringes of the Suisun Marsh, in the Yolo Bypass, and along the southwestern perimeter of the study area (BDCP, Chapter 5, *Effects Analysis*). Alternative 9 as a whole would result in the permanent loss of and temporary effects on 12,872 acres of breeding habitat and 29,289 acres of nonbreeding habitat for tricolored blackbird during the term of the Plan (8% of the total breeding habitat in the study area and 11% of the total nonbreeding habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration*, and *CM8 Grassland Natural Community Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community, protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, protect 8,100 acres of managed wetland, and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3, *Description of Alternatives*).

Species-specific biological goals and objectives for tricolored blackbird commit to protecting or restoring at least 50 acres of occupied or recently occupied (within the last 15 years) tricolored blackbird nesting habitat located within 5 miles of high-value foraging habitat in CZs 1, 2, 8, or 11 (Objective TRBL1.1). Foraging habitat value classes for tricolored blackbird are found in Table 12-9-38. To ensure that natural community conservation benefits tricolored blackbird, the Plan further specifies that cultivated lands protected for tricolored blackbird retain residual wetland, grassland patches, shrub stands, and herbaceous edge habitats which may provide suitable nesting, foraging or roosting habitat for the species (Objective CLNC1.3). In addition, 26,300 acres of moderate-, high-, or very high-value cultivated lands would be conserved and managed as nonbreeding foraging habitat, 50% of which would be of high- or very high-value (Objective TRBL1.2). At least 11,050 acres of cultivated lands managed as high to very high breeding foraging habitat would be conserved within 5 miles of occupied or recently occupied (within the last 15 years) tricolored blackbird nesting habitat in CZs 1, 2, 3, 4, 7, 8, or 11 (Objective TRBL1.2). Most of the loss of breeding and nonbreeding habitat would be to cultivated lands that are abundant throughout the study area, so the loss is not expected to adversely affect the population in the study area.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6.12.2, *Effects Analysis*) estimates that the restoration and protection actions discussed above could result in the protection of an estimated 46,566 acres of tricolored blackbird habitat (16,476 acres breeding habitat and 31,090 acres nonbreeding habitat) and restoration of 31,001 acres of tricolored blackbird habitat (2,190 acres breeding habitat and 28,811 acres nonbreeding habitat).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Considering these protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for habitats lost to construction and restoration activities, and with implementation of AMM1–AMM7 and *AMM21 Tricolored Blackbird*, the loss of habitat or direct mortality though the implementation of Alternative 9 as a whole would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the alternative would have a less-than-significant impact on tricolored blackbird.

Other factors relevant to effects on tricolored blackbird are listed here.

- Very little loss of nesting habitat would occur (up to 84 acres of permanent loss and 88 acres of temporary loss).
- Most of the loss of breeding and nonbreeding habitat would be to cultivated lands that are abundant throughout the Plan Area, so the loss is not expected to adversely affect the population in the Plan Area.

- Most temporary impacts would be to cultivated lands and grasslands that could be restored relatively quickly to suitable foraging habitat after completion of construction activities.

Considering these protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for habitats lost to construction and restoration activities, and implementation of AMM1–AMM7 and *AMM21 Tricolored Blackbird*, the loss of habitat or direct mortality though the implementation of Alternative 9 as a whole would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the alternative would have a less-than-significant impact on tricolored blackbird.

Impact BIO-88: Effects on Tricolored Blackbird Associated with Electrical Transmission Facilities

New transmission lines would increase the risk that tricolored blackbirds could be subject to power line strikes, which could result in injury or mortality of individuals. Tricolored blackbirds would have the potential to intersect the proposed transmission lines largely due to winter movements throughout the study area, when individuals are migrating in large flocks and dense fog is common in the area. Although migratory movements

and daily flights between roosting and foraging habitat make tricolored blackbird vulnerable to collision with transmission lines, daily flights associated with winter foraging likely occurs in smaller flocks at heights that are lower than the transmission lines (BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). For example, Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. As described in *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters, which would further reduce any potential for tricolored blackbird collision with transmission lines.

Transmission line poles and towers provide perching substrate for raptors, which are predators on tricolored blackbird. Although there is potential for transmission lines to result in increased perching opportunities for raptors and result in increased predation pressure on tricolored blackbirds, the existing network of transmission lines in the Plan Area currently poses these risks, and any incremental risk associated with the new power line corridors would not be expected to affect the study area population. Therefore, it is assumed that the increased risk of predation on tricolored blackbird from an increase in raptor perching opportunities would be minimal.

***NEPA Effects*:** New transmission lines would increase the risk for tricolored blackbird powerline strikes, primarily during daily flights between roosting and foraging sites and during winter during migration movements. *AMM20 Greater Sandhill Crane*contains the commitment to place bird strike diverters on all new powerlines, which would reduce the potential impact of the construction of new transmission lines on tricolored blackbird. The increased risk of predation on tricolored blackbird from an increase in raptor perching opportunities would be minimal. Therefore, the construction and operation of new transmission lines under Alternative 9 would not result in an adverse effect on tricolored blackbird.

***CEQA Conclusion*:** New transmission lines would increase the risk for tricolored blackbird powerline strikes, primarily during daily flights between roosting and foraging sites and during winter during migration movements. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would reduce the potential impact of the construction of new transmission lines on tricolored blackbird. The increased risk of predation on tricolored blackbird from an increase in raptor perching opportunities would be minimal. The construction and operation of new transmission lines under Alternative 9 would not substantially reduce the number or restrict the range of the species and would therefore result in a less-than-significant impact on tricolored blackbird

Impact BIO-89: Indirect Effects of Plan Implementation on Tricolored Blackbird

Indirect Construction- and Operation-Related Effects: Tricolored blackbird nesting habitat within the vicinity of proposed construction areas that could be indirectly affected by construction activities. Construction noise above background noise levels (greater than 50 dBA) could extend 1.900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect tricolored blackbird. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet from the construction edge. Construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. *AMM21 Tricolored Blackbird* would require preconstruction surveys, and if detected, covered activities would be avoided within a minimum 250 feet of an active nesting colony and up to 1,300 feet where practicable until breeding has ceased. Construction and restoration projects would also be designed, in consultation with CDFW, to avoid construction activity within at least 300 feet from occupied active tricolored blackbird roosting habitat. In addition, monitoring would be implemented to ensure that construction does not adversely affect the nesting colony or nest site. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect tricolored blackbird in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to tricolored blackbird habitat could also affect the species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including tricolored blackbird. Marsh (tidal and nontidal) and floodplain restoration also have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury.

A detailed review of the methylmercury issues associated with implementation of the BDCP is contained in Appendix 11F, *Substantive BDCP Revisions*. This review includes an overview of the BDCP-related mechanisms that could result in increased mercury in the foodweb, and how exposure to individual species may occur based on feeding habits and where their habitat overlaps with the areas where mercury bioavailability could increase.

Due to the complex and very site-specific factors that determine if mercury becomes mobilized into the foodweb, *CM12 Methylmercury Management* (as revised in Appendix 11F, *Substantive BDCP Revisions*) is included to provide for site-specific evaluation for each restoration project. On a project-specific basis, where high potential for methylmercury production is identified that restoration design and adaptive management cannot fully address while also meeting restoration objectives, alternate restoration areas will be considered. CM12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This conservation measure would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including tricolored blackbird. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on tricolored blackbird.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on tricolored blackbird from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: The effects of noise, potential spills of hazardous material, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would not be adverse with the implementation of AMM1–AMM7 and *AMM21 Tricolored Blackbird*. Tidal habitat restoration could result in increased exposure of tricolored blackbird to selenium. This effect would be addressed through the implementation of *AMM26, Selenium Management* which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of tricolored blackbird to methylmercury. It is unlikely that breeding tricolored blackbird would be highly susceptible to methylmercury exposure because tidal wetlands are not expected to be a major foraging area for the species. However, it is unknown what concentrations of methylmercury are harmful to this species and the potential for increased exposure varies substantially within the study area. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on tricolored blackbird.

CEQA Conclusion: Impacts of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would be less than significant with the implementation of *AMM21 Tricolored Blackbird* and AMM1–AMM7. Tidal habitat restoration could result in increased exposure of tricolored blackbird to selenium. This impact would be addressed through the implementation of *AMM26, Selenium Management* which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of tricolored blackbird to methylmercury. It is unlikely that breeding tricolored blackbird would be highly susceptible to methylmercury exposure because tidal wetlands are not expected to be a major foraging area for the species. However, it is unknown what concentrations of methylmercury are harmful to this species. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on tricolored blackbird.

Therefore, with AMM1-7, AMM21, AMM27, and CM12 in place, the indirect effects of Alternative 9 implementation would not result in a substantial adverse effect through habitat modification or potential mortality. Therefore, the indirect effects of Alternative 9 implementation would have a less-than-significant impact on tricolored blackbird.

Impact BIO-90: Periodic Effects of Inundation of Tricolored Blackbird Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass (CM2) would inundate 2,447–4,312 acres of breeding habitat and 263–1,252 acres of nonbreeding habitat (Table 12-9-37). Based on hypothetical floodplain restoration, construction of setback levees for *CM5 Seasonally Inundated Floodplain Restoration* could result in periodic inundation of approximately 2,509 acres of breeding habitat (30 acres of nesting, 2,124 acres of cultivated lands, 355 acres of noncultivated lands suitable for foraging) and 2,694 acres of nonbreeding habitat(29 acres of roosting, 2,506 acres of cultivated lands, 158 acres of noncultivated lands suitable for foraging, Table 12-9-37) resulting in the temporary loss of these habitats. Tricolored blackbirds are highly nomadic during the winter and would be expected to move to adjacent suitable foraging habitat when the bypass is inundated, as they do under the current flooding regime. However, this inundation could reduce the availability of nesting habitat during years when flooding extends into the nesting season (past March).The periodic inundation of the Yolo Bypass (CM2) and of other floodplains (CM5) is expected to restore a more natural flood regime in support of wetland and riparian vegetation types that support nesting habitat. There would be no expected adverse effect on tricolored blackbird.

NEPA Effects: Implementation of CM2 and CM5 would result in periodic inundation of nesting and foraging habitat for tricolored blackbird. Periodic inundation would not result in an adverse effect on tricolored blackbird because inundation is expected to take place outside of the breeding season. Although foraging habitat would be temporarily unavailable, tricolored blackbirds are highly nomadic in winter and wintering birds would be expected to move to adjacent foraging habitat.

CEQA Conclusion: Implementation of CM2 and CM5 would result in periodic inundation of nesting and foraging habitat for tricolored blackbird. Periodic inundation would have a less-than-significant impact on tricolored blackbird because inundation is expected to take place outside of the breeding season. Although foraging habitat would be temporarily unavailable, tricolored blackbirds are highly nomadic in winter and wintering birds would be expected to move to adjacent foraging habitat.

Western Burrowing Owl

Western burrowing owl modeled habitat consisted of high- and low-value habitat for nesting and foraging. High-value habitat consists of plant alliances within the grassland and vernal pool natural communities and pasture. Low-value habitat includes plant alliances and crop types from managed wetland, alkali seasonal wetland, and cultivated lands. Value was determined through reported species use patterns from the literature.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of western burrowing owl modeled habitat as indicated in Table 12-9-39. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit the western burrowing owl (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect at least 1,000 acres of cultivated lands in CZs 1 and 11 that support high-value burrowing owl habitat and are within 0.5 mile of high-value grassland habitat or occupied low-value habitat (Objective WBO1.1, associated with CM3).

- Protect at least 8.000 acres of grassland, with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at last 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).
- Restore or create alkali seasonal wetlands and vernal pool complex in CZs 1, 8, and/or 11 to achieve no net loss of wetted acres (Objectives ASWNC1.2 and VPNC1.2, associated with CM9).
- Increase burrow availability and prey abundance and accessibility (Objectives ASWNC2.3, ASWNC2.4, VPNC2.4, VPNC2.5, GNC2.3, and GNC2.4, associated with CM11).
- Protect at least 48,600 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species and maintain and protect the small patches of important wildlife habitats associated with cultivated lands (Objectives CLNC1.1 and CLNC1.3, associated with CM3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for the species and implementation of AMM1–AMM7, and *AMM23 Western Burrowing Owl*, impacts on western burrowing owl would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-39. Changes in Western Burrowing Owl Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	High-value	87	87	407	407	NA	NA
	Low-value	298	298	2,120	2,120	NA	NA
Total Impacts CM1		**385**	**385**	**2,527**	**2,527**	**NA**	**NA**
CM2–CM18	High-value	4,487	11,570	245	328	1,390–3,303	779
	Low-value	3,527	28,506	144	971	1,522–2,927	6,162

TOTAL IMPACTS		**8,399**	**40,461**	**2,916**	**3,826**		

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-91: Loss or Conversion of Habitat for and Direct Mortality of Western Burrowing Owl

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 44,287 acres of modeled habitat for western burrowing owl (of which 12,392 acres is of high value and 31,895 acres is of low value, Table 12-9-39). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM10 Nontidal Marsh Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate western burrowing owl habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 494 acres of acres of modeled high-value western burrowing owl habitat (87 acres of permanent loss, 407 acres of temporary loss) from CZs 4, 5, 6, 7, and 8. In addition, 2,418 acres of low-value burrowing owl habitat would be removed (298 acres of permanent loss, 2,120 acres of temporary loss). The permanent and temporary losses to habitat would occur at numerous locations where dredging, construction of operable barriers and canals, and channel enlargement would be undertaken. The CM1 footprint does not overlap with any western burrowing owl occurrences. However, there is suitable habitat throughout the study area. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 1,127 acres of high-value western burrowing owl habitat (882 acres of permanent loss, 245 acres of temporary loss) in the Yolo Bypass in CZ 2. In addition, 242 acres of low-value habitat would be removed (98 acres of permanent loss, 144 acres of temporary loss). The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 29,668 acres of modeled western burrowing owl habitat in CZs 1, 2, 4, 5, 6, 7, 8, 10, and 11. The majority of removed or converted acres (19,739 acres) is composed of low-value habitat. However, 9,929 acres of high-value habitat would also be lost from tidal restoration actions. Tidal restoration would directly impact and fragment remaining high-value grassland habitat just north of Rio Vista in and around French and Prospect Islands, and in an area south of Rio Vista around Threemile Slough. Tidal natural community restoration efforts would impact one extant record of burrowing owl just northeast of Oakley along Dutch Slough and one possibly extirpated record in Suisun Marsh.

- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 2,504 acres of modeled western burrowing owl in CZs 2, 4, and 7. This total is comprised of

2,279 acres of low-value habitat. Also, 225 acres of high-value grassland habitat would be removed (142 permanent, 83 temporary) consisting of small patches of habitat along the San Joaquin, Old, and Middle Rivers in CZ 7.

- *CM6 Channel Margin Enhancement*: Sites for channel margin enhancement would be located along levees where western burrowing owl could be present. The species is known to use often the grassland edges along canals and levees in agricultural areas. The implementation of *AMM23 Western Burrowing Owl* would reduce the potential for channel margin enhancement activities to disturb owls or affect active nests.

- *CM7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 11 acres of high-value burrowing owl habitat as part of tidal restoration. In addition, 960 acres of low-value habitat would be removed as a part of tidal restoration and 3,991 acres would be removed as part of seasonal floodplain restoration through CM7.

- *CM8 Grassland Natural Community Restoration*: Grassland restoration would primarily be implemented on agricultural lands and would result in the permanent loss of 1,676 acres (362 acres of high-value and 1,314 acres of low-value) of western burrowing owl habitat. The conversion of 1,676 acres of low-value habitat to high-value grassland, would temporarily remove available habitat but would ultimately have a beneficial effect on the western burrowing owl.

- *CM10 Nontidal Marsh Restoration*: Implementation would result in the permanent removal of 159 acres of high-value and 952 acres of low-value western burrowing owl habitat.

- *CM11 Natural Communities Enhancement and Management*: A variety of habitat management actions that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of western burrowing owl habitat. The burrowing owl's fossorial habits make the species more sensitive to the effects of ground disturbance than other raptors. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available western burrowing owl habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. CM11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. However, approximately 50 acres of grassland habitat would be lost from the construction of trails and facilities.

  Habitat management- and enhancement-related activities and equipment operation could destroy nests burrows, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. The potential for these activities to result in nest failure and mortality or other adverse effects on western burrowing owl would be avoided or minimized with the incorporation of *AMM23 Western Burrowing Owl* into the BDCP which would require surveys to determine presence or absence and the establishment of no-disturbance buffers around active sites.

- *CM18 Conservation Hatcheries*: Implementation of CM18 would remove up to 35 acres of high-value western burrowing owl habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect western burrowing owl use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and conservation actions as described below.
- Injury and Direct Mortality: Construction would not be expected to result in direct mortality of western burrowing owl. However, if nest burrows were occupied in the vicinity of construction activities, equipment operation could destroy nests and noise and visual disturbances could lead to abandonment. *AMM23 Western Burrowing Owl* would ensure that preconstruction surveys detected any occupied burrows and no-disturbance buffers would be implemented.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 5,226 acres (4,574 acres permanent, 652 acres temporary) of high-value habitat for western burrowing owl in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 494 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—4,732 acres). In addition, 7,373 acres of low-value habitat would be removed or converted in the near-term (CM1, 2,120 acres; *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—3,671 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 2:1 protection of high-value habitat, and 1:1 protection of low-value habitat. A proportion of the loss of low-value habitat would result from conversion and enhancement to high-value habitats. Using these typical ratios would indicate that 988 acres should be protected to compensate for the loss of high-value habitat from CM1 and that 4,836 acres should be protected to compensate for the loss of low-value habitat from CM1. The near-term effects of other conservation actions would require 9,464 acres of protection to compensate for the loss of high-value habitat and 3,671 acres of protection to compensate for the loss of low-value habitat using the same typical NEPA and CEQA ratios (2:1 protection for the loss of high-value habitat, 1:1 protection for the loss of low-value habitat).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4

in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses.

The protection of high-value grasslands is essential in order to sustain existing western burrowing owl populations in the study area. Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide habitat for western burrowing owl and reduce the effects of current levels of habitat fragmentation. This protection would not only expand the amount of protected high-value habitat in the study area, but also support existing western burrowing owl populations that occur to the west of CZ 8 and in the areas surrounding CZs 1 and 11, which would especially benefit declining populations in the vicinity of Suisun Marsh and San Pablo Bay. Certain types of cultivated lands such as irrigated pasture, alfalfa and other hay crops, and some row crops can provide foraging habitat for western burrowing owl. Under appropriate management regimes, cultivated lands can support breeding and wintering burrowing owls. Under *CM11 Natural Communities Enhancement and Management*, small mammal and insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). In addition, burrow availability would be increased on protected natural communities by encouraging ground squirrel occupancy and expansion through the creation of berms, mounds, edges, and through the prohibition of ground squirrel control programs (i.e., poisoning, Objectives ASWNC2.3, VPNC2.4, GNC2.3). These Plan objectives represent performance standards for considering the effectiveness of conservation actions.

The combined acres of restoration and protection of 3,660 acres of grassland, vernal pool complex, and alkali seasonal wetland contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on western burrowing owl habitat. Some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would include high-value crop types. These acres, in addition to the management and enhancement activities that are contained in the Plan goals, would satisfy the typical mitigation ratios that would be applied to the other near-term conservation actions, providing that the 15,400 acres of cultivated lands protected in the near-term were managed in suitable crop types to compensate for the loss of high-value habitat at a ratio of 2:1. Mitigation Measure BIO-91, *Compensate for the Near-Term Loss of High-Value Burrowing Owl Habitat,* would be available to address the adverse effect of high-value habitat loss in the near-term. The acres of protection of cultivated lands would be sufficient to compensate for the loss of low-value burrowing owl habitat from CM1 and from the other near-term conservation actions.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM23 Western Burrowing Owl*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Late Long-Term Timeframe

Based on the habitat model, the study area supports approximately 152,014 acres of high-value and 254,352 acres of low-value habitat for western burrowing owl. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 12,392 acres of high-value habitat and 31,895 acres of low value habitat over the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration,* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide habitat for western burrowing owl and reduce the effects of current levels of habitat fragmentation. This protection would not only expand the amount of protected high-value habitat in the Plan Area, but also support existing western burrowing owl populations that occur to the west of CZ 8 and in the areas surrounding CZs 1 and 11, which would especially benefit declining populations in the vicinity of Suisun Marsh and San Pablo Bay. Certain types of cultivated lands such as irrigated pasture, alfalfa and other hay crops, and some row crops can provide foraging habitat for western burrowing owl. Under appropriate management regimes, cultivated lands can support breeding and wintering burrowing owls. To ensure that cultivated lands conservation benefits western burrowing owl, the Plan's biological goals and objectives further specify that, of the cultivated lands protected in the late long-term, at least 1,000 acres would be protected in CZs 1 and 11 that support high-value burrowing owl habitat and are within 0.5 miles of high-value grassland habitat or occupied low-value habitat (Objective WBO1.1). Under *CM11 Natural Communities Enhancement and Management*, small mammal and insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). In addition, burrow availability would be increased on protected natural communities by encouraging ground squirrel occupancy and expansion through the creation of berms, mounds, edges, and through the prohibition of ground squirrel control programs (i.e., poisoning, Objectives ASWNC2.3, VPNC2.4, GNC2.3).

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the protection of an estimated 33,766 acres of western burrowing owl habitat (8,589 acres high-value and 25,177 acres low-value habitat) and restoration of 1,645 acres of western burrowing owl habitat (1,642 acres high-value and 3 acres low-value habitat).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since

been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

NEPA Effects: The loss of western burrowing owl habitat and potential mortality of this special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection and restoration associated with CM3, CM8, and CM11, guided by biological goals and objectives and by AMM1–AMM7 and *AMM23 Western Burrowing Owl,* and with the implementation of Mitigation Measure BIO-91, *Compensate For the Near-Term Loss of High-Value Burrowing Owl Habitat*, which would be available to guide the near-term protection and management of cultivated lands, the effects of habitat loss and potential mortality on western burrowing owl would not be adverse under Alternative 9.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Alternative 9 would remove 5,226 acres (4,574 acres permanent, 652 acres temporary) of high-value habitat for western burrowing owl in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 494 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—4,732 acres). In addition, 7,373 acres of low-value habitat would be removed or converted in the near-term (CM1, 2,120 acres; *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—3,671 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 2:1 protection of high-value habitat, and 1:1 protection of low-value habitat. A proportion of the loss of low-value habitat would result from conversion and enhancement to high-value habitats. Using these typical ratios would indicate that 988 acres should be protected to compensate for the loss of high-value habitat from CM1 and that 4,836 acres should be protected to compensate for the loss of low-value habitat from CM1. The near-term effects of other conservation actions would require 9,464 acres of protection to compensate for the loss of high-value habitat and 3,671 acres of protection to compensate for the loss of low-value habitat using the same typical NEPA and CEQA ratios (2:1 protection for the loss of high-value habitat, 1:1 protection for the loss of low-value habitat).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses.

The protection of high-value grasslands is essential in order to sustain existing western burrowing owl populations in the study area. Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide habitat for western burrowing owl and reduce the effects of current levels of habitat fragmentation. This protection would not only expand the amount of protected high-value habitat in the study area, but also support existing western burrowing owl populations that occur to the west of CZ 8 and in the areas surrounding CZs 1 and 11, which would especially benefit declining populations in the vicinity of Suisun Marsh and San Pablo Bay. Certain types of cultivated lands such as irrigated pasture, alfalfa and other hay crops, and some row crops can provide foraging habitat for western burrowing owl. Under appropriate management regimes, cultivated lands can support breeding and wintering burrowing owls. Under *CM11 Natural Communities Enhancement and Management*, small mammal and insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). In addition, burrow availability would be increased on protected natural communities by encouraging ground squirrel occupancy and expansion through the creation of berms, mounds, edges, and through the prohibition of ground squirrel control programs (i.e., poisoning, Objectives ASWNC2.3, VPNC2.4, GNC2.3). These Plan objectives represent performance standards for considering the effectiveness of conservation actions.

The combined acres of restoration and protection of 3,660 acres of grassland, vernal pool complex, and alkali seasonal wetland contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on western burrowing owl habitat. Some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would include high-value crop types. These acres, in addition to the management and enhancement activities that are contained in the Plan goals, would satisfy the typical mitigation ratios that would be applied to the other near-term conservation actions, providing that the 15,400 acres of cultivated lands protected in the near-term were managed in suitable crop types to compensate for the loss of high-value habitat at a ratio of 2:1. Mitigation Measure BIO-91, *Compensate for the Near-Term Loss of High-Value Burrowing Owl Habitat,* would reduce the significant effect of high-value habitat loss in the near-term. The acres of protection of cultivated lands would be sufficient to compensate for the loss of low-value burrowing owl habitat from CM1 and from the other near-term conservation actions.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM23 Western Burrowing Owl*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

Late Long-Term Timeframe

Based on the habitat model, the study area supports approximately 152,014 acres of high-value and 254,352 acres of low-value habitat for western burrowing owl. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 12,392 acres of high-value habitat and 31,895 acres of low value habitat over the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration,* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide habitat for western burrowing owl and reduce the effects of current levels of habitat fragmentation. This protection would not only expand the amount of protected high-value habitat in the Plan Area, but also support existing western burrowing owl populations that occur to the west of CZ 8 and in the areas surrounding CZs 1 and 11, which would especially benefit declining populations in the vicinity of Suisun Marsh and San Pablo Bay. Certain types of cultivated lands such as irrigated pasture, alfalfa and other hay crops, and some row crops can provide foraging habitat for western burrowing owl. Under appropriate management regimes, cultivated lands can support breeding and wintering burrowing owls. To ensure that cultivated lands conservation benefits western burrowing owl, the Plan's biological goals and objectives further specify that, of the cultivated lands protected in the late long-term, at least 1,000 acres would be protected in CZs 1 and 11 that support high-value burrowing owl habitat and are within 0.5 miles of high-value grassland habitat or occupied low-value habitat (Objective WBO1.1). Under *CM11 Natural Communities Enhancement and Management*, small mammal and insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). In addition, burrow availability would be increased on protected natural communities by encouraging ground squirrel occupancy and expansion through the creation of berms, mounds, edges, and through the prohibition of ground squirrel control programs (i.e., poisoning, Objectives ASWNC2.3, VPNC2.4, GNC2.3).

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the protection of an estimated 33,766 acres of western burrowing owl habitat (8,589 acres high-value and 25,177 acres low-value habitat) and restoration of 1,645 acres of western burrowing owl habitat (1,642 acres high-value and 3 acres low-value habitat).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Considering Alternative 9's protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with implementation of AMM1–AMM7, *AMM23 Western*

Burrowing Owl, and Mitigation Measure BIO-91, *Compensate for Near-Term Loss of High-Value Western Burrowing Owl Habitat*, which would be available to guide the near-term protection and management of cultivated lands, the loss of habitat and direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on western burrowing owl.

Mitigation Measure BIO-91: Compensate for Near-Term Loss of High-Value Western Burrowing Owl Habitat

Because the BDCP lacks an acreage commitment for specific crop types that would be managed within the 15,400 acres of cultivated lands protected in the near-term time period, DWR will compensate for the loss of high-value burrowing owl habitat with high-value natural communities or cultivated crop types a ratio of 2:1 in the near-term time period.

Impact BIO-92: Effects on Western Burrowing Owl Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes and/or electrocution, which could result in injury or mortality of western burrowing owl. The species is large-bodied but with relatively long and rounded wings, making it moderately maneuverable. While burrowing owls may nest in loose colonies, they do not flock or congregate in roosts or foraging groups. Collectively, the species' keen eyesight and largely ground-based hunting behavior make it a relatively low-risk species for powerline collision. While the species in not widespread in the study area, it may become more widely distributed as grassland enhancement improves habitat for the species. Even so, the risk of effects on the population are low, given its physical and behavioral characteristics (BDCP Appendix 5.J, Attachment 5J.C*, Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*) New transmission lines would not be expected to have an adverse effect on the species. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new project transmission lines would be fitted with flight diverters. Bird flight diverters would make transmission lines highly visible to western burrowing owls and would further reduce any potential for powerline collisions.

NEPA Effects: The construction and presence of new transmission lines would not result in an adverse effect on western burrowing owl because the risk of bird strike is considered to be minimal based on the owl's physical and behavioral characteristics. All new transmission lines constructed as a result of the project would be fitted with bird diverters (*AMM20 Greater Sandhill Crane*), which have been shown to reduce avian mortality by 60% and which would further reduce any potential for powerline collisions.

CEQA Conclusion: The construction and presence of new transmission lines would have a less-than-significant impact on western burrowing owl because the risk of bird strike is considered to be minimal based on the owl's physical and behavioral characteristics. All new transmission lines constructed as a result of the project would be fitted with bird diverters (*AMM20 Greater Sandhill Crane*), which have been shown to reduce avian mortality by 60% and which would further reduce any potential for powerline collisions.

Impact BIO-93: Indirect Effects of Plan Implementation on Western Burrowing Owl

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect western burrowing owl use of modeled habitat adjacent to proposed construction areas. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Any disturbance within 250 feet of a burrow occupied by burrowing owl during the breeding season (February 1–August 31) and within 160 feet during the nonbreeding season (September 1–January 31) could potential displace winter owls or cause abandonment of active nests. These potential effects would be minimized with the implementation of *AMM23 Western Burrowing Owl* into the BDCP. AMM23, would require preconstruction surveys and establish no-disturbance buffers around active burrows. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect western burrowing owl.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect western burrowing owl in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to western burrowing owl habitat could also affect the species. AMM1–AMM7 in addition to *AMM23 Western Burrowing Owl* would minimize the likelihood of such spills from occurring and ensure that measures were in place to prevent runoff from the construction area and any adverse effects of dust on active nests.

NEPA Effects: Indirect effects on western burrowing owl as a result of Alternative 9 implementation could have adverse effects on this species through the modification of habitat and potential for direct mortality. Construction of the new forebay in CZ 8 would have the potential to disrupt nesting owls or active burrows in the high-value grassland habitat surrounding Clifton Court Forebay and adjacent to work area. With the implementation of AMM1–AMM7 and *AMM23 Western Burrowing Owl*, the indirect effects from Alternative 9 implementation would not be adverse under NEPA.

CEQA Conclusion: Indirect effects on western burrowing owl as a result of Alternative 9 implementation could have significant impacts on these species through the modification of habitat and potential for direct mortality. Construction of the new forebay in CZ 8 would have the potential to disrupt nesting owls or active burrows in the high-value grassland habitat surrounding Clifton Court Forebay and adjacent to work areas. With the implementation of AMM1–AMM7 and *AMM23 Western Burrowing Owl*, the indirect effects resulting from Alternative 9 implementation would have a less-than-significant impact on western burrowing owl.

Impact BIO-94: Periodic Effects of Inundation on Western Burrowing Owl Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on approximately 1,390–3,303 acres of high-value habitat and 1,522–2,927 acres of low-value habitat (Table 12-9-39).

Based on hypothetical footprints, implementation of *CM5 Seasonally Inundated Floodplain Restoration* could result in the periodic inundation of up to approximately 6,941 acres of modeled habitat (6,162 acres, of which would be low-value foraging habitat; Table 12-9-39).

Burrowing owls cannot use inundated areas for foraging or nesting, and increased inundation frequency and duration of cultivated lands and grassland habitats may affect prey populations that have insufficient time to recover following inundation events. Depending on timing, seasonal inundation of western burrowing owl habitat could result in displacement from nesting burrows or drowning of individuals. The potential for this effect is considered low because suitable burrow sites would most likely be located along setback levees, which are expected to be subject to inundation less frequently than floodplain surfaces that would be less likely to support suitable nesting burrows.

NEPA Effects: The periodically inundated habitat would not be expected to have an adverse effect on the population. The potential for direct mortality of western burrowing owl caused by inundation would be low because the locations of burrows would likely be above elevations consistently subject to inundation; therefore, the potential impact would not be adverse.

CEQA Conclusion: The potential for direct mortality of western burrowing owl caused by inundation would be low because the locations of burrows would likely be above elevations consistently subject to inundation. Therefore, periodic inundation would be expected to have a less-than-significant impact on the population.

Western Yellow-Billed Cuckoo

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on the western yellow-billed cuckoo. The habitat model for western yellow-billed cuckoo includes potential breeding habitat, which includes plant alliances from the valley/foothill riparian modeled habitat that contain a dense forest canopy for foraging with understory willow for nesting, and a minimum patch size of 25 acres, and migratory habitat, which includes the same plant alliances as breeding habitat without the minimum 25 acres patch size requirement.

The western yellow-billed cuckoo is uncommon in the study area at present, and the likelihood that it would be found using the modeled habitat (Table 12-9-40) is low relative to more abundant riparian species. Nesting of the species in the study area has not been confirmed for approximately 100 years. Western yellow-billed cuckoo was detected in the study area during 2009 DHCCP surveys, but nesting was not confirmed and the bird is suspected to have been a migrant (Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*). Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of western yellow-billed cuckoo modeled habitat as indicated in Table 12-9-40. Full implementation Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit the western yellow-billed cuckoo (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 5,000 acres of valley/foothill riparian natural community, with at least 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM7).
- Protect at least 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).
- Maintain at least 500 acres of mature riparian forest in CZ 4 or CZ 7 (Objective VFRNC2.3, associated with CM3 and CM7).

- Maintain the 500 acres of mature riparian forest (VFRNC2.3) intermixed with a portion of the early- to mid-successional riparian vegetation (VFRNC2.2) in large blocks with a minimum patch size of 50 acres and minimum width of 330 feet (Objective VFRNC2.4, associated with CM3 and CM7).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species and implementation of AMM1–AMM7 and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, impacts on western yellow-billed cuckoo would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-40. Changes in Western Yellow-Billed Cuckoo Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent NT	Permanent LLT[c]	Temporary NT	Temporary LLT[c]	Periodic[d] CM2	Periodic[d] CM5

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-95: Loss or Conversion of Habitat for and Direct Mortality of Western Yellow-Billed Cuckoo

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 890 acres of modeled habitat for western yellow-billed cuckoo (178 acres of breeding habitat, 712 acres of migratory habitat; Table 12-9-40). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), and floodplain restoration (CM5). Habitat enhancement and management activities (CM11) which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate western yellow-billed cuckoo modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 water conveyance facilities would result in the combined permanent and temporary loss of up to 26 acres of breeding habitat (14 acres of permanent loss, 12 acres of temporary loss) and 235 acres of migratory habitat (30 acres of permanent loss, 205 acres of temporary loss) for western yellow-billed cuckoo (Table 12-9-40). Permanent losses would primarily consist of channel enlargement at the Sacramento River and Meadows Slough. Temporary losses would occur primarily along Middle River between Victoria Canal and Mildred Island, where large dredging work areas and operable barrier work areas would be placed. The riparian habitat in these areas is composed of very small patches or stringers bordering waterways, which are composed of valley oak and scrub vegetation. There are no extant occurrences of yellow-billed cuckoo nests in the study area. However, this loss would have the potential to displace individuals, if present, and remove the functions and value of modeled habitat for nesting, protection, or foraging. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Impacts from CM1 would occur within the first 10 years of Alternative 9 implementation.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo bypass fisheries enhancement would result in the loss of approximately 31 acres of breeding habitat (26 acres of permanent loss and 5 acres of temporary loss) and 140 acres of migratory habitat (57 acres of permanent loss and 83 acres of temporary loss) for yellow-billed cuckoo in the Yolo Bypass in CZ 2. The loss is expected to occur during the first 10 years of Alternative 9 implementation. There are no extant occurrences of yellow-billed cuckoo nesting in the study area.

- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 110 acres of modeled yellow-billed cuckoo breeding habitat and 310 acres of modeled migratory habitat in CZ 1, 2, 6, and 11. There are no extant nesting records of yellow-billed cuckoo in the study area. However, a yellow-billed cuckoo detection was recorded during DHCCP surveys in 2009 (Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*) in CZ 5 between Twin Cities Road and Walnut Grove. These detections do not overlap with the hypothetical restoration areas for CM4.

- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 11 acres of modeled yellow-billed cuckoo breeding habitat (6 acres of permanent loss and 5 acres of temporary loss) and 27 acres of migratory habitat (16 acres of permanent loss and 11 acres of temporary loss) in CZ 7. Based on the riparian habitat restoration assumptions, approximately 3,000 acres of valley/foothill riparian habitat would be restored as a component of seasonally inundated floodplain restoration actions. The actual number of acres that would be restored may differ from these estimates, depending on how closely the outcome of seasonally inundated floodplain restoration approximates the assumed outcome. Once this restored riparian vegetation has developed habitat functions, a portion of it would be suitable to support western yellow-billed cuckoo habitat once the riparian vegetation has developed habitat functions for the cuckoo.

- *CM11 Natural Communities Enhancement and Management*: Habitat protection and management activities that could be implemented in protected western yellow-billed cuckoo habitats would maintain and improve the functions of the habitat over the term of the BDCP. With conditions favorable for its future establishment in the study area, western yellow-billed cuckoo would be expected to benefit from the increase in protected habitat. However, habitat management- and enhancement-related activities could disturb western yellow-billed cuckoo nests if they were present near work sites. *CM11 Natural Communities Enhancement and Management* actions designed to enhance wildlife values in restored riparian habitats may result in localized ground disturbances that could temporarily remove small amounts of western yellow-billed cuckoo habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available western yellow-billed cuckoo habitat and would be expected to result in overall improvements and maintenance of western yellow-billed cuckoo habitat values over the term of the BDCP.

- Permanent and temporary habitat losses from the above CMs, would primarily consist of small, fragmented riparian stands in CZ 2–CZ 8 that do not provide high-value habitat for the species. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities. Although the effects are considered temporary, the restored riparian habitat would require 5 years to several decades, for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. The majority of the riparian vegetation to be temporarily removed is early- to mid-successional; therefore, the replaced riparian vegetation would be expected to have structural components comparable to the temporarily removed vegetation within the first 5 to 10 years after the initial restoration activities are complete.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect western yellow-billed cuckoo use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and conservation actions as described below.

- Injury and Direct Mortality: Western yellow-billed cuckoo nesting has not been confirmed in the Delta for approximately 100 years. However, an unconfirmed breeding detection in 2009 in DHCCP surveys (Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*) and the present of suitable habitat indicates that the species is potentially breeding in the study area, or may nest there in the future. Construction-related activities would not be expected to result in direct mortality of adult or fledged western yellow-billed cuckoo if they were present in the study area, because they would be expected to avoid contact with construction and other equipment. If western yellow-billed cuckoo were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. These effects would be avoided and minimized with the incorporation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* into the BDCP.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 656 acres of modeled habitat for yellow-billed cuckoo in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 261 acres of modeled breeding and migratory habitat), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—395 acres of modeled breeding and migratory habitat). These habitat losses would primarily consist of small, fragmented riparian stands in CZ 2-CZ 8 that do not provide high-value habitat for the species.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 and that are identified in the biological goals and objectives for yellow-billed cuckoo in Chapter 3 of the BDCP would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat. Using these ratios would indicate that 261 acres of valley/foothill riparian habitat should be restored/created and 261 acres should be protected to compensate for the CM1 losses of yellow-billed cuckoo habitat. The near-term effects of other conservation actions would remove 395 acres of modeled habitat, and therefore require 395 acres of restoration and 395 acres of protection of valley/foothill riparian using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of the valley/foothill riparian natural community in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3 and CM7 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on yellow-billed cuckoo. The majority of the riparian restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2, BDCP Chapter 3, *Conservation Strategy*). Goals and objectives in the Plan for riparian restoration also include the restoration, maintenance and enhancement of structural heterogeneity with adequate vertical and horizontal overlap among vegetation components and over adjacent riverine channels, freshwater emergent wetlands, and grasslands (Objective VFRNC2.1). These natural community biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of conservation actions for the species.

The acres of protection contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and other near-term impacts. However, the restored riparian habitat would require several years (early-mid successional) and several decades (mature riparian forest), for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. Because the western yellow-billed cuckoo is not known to be an established breeder in the study area, the time lag in riparian restoration from BDCP actions would not be expected to have an adverse population-level effect on the species. Overall, BDCP riparian habitat restoration actions would be expected to benefit western yellow-billed cuckoo by increasing opportunities for a breeding population to become reestablished in the study area.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The habitat model indicates that the study area supports approximately 12,395 acres of modeled breeding and migratory habitat for yellow-billed cuckoo. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 890 acres of modeled habitat (7% of the modeled habitat in the study area). These losses would occur from the construction of the water conveyance facilities (CM1) and from *CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*. The locations of these losses would be in fragmented riparian habitat throughout the study area.

The Plan includes conservation commitments through *CM7 Riparian Natural Community Restoration* and *CM3 Natural Communities Protection and Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian woodland. Of the 5,000 acres of restored riparian natural communities, a minimum of 3,000 acres of valley/foothill riparian would be restored within the seasonally inundated floodplain, and 1,000 acres would be managed as dense early to mid-successional riparian forest (Objectives VFRNC1.1 and VFRNC1.2). In addition, at least 500 acres of mature riparian forest would be maintained in CZ 4 or CZ 7(Objective VFRNC2.3). This mature, riparian forest would be mixed with a portion of the early- to mid-successional riparian vegetation in large blocks with a minimum patch size of 50 acres and a minimum width of 330 feet (Objective VFRNC2.2 and VFRNC2.4), which would provide suitable nesting habitat for the cuckoo. The protection of 750 acres of existing valley/foothill riparian forest in CZ 7 would not provide in its entirety the vegetative structure needed to support these species, because patch sizes may not be large enough to support yellow-billed cuckoo breeding habitat. However, a portion of the protected habitat would provide suitable habitat for the species. Restoration actions through CM7 and CM11 would expand the patches of existing riparian forest in order to support the species should they become established breeders in the study area.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 3,397 acres and the protection of 517 acres of habitat for the yellow-billed cuckoo.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

NEPA Effects: The loss of western yellow-billed cuckoo habitat associated with Alternative 9 would represent an adverse effect in the absence of other conservation actions. The species is not an established breeder in the study area and current presence is limited to migrants. In addition, the habitat lost would consist of small, fragmented riparian stands that would not provide high-value habitat for the species. With habitat protection and restoration associated with CM3, CM7, and CM11, guided by biological goals and objectives and by AMM1–AMM7 and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, which would be in place throughout the construction period, the effects of habitat loss and potential mortality under Alternative 9 on western yellow-billed cuckoo would not be adverse.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Alternative 9 would remove 656 acres of modeled habitat for yellow-billed cuckoo in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 261 acres of modeled breeding and migratory habitat), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—395 acres of modeled breeding and migratory habitat). These habitat losses would primarily consist of small, fragmented riparian stands in CZ 2-CZ 8 that do not provide high-value habitat for the species.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 and that are identified in the biological goals and objectives for yellow-billed cuckoo in Chapter 3 of the BDCP would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat. Using these ratios would indicate that 261 acres of valley/foothill riparian habitat should be restored/created and 261 acres should be protected to compensate for the CM1 losses of yellow-billed cuckoo habitat. The near-term effects of other conservation actions would remove 395 acres of modeled habitat, and therefore require 395 acres of restoration and 395 acres of protection of valley/foothill riparian using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of the valley/foothill riparian natural community in the study area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3 and CM7 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on yellow-billed cuckoo. The majority of the riparian restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2, BDCP Chapter 3, *Conservation Strategy*). Goals and objectives in the Plan for riparian restoration also include the restoration, maintenance and enhancement of structural heterogeneity with adequate vertical and horizontal overlap among vegetation components and over adjacent riverine channels, freshwater emergent wetlands, and grasslands (Objective VFRNC2.1). These natural community biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of conservation actions for the species.

The acres of protection contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and other near-term impacts. However, the restored riparian habitat would require several years (early-mid successional) and several decades (mature riparian forest), for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. Because the western yellow-billed cuckoo is not known to be an established breeder in the study area, the time lag in riparian restoration from BDCP actions would not be expected to have an adverse population-level effect on the species. Overall, BDCP riparian habitat restoration actions would be expected to benefit western yellow-billed cuckoo by increasing opportunities for a breeding population to become reestablished in the study area.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The habitat model indicates that the study area supports approximately 12,395 acres of modeled breeding and migratory habitat for yellow-billed cuckoo. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 890 acres of modeled habitat (7% of the modeled habitat in the study area). These losses would occur from the construction of the water conveyance facilities (CM1) and from *CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*. The locations of these losses would be in fragmented riparian habitat throughout the study area.

The Plan includes conservation commitments through *CM7 Riparian Natural Community Restoration* and *CM3 Natural Communities Protection and Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian woodland. Of the 5,000 acres of restored riparian natural communities, a minimum of 3,000 acres of valley/foothill riparian would be restored within the seasonally inundated floodplain, and 1,000 acres would be managed as dense early to mid-successional riparian forest (Objectives VFRNC1.1 and VFRNC1.2). In addition, at least 500 acres of mature riparian forest would be maintained in CZ 4 or CZ 7(Objective VFRNC2.3). This mature, riparian forest would be mixed with a portion of the early- to mid-successional riparian vegetation in large blocks with a minimum patch size of 50 acres and a minimum width of 330 feet (Objectives VFRNC2.2 and VFRNC2.4), which would provide suitable nesting habitat for the cuckoo. The protection of 750 acres of existing valley/foothill riparian forest in CZ 7 would not provide in its entirety the vegetative structure needed to support these species, because patch sizes may not be large enough to support yellow-billed cuckoo breeding habitat. However, a portion of the protected habitat would provide suitable habitat for the species. Restoration actions through CM7 and CM11 would expand the patches of existing riparian forest in order to support the species should they become established breeders in the study area.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 3,397 acres and the protection of 517 acres of habitat for the yellow-billed cuckoo.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Pla*n, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

In the absence of other conservation actions, effects on western yellow-billed cuckoo from Alternative 9 would represent an adverse effect as a result of habitat modification and potential for direct mortality of a special-status species; however, considering Alternative 9's protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for the time lag of restoring habitats lost to construction and restoration activities, and with implementation of AMM1–AMM7 and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on western yellow-billed cuckoo.

Impact BIO-96: Fragmentation of Western Yellow-Billed Cuckoo Habitat as a Result of Constructing the Water Conveyance Facilities

Grading, filling, contouring, and other initial ground-disturbing operations for water conveyance facilities construction may temporarily fragment modeled western yellow-billed cuckoo habitat. This could temporarily reduce the extent and functions supported by the affected habitat. Because western yellow-billed cuckoo is not currently known to breed in the study area, and the protection and restoration of riparian habitat will expand contiguous habitat block requirements, habitat fragmentation would have a, minimal effect on the species.

NEPA Effects: Fragmentation of habitat would not have an adverse effect on western yellow-billed cuckoo. The habitat functions in the study area for the species would be greatly improved through the implementation of CM5, which would restore and protect large contiguous patches of riparian habitat.

CEQA Conclusion: Fragmentation of habitat would have a less-than-significant impact on western yellow-billed cuckoo. The habitat functions in the study area for the species would be greatly improved through the implementation of CM5, which would restore and protect large contiguous patches of riparian habitat.

Impact BIO-97: Effects on Western Yellow-Billed Cuckoo Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of western yellow-billed cuckoo. Because the western yellow-billed cuckoo uses riparian forests to meet all of its breeding and wintering life requisites, the species remains primarily within the canopy of riparian forests and rarely ventures into open spaces except during migration, limiting its opportunity to encounter the proposed transmission lines. As a summer resident, if the species were to occur in the study area, it would be during periods of relatively high visibility and clear weather conditions, thus further reducing collision risk from daily use patterns or seasonal migration flights. Finally, western yellow-billed cuckoo wing shape is characterized by low wing loading and a moderate aspect ratio, making the species moderately maneuverable and presumably able to avoid collisions, especially during high-visibility conditions (BDCP Appendix 5.J, Attachment 5J.C*, Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*).

Transmission line poles and towers also provide perching substrate for raptors,

which are predators on western yellow-billed cuckoo. Although there is potential for transmission lines to result in increased perching opportunities for raptors, the existing network of transmission lines in the study area currently poses these risks and any incremental risk associated with the new power line corridors would not be expected to affect the population. Because there is low probability for the species to occur in the study area, any increased risk of predation risk on western yellow-billed cuckoo from an increase in raptor perching opportunities would be minimal.

NEPA Effects: The risk of bird-strike is considered to be minimal based on the species' rarity in the study area, its proclivity to remain in the riparian canopy, its presence in the study area during periods of relative high visibility, and its overall ability to successfully negotiate around overhead wires that it may encounter. Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure on western yellow-billed cuckoo. However, because there is a low probability for the species to occur in the study area, any increased risk in predation on western yellow-billed cuckoo from an increase in raptor perching opportunities would be minimal. Therefore the construction and operation of new transmission lines under Alternative 9 would not result in an adverse effect on western yellow-billed cuckoo.

CEQA Conclusion: The construction and presence of new transmission lines would have a less-than-significant impact on western yellow-billed cuckoo because the risk of bird-strike is considered to be minimal based on the species' rarity in the study area, its proclivity to remain in the riparian canopy, its presence during periods of relative high visibility, and its overall ability to successfully negotiate around overhead wires that it may encounter. Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure on western yellow-billed cuckoo. Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure on western yellow-billed cuckoo. However, because there is a low probability for the species to occur in the study area, any increased risk in predation on western yellow-billed cuckoo from an increase in raptor perching opportunities would be minimal. Therefore, the construction and operation of new transmission lines under Alternative 9 would result in a less-than-significant impact on western yellow-billed cuckoo.

Impact BIO-98: Indirect Effects of Plan Implementation on Western Yellow-Billed Cuckoo

Indirect Construction- and Operation-Related Effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect western yellow-billed cuckoo use of modeled habitat adjacent to proposed construction areas. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect western yellow-billed cuckoo. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet from the construction edge. If western yellow-billed cuckoo were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. These potential effects would be minimized with incorporation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* into the BDCP. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect western yellow-billed cuckoo in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to western yellow-billed cuckoo habitat could also affect the species. AMM1–AMM7, including *AMM2 Construction BMPs and Monitoring*, in addition to *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would minimize the likelihood of such spills and ensure that measures were in place to prevent runoff from the construction area and any adverse effects of dust on active nests.

Methylmercury Exposure: Western yellow-billed cuckoo modeled habitat includes primarily middle marsh habitat with select emergent wetland plant alliances in Suisun Marsh. High marsh is also used if it is of high value, and low marsh provides foraging habitat for the species. Cuckoos are a top predator in the benthic food chain; they forage by probing their beaks into the mud (Zembal and Fancher 1988) and prey primarily on mussels, spiders, seeds and hulls of cordgrass, and insects (Eddleman and Conway 1998).

Largemouth bass was used as a surrogate species for analysis (see Appendix 11F, *Substantive BDCP Revisions*). Results of the quantitative modeling of mercury effects on largemouth bass as a surrogate species would overestimate the effects on western yellow-billed cuckoo. Organisms feeding within pelagic-based (algal) foodwebs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic foodwebs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009).

Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, Alternative 9 restoration activities that create newly inundated areas could increase bioavailability of mercury. Concentrations of methylmercury known to be toxic to bird embryos have been found in the eggs of San Francisco Bay clapper rails (Schwarzbach and Adelsbach 2003); however, currently, it is unknown how much of the sediment-derived methylmercury enters the food chain in Suisun Marsh or what tissue concentrations are actually harmful to the western yellow-billed cuckoo. In general, the highest methylation rates are associated with high tidal marshes that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). In Suisun Marsh, the conversion of managed wetlands to tidal wetlands is expected to result in an overall reduction in mercury methylation. Due to the complex and very site-specific factors that determine if mercury becomes mobilized into the foodweb, *CM12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. CM12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This conservation measure would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability.
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009), and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including western yellow-billed cuckoo. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and, therefore, increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 9 restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations are analyzed in Chapter 8, *Water Quality*, which concludes that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on western yellow-billed cuckoo.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on western yellow-billed cuckoo from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Indirect effects on western yellow-billed cuckoo as a result of Alternative 9 implementation could have adverse effects on the species through the modification of habitat and potential for direct mortality. Restoration actions that would create tidal marsh could provide biogeochemical conditions for methylation of mercury in the newly inundated soils. There is potential for increased exposure of the western yellow-billed cuckoo foodweb to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the conversion of managed wetlands to tidal wetlands in Suisun Marsh would be expected to reduce the overall production of methylmercury, resulting in a net benefit to species. Implementation of CM12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

Tidal habitat restoration could result in increased exposure of western yellow-billed cuckoo to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Because of the species' minimal presence in the study area, and with the incorporation of AMM1–AMM7, *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, and *AMM27 Selenium Management* into the BDCP, indirect effects would not have an adverse effect on western yellow-billed cuckoo.***CEQA Conclusion***: Indirect effects on western yellow-billed cuckoo as a result of Alternative 9 implementation could have a significant impact on the species from modification of habitat. Restoration actions that would create tidal marsh could provide biogeochemical conditions for methylation of mercury in the newly inundated soils. There is potential for increased exposure of the western yellow-billed cuckoo foodweb to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the conversion of managed wetlands to tidal wetlands in Suisun Marsh would be expected to reduce the overall production of methylmercury, resulting in a net benefit to species. Implementation of CM12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

Tidal habitat restoration could result in increased exposure of western yellow-billed cuckoo to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

With the incorporation of AMM1–AMM7, *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, and *AMM27 Selenium Management* into the BDCP, indirect effects as a result of Alternative 9 implementation would have a less-than-significant impact on western yellow-billed cuckoo.

Impact BIO-99: Periodic Effects of Inundation of Western Yellow-Billed Cuckoo Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (CM2) would increase the frequency and duration of inundation of approximately 11–20 acres of modeled western yellow-billed cuckoo breeding habitat and 37–64 acres of modeled migratory habitat. No adverse effects of increased inundation frequency on western yellow-billed cuckoo or its habitat are expected because the cuckoo breeding period is outside the period the weir would be operated. In addition, riparian vegetation supporting habitat has persisted under the existing Yolo Bypass flooding regime, and changes to frequency and inundation would be within the tolerance of these vegetation types.

Based on hypothetical floodplain restoration, CM5 implementation could result in periodic inundation of up to 142 acres of modeled western yellow-billed cuckoo habitat (17 acres of breeding habitat, 125 acres of migratory habitat). Inundation of restored floodplains is not expected to affect western yellow-billed cuckoo or its habitat adversely because the cuckoo breeding period is outside the period the floodplains would likely be inundated, and periodic inundation of floodplains is expected to restore a more natural flood regime in support of riparian vegetation types that provide nesting and migratory habitat for western yellow-billed cuckoo. The overall effect of seasonal inundation in existing riparian natural communities is likely to be beneficial for western yellow-billed cuckoo, because, historically, flooding was the main natural disturbance regulating ecological processes in riparian areas, and flooding promotes the germination and establishment of many native riparian plants.

NEPA Effects: Periodic effects of inundation would not have an adverse on yellow-billed cuckoo if they were to establish as breeders in the study area, because flooding is expected to occur outside of the breeding season.

CEQA Conclusion: Periodic effects of inundation would have a less-than-significant impact on yellow-billed cuckoos if they were to establish as breeders in the study area, because flooding is expected to occur outside of the breeding season.

White-Tailed Kite

The habitat model used to assess impacts on white-tailed kite includes breeding habitat and foraging habitat. Most white-tailed kites in the Sacramento Valley are found in oak and cottonwood riparian forests, valley oak woodlands, or other groups of trees and are usually associated with compatible foraging habitat for the species in patches greater than 1,500 square meters (Erichsen et al. 1996). Modeled foraging habitat for white-tailed kite consists of pasture and hay crops, compatible row and grain crops and natural vegetation such as seasonal wetlands and annual grasslands (Erichsen et al. 1995).

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of white-tailed kite modeled habitat as indicated in Table 12-9-41. The majority of the losses would take place over an extended period of time as tidal marsh is restored in the study area. Although restoration for the loss of nesting and foraging habitat would be initiated in the same timeframe as the losses, it could take one or more decades (for nesting habitat) for restored habitats to replace the functions of habitat lost. This time lag between impacts and restoration of habitat function would be minimized by specific requirements of *AMM39 White-Tailed Kite*, including the planting of mature trees in the near-term time period. Full implementation of Alternative 9 would also include the following biological objectives over the term of the BDCP to benefit the white-tailed kite (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 5,000 acres of valley/foothill riparian natural community, with at least 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM7).
- Protect at least 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).
- Protect at least 8,000 acres of grassland with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).
- Protect and enhance at least 8,100 acres of managed wetland, at least 1,500 acres of which are in the Grizzly Island Marsh Complex (Objective MWNC1.1, associated with CM3).
- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4, VPNC2.5, and GNC2.4, associated with CM11).
- Protect at least 48,625 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species (Objective CLNC1.1, associated with CM3).
- Plant and maintain native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SH2.1, associated with CM11).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands within the reserve system including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).
- Establish 20- to 30- foot-wide hedgerows along fields and roadsides to promote prey populations throughout protected cultivated lands (Objective SH2.2, associated with CM3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species and implementation of AMM1–AMM7 and *AMM39 White-Tailed Kite,* impacts on white-tailed kite would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-41. Changes in White-Tailed Kite Modeled Habitat Associated with Alternative 9 (acres)[a]

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-100: Loss or Conversion of Habitat for and Direct Mortality of White-Tailed Kite

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 57,835 acres of modeled habitat for white-tailed kite (760 acres of nesting habitat, 57,075 acres foraging habitat; Table 12-9-41). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), riparian habitat restoration, (CM7), grassland restoration (CM8), vernal pool and wetland restoration (CM9), nontidal marsh restoration (CM10), and construction of conservation hatcheries (CM18). Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could affect white-tailed kite modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 water conveyance facilities would result in the combined permanent and temporary loss of up to 132 acres of white-tailed kite nesting habitat (43 acres of permanent loss and 89 acres of temporary loss). In addition, 2,916 acres of foraging habitat would be removed (374 acres of permanent loss, 2,542 acres of temporary loss, Table 12-9-41). Activities that would impact modeled White-tailed kite habitat include channel dredging, intakes, fish barriers, access roads, and construction of transmission lines. Permanent losses of nesting habitat would primarily consist of channel enlargement at the Sacramento River and Meadows Slough. Temporary losses would occur primarily along Middle River between Victoria Canal and Mildred Island, where large dredging work areas and operable barrier work areas would be placed. The riparian habitat in these areas is composed of very small patches or stringers bordering waterways, which include valley oak and scrub vegetation. Permanent impacts on foraging habitat would occur from the construction of the canals in CZ 8 east and south of Clifton Court Forebay and other conveyance structures in CZs 4, 5, 6, 7, and 8. Temporary impacts would primarily occur from borrow and spoil areas and temporary work areas. The CM1 footprint does not overlap with any occurrences of white-tailed kite. However, the implementation of *AMM39 White-Tailed Kite* would minimize effects on white-tailed kites if they were to nest within or adjacent to the construction footprint. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations.

- *CM2 Yolo Bypass Fisheries Enhancement:* Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 170 acres of nesting habitat (82 acres of permanent loss, 88 acres of temporary loss) in the Yolo Bypass in CZ 2. In addition, 1,525 acres of foraging habitat would be removed (1,008 acres of permanent loss, 516 acres of temporary loss). Activities through CM2 could involve excavation and grading in valley/foothill riparian areas to improve passage of fish through the bypasses. Most of the riparian losses would occur at the north end of Yolo Bypass where major fish passage improvements are planned. Excavation to improve water movement in the Toe Drain and in the Sacramento Weir would also remove white-tailed kite habitat. The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 383 acres of white-tailed kite nesting habitat and 41,625 acres of foraging habitat. The majority of the acres lost would consist of cultivated lands in CZs 1, 2, 4, 5, 6, and/or 7. Grassland losses would likely occur in the vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the upslope fringes of Suisun Marsh, and along narrow bands adjacent to waterways in the South Delta ROA. Tidal restoration would directly impact and fragment grassland just north of Rio Vista in and around French and Prospect Islands, and in an area south of Rio Vista around Threemile Slough. Losses of alkali seasonal wetland complex habitat would likely occur in the south end of the Yolo Bypass and on the northern fringes of Suisun Marsh. The conversion of cultivated lands to tidal wetlands over fairly broad areas within the tidal restoration footprints could result in the removal or abandonment of nesting territories that occur within or adjacent to the restoration areas. Trees would not be actively removed but tree mortality would be expected over time as areas became tidally inundated. Depending on the extent and value of remaining habitat, this could reduce the local nesting population.

- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain and riparian restoration actions would remove approximately 75 acres of white-tailed kite nesting habitat (42 acres of permanent loss, 33 acres of temporary loss) and 2,675 acres of foraging habitat (1,706 acres of permanent loss, 968 acres of temporary loss). These losses would be expected after the first 10 years of Alternative 9 implementation along the San Joaquin River and other major waterways in CZ 7.

- *CM7 Riparian Natural Community Restoration:* Riparian restoration would permanently remove approximately 971 acres of white-tailed kite foraging habitat as part of tidal restoration and 3,991 acres as part of seasonal floodplain restoration through CM7.
- *CM8 Grassland Natural Community Restoration*: Restoration of grassland is expected to be implemented on agricultural lands and would result in the conversion of 1,849 acres of white-tailed kite agricultural foraging habitat to grassland foraging habitat in CZs 1, 2, 4, 5, 7, 8, and 11. If agricultural lands supporting higher value foraging habitat than the restored grassland were removed, there would be a loss of white-tailed kite foraging habitat value.
- *CM10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh (CM10) would result in the permanent conversion of 1,440 acres of cultivated lands to nontidal marsh in CZ 2 and CZ 4. This would not result in a loss of foraging habitat as both natural communities are foraging habitat for white-tailed kite. Small patches of riparian vegetation that support White-tailed kite nesting habitat may develop along the margins of restored nontidal marsh restoration would also provide foraging habitat for the species.
- *CM11 Natural Communities Enhancement and Management*: Habitat management- and enhancement-related activities could disturb white-tailed kite nests if they were present near work sites. A variety of habitat management actions that are designed to enhance wildlife values in BDCP-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of white-tailed kite habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available white-tailed kite habitat and are expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below. CM11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. However, approximately 50 acres of white-tailed kite grassland foraging habitat would be lost from the construction of trails and facilities.
- *CM18 Conservation Hatcheries*: Implementation of CM18 would remove up to 35 acres of high-white-tailed kite foraging habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1. The loss is expected to occur during the first 10 years of Plan implementation.

  Permanent and temporary white-tailed kite nesting habitat losses from the above conservation measures, would primarily consist of small, fragmented riparian stands. Temporarily affected nesting habitat would be restored as riparian habitat within 1 year following completion of construction activities. The restored riparian habitat would require 1 to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by white-tailed kite. *AMM39 White-Tailed Kite* contains actions described below to reduce the effect of temporal loss of nesting habitat, including the transplanting of mature trees and planting of trees near high-value foraging habitat. The functions of agricultural and grassland communities that provide foraging habitat for white-tailed kite are expected to be restored relatively quickly.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect white-tailed kite use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7 and *AMM39 White-Tailed Kite* in addition to conservation actions as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged white-tailed kite if they were present in the study area, because they would be expected to avoid contact with construction and other equipment. However, if white-tailed kite were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could affect nests or lead to their abandonment, potentially resulting in mortality of eggs and nestlings. These effects would be avoided and minimized with the incorporation of *AMM39 White-Tailed Kite* into the BDCP.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effect of construction would not be adverse under NEPA. Alternative 9 would remove 532 acres (355 acres of permanent loss, 177 acres of temporary loss) of white-tailed kite nesting habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 132 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—400 acres). In addition, 12,155 acres of white-tailed kite foraging habitat would be removed or converted in the near-term (CM1, 2,916 acres; *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—9,239 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 and that are identified in the biological goals and objectives for white-tailed kite in Chapter 3 of the BDCP would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for nesting habitat, and 1:1 protection for foraging habitat. Using these ratios would indicate that 132 acres of nesting habitat should be restored/created and 132 acres should be protected to mitigate the CM1 losses of white-tailed kite nesting habitat. In addition, 2,916 acres should be protected to compensate for the CM1 losses of white-tailed kite foraging habitat. The near-term effects of other conservation actions would remove 400 acres of modeled nesting habitat, and therefore require 400 acres of restoration and 400 acres of protection of nesting habitat. Similarly, the near-term effects of other conservation actions would result in the loss or conversion of 9,239 acres of modeled foraging habitat, and therefore require 9,239 acres of protection of foraging habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection of nesting habitat; 1:1 for restoration and 1:1 for protection of foraging habitat).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of valley/foothill riparian natural community, protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, protecting 4,800 acres of managed wetland natural community, protecting 15,400 acres of non-rice cultivated lands, protecting 900 acres of rice or rice equivalent habitat, and restoring 19,150 acres of tidal wetlands (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM4, CM7, and CM8 and would occur in the same timeframe as the construction and early restoration losses.

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2, BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for the species. White-tailed kite is excluded from narrow bands of riparian vegetation by Swainson's hawks and therefore requires wide patches of nesting habitat where its range overlaps with Swainson's hawk. The distribution and abundance of potential white-tailed kite nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1). In addition, small but essential nesting habitat associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide foraging habitat for white-tailed kite and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) that dry during the spring would also serve as foraging habitat for white-tailed kite as prey species recolonize the fields (Objective MWNC1.1). In addition, the restoration of 19,150 acres of tidal natural communities, including transitional uplands would provide high-value foraging habitat for the white-tailed kite. At least 15,400 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1). These biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on white-tailed kite foraging habitat, as well as mitigate the near-term effects of the other conservation measures.

The 750 acres of protection and 800 acres of restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and

other near-term impacts on white-tailed kite nesting habitat. The 800 acres of restored riparian habitat would be initiated in the near-term to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by white-tailed kites. This time lag between the removal and restoration of nesting habitat could have a substantial impact on white-tailed kite in the near-term time period. Nesting habitat is limited throughout much of the study area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active white-tailed kite nests within the study area until restored riparian habitat is sufficiently developed.

AMM39 White-Tailed Kite would implement a program to plant large mature trees, including transplanting trees scheduled for removal, to compensate for the temporal loss of Swainson's hawk nest sites, defined as a 125-acre area where more than 50% of suitable nest trees (20 feet or taller) within the 125-acre block are removed. These mature trees would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the BDCP reserve system for every tree 20 feet or taller removed by construction during the near-term period. A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Trees would be planted within the BDCP reserve system in areas that support high value foraging habitat to increase nest sites, or within riparian plantings as a component of the riparian restoration (CM5, CM7) where they are in close proximity to suitable foraging habitat. Replacement trees that were incorporated into the riparian restoration would not be clustered in a single region of the study area, but would be distributed throughout the lands protected as foraging habitat for white-tailed kite. With this program in place, Alternative 9 would not have a substantial adverse effect on white-tailed kite in the near-term timeframe, either through direct mortality or through habitat modifications. Further details of AMM39 are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The study area supports approximately 14,069 acres of modeled nesting habitat and 507,922 acres of modeled foraging habitat for white-tailed kite. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 760 acres of potential nesting habitat (5% of the potential nesting habitat in the study area) and the loss or conversion of 57,075 acres of foraging habitat (11% of the foraging habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration, and CM8 Grassland Natural Community Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community, protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, protect 8,100 acres of managed wetland, protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species, and restore at least 65,000 acres of tidal wetlands (Table 3-4 in Chapter 3, *Description of Alternatives*).

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for the species. White-tailed kite is excluded from narrow bands of riparian vegetation by Swainson's hawks and therefore requires wide patches of nesting habitat where its range overlaps with Swainson's hawk. The distribution and abundance of potential white-tailed kite nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1). In addition, small but essential nesting habitat associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide foraging habitat for white-tailed kite and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) that dry during the spring would also serve as foraging habitat for white-tailed kite as prey species recolonize the fields (Objective MWNC1.1). In addition, the restoration of at least 65,000 acres of tidal natural communities, including transitional uplands would provide high-value foraging habitat for the white-tailed kite. At least 45,405 acres of cultivated lands that provide foraging habitat for white-tailed kite would be protected by the late long-term time period (Objective CLNC1.1).

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 3,800 acres and the protection of 570 acres of nesting habitat and the restoration of 49,875 acres and the protection of 2,050 acres of foraging habitat for white-tailed kite.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

NEPA Effects: The loss of white-tailed kite habitat and potential direct mortality of this special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection and restoration associated with CM3, CM5, CM7, CM8, CM9, and CM11, guided by biological goals and objectives and by AMM1–AMM7 and *AMM39 White-Tailed Kite*, which would be in place throughout the construction period, the effects of habitat loss and potential mortality on white-tailed kite under Alternative 9 would not be adverse.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effect of construction would be less than significant under CEQA. Alternative 9 would remove 532 acres (355 acres of permanent loss, 177 acres of temporary loss) of white-tailed kite nesting habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 132 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—400 acres). In addition, 12,155 acres of white-tailed kite foraging habitat would be removed or converted in the near-term (CM1, 2,916 acres; *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management*, and *CM18 Conservation Hatcheries*—9,239 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 and that are identified in the biological goals and objectives for white-tailed kite in Chapter 3 of the BDCP would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for nesting habitat, and 1:1 protection for foraging habitat. Using these ratios would indicate that 132 acres of nesting habitat should be restored/created and 132 acres should be protected to mitigate the CM1 losses of white-tailed kite nesting habitat. In addition, 2,916 acres should be protected to compensate for the CM1 losses of white-tailed kite foraging habitat. The near-term effects of other conservation actions would remove 400 acres of modeled nesting habitat, and therefore require 400 acres of restoration and 400 acres of protection of nesting habitat. Similarly, the near-term effects of other conservation actions would result in the loss or conversion of 9,239 acres of modeled foraging habitat, and therefore require 9,239 acres of protection of foraging habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection of nesting habitat; 1:1 for restoration and 1:1 for protection of foraging habitat).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of valley/foothill riparian natural community, protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, protecting 4,800 acres of managed wetland natural community, protecting 15,400 acres of non-rice cultivated lands, protecting 900 acres of rice or rice equivalent habitat, and restoring 19,150 acres of tidal wetlands (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM4, CM7, and CM8 and would occur in the same timeframe as the construction and early restoration losses.

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for the species. White-tailed kite is excluded from narrow bands of riparian vegetation by Swainson's hawks and therefore requires wide patches of nesting habitat where its range overlaps with Swainson's hawk. The distribution and abundance of potential white-tailed kite nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1). In addition, small but essential nesting habitat associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide foraging habitat for white-tailed kite and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) that dry during the spring would also serve as foraging habitat for white-tailed kite as prey species recolonize the fields (Objective MWNC1.1). In addition, the restoration of 19,150 acres of tidal natural communities, including transitional uplands would provide high-value foraging habitat for the white-tailed kite. At least 15,400 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1). These biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on white-tailed kite foraging habitat, as well as mitigate the near-term effects of the other conservation measures.

The 750 acres of protection and 800 acres of restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and

other near-term impacts on white-tailed kite nesting habitat. The 800 acres of restored riparian habitat would be initiated in the near-term to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by white-tailed kites. This time lag between the removal and restoration of nesting habitat could have a substantial impact on white-tailed kite in the near-term time period. Nesting habitat is limited throughout much of the study area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active white-tailed kite nests within the study area until restored riparian habitat is sufficiently developed.

AMM39 White-Tailed Kite would implement a program to plant large mature trees, including transplanting trees scheduled for removal, to compensate for the temporal loss of Swainson's hawk nest sites, defined as a 125-acre area where more than 50% of suitable nest trees (20 feet or taller) within the 125-acre block are removed. These mature trees would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the BDCP reserve system for every tree 20 feet or taller removed by construction during the near-term period. A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Trees would be planted within the BDCP reserve system in areas that support high-value foraging habitat to increase nest sites, or within riparian plantings as a component of the riparian restoration (CM5, CM7) where they are in close proximity to suitable foraging habitat. Replacement trees that were incorporated into the riparian restoration would not be clustered in a single region of the study area, but would be distributed throughout the lands protected as foraging habitat for white-tailed kite. With this program in place, Alternative 9 would not have a substantial adverse effect on white-tailed kite in the near-term timeframe, either through direct mortality or through habitat modifications. Further details of AMM39 are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The study area supports approximately 14,069 acres of modeled nesting habitat and 507,922 acres of modeled foraging habitat for white-tailed kite. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 760 acres of potential nesting habitat (5% of the potential nesting habitat in the study area) and the loss or conversion of 57,075 acres of foraging habitat (11% of the foraging habitat in the study area).

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration, CM5 Seasonally Inundated Floodplain*

Restoration, CM7 Riparian Natural Community Restoration, and *CM8 Grassland Natural Community Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community, protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, protect 8,100 acres of managed wetland, protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species, and restore at least 65,000 acres of tidal wetlands (Table 3-4 in Chapter 3, *Description of Alternatives*).

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for the species. White-tailed kite is excluded from narrow bands of riparian vegetation by Swainson's hawks and therefore requires wide patches of nesting habitat where its range overlaps with Swainson's hawk. The distribution and abundance of potential white-tailed kite nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1). In addition, small but essential nesting habitat associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide foraging habitat for white-tailed kite and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) that dry during the spring would also serve as foraging habitat for white-tailed kite as prey species recolonize the fields (Objective MWNC1.1). In addition, the restoration of at least 65,000 acres of tidal natural communities, including transitional uplands would provide high-value foraging habitat for the white-tailed kite. At least 45,405 acres of cultivated lands that provide foraging habitat for white-tailed kite would be protected by the late long-term time period (Objective CLNC1.1).

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 3,800 acres and the protection of 570 acres of nesting habitat and the restoration of 49,875 acres and the protection of 2,050 acres of foraging habitat for white-tailed kite.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and*

Countermeasure Plan, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

In the absence of other conservation actions, the effects on white-tailed kite habitat from Alterative 9 would represent an adverse effect as a result of habitat modification and potential for direct mortality of a special status species; however, considering Alternative 9's protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for the time lag of restoring riparian and foraging habitats lost to construction and restoration activities, and with implementation of AMM1–AMM7 and *AMM39 White-Tailed Kite*, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. In particular, 95% of the loss of foraging habitat effects involve the conversion from one habitat type to another form of suitable foraging habitat. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on white-tailed kite.

Impact BIO-101: Effects on White-Tailed Kite Associated with Electrical Transmission Facilities

There are several known occurrences of nesting white-tailed kite within 5 miles of the proposed transmission line alignment. While white-tailed kite flight behavior puts them regularly within the range of heights proposed for the new transmission lines (50 to 110 feet), their keen vision and high maneuverability substantially reduce powerline collision risk for the species. Like other diurnal raptors, white-tailed kites have highly developed eyesight (Jones et al. 2007), allowing them to detect small prey while hunting from relatively high altitudes. Keen eyesight also allows for detection and avoidance of other aerial objects, including above-ground utility lines. Like many other falcons, the white-tailed kite has long, narrow, tapered wings and body size that allow for efficient soaring flight and highly developed aerial maneuverability. White-tailed kite are at low risk of bird strike mortality from the construction of new transmission lines based on its general maneuverability, its keen eyesight, and lack of flocking behavior (BDCP Appendix 5.J, Attachment 5.J-2, *Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. With the implementation of *AMM20 Greater Sandhill Crane*, all new transmission lines would be fitted with flight diverters, which would substantially reduce any risk of collision with lines.

NEPA Effects: The construction and presence of new transmission lines would not represent an adverse effect because the risk of bird strike is considered to be minimal based on the species' general maneuverability, keen eyesight, and lack of flocking behavior. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would eliminate or nearly eliminate the risk of mortality from bird strike for white-tailed kite as a result of the project. Therefore, the construction and operation of new transmission lines under Alternative 9 would not result in an adverse effect on white-tailed kite.

CEQA Conclusion: The construction and presence of new transmission lines would not represent a significant impact because the risk of bird strike is considered to be minimal based on the species' general maneuverability, keen eyesight, and lack of flocking behavior. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would eliminate or nearly eliminate the risk of mortality from bird strike for white-tailed kite as a result of the project. Therefore, the construction and operation of new transmission lines under Alternative 9 would result in a less-than-significant impact on white-tailed kite.

Impact BIO-102: Indirect Effects of Plan Implementation on White-Tailed Kite

White-tailed kite nesting habitat within the vicinity of proposed construction areas could be indirectly affected by construction activities. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect white-tailed kite. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet from the construction edge. If white-tailed kite were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. *AMM39 White-Tailed Kite* would require preconstruction surveys, and if detected, 200-yard no-disturbance buffers would be established around active nests. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect white-tailed kite in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to white-tailed kite habitat could also affect the species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including white-tailed kite. Marsh (tidal and nontidal) and floodplain restoration also have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Increased methylmercury associated with natural community and floodplain restoration may indirectly affect white-tailed kite (see BDCP Appendix 5.D, *Contaminants*). However, the potential mobilization or creation of methylmercury within the study area varies with site-specific conditions and would need to be assessed at the project level. *CM12 Methylmercury Management* includes provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on white-tailed kite.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults,

and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including white-tailed kite. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on white-tailed kite.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on white-tailed kite from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Noise and visual disturbances from the construction of water conveyance facilities could reduce white-tailed kite use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect white-tailed kite use of the surrounding habitat. Noise, potential spills of hazardous materials, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 9 would not have an adverse effect on white-tailed kite with the implementation of AMM1–AMM7 and *AMM39 White-Tailed Kite.* Tidal habitat restoration could result in increased exposure of white-tailed kite to selenium. This effect would be addressed through the implementation of *AMM26, Selenium Management* which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The indirect effects associated with noise and visual disturbances, potential spills of hazardous material, and increased exposure to selenium from Alternative 9 implementation would not have an adverse effect on white-tailed kite. Tidal habitat restoration is unlikely to have an adverse effect on white-tailed kite through increased exposure to methylmercury, as kites currently forage in tidal marshes where elevated methylmercury levels exist. However, it is unknown what concentrations of methylmercury are harmful to the species and the potential for increased exposure varies substantially within the study area. Site-specific restoration plans in addition to monitoring and adaptive management, described in CM12 *Methylmercury Management,* would address the uncertainty of methylmercury levels in restored tidal marsh. The site-specific planning phase of marsh restoration would be the appropriate place to assess the potential for risk of methylmercury exposure for white-tailed kite, once site specific sampling and other information could be developed.

***CEQA Conclusion*:** Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 9 would have a less-than-significant impact on white-tailed kite with the implementation of *AMM39 White-Tailed Kite*, and AMM1–AMM7. Tidal habitat restoration could result in increased exposure of white-tailed kite to selenium. This effect would be addressed through the implementation of *AMM26, Selenium Management* which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of white-tailed kite to methylmercury. However, it is unknown what concentrations of methylmercury are harmful to this species. *CM12 Methylmercury Management* includes provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12, would better inform potential impacts and address the uncertainty of methylmercury levels in restored tidal marsh in the study area on white-tailed kite. With these measures in place, the indirect effects associated with noise and visual disturbances, potential spills of hazardous material, and increased exposure to selenium from Alternative 9 implementation would have a less-than-significant impact on white-tailed kite.

Impact BIO-103: Periodic Effects of Inundation of White-Tailed Kite Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (related to *CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on approximately 48–82 acres of modeled white-tailed kite nesting habitat and 3,030–6,651 acres of modeled white-tailed kite foraging habitat (Table 12-9-41). During inundation years, affected cultivated lands and grassland would not be available as foraging habitat until prey populations have re-inhabited inundated areas. This would result in temporary periodic reduction in availability of foraging habitat. If late-season Fremont Weir operations were to preclude the planting of some crop types, there could be a further loss of foraging habitat value if the crop type that would have been planted would provide greater foraging habitat value than the fallowed fields. No known white-tailed kite nest sites would be affected, and increased periodic flooding is not expected to cause any adverse effect on nest sites that may be within the inundation area because existing trees already withstand floods in the area, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and any nest sites would be located above floodwaters.

Based on hypothetical floodplain restoration, CM5 implementation could result in periodic inundation of up to approximately 230 acres of modeled white-tailed kite nesting habitat and 7,402 acres of modeled white-tailed kite foraging habitat (Table 12-9-41). Inundation of foraging habitat could result in a periodic reduction of available foraging habitat due to the reduction in available prey. Following draw-down, inundated habitats are expected to recover and provide suitable foraging conditions until the following inundation period. Thus, this is considered a periodic impact that is unlikely to affect white-tailed kite distribution and abundance, or foraging use of the study area.

Periodic inundation of floodplains (through CM2 and CM5) would be expected to restore a more natural flood regime in support of riparian vegetation types that support white-tailed kite nesting habitat. No adverse effects of inundation on white-tailed kite riparian habitat are expected because valley/foothill riparian vegetation is expected to benefit from seasonal inundation.

***NEPA Effects*:** Although foraging habitat would be periodically unavailable to white-tailed kite because of CM2 and CM5 implementation, inundated habitats are expected to recover following draw-down. Any effects are considered short-term and would not result in an adverse effect.

***CEQA Conclusion*:** Although foraging habitat would be periodically unavailable to white-tailed kite because of CM2 and CM5 implementation, inundated habitats are expected to recover following draw-down. Any effects are considered short-term and would be expected to have a less-than-significant impact on white-tailed kite.

Yellow-Breasted Chat

Yellow-breasted chat modeled habitat includes suitable nesting and migratory habitat as those plant alliances from the valley/foothill riparian modeled habitat that contain a shrub component and an overstory component. Primary nesting and migratory habitat is qualitatively distinguished from secondary habitat in Delta areas as those plant associations that support a greater percentage of a suitable shrub cover, particularly blackberry, and California wild rose, and have an open to moderately dense overstory canopy, using data from Hickson and Keeler-Wolf (2007). No distinction is made between primary and secondary habitat for Suisun Marsh/Yolo Basin habitats because supporting information is lacking. For this reason, the effects analysis only provides the breakdown between primary and secondary habitat in the habitat loss totals and associated tables, and does not provide this breakdown in the text by activity or effect type.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of yellow-breasted chat modeled habitat as indicated in Table 12-9-42. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit the yellow-breasted chat (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 5,000 acres of valley/foothill riparian natural community, with at least 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM7).

- Protect at least 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).
- Restore, maintain and enhance structural heterogeneity with adequate vertical and horizontal overlap among vegetation components and over adjacent riverine channels, freshwater emergent wetlands, and grasslands (Objective VFRNC2.1, associated with CM7).
- Maintain at least 1,000 acres of early- to mid-successional vegetation with a well-developed understory of dense shrubs on restored seasonally inundated floodplain (Objective VFRNC2.2, associated with CM7).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species and implementation of AMM1–AMM7 and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, impacts on yellow-breasted chat would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-42. Changes in Yellow-Breasted Chat Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Nesting and Migratory Habitat Type	Permanent		Temporary		Periodic[d]

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-104: Loss or Conversion of Habitat for and Direct Mortality of Yellow-Breasted Chat

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 1,047 acres of modeled habitat for yellow-breasted chat (Table 12-9-42). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), and floodplain restoration (CM5). Habitat enhancement and management activities (CM11) which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate yellow-breasted chat habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 283 acres of modeled yellow-breasted chat habitat (94 acres of primary nesting habitat, 189 acres of secondary habitat) from CZs 4, 5, 6, 7, and 8 (Table 12-9-42). Most of the permanent loss would occur as wider and deeper channels are dredged in Middle River and Victoria Canal, and as operable barriers and new Sacramento River diversions are constructed in various waterways across the Delta. Temporary losses of habitat would occur primarily along Middle River between Victoria Canal and Mildred Island, where large dredging work areas and operable barrier work areas would be placed. Some of this vegetation may be temporarily removed as dredging progresses, while other areas could remain in place but be temporarily affected by sedimentation and equipment movement associated with dredging. The CM1 construction footprint overlaps with 6 occurrences of yellow-breasted chat. Six occurrences detected on inchannel islands (south of Mildred Island) intersect with temporary dredging work areas, and 3 intersect with a temporary operable barrier work area on north Mandeville Island. Preconstruction surveys under *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would minimize potential effects on nesting yellow-breasted chat in the study area. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo bypass fisheries enhancement would permanently remove approximately 83 acres and temporarily remove 88 acres of yellow-breasted chat habitat in the Yolo Bypass in CZ 2. The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 545 acres of modeled yellow-breasted chat habitat in CZ 1, 2, 6, and 11. This total is composed of an estimated 182 acres of primary nesting and migratory habitat, 349 acres of secondary nesting and migratory habitat, and 14 acres of nesting and migratory habitat in the Suisun Marsh and upper Yolo Bypass areas.

- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 49 acres of modeled yellow-breasted chat habitat in CZ 7. This total is comprised of 28 acres of primary nesting and migratory habitat and 21 acres of secondary nesting and migratory habitat. Based on the riparian habitat restoration assumptions, approximately 3,000 acres of valley/foothill riparian habitat would be restored as a component of seasonally inundated floodplain restoration actions. The actual number of acres that would be restored may differ from these estimates, depending on how closely the outcome of seasonally inundated floodplain restoration approximates the assumed outcome. Once this restored riparian vegetation has developed habitat functions, a portion of it would be suitable to support yellow-breasted chat habitat.

- *CM11 Natural Communities Enhancement and Management:* Habitat protection and management activities that could be implemented in protected yellow-breasted chat habitats would be expected to maintain and improve the functions of the habitat over the term of the BDCP. Yellow-breasted chat would be expected to benefit from the increase in protected habitat, which would maintain conditions favorable for the chat's use of the study area.

  Habitat management- and enhancement-related activities could disturb yellow-breasted chat nests if they are present near work sites. Equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would ensure that these activities do not result in direct mortality of yellow-breasted chat or other adverse effects.

  Occupied habitat would be monitored to determine if there is a need to implement controls on brood parasites (brown-headed cowbird) or nest predators. If implemented, these actions would be expected to benefit the yellow-breasted chat by removing a potential stressor that could, if not addressed, adversely affect the stability of newly established populations.

  A variety of habitat management actions included in *CM11 Natural Communities Enhancement and Management* that are designed to enhance wildlife values in restored riparian habitats may result in localized ground disturbances that could temporarily remove small amounts of yellow-breasted chat habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, are expected to have minor adverse effects on available yellow-breasted chat habitat and are expected to result in overall improvements to and maintenance of yellow-breasted chat habitat values over the term of the BDCP.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect least Bell's vireo and yellow warbler use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and conservation actions as described below.

- Injury and Direct Mortality: Construction is not expected to result in direct mortality of yellow-breasted chat because adults and fledged young are expected to occur only in very small numbers and, if present, would avoid contact with construction and other equipment. If yellow-breasted chat were to nest in the vicinity of construction activities, equipment operation could destroy nests and noise and visual disturbances could lead to nest abandonment. *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would avoid and minimize this effect.

- Permanent and temporary habitat losses from the above CMs, would primarily consist of small, fragmented riparian stands in CZ 2–CZ 8 that do not provide high-value habitat for the species. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities. Although the effects are considered temporary, the restored riparian habitat would require 5 years to several decades, for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. The majority of the riparian vegetation to be temporarily removed is early- to mid-successional; therefore, the replaced riparian vegetation would be expected to have structural components comparable to the temporarily removed vegetation within the first 5 to 10 years after the initial restoration activities are complete.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 751 acres of modeled habitat for yellow-breasted chat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 283 acres of modeled nesting and migratory habitat), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—468 acres of modeled nesting and migratory habitat). These habitat losses would primarily consist of small, fragmented riparian stands in CZ 2-CZ 8 that do not provide high-value habitat for the species.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 and that are identified in the biological goals and objectives for yellow-breasted chat in Chapter 3 of the BDCP would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat. Using these ratios would indicate that 283 acres of valley/foothill riparian habitat should be restored/created and 283acres should be protected to compensate for the CM1 losses of yellow-breasted chat habitat. The near-term effects of other conservation actions would remove 468 acres of modeled habitat, and therefore require 468 acres of restoration and 468 acres of protection of valley/foothill riparian using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of the valley/foothill riparian natural community in the study area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3 and CM7 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on yellow-breasted chat. The majority of the riparian restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Goals and objectives in the Plan for riparian restoration also include the restoration, maintenance and enhancement of structural heterogeneity with adequate vertical and horizontal overlap among vegetation components and over adjacent riverine channels, freshwater emergent wetlands, and grasslands (Objective VFRNC2.1). The yellow-breasted chat has specific structural habitat requirements, so only the early- to mid-successional portions of the restored and protected riparian natural would be expected to provide suitable habitat characteristics for the species. These natural community biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of conservation actions for the species.

The acres of protection contained in the near-term Plan goals and the additional detail in the biological objectives for yellow-breasted chat satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1, as well as mitigate the near-term effects of the other conservation measures. The restored riparian habitat could require 5 years to several decades, for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. However, because the modeled habitat impacted largely consists of small patches of blackberry, willow, and riparian scrub, BDCP actions would not be expected to have an adverse population-level effect on the species in the near-term time period.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The habitat model indicates that the study area supports approximately 14,547 acres of modeled nesting and migratory habitat for yellow-breasted chat. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 1,047 acres of modeled habitat (7% of the modeled habitat in the study area). These losses would occur from the construction of the water conveyance facilities (CM1) and from *CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration*. The locations of these losses would be in fragmented riparian habitat throughout the study area.

The Plan includes conservation commitments through *CM7 Riparian Natural Community Restoration* and *CM3 Natural Communities Protection and Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian woodland. Of the 5,000 acres of restored riparian natural communities, a minimum of 3,000 acres of valley/foothill riparian would be restored within the seasonally inundated floodplain, and 1,000 acres would be managed as dense early to mid-successional riparian forest (Objectives VFRNC1.1 and VFRNC1.2). The yellow-breasted chat has specific structural habitat requirements, so only the early- to mid-successional portions of the restored and protected riparian natural would be expected to provide suitable habitat characteristics for the species. Fluvial disturbance in restored riparian floodplains would help to maintain early- to mid-successional vegetation. The resulting riparian systems would be subject to natural erosion and deposition, which would provide conditions conducive to the establishment of dense willow stands that are preferred by yellow-breasted chat for nesting. In addition, if monitoring determined that cowbird parasitism was having an effect on the yellow-breasted population in the study area, a cowbird control program would be implemented through *CM11 Natural Communities Enhancement and Management*. Goals and objectives in the Plan for riparian restoration also include the maintenance and enhancement of structural heterogeneity (Objective VFRNC2.1) which would provide suitable habitat for yellow-breasted chat.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 2,683 acres and the protection of 594 acres of habitat for the yellow-breasted chat.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

NEPA Effects: The loss of yellow-breasted chat habitat and potential direct mortality of this special-status species would represent an adverse effect in the absence of other conservation actions. The restored riparian habitat would require 5 years to several decades for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. However, the habitat that would be lost consists of small, fragmented riparian stands that do not provide high-value habitat for the species. And because the nesting and migratory habitat that would be lost is small relative to the species range throughout California and North America, BDCP actions would not be expected to have an adverse population-level effect on the species. With habitat protection and restoration associated with CM3, CM7, and CM11, guided by biological goals and objectives and by *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, which would be in place throughout the construction period, the effects of habitat loss and potential mortality on yellow-breasted chat under Alternative 9 would not be adverse.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the impact of construction would be less than significant under CEQA. Alternative 9 would remove 751 acres of modeled habitat for yellow-breasted chat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 283 acres of modeled nesting and migratory habitat), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—468 acres of modeled nesting and migratory habitat). These habitat losses would primarily consist of small, fragmented riparian stands in CZ 2-CZ 8 that do not provide high-value habitat for the species.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 and that are identified in the biological goals and objectives for yellow-breasted chat in Chapter

3 of the BDCP would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat. Using these ratios would indicate that 283 acres of valley/foothill riparian habitat should be restored/created and 283acres should be protected to compensate for the CM1 losses of yellow-breasted chat habitat. The near-term effects of other conservation actions would remove 468 acres of modeled habitat, and therefore require 468 acres of restoration and 468 acres of protection of valley/foothill riparian using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of the valley/foothill riparian natural community in the study area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3 and CM7 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on yellow-breasted chat. The majority of the riparian restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Goals and objectives in the Plan for riparian restoration also include the restoration, maintenance and enhancement of structural heterogeneity with adequate vertical and horizontal overlap among vegetation components and over adjacent riverine channels, freshwater emergent wetlands, and grasslands (Objective VFRNC2.1). The yellow-breasted chat has specific structural habitat requirements, so only the early- to mid-successional portions of the restored and protected riparian natural would be expected to provide suitable habitat characteristics for the species. These natural community biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of conservation actions for the species.

The acres of protection contained in the near-term Plan goals and the additional detail in the biological objectives for yellow-breasted chat satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1, as well as mitigate the near-term effects of the other conservation measures. The restored riparian habitat could require 5 years to several decades, for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. However, because the modeled habitat impacted largely consists of small patches of blackberry, willow, and riparian scrub, BDCP actions would not be expected to have a significant population-level impact on the species in the near-term time period.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

The habitat model indicates that the study area supports approximately 14,547 acres of modeled nesting and migratory habitat for yellow-breasted chat. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 1,047 acres of modeled habitat (7% of the modeled habitat in the study area). These losses would occur from the construction of the water conveyance facilities (CM1) and from *CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration*. The locations of these losses would be in fragmented riparian habitat throughout the study area.

The Plan includes conservation commitments through *CM7 Riparian Natural Community Restoration* and *CM3 Natural Communities Protection and Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian woodland. Of the 5,000 acres of restored riparian natural communities, a minimum of 3,000 acres of valley/foothill riparian would be restored within the seasonally inundated floodplain, and 1,000 acres would be managed as dense early to mid-successional riparian forest (Objectives VFRNC1.1 and VFRNC1.2). The yellow-breasted chat has specific structural habitat requirements, so only the early- to mid-successional portions of the restored and protected riparian natural would be expected to provide suitable habitat characteristics for the species. Fluvial disturbance in restored riparian floodplains would help to maintain early- to mid-successional vegetation. The resulting riparian systems would be subject to natural erosion and deposition, which would provide conditions conducive to the establishment of dense willow stands that are preferred by yellow-breasted chat for nesting. In addition, if monitoring determined that cowbird parasitism was having an effect on the yellow-breasted population in the study area, a cowbird control program would be implemented through *CM11 Natural Communities Enhancement and Management*. Goals and objectives in the Plan for riparian restoration also include the maintenance and enhancement of structural heterogeneity (Objective VFRNC2.1) which would provide suitable habitat for yellow-breasted chat.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 2,683 acres and the protection of 594 acres of habitat for the yellow-breasted chat.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

In the absence of other conservation actions, the effects on yellow-breasted chat habitat from Alternative 9 would represent an adverse effect as a result of habitat modification and potential for direct mortality of special-status species. Considering these protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with implementation of AMM1–AMM7 and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on yellow-breasted chat.

Impact BIO-105: Fragmentation of Yellow-Breasted Chat Habitat as a Result of Constructing the Water Conveyance Facilities

Grading, filling, contouring, and other initial ground-disturbing activities for water conveyance facilities construction may temporarily fragment modeled yellow-breasted chat habitat. This could temporarily reduce the extent of and functions supported by the affected habitat. Because of the current infrequent occurrence and small numbers of yellow-breasted chat in the Plan Area, and because *CM5 Seasonally Inundated Floodplain Restoration* would restore and protect contiguous high-value riparian habitat in CZ 7, any such habitat fragmentation is expected to have no or minimal effect on the species.

NEPA Effects: Temporary fragmentation of habitat would not result in an adverse effect on yellow-breasted chat. The habitat functions for the species would be significantly improved through the implementation of CM5, which would restore and protect large contiguous patches of riparian habitat.

CEQA Conclusion: Temporary fragmentation of habitat would have a less-than-significant impact on yellow-breasted chat. The habitat functions for the species would be significantly improved through the implementation of CM5, which would restore and protect large contiguous patches of riparian habitat.

Impact BIO-106: Effects on Yellow-Breasted Chat Associated with Electrical Transmission Facilities

Yellow-breasted chats are migratory and usually arrive at California breeding grounds in April from their wintering grounds in Mexico and Guatemala. Departure for wintering grounds occurs from August to September. These are periods of relative high visibility when the risk of powerline collisions will be low. The species' small, relatively maneuverable body; its foraging behavior; and its presence in the Plan Area during the summer contribute to a low risk of collision with the proposed transmission lines (BDCP Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new project transmission lines would be fitted with flight diverters. Bird flight diverters would further reduce any potential for powerline collisions.

NEPA Effects: The construction and presence of new transmission lines would not result in an adverse effect on yellow-breasted chat because the risk of bird strike is considered to be minimal based on the species' small, relatively maneuverable body; its foraging behavior; and its presence in the Plan Area during the summer during periods of high visibility. Under *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with bird diverters, which would further reduce any potential for powerline collisions.

CEQA Conclusion: The construction and presence of new transmission lines would have a less-than-significant impact on yellow-breasted chat because the risk of bird strike is considered to be minimal based on the species' small, relatively maneuverable body; its foraging behavior; and its presence in the Plan Area during the summer during periods of high visibility. Under *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with bird diverters, which would further reduce any potential for powerline collisions.

Impact BIO-107: Indirect Effects of Plan Implementation on Yellow-Breasted Chat

Indirect Construction- and Operation-Related Effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect yellow-breasted chat use of modeled habitat adjacent to proposed construction areas. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect yellow-breasted chat. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet from the construction edge. If yellow-breasted chat were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. These potential effects would be minimized with incorporation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* into the BDCP, which would ensure 250 foot no-disturbance buffers were established around active nests. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect yellow-breasted chat in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to yellow-breasted chat habitat could also affect the species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, in addition to *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would minimize the likelihood of such spills from occurring and ensure that measures were in place to prevent runoff from the construction area and any adverse effects of dust on active nests. If present, yellow-breasted chat individuals could be temporarily affected by noise and visual disturbances adjacent to water conveyance construction sites, reducing the use of an estimated 59 acres of modeled primary nesting and migratory habitat and 119 acres of secondary nesting and migratory habitat. *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would avoid and minimize this effect on the species.

Methylmercury Exposure: Yellow-breasted chat modeled habitat includes primarily middle marsh habitat with select emergent wetland plant alliances in Suisun Marsh. High marsh is also used if it is of high value, and low marsh provides foraging habitat for the species. Chats are a top predator in the benthic food chain; they forage by probing their beaks into the mud (Zembal and Fancher 1988) and prey primarily on mussels, spiders, seeds and hulls of cordgrass, and insects (Eddleman and Conway 1998).

Largemouth bass was used as a surrogate species for analysis (see Appendix 11F, *Substantive BDCP Revisions*). Results of the quantitative modeling of mercury effects on largemouth bass as a surrogate species would overestimate the effects on yellow-breasted chat. Organisms feeding within pelagic-based (algal) foodwebs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic foodwebs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009).

Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, Alternative 9 restoration activities that create newly inundated areas could increase bioavailability of mercury. Concentrations of methylmercury known to be toxic to bird embryos have been found in the eggs of San Francisco Bay clapper rails (Schwarzbach and Adelsbach 2003); however, currently, it is unknown how much of the sediment-derived methylmercury enters the food chain in Suisun Marsh or what tissue concentrations are actually harmful to the yellow-breasted chat. In general, the highest methylation rates are associated with high tidal marshes that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). In Suisun Marsh, the conversion of managed wetlands to tidal wetlands is expected to result in an overall reduction in mercury methylation. Due to the complex and very site-specific factors that determine if mercury becomes mobilized into the foodweb, *CM12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. CM12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This conservation measure would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability.
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009), and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including yellow-breasted chat. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and, therefore, increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 9 restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations are analyzed in Chapter 8, *Water Quality*, which concludes that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on yellow-breasted chat.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on yellow-breastede chat from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: The potential for noise and visual disturbance, hazardous spills, increased dust and sedimentation, and the potential impacts of operations and maintenance of the water conveyance facilities would not result in an adverse effect on yellow-breasted chat with the incorporation of AMM1–AMM7 and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* into the BDCP.

Restoration actions that would create tidal marsh could provide biogeochemical conditions for methylation of mercury in the newly inundated soils. There is potential for increased exposure of the yellow-breasted chat foodweb to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the conversion of managed wetlands to tidal wetlands in Suisun Marsh would be expected to reduce the overall production of methylmercury, resulting in a net benefit to species. Implementation of CM12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

Tidal habitat restoration could result in increased exposure of yellow-breasted chat to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

CEQA Conclusion: The potential for noise and visual disturbance, hazardous spills, increased dust and sedimentation, and the potential impacts of operations and maintenance of the water conveyance facilities would have a less-than-significant impact on yellow-breasted chat with the incorporation of AMM1–AMM7, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* into the BDCP.

Restoration actions that would create tidal marsh could provide biogeochemical conditions for methylation of mercury in the newly inundated soils. There is potential for increased exposure of the yellow-breasted chat foodweb to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the conversion of managed wetlands to tidal wetlands in Suisun Marsh would be expected to reduce the overall production of methylmercury, resulting in a net benefit to species. Implementation of CM12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

Tidal habitat restoration could result in increased exposure of yellow-breasted chat to selenium. With implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats, the impact of potential increased exposure to selenium would be less than significant.

Impact BIO-108: Periodic Effects of Inundation of Yellow-Breasted Chat Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (CM2) would increase the frequency and duration of inundation of approximately 48–88 acres of modeled yellow-breasted chat nesting and migratory habitat. No adverse effects of increased inundation frequency on yellow-breasted chat or its habitat are expected because the chat breeding period is outside the period the weir would be operated. Moreover, riparian vegetation supporting habitat has persisted under the existing Yolo Bypass flooding regime, and changes to frequency and inundation would be within the tolerance of these vegetation types.

Based on hypothetical floodplain restoration, CM5 could result in periodic inundation of up to 148 acres of modeled yellow-breasted chat habitat. Inundation of restored floodplains is not expected to affect yellow-breasted chat or its habitat because the chat breeding period is outside the period the floodplains would likely be inundated. In addition, providing for periodic inundation of floodplains is expected to restore a more natural flood regime in support of riparian vegetation types that provide nesting and migratory habitat for yellow-breasted chat. The overall effect of seasonal inundation in existing riparian natural communities is likely to be beneficial because, historically, flooding was the main natural disturbance regulating ecological processes in riparian areas, and flooding promotes the germination and establishment of many native riparian plants.

NEPA Effects: Increases in the frequency and duration of Yolo Bypass flooding and CM5 floodplain restoration would be expected to create more natural flood regimes that would support riparian habitat, which would not result in an adverse effect on yellow breasted chat.

CEQA Conclusion: Periodic inundation would have a less-than-significant impact on yellow-breasted chat because inundation would occur outside of the breeding season and would not be expected to adversely modify habitat or result in direct mortality of the species. Flooding promotes the germination and establishment of many native riparian plants. Therefore, the overall impact of seasonal inundation would be beneficial for yellow-breasted chat.

Cooper's Hawk and Osprey

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on Cooper's hawk and osprey. Although osprey often nest on manmade structures such as telephone poles, and Cooper's hawk will nest in more developed landscapes, modeled breeding habitat for these species is restricted to valley/foothill riparian forest.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of Cooper's hawk and osprey modeled habitat as indicated in Table 12-9-43. The majority of the losses would take place over an extended period of time as tidal marsh is restored in the study area. Although restoration for the loss of nesting habitat would be initiated in the same timeframe as the losses, it could take one or more decades for restored habitats to replace the functions of habitat lost. This time lag between impacts and restoration of habitat function would be minimized by specific requirements of *AMM18 Swainson's Hawk*, including the planting of mature trees in the near-term time period. Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP that would also benefit Cooper's hawk and osprey (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 5,000 acres of valley/foothill riparian natural community, with at least 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM7)
- Protect at least 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).
- Plant and maintain native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SH2.1, associated with CM11).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands within the reserve system including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).

As explained below, with the acres of restoration or protection included in the Plan, in addition to management activities to enhance natural communities for species and implementation of AMM1–AMM7, *AMM18 Swainson's Hawk*, and Mitigation Measure BIO-75, impacts on Cooper's hawk and osprey would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-43. Changes in Cooper's Hawk and Osprey Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent NT	Permanent LLT[c]	Temporary NT	Temporary LLT[c]	Periodic[d] CM2	Periodic[d] CM5
CM1	Nesting	43	43	89	89	NA	NA

CM2–CM18	Nesting	312	507	88	121	48–82	230
Total Impacts CM2–CM18		**312**	**507**	**88**	**121**	**48–82**	**230**
TOTAL IMPACTS		**355**	**550**	**177**	**210**	**48–82**	**230**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-109: Loss or Conversion of Habitat for and Direct Mortality of Cooper's Hawk and Osprey

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 760 acres of modeled nesting habitat for Cooper's hawk and osprey (Table 12-9-43). Conservation measures that would result in these losses are *CM1 Water Facilities and Operations* (which would involve conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), and floodplain restoration (CM5). Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could affect Cooper's hawk and osprey modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 water conveyance facilities would result in the combined permanent and temporary loss of up to 132 acres of modeled Cooper's hawk and osprey habitat (Table 12-9-43). Of the 132 acres of modeled habitat that would be removed for the construction of the conveyance facilities, 43 acres would be a permanent loss and 89 acres would be a temporary loss of habitat. Activities that would impact nesting habitat include channel dredging, intakes, fish barriers, access roads, and construction of transmission lines. Of the 132 acres of nesting habitat that would be removed for the construction of the conveyance facilities, 43 acres would be a permanent loss and 89 acres would be a temporary loss of habitat. Permanent losses would primarily consist of channel enlargement at the Sacramento River and Meadows Slough. Temporary losses would occur primarily along Middle River between Victoria Canal and Mildred Island, where large dredging work areas and operable barrier work areas would be placed. The riparian habitat in these areas is composed of very small patches or stringers bordering waterways, which are composed of valley oak and scrub vegetation. There are no occurrences of Cooper's hawk or osprey that overlap with the construction footprint for CM1. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address potential effects on cooper's hawk and osprey if either species were to nest in or adjacent to the construction footprint. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Impacts from CM1 would occur within the first 10 years of Alternative 9 implementation.

- *CM2 Yolo Bypass Fisheries Enhancement:* Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 170 acres of Cooper's hawk and osprey nesting habitat (82 acres of permanent loss, 88 acres of temporary loss) in the Yolo Bypass in CZ 2. Activities through CM2 could involve excavation and grading in valley/foothill riparian areas to improve passage of fish through the bypasses. Most of the riparian losses would occur at the north end of Yolo Bypass where major fish passage improvements are planned. Excavation to improve water movement in the Toe Drain and in the Sacramento Weir would also remove potential Cooper's hawk and osprey habitat. The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration could permanently remove up to 383 acres of potential Cooper's hawk and osprey nesting habitat. Trees would not be actively removed but tree mortality would be expected over time as areas became tidally inundated.

- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain and riparian restoration actions would remove approximately 75 acres of Cooper's hawk and osprey nesting habitat (42 acres of permanent loss, 33 acres of temporary loss). These losses would be expected after the first 10 years of Alternative 9 implementation along the San Joaquin River and other major waterways in CZ 7.

- *CM11 Natural Communities Enhancement and Management:* Habitat management- and enhancement-related activities could disturb Cooper's hawk and osprey nests if they were present near work sites. A variety of habitat management actions included in *CM11 Natural Communities Enhancement and Management* that are designed to enhance wildlife values in BDCP-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of Cooper's hawk and osprey habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available Cooper's hawk and osprey habitat and are expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.

Permanent and temporary habitat losses from the above conservation measures would primarily consist of fragmented riparian stands. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities. Although the effects are considered temporary, the restored riparian habitat would require 1 to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by Cooper's hawk or osprey. *AMM18 Swainson's Hawk* contains actions described below to reduce the effect of temporal loss of nesting habitat, including the transplanting of mature trees.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect Cooper's hawk or osprey use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7 and conservation actions as described below.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged Cooper's hawk or osprey if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If Cooper's hawk or osprey were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could affect nests or lead to their abandonment, potentially resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these effects on Cooper's hawk and osprey.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effect of construction would not be adverse under NEPA. Alternative 9 would remove 532 acres (355 acres of permanent loss, 177 acres of temporary loss) of Cooper's hawk and osprey nesting habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 132 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—400 acres of habitat).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat. Using these ratios would indicate that 132 acres of nesting habitat should be restored/created and 132 acres should be protected to compensate for the CM1 losses of modeled Cooper's hawk and osprey habitat. In addition, the near-term effects of other conservation actions would remove 400 acres of modeled breeding habitat, and therefore require 400 acres of restoration and 400 acres of protection of modeled Cooper's hawk and osprey using the same typical NEPA and CEQA ratios.

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of valley/foothill riparian natural community (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, and CM7 and would occur in the same timeframe as the construction and early restoration losses. The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for riparian species. The Plan's objectives would also benefit Cooper's hawk and osprey by protecting small but essential habitats that occur within cultivated lands, such as tree rows along field borders or roads, and small clusters of trees in farmyards or rural residences (Objective CLNC1.3). In addition, the distribution and abundance of potential nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1).

The 750 acres of protection and 800 acres of restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and other near-term impacts on Cooper's hawk and osprey nesting habitat. The 800 acres of restored riparian habitat would be initiated in the near-term to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by these species. This time lag between the removal and restoration of nesting habitat could have a substantial impact on nesting raptors in the near-term time period. Nesting habitat is limited throughout much of the study area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active nests within the study area until restored riparian habitat is sufficiently developed.

AMM18 Swainson's Hawk would implement a program to plant large mature trees, including transplanting trees scheduled for removal, to compensate for the temporal loss of Swainson's hawk nest sites, defined as a 125-acre area where more than 50% of suitable nest trees (20 feet or taller) within the 125-acre block are removed. These mature trees would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the BDCP reserve system for every tree 20 feet or taller removed by construction during the near-term period. A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Trees would be planted within the BDCP reserve system in areas that support high-value Swainson's hawk foraging habitat to increase nest sites, or within riparian plantings as a component of the riparian restoration (CM5, CM7). Replacement trees that were incorporated into the riparian restoration would not be clustered in a single region of the study area, but would be distributed throughout the conserved lands. Further details of AMM18 are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Cooper's hawk and osprey are not species that are covered under the BDCP. In order for the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that active nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

Late Long-Term Timeframe

The study area supports approximately 14,069 acres of modeled nesting habitat for Cooper's hawk and osprey. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 760 acres of potential nesting habitat (5% of the potential nesting habitat in the study area).

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM5 Seasonally Inundated Floodplain Restoration,* and *CM7 Riparian Natural Community Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community (Table 3-4 in Chapter 3, *Description of Alternatives*). The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for riparian species. The Plan's objectives would also benefit Cooper's hawk and osprey by protecting small but essential habitats that occur within cultivated lands, such as tree rows along field borders or roads, and small clusters of trees in farmyards or rural residences (Objective CLNC1.3). In addition, the distribution and abundance of potential nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Cooper's hawk and osprey are not species that are covered under the BDCP. In order for the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that active nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would be available to address this adverse effect.

NEPA Effects: The loss of Cooper's hawk and osprey habitat and potential direct mortality of these special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. However, with habitat protection and restoration associated with CM3, CM5, CM7, guided by biological goals and objectives and by AMM1–AMM7 and *AMM18 Swainson's Hawk*, which would be in place throughout the construction period, the effects of habitat loss on Cooper's hawk and osprey under Alternative 9 would not be adverse. Cooper's hawk and osprey are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75 would be available to address this effect.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effect of construction would not be adverse under NEPA. Alternative 9 would remove 532 acres (355 acres of permanent loss, 177 acres of temporary loss) of Cooper's hawk and osprey nesting habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 132 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—400 acres of habitat).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat Using these ratios would indicate that 132 acres of nesting habitat should be restored/created and 132 acres should be protected to compensate for the CM1 losses of modeled Cooper's hawk and osprey habitat. In addition, the near-term effects of other conservation actions would remove 400 acres of modeled breeding habitat, and therefore require 400 acres of restoration and 400 acres of protection of modeled Cooper's hawk and osprey using the same typical NEPA and CEQA ratios.

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of valley/foothill riparian natural community (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, and CM7 and would occur in the same timeframe as the construction and early restoration losses. The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for riparian species. The Plan's objectives would also benefit Cooper's hawk and osprey by protecting small but essential habitats that occur within cultivated lands, such as tree rows along field borders or roads, and small clusters of trees in farmyards or rural residences (Objective CLNC1.3). In addition, the distribution and abundance of potential nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1).

The 750 acres of protection and 800 acres of restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and other near-term impacts on Cooper's hawk and osprey nesting habitat. The 800 acres of restored riparian habitat would be initiated in the near-term to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by these species. This time lag between the removal and restoration of nesting habitat could have a substantial impact on nesting raptors in the near-term time period. Nesting habitat is limited throughout much of the study area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active nests within the study area until restored riparian habitat is sufficiently developed.

AMM18 Swainson's Hawk would implement a program to plant large mature trees, including transplanting trees scheduled for removal, to compensate for the temporal loss of Swainson's hawk nest sites, defined as a 125-acre area where more than 50% of suitable nest trees (20 feet or taller) within the 125-acre block are removed. These would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the BDCP reserve system for every tree 20 feet or taller removed by construction during the near-term period. A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Trees would be planted within the BDCP reserve system in areas that support high-value Swainson's hawk foraging habitat to increase nest sites, or within riparian plantings as a component of the riparian restoration (CM5, CM7). Replacement trees that were incorporated into the riparian restoration would not be clustered in a single region of the study area, but would be distributed throughout the conserved lands. Further details of AMM18 are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Cooper's hawk and osprey are not species that are covered under the BDCP. In order for the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that active nests are detected and avoided. Implementation of Mitigation Measure BIO-75 would reduce the potential impact on nesting Cooper's hawk and osprey to a less-than–significant level.

Late Long-Term Timeframe

The study area supports approximately 14,069 acres of modeled nesting habitat for Cooper's hawk and osprey. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 760 acres of potential nesting habitat (5% of the potential nesting habitat in the study area).

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM5 Seasonally Inundated Floodplain Restoration,* and *CM7 Riparian Natural Community Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community (Table 3-4 in Chapter 3, *Description of Alternatives*). The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for riparian species. The Plan's objectives would also benefit Cooper's hawk and osprey by protecting small but essential habitats that occur within cultivated lands, such as tree rows along field borders or roads, and small clusters of trees in farmyards or rural residences (Objective CLNC1.3). In addition, the distribution and abundance of potential nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Cooper's hawk and osprey are not species that are covered under the BDCP. In order for the BDCP to have a less-than-significant impact on individuals, preconstruction surveys for noncovered avian species would be required to ensure that active nests are detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Considering Alternative 9's protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for the time lag of restoring riparian habitats lost to construction and restoration activities, and with implementation of AMM1–AMM7, *AMM18 Swainson's Hawk*, and Mitigation Measure BIO-75, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of Cooper's hawk and osprey. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on Cooper's hawk and osprey.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-110: Effects on Cooper's Hawk and Osprey Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of Cooper's hawk and osprey. However, the flight behavior of these species, their keen vision, and high maneuverability substantially reduce the risk of powerline collisions. The existing network of transmission lines in the project area currently poses the same small risk for Cooper's hawk and osprey, and any incremental risk associated with the new power line corridors would also be expected to be low. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. With the implementation of *AMM20 Greater Sandhill Crane*, all new transmission lines would be fitted with flight diverters, which would further reduce any risk of collision with lines.

NEPA Effects: The construction and presence of new transmission lines would not represent an adverse effect because the risk of bird strike is considered to be minimal based on the flight behavior, the general maneuverability, and keen eyesight of Cooper's hawk and osprey. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would further reduce any risk of mortality from bird strike for Cooper's hawk and osprey as a result of the project. Therefore, the construction and operation of new transmission lines under Alternative 9 would not result in an adverse effect on Cooper's hawk and osprey.

CEQA Conclusion: The construction and presence of new transmission lines would not represent an adverse effect because the risk of bird strike is considered to be minimal based on the flight behavior, the general maneuverability, and keen eyesight of Cooper's hawk and osprey. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would further reduce any risk of mortality from bird strike for Cooper's hawk and osprey as a result of the project. Therefore, the construction and operation of new transmission lines under Alternative 9 would result in a less-than-significant impact on Cooper's hawk and osprey.

Impact BIO-111: Indirect Effects of Plan Implementation on Cooper's Hawk and Osprey

Indirect Construction- and Operation-Related Effects: Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect Cooper's hawk or osprey. If Cooper's hawk or osprey were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would avoid the potential for adverse effects of construction-related activities on survival and productivity of nesting Cooper's hawk and osprey. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect Cooper's hawk and osprey in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including Cooper's hawk and osprey. Future operational impacts under CM1 were analyzed using a DSM-2 based model to assess potential effects on mercury concentration and bioavailability resulting from proposed flows. Subsequently, a regression model was used to estimate fish-tissue concentrations under these future operational conditions (evaluated starting operations or ESO). Results indicated that changes in total mercury levels in water and fish tissues due to ESO were insignificant (see BDCP Appendix 5.D, Tables 5D.4-3, 5D.4-4, and 5D.4-5).

Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect cooper's hawk and osprey, via uptake in lower trophic levels (as described in BDCP Appendix 5.D, *Contaminants*).

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. *CM12 Methylmercury*

Management contains provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on cooper's hawk and osprey.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009), and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including Cooper's hawk and osprey. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and, therefore, increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 9 restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations are analyzed in Chapter 8, *Water Quality*, which concludes that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on Cooper's hawk and osprey.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on Cooper's hawk and osprey from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

***NEPA Effects*:** Noise and visual disturbances from the construction of water conveyance facilities could reduce Cooper's hawk and osprey use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect Cooper's hawk and osprey use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting individuals in addition to AMM1–AMM7.

The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of Cooper's hawk or osprey to methylmercury, through the ingestion of fish or small mammals in tidally restored areas. However, it is currently unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would better inform potential impacts and address the uncertainty of methylmercury levels in restored tidal marsh in the study area on cooper's hawk and osprey. The site-specific planning phase of marsh restoration would be the appropriate place to assess the potential for risk of methylmercury exposure for Cooper's hawk and osprey, once site specific sampling and other information could be developed.

Tidal habitat restoration could result in increased exposure of Cooper's hawk and osprey to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

***CEQA Conclusion*:** Noise and visual disturbances from the construction of water conveyance facilities could reduce Cooper's hawk and osprey use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect Cooper's hawk and osprey use of the surrounding habitat. Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 9 would have a less-than-significant impact on Cooper's hawk and osprey with the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and AMM1–AMM7.

The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of Cooper's hawk or osprey to methylmercury through the ingestion of fish or small mammals in restored tidal areas. However, it is currently unknown what concentrations of methylmercury are harmful to these species. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12, would address the uncertainty of methylmercury levels in restored tidal marsh in the study area and better inform potential impacts on Cooper's hawk and osprey.

Tidal habitat restoration could result in increased exposure of Cooper's hawk and osprey to selenium. With implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats, the impact of potential increased exposure to selenium would be less than significant.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-112: Periodic Effects of Inundation of Cooper's Hawk and Osprey Nesting Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (CM2) would increase the frequency and duration of inundation of approximately 48–82 acres of modeled Cooper's hawk and osprey breeding habitat However, increased periodic flooding is not expected to cause any adverse effect on breeding habitat because trees in which nest sites are situated already withstand floods, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and nest sites are located above floodwaters.

Based on hypothetical floodplain restoration, CM5 implementation could result in periodic inundation of up to 230 acres of breeding habitat for Cooper's hawk and osprey. The overall effect of seasonal inundation in existing riparian natural communities is likely to be beneficial for these species, because, historically, flooding was the main natural disturbance regulating ecological processes in riparian areas, and flooding promotes the germination and establishment of many native riparian plants.

NEPA Effects: Increased periodic flooding would not be expected to cause any adverse effect on nest sites because trees in which nest sites are situated already withstand floods, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and nest sites are located above floodwaters. Therefore, increased duration and inundation from CM2 and CM5 would not have an adverse effect on Cooper's hawk and osprey.

CEQA Conclusion: Increased periodic flooding would not be expected to cause any adverse effect on nest sites because trees in which nest sites are situated already withstand floods, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and nest sites are located above floodwaters. Therefore, increased duration and inundation from CM2 and CM5 would have a less-than-significant impact on Cooper's hawk and osprey.

Golden Eagle and Ferruginous Hawk

Modeled foraging habitat for these species consists of grassland, alkali seasonal wetland, vernal pool complex, alfalfa, grain and hay, pasture, and idle cropland throughout the study area.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of golden eagle and ferruginous hawk modeled foraging habitat as indicated in Table 12-9-44. Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP that would benefit golden eagle and ferruginous hawk (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect at least 8,000 acres of grassland, with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at last 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).

- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).
- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4, VPNC2.5, and GNC2.4, associated with CM11).
- Protect at least 48,625 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species (Objective CLNC1.1, associated with CM3).
- Within the 48,625 acres of protected cultivated lands, protect at least 42,275 acres of cultivated lands as Swainson's hawk foraging habitat with at least 50% in very high-value habitat in CZs 2, 3, 4, 5, 7, 8, 9, and 11 (Objective SH1.2, associated with CM3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities to enhance natural communities for species and implementation of AMM1–AMM7, impacts on golden eagle and ferruginous hawk would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-44. Changes in Golden Eagle and Ferruginous Hawk Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	Foraging	318	318	1,281	1,281	NA	NA
Total Impacts CM1		**318**	**318**	**1,281**	**1,281**	**NA**	**NA**
CM2–CM18	Foraging	5,450	26,198	376	893	1,158–3,650	3,823
Total Impacts CM2–CM18		**5,450**	**26,198**	**376**	**893**	**1,158–3,650**	**3,823**
TOTAL IMPACTS		**5,768**	**26,516**	**1,657**	**2,174**	**1,158–3,650**	**3,823**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-113: Loss or Conversion of Habitat for and Direct Mortality of Golden Eagle and Ferruginous Hawk

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 28,690 acres of modeled foraging habitat for golden eagle and ferruginous hawk (26,516 acres of permanent loss and 2,174 acres of temporary loss, Table 12-9-44). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), riparian restoration (CM7), grassland restoration (CM8), vernal pool and wetland restoration (CM9), nontidal marsh restoration (CM10), and construction of conservation hatcheries (CM18). The majority of habitat loss (20,880 acres) would result from CM4. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, and the construction of recreational trails, signs, and facilities, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate foraging habitat for both species. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 427 acres of modeled golden eagle and ferruginous hawk foraging habitat (83 acres of permanent loss, 344 acres of temporary loss) from CZ 4, 5, 6, 7, and 8. The permanent and temporary losses to habitat would occur at numerous locations where dredging, construction of operable barriers and canals, and channel enlargement would be undertaken. The CM1 construction footprint does not overlap with any occurrences of golden eagle or ferruginous hawk. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Impacts from CM1 would occur within the first 10 years of Alternative 9 implementation.
- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 1,274 acres of modeled golden eagle and ferruginous hawk foraging habitat (898 acres of permanent loss, 376 acres of temporary loss) in the Yolo Bypass in CZ 2. Impacted habitat would consist primarily of grassland and pasture. Most of the grassland losses would occur at the north end of the bypass below Fremont Weir, along the Toe Drain/Tule Canal, and along the west side channels. Realignment of Putah Creek could also involve excavation and grading in alkali seasonal wetland complex habitat as a new channel is constructed. The loss is expected to occur during the first 10 years of Alternative 9 implementation.
- *CM4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 20,880 acres of modeled golden eagle and ferruginous hawk habitat. The majority of the acres lost would consist of cultivated lands in CZs 1, 2, 4, 5, 6, and/or 7. Grassland losses would likely occur in the vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the upslope fringes of Suisun Marsh, and along narrow bands adjacent to waterways in the South Delta ROA. Tidal restoration would directly impact and fragment grassland just north of Rio Vista in and around French and Prospect Islands, and in an area south of Rio Vista around Threemile Slough. Losses of alkali seasonal wetland complex habitat would likely occur in the south end of the Yolo Bypass and on the northern fringes of Suisun Marsh.
- *CM5 Seasonally Inundated Floodplain Restoration:* Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 1,450 acres of modeled golden eagle and ferruginous hawk foraging habitat (933 permanent, 517 temporary). These losses would be expected after the first 10 years of Alternative 9 implementation along the San Joaquin River and other major waterways in CZ 7.

- *CM8 Grassland Natural Community Restoration* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:* Temporary construction-related disturbance of grassland habitat would result from implementation of CM8 and CM9 in in CZs 1, 2, 4, 5, 7, 8, and 11. However, all areas would be restored after the construction periods. Grassland restoration would be implemented on agricultural lands that also provide foraging habitat for golden eagle and ferruginous hawk and would result in the conversion of 837 acres of cultivated lands to grassland.
- *CM10 Nontidal Marsh Restoration:* Implementation of CM10 would result in the permanent removal of 705 acres of golden eagle and ferruginous hawk foraging habitat.
- *CM11 Natural Communities Enhancement and Management:* A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of golden eagle and ferruginous hawk foraging habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat for these species. CM11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. However, approximately 50 acres of grassland habitat would be lost from the construction of trails and facilities.
- *CM18 Conservation Hatcheries*: Implementation of CM18 would remove up to 35 acres of modeled golden eagle and ferruginous hawk foraging habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1.
- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect golden eagle and ferruginous hawk use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7 and conservation actions as described below.
- Injury and Direct Mortality: Construction would not be expected to result in direct mortality of golden eagle and ferruginous hawk because foraging individuals would be expected to temporarily avoid the increased noise and activity associated with construction areas.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 7,425 acres (5,768 permanent, 1,657 temporary) of modeled golden eagle and ferruginous hawk foraging habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,599 acres), and implementing other conservation measures

(*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—5,826 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 3,198 acres should be protected to compensate for the CM1 losses of 1,599 acres of golden eagle and ferruginous hawk foraging habitat. The near-term effects of other conservation actions would remove 5,826 acres of modeled habitat, and therefore require 11,652 acres of protection of golden eagle and ferruginous hawk habitat using the same typical NEPA and CEQA ratio (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses thereby avoiding adverse effects of habitat loss on golden eagle and ferruginous hawk foraging in the study area. Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand golden eagle and ferruginous hawk foraging habitat and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect and mammal prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Burrow availability would be increased on protected natural communities by encouraging ground squirrel occupancy and expansion through the creation of berms, mounds, edges, and through the prohibition of ground squirrel control programs (i.e., poisoning).

Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential foraging habitat for golden eagle and ferruginous hawk (Objective CLNC1.1). Approximately 87% of cultivated lands protected by the late long-term time period would be in alfalfa and pasture crop types (very high- and high-value crop types) for Swainson's hawk (Objective SH1.2) which are also suitable for golden eagle and ferruginous hawk. This biological objective provides an estimate for the high proportion of cultivated lands protected in the near-term time period which would be suitable for golden eagle and ferruginous hawk.

The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on golden eagle and ferruginous hawk, as well as mitigate the near-term effects of the other conservation measures with the consideration that some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would be managed in suitable crop types to compensate for the loss of habitat at a ratio of 2:1. Mitigation Measure BIO-113, *Compensate for the Near-Term Loss of Golden Eagle and Ferruginous Hawk Foraging Habitat* would be available to address the adverse effect of habitat loss in the near-term.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and*

Countermeasure Plan, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 28,690 acres of modeled golden eagle and ferruginous hawk foraging habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration,* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3, *Description of Alternatives*). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand foraging habitat for golden eagle and ferruginous hawk and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect and small mammal prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Burrow availability would be increased on protected natural communities by encouraging ground squirrel occupancy and expansion through the creation of berms, mounds, edges, and through the prohibition of ground squirrel control programs (i.e., poisoning). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential habitat for golden eagle and ferruginous hawk (Objective CLNC1.1). Approximately 42,275 acres of cultivated lands protected would be in alfalfa and pasture crop types (very high- and high-value crop types) for Swainson's hawk (Objective SH1.2) which are also suitable for golden eagle and ferruginous hawk.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

NEPA Effects**:** The loss of golden eagle and ferruginous hawk habitat and potential mortality of these special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection and restoration associated with CM3, CM8, CM9, and CM11, guided by biological goals and objectives and AMM1–AMM7, which would be in place throughout the construction period, and with implementation of Mitigation Measure BIO-113, *Compensate for the Near-Term Loss of Golden Eagle and Ferruginous Hawk Foraging Habitat*, the effects of habitat loss and potential direct mortality on golden eagle and ferruginous hawk under Alternative 9 would not be adverse.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Alternative 9 would remove 7,425 acres (5,768 permanent, 1,657 temporary) of modeled golden eagle and ferruginous hawk foraging habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,599 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—5,826 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 3,198 acres should be protected to compensate for the CM1 losses of 1,599 acres of golden eagle and ferruginous hawk foraging habitat. The near-term effects of other conservation actions would remove 5,826 acres of modeled habitat, and therefore require 11,652 acres of protection of golden eagle and ferruginous hawk habitat using the same typical NEPA and CEQA ratio (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses thereby avoiding significant impacts of habitat loss on golden eagle and ferruginous hawk foraging in the study area. Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand golden eagle and ferruginous hawk foraging habitat and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect and mammal prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Burrow availability would be increased on protected natural communities by encouraging ground squirrel occupancy and expansion through the creation of berms, mounds, edges, and through the prohibition of ground squirrel control programs (i.e., poisoning). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential foraging habitat for golden eagle and ferruginous hawk (Objective CLNC1.1). Approximately 87% of cultivated lands protected by the late long-term time period would be in alfalfa and pasture crop types (very high- and high-value crop types) for Swainson's hawk (Objective SH1.2) which are also suitable for golden eagle and ferruginous hawk. This biological objective provides an estimate for the high proportion of cultivated lands protected in the near-term time period which would be suitable for golden eagle and ferruginous hawk.

These Plan objectives represent performance standards for considering the effectiveness of conservation actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on golden eagle and ferruginous hawk, as well as mitigate the near-term effects of the other conservation measures with the consideration that some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would be managed in suitable crop types to compensate for the loss of habitat at a ratio of 2:1. The implementation of Mitigation Measure BIO-113, *Compensate for the Near-Term Loss of Golden Eagle and Ferruginous Hawk Foraging Habitat* would reduce the impact of habitat loss in the near-term to a less-than-significant level.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 28,690 acres of modeled golden eagle and ferruginous hawk foraging habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration,* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand foraging habitat for golden eagle and ferruginous hawk and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect and small mammal prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Burrow availability would be increased on protected natural communities by encouraging ground squirrel occupancy and expansion through the creation of berms, mounds, edges, and through the prohibition of ground squirrel control programs (i.e., poisoning). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential habitat for golden eagle and ferruginous hawk (Objective CLNC1.1). Approximately 42,275 acres of cultivated lands protected would be in alfalfa and pasture crop types. These are very high- and high-value crop types for Swainson's hawk (Objective SH1.2) which are also suitable for golden eagle and ferruginous hawk.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

In the absence of other conservation actions, the effects on golden eagle and ferruginous hawk foraging habitat would represent an adverse effect as a result of habitat modification and potential for direct mortality of special-status species; however, considering Alternative 9's protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7, and Mitigation Measure BIO-113, *Compensate for the Near-Term Loss of Golden Eagle and Ferruginous Hawk Foraging Habitat,* the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of either species. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on golden eagle and ferruginous hawk.

Mitigation Measure BIO-113: Compensate for the Near-Term Loss of Golden Eagle and Ferruginous Hawk Foraging Habitat

DWR will manage and protect sufficient acres of cultivated lands such as pasture, grain and hay crops, or alfalfa to provide golden eagle and ferruginous hawk foraging habitat such that the total acres of high-value habitat impacted in the near-term timeframe are mitigated at a ratio of 2:1. Additional grassland protection, enhancement, and management may be substituted for the protection of high-value cultivated lands.

Impact BIO-114: Effects on Golden Eagle and Ferruginous Hawk Associated with Electrical Transmission Facilities

Golden eagle and ferruginous hawk would be at low risk of bird strike mortality from the construction of new transmission lines based on their maneuverability, their keen eyesight, their lack of flocking behavior, and other factors assessed in the bird strike vulnerability analysis (BDCP Appendix 5.J, Attachment 5.J-2, *Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. With the implementation of *AMM20 Greater Sandhill Crane*, all new transmission lines would be fitted with flight diverters. which would substantially reduce any potential for powerline collisions.

***NEPA Effects*:** Golden eagle and ferruginous hawk are already at a low risk of bird strike mortality based on their general maneuverability, keen eyesight and lack of flocking behavior. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. With implementation of *AMM20 Greater*

Sandhill Crane, the construction and operation of transmission lines would not result in an adverse effect on golden eagle and ferruginous hawk.

***CEQA Conclusion*:** Golden eagle and ferruginous hawk are already at a low risk of bird strike mortality based on their general maneuverability, keen eyesight and lack of flocking behavior. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. With implementation of *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines would result in a less-than-significant impact on golden eagle and ferruginous hawk.

Impact BIO-115: Indirect Effects of Plan Implementation on Golden Eagle and Ferruginous Hawk

Indirect Construction- and Operation-Related Effects: Construction- and subsequent maintenance-related noise and visual disturbances could disrupt foraging, and reduce the functions of suitable foraging habitat for golden eagle and ferruginous hawk. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect golden eagle or ferruginous hawk. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to golden eagle and ferruginous hawk grassland habitat could also have a negative effect on the species. However, AMM1–AMM7 would also ensure that measures would be in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

***NEPA Effects*:** Indirect effects on golden eagle and ferruginous hawk as a result of Alternative 9 implementation could have adverse effects on these species through the modification of habitat. With the incorporation of AMM1–AMM7 into the BDCP, indirect effects as a result of Alternative 9 implementation would not have an adverse effect on golden eagle and ferruginous hawk.

***CEQA Conclusion*:** Indirect effects on golden eagle and ferruginous hawk as a result of Alternative 9 implementation could have a significant impact on the species from modification of habitat. With the incorporation of AMM1–AMM7 into the BDCP, indirect effects as a result of Alternative 9 implementation would have a less-than-significant impact on golden eagle and ferruginous hawk.

Impact BIO-116: Periodic Effects of Inundation on Golden Eagle and Ferruginous Hawk Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on approximately 1,158–3,650acres of modeled golden eagle and ferruginous hawk foraging habitat (Table 12-9-44).

Based on hypothetical footprints, implementation of *CM5 Seasonally Inundated Floodplain Restoration* could result in the periodic inundation of up to approximately 3,823 acres of modeled habitat (Table 12-9-44).

Golden eagles and ferruginous hawks would not likely use inundated areas for foraging, and increased inundation frequency and duration of inundation of grassland habitats may affect prey populations that have insufficient time to recover following inundation events. However, periodically inundated habitat would not be expected to have an adverse effect on local or migratory golden eagles or the wintering ferruginous hawk population in the area.

NEPA Effects: Implementation of CM2 would increase the frequency and duration of inundation on approximately 1,158–3,650 acres of modeled golden eagle and ferruginous hawk foraging habitat. In addition, implementation of CM5 could result in the periodic inundation of up to 3,823 acres of modeled habitat. However, periodic inundation would not be expected to have an adverse effect on the wintering golden eagle or ferruginous hawk populations in the study area.

CEQA Conclusion: Implementation of CM2 would increase the frequency and duration of inundation on approximately 1,158–3,650 acres of modeled golden eagle and ferruginous hawk foraging habitat. In addition, implementation of CM5 could result in the periodic inundation of up to 3,823 acres of modeled habitat. However, periodic inundation would be expected to have a less-than-significant impact on the golden eagle and ferruginous hawk populations in the study area.

Cormorants, Herons and Egrets

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron. Modeled breeding habitat for these species consists of valley/foothill riparian forest.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of cormorant, heron, and egret modeled habitat as indicated in Table 12-9-45. The majority of the losses would take place over an extended period of time as tidal marsh is restored in the study area. Although restoration for the loss of nesting habitat would be initiated in the same timeframe as the losses, it could take one or more decades for restored habitats to replace the functions of lost habitat. This time lag between impacts and restoration of habitat function would be minimized by specific requirements of *AMM18 Swainson's Hawk*, including the planting of mature trees in the near-term time period. Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP that would also benefit cormorants, herons, and egrets (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 5,000 acres of valley/foothill riparian natural community, with at least 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM7).
- Protect at least 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities to enhance natural communities for species and implementation of AMM1–AMM7, *AMM18 Swainson's Hawk*, and Mitigation Measures BIO-75 and BIO-117, impacts on cormorants, herons, and egrets would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-45. Changes in Cormorant, Heron and Egret Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	Nesting (Rookeries)	61	61	248	248	NA	NA
Total Impacts CM1		**61**	**61**	**248**	**248**	NA	NA
CM2–CM18	Nesting (Rookeries)	387	684	88	123	51–92	266
Total Impacts CM2–CM18		**387**	**684**	**88**	**123**	**51–92**	**266**
TOTAL IMPACTS		**448**	**745**	**336**	**371**	**51–92**	**266**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-117: Loss or Conversion of Nesting Habitat for and Direct Mortality of Cormorants, Herons and Egrets

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 1,116 acres of modeled habitat (745 acres of permanent loss, 371 acres of temporary loss) for double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron (Table 12-9-45). Conservation measures that would result in these losses are *CM1 Water Facilities and Operation* (which would involve conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas), *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate cormorant, heron, and egret modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts, NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 water conveyance facilities would result in the combined permanent and temporary loss of up to 309 acres of modeled Cormorant, heron, and egret habitat (Table 12-9-45). Of the 309 acres of modeled habitat that would be removed for the construction of the conveyance facilities, 61 acres would be a permanent loss and 248 acres would be a temporary loss of habitat. Permanent losses would primarily consist of channel enlargement at the Sacramento River and Meadows Slough. Temporary losses would occur primarily along Middle River between Victoria Canal and Mildred Island, where large dredging work areas and operable barrier work areas would be placed. The riparian habitat in these areas is composed of very small patches or stringers bordering waterways, which are composed of valley oak and scrub vegetation. Impacts from CM1 would occur within the first 10 years of Alternative 9 implementation.

  The primary impact of concern regarding double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron is the loss of existing known nest trees, and other large trees associated with known nest sites. The CM1 footprint overlaps with one great blue heron rookery on an instream island northeast of Woodward Island. This rookery occurrence was recorded in 2000 by the CNDDB and was recorded again during DHCCP surveys in 2009. The CM1 footprint includes dredging of Middle River and inchannel island dredging that would remove the island on which the rookery is located. In addition, the rookery could be indirectly affected by the barge facility work area and dredging work area to the west on Woodward Island. Because the species is highly traditional in their use of rookeries, the establishment of new nest sites is unpredictable. Therefore to avoid adverse effects on great blue herons (and cormorants, herons, and egrets, should future surveys detect additional rookeries), this rookery would have to be avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries,* would be available to address this adverse effect on great blue herons. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations.

- *CM2 Yolo Bypass Fisheries Enhancement:* Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 177 acres of nesting habitat (89 acres of permanent loss, 88 acres of temporary loss) in the Yolo Bypass in CZ 2. Activities through CM2 could involve excavation and grading in valley/foothill riparian areas to improve passage of fish through the bypasses. Most of the riparian losses would occur at the north end of Yolo Bypass where major fish passage improvements are planned. Excavation to improve water movement in the Toe Drain and in the Sacramento Weir would also remove potential nesting habitat. The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated552 acres of nesting habitat for cormorants, herons and egrets. Trees would not be actively removed but tree mortality would be expected over time as areas became tidally inundated. Depending on the extent and value of remaining habitat, this could reduce use of these habitats by these species. There is one CNDDB occurrence of a great blue heron rookery that overlaps with the hypothetical restoration footprint for tidal restoration. The occurrence is on Decker Island and tidal restoration could potentially impact the nest trees from inundation. This potential effect would need to be addressed within the project-specific analysis for tidal restoration projects.

- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain would permanently remove approximately 43 acres and temporarily remove approximately 35 acres of potential cormorants, heron, and egret nesting habitat. These losses would be expected after the first 10 years of Alternative 9 implementation along the San Joaquin River and other major waterways in CZ 7.

- *CM11 Natural Communities Enhancement and Management:* Habitat management- and enhancement-related activities could disturb cormorant, heron, and egret nests if they were present near work sites. A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in BDCP-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of cormorant, heron, and egret habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available habitat for these species and are expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.

- Permanent and temporary habitat losses from the above conservation measures would primarily consist of fragmented riparian stands. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities. Although the effects are considered temporary, the restored riparian habitat would require years to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure for established rookeries. *AMM18 Swainson's Hawk* contains actions described below to reduce the effect of temporal loss of mature riparian habitat, including the transplanting of mature trees.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect use of the surrounding habitat by cormorants, herons or egrets. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and conservation actions as described below.

- The primary impact of concern regarding double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron is the loss of existing known nest trees, and other large trees associated with known nest sites. Because these species are highly traditional in their use of rookeries, the establishment of new nest sites is unpredictable. To avoid adverse effects on these species, existing known nest sites would have to be avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries,* would be available to address these potential effects on cormorants, herons, and egrets.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If birds were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could affect nests including any nests that are built on the ground (e.g. Cormorant nests that have been built on the ground after nest trees fall over or die from stress and guano produced by a rookery) or lead to their abandonment, potentially resulting in mortality of eggs and nestlings. Mitigation Measures BIO-75 and BIO-117 would be available to address these effects on cormorants, herons, and egrets.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 784 acres of nesting habitat for cormorants, herons, and egrets in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 309 acres of nesting habitat), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancemen*t, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—475 acres of nesting habitat).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for breeding habitat. Using these ratios would indicate that 309 acres of breeding habitat should be restored/created and 309 acres should be protected to compensate for the CM1 losses of modeled cormorant, heron, and egret habitat. In addition, the near-term effects of other conservation actions would remove 475 acres of modeled breeding habitat, and therefore require 475 acres of restoration and 475 acres of protection of modeled cormorant, heron, and egret habitat using the same typical NEPA and CEQA ratios.

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for these species. In addition, small but essential nesting habitat associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).

The 750 acres of protection and 800 acres of restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and other near-term impacts on cormorant, heron, and egret nesting habitat. The 800 acres of restored riparian habitat would be initiated in the near-term to offset the loss of potential nesting habitat, but would require years to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for established rookeries. This time lag between the removal and restoration of nesting habitat could have a substantial impact on cormorants, herons and egrets in the near-term time period.

AMM18 Swainson's Hawk would implement a program to plant large mature trees, including transplanting trees scheduled for removal, to compensate for the temporal loss of Swainson's hawk nest sites, defined as a 125-acre area where more than 50% of suitable nest trees (20 feet or taller) within the 125-acre block are removed. These mature trees would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the BDCP reserve system for every tree 20 feet or taller removed by construction during the near-term period. A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Replacement trees that were incorporated into the riparian restoration would not be clustered in a single region of the study area, but would be distributed throughout protected lands. Further details of AMM18 are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron are not species that are covered under the BDCP. For the BDCP to avoid adverse effects on individuals, existing nests and rookeries would have to be avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries,* would be available to address adverse effects on nesting cormorants, herons, and egrets.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 17,966 acres of modeled nesting habitat for cormorants, herons, and egrets. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 1,116 acres of potential breeding habitat (6% of the potential breeding habitat in the study area).

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM5 Seasonally Inundated Floodplain Restoration,* and *CM7 Riparian Natural Community Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community (Table 3-4 in Chapter 3, *Description of Alternatives*). The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for riparian species. The Plan's objectives would also benefit cormorants, herons, and egrets by protecting small but essential habitats that occur within cultivated lands, such as tree rows along field borders or roads, and small clusters of trees in farmyards or rural residences (Objective CLNC1.3). In addition, the distribution and abundance of potential nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and*

Countermeasure Plan, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS. Double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron are not species that are covered under the BDCP. These species are highly traditional in their use of nest sites, and, in order for the BDCP to avoid a significant impact on individuals, preconstruction surveys would be required to ensure that nests are detected and any direct and indirect impacts on rookeries are avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds* and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries*, would be available to address adverse effects on nesting cormorants, herons, and egrets.

NEPA Effects: The loss of cormorant, heron, and egret habitat and potential direct mortality of these special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection and restoration associated with CM3, CM5, CM7, CM8, CM9, and CM11, guided by biological goals and objectives and by AMM1–AMM7 and *AMM18 Swainson's Hawk*, which would be in place throughout the construction period, the effects of habitat loss and potential mortality on cormorants, herons, and egrets under Alternative 9 would not be adverse. Double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron are not species that are covered under the BDCP. Preconstruction surveys for noncovered species would be required for the BDCP to avoid an adverse effect on individuals. Mitigation Measure BIO-75 and Mitigation Measure BIO-117 would be available to address effects on nesting cormorants, herons, and egrets.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under NEPA. Alternative 9 would remove 784 acres of nesting habitat for cormorants, herons, and egrets in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 309 acres of nesting habitat), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancemen*t, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—475 acres of nesting habitat).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for breeding habitat. Using these ratios would indicate that 309 acres of breeding habitat should be restored/created and 309 acres should be protected to compensate for the CM1 losses of modeled cormorant, heron, and egret habitat. In addition, the near-term effects of other conservation actions would remove 475 acres of modeled breeding habitat, and therefore require 475 acres of restoration and 475 acres of protection of modeled cormorant, heron, and egret habitat using the same typical NEPA and CEQA ratios.

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community

(Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for these species. In addition, small but essential nesting habitat associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).

The 750 acres of protection and 800 acres of restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and other near-term impacts on cormorant, heron, and egret nesting habitat. The 800 acres of restored riparian habitat would be initiated in the near-term to offset the loss of potential nesting habitat, but would require years to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for established rookeries. This time lag between the removal and restoration of nesting habitat could have a substantial impact on cormorants, herons and egrets in the near-term time period.

AMM18 Swainson's Hawk would implement a program to plant large mature trees, including transplanting trees scheduled for removal, to compensate for the temporal loss of Swainson's hawk nest sites, defined as a 125-acre area where more than 50% of suitable nest trees (20 feet or taller) within the 125-acre block are removed. These mature trees would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the BDCP reserve system for every tree 20 feet or taller removed by construction during the near-term period. A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Replacement trees that were incorporated into the riparian restoration would not be clustered in a single region of the study area, but would be distributed throughout protected lands. Further details of AMM18 are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron are not species that are covered under the BDCP. For the BDCP to avoid a significant impact on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries,* would reduce this potential impact to a less-than-significant level.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 17,966 acres of modeled nesting habitat for cormorants, herons, and egrets. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 1,116 acres of potential breeding habitat (5% of the potential breeding habitat in the study area).

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM5 Seasonally Inundated Floodplain Restoration,* and *CM7 Riparian Natural Community Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community (Table 3-4 in Chapter 3, *Description of Alternatives*). The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for riparian species. The Plan's objectives would also benefit cormorants, herons, and egrets by protecting small but essential habitats that occur within cultivated lands, such as tree rows along field borders or roads, and small clusters of trees in farmyards or rural residences (Objective CLNC1.3). In addition, the distribution and abundance of potential nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron are not species that are covered under the BDCP. These species are highly traditional in their use of nest sites and, for the BDCP to avoid a significant impact on individuals, preconstruction surveys would be required to ensure that nests are detected and any direct and indirect impacts on rookeries are avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries*, would reduce this potential impact to a less-than-significant level.

In the absence of other conservation actions, effects on nesting cormorants, herons, and egrets would represent an adverse effect as a result of habitat modification and potential for direct mortality of special-status species. This impact would be considered significant. Considering Alternative 9's protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts sufficient to compensate for the loss of riparian habitats lost to construction and restoration activities, and considering implementation of AMM1–AMM7, Mitigation Measure BIO-75, and Mitigation Measure BIO-117, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of cormorants, herons, and egrets. Therefore, the loss of habitat and potential mortality under this alternative would have a less-than-significant impact on cormorants, herons, and egrets.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Mitigation Measure BIO-117: Avoid Impacts on Rookeries

Herons, egrets, and cormorants are highly traditional in their use of nest sites (rookeries): therefore, DWR will avoid all direct and indirect impacts on rookeries.

Impact BIO-118: Effects Associated with Electrical Transmission Facilities on Cormorants, Herons and Egrets

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of cormorants, herons and egrets. New transmission lines would increase the risk for bird-power line strikes. Waterbirds have a higher susceptibility to collisions than passerines, raptors, and other birds. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. With the implementation of *AMM20 Greater Sandhill Crane*, all new transmission lines constructed as a result of the project would be fitted with flight diverters, which would reduce bird strike risk of cormorants, herons, and egrets.

NEPA Effects**:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of cormorants, herons, and egrets. The implementation of *AMM20 Greater Sandhill Crane* would require the installation of bird flight diverters on all new transmission lines, which could reduce bird strike risk of cormorants, herons, and egrets by 60%. With the installation of bird flight diverters, the construction and operation of new transmission lines under Alternative 9 would not result in an adverse effect on cormorants, herons, and egrets.

CEQA Conclusion**:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of cormorants, herons, and egrets. The implementation of *AMM20 Greater Sandhill Crane* would require the installation of bird flight diverters on all new transmission lines, which could reduce bird strike risk of cormorants, herons, and egrets by 60%. With the installation of bird flight diverters, the construction and operation of new transmission lines under Alternative 9 would result in a less-than-significant impact on cormorants, herons, and egrets.

Impact BIO-119: Indirect Effects of Plan Implementation on Cormorants, Herons and Egrets

Indirect Construction- and Operation-Related Effects: Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect cormorants, herons, or egrets. If cormorants, herons or egrets were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would avoid the potential for adverse effects of construction-related activities on survival and productivity of nesting cormorants, herons or egrets. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect cormorants, herons or egrets in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including cormorants, herons or egrets.

A detailed review of the methylmercury issues associated with implementation of the BDCP is contained in Appendix 11F, *Substantive BDCP Revisions*. This review includes an overview of the BDCP-related mechanisms that could result in increased mercury in the foodweb, and how exposure to individual species may occur based on feeding habits and where their habitat overlaps with the areas where mercury bioavailability could increase. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008).Bioaccumulation of methylmercury varies by species as there are taxonomic differences in rates of detoxification within the liver (Eagles-Smith et al. 2009). Organisms feeding within pelagic-based (algal) foodwebs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic foodwebs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009). That is, the pelagic food chain tends to be longer than the benthic food chain, which allows for greater biomagnification of methylmercury in top predators. Also, there is less prey diversity at the top of the pelagic food chain than in the benthic food chain; pelagic top predators eat smaller fish and little else, while benthic top predators consume a variety of organisms, many of which are lower in the food chain than fishes and thus have less potential for methylmercury biomagnification.

Largemouth bass was used as a surrogate species for analysis (Appendix 11F, *Substantive BDCP Revisions*) and the modeled effects of mercury concentrations from changes in water operations under CM1 on largemouth bass did not differ substantially from existing conditions; therefore, results also indicate that cormorant, heron, and egret tissue concentrations would not measurably increase as a result of CM1 implementation.

Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury. Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly effect on cormorants, herons or egrets, via uptake in lower trophic levels (as described in BDCP Appendix 5.D, *Contaminants*). Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury. Given that some species have elevated mercury tissue levels pre-BDCP, these low level increases could result in some level of effects. Restoration in Suisun Marsh would convert managed wetlands to tidal wetlands, which would be expected to result in an overall reduction in mercury methylation.

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. *CM12 Methylmercury*

Management contains provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on cormorants, herons or egrets.

Due to the complex and very site-specific factors that determine if mercury becomes mobilized into the foodweb, *CM12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. On a project-specific basis, where high potential for methylmercury production is identified that restoration design and adaptive management cannot fully address while also meeting restoration objectives, alternate restoration areas would be considered. CM12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This conservation measure would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including cormorants, herons, and egrets. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4–CM5) would lead to adverse effects on cormorants, herons, and egrets.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on cormorants, herons, and egrets from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

***NEPA Effects*:** Noise and visual disturbances from the construction of water conveyance facilities could reduce cormorant, heron, and egret use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect cormorant, heron, and egret use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries*, would be available to address adverse effects on nesting individuals in addition to AMM1–AMM7. Tidal habitat restoration could result in increased exposure of cormorants, herons, and egrets to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of cormorants, herons or egrets to methylmercury through the ingestion of fish in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on cormorants, herons, and egrets.

***CEQA Conclusion*:** Impacts of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would

represent an adverse effect in the absence of other conservation actions. This impact would be significant. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* Mitigation Measure BIO-117, *Avoid Impacts on Rookeries*, and AMM1–AMM7, would reduce this impact to a less-than-significant level.

Tidal habitat restoration could result in increased exposure of cormorants, herons, and egrets to selenium which could result in mortality of special-status species. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. With implementation of AMM27, potential for increased selenium exposure would result in no adverse effect on the species.

The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of cormorants, herons or egrets to methylmercury, through the ingestion of fish in tidally restored areas. However, it is unknown what concentrations of methylmercury are harmful to these species. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

With AMM1-7, AMM27, and CM12 in place, in addition to the implementation of Mitigation Measure BIO-75 and BIO-117 measures in place, indirect effects of plan implementation would not result in a substantial adverse effect on cormorants, herons, and egrets through habitat modification or potential mortality. Therefore, the indirect effects of Alternative 9 implementation would have a less-than-significant impact on cormorants, herons, and egrets.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Measure BIO-117: Avoid Impacts on Rookeries

Herons, egrets, and cormorants are highly traditional in their use of nest sites (rookeries); therefore, DWR will avoid all direct and indirect impacts on rookeries.

Impact BIO-120: Periodic Effects of Inundation on Cormorants, Herons and Egrets as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (CM2) would increase the frequency and duration of inundation of approximately 51–92 acres of modeled breeding habitat for cormorants, herons and egrets. However, increased periodic flooding is not expected to cause any adverse effect on breeding habitat because trees in which nest sites are situated already withstand floods, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and nest sites are located above floodwaters.

Based on hypothetical floodplain restoration, CM5 implementation could result in periodic inundation of up to 266 acres of breeding habitat for cormorants, herons and egrets. The overall effect of seasonal inundation in existing riparian natural communities is likely to be beneficial for these species, because, historically, flooding was the main natural disturbance regulating ecological processes in riparian areas, and flooding promotes the germination and establishment of many native riparian plants.

NEPA Effects: Increased periodic flooding would not be expected to cause any adverse effect on nest sites because trees in which nest sites are situated already withstand floods, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and nest sites are located above floodwaters. Therefore, increased duration of periodic inundation from CM2 and CM5 would not result in an adverse effect on cormorants, herons and egrets.

CEQA Conclusion: Increased periodic flooding would not be expected to cause any adverse effect on nest sites because trees in which nest sites are situated already withstand floods, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and nest sites are located above floodwaters. Therefore, increased duration of periodic inundation from CM2 and CM5 would have a less-than-significant impact on cormorants, herons and egrets.

Short-Eared Owl and Northern Harrier

Modeled habitat for short-eared owl and northern harrier consists of tidal brackish and freshwater emergent wetland, nontidal freshwater perennial emergent wetland, other natural seasonal wetland, grassland, and selected cultivated lands (grain and hay crops, pasture [including alfalfa], rice, truck, nursery, and berry crops [including tomatoes and melons], beets, and idle lands).

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of modeled habitat for short-eared owl and northern harrier as indicated in Table 12-9-46. Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP that would benefit short-eared owl and northern harrier (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 6,000 acres of tidal brackish emergent wetland in CZ 11 including at least 1,500 acres of middle and high marsh (Objectives TBEWNC1.1 and TBEWNC1.2, associated with CM4).
- Restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.2, associated with CM4).
- Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities (Objective NFEW/NPANC1.1, associated with CM10).
- Protect at least 8,000 acres of grassland, with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).
- Protect and enhance at least 8,100 acres of managed wetland, at least 1,500 acres of which are in the Grizzly Island Marsh Complex (Objective MWNC1.1, associated with CM3).
- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4, VPNC2.5, and GNC2.4, associated with CM11).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for these species and implementation of AMM1–AMM7, *AMM27 Selenium Management* and Mitigation Measure BIO-75, impacts on short-eared owl and northern harrier would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-46. Changes in Short-Eared Owl and Northern Harrier Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	Nesting and Foraging	419	419	1,468	1,468	NA	NA
Total Impacts CM1		**419**	**419**	**1,468**	**1,468**	**NA**	**NA**
CM2–CM18	Nesting and Foraging	12,281	46,700	471	1,224	2,926–8,060	5,978
Total Impacts CM2–CM18		**12,281**	**46,700**	**471**	**1,224**	**2,926–8,060**	**5,978**
TOTAL IMPACTS		**12,700**	**47,119**	**1,939**	**2,692**	**2,926–8,060**	**5,978**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-121: Loss or Conversion of Habitat for and Direct Mortality of Short-Eared Owl and Northern Harrier

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 34,689 acres of modeled habitat for short-eared owl and northern harrier (of which 32,369 acres would be a permanent loss and 2,320 acres would be a temporary loss of habitat, Table 12-9-46). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), grassland restoration (CM8), vernal pool and wetland restoration (CM9), marsh restoration (CM10) and construction of conservation hatcheries (CM18). The majority of habitat loss would result from CM4. Habitat enhancement and management activities (CM11), which would include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate short-eared owl and northern harrier modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 1,887 acres of modeled short-eared owl and northern harrier habitat (419 acres of permanent loss, 1,468 acres of temporary loss) from CZs 4, 5, 6, 7, and 8. The majority of habitat removed would be grassland and cultivated lands. However, fringes of tidal freshwater emergent wetland along channels and island edges would also be impacted from construction activities. There are no occurrences of nesting short-eared owl and northern harrier that overlap with the construction footprint of CM1. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address potential effects on short-eared owls and northern harriers if they were to nest in or adjacent to construction activities. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Impacts from CM1 would occur within the first 10 years of Alternative 9 implementation.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo bypass fisheries enhancement would permanently remove 1,021 acres of modeled short-eared owl and northern harrier habitat in the Yolo Bypass in CZ 2. In addition, 471 acres of habitat would be temporarily removed. The impact would primarily consist of loss of acreages of pastures. The conversion is expected to occur during the first 10 years of Alternative 9 implementation.
- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 39,017 acres of modeled short-eared owl and northern harrier habitat. The majority of the losses would be managed wetlands and cultivated lands in CZs 1, 2, 4, 5, 6, 7, 8, 10, and 11. Tidal restoration actions through CM4 would restore an estimated 55,000 acres of tidal natural communities. These restored wetland areas could provide suitable nesting habitat for short-eared owl and northern harrier. Consequently, although existing nesting habitat for short-eared owl and northern harrier would be removed, restoration of wetland habitats is expected to benefit marsh associated ground nesting birds by increasing the extent and value of their nesting habitat. Grizzley Island supports the only known resident population of short-eared owls in the Suisun Marsh and Sacramento-San Joaquin River Delta (Roberson 2008). Grizzley Island does not overlap with the hypothetical footprint for CM4. However, this is an important breeding area for short-eared owl and if restoration footprints were changed during the implementation process of BDCP to overlap with this area, the effects on breeding short-eared owls could likely be adverse. Future NEPA and CEQA analysis would be conducted for restoration projects under BDCP and if restoration was proposed to occur outside of the hypothetical footprints used for this programmatic analysis, potential impacts on these species would be captured in the project-level analysis (Appendix 3B, *Environmental Commitments, AMMs, and CMs*).
- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 2,086 acres of modeled short-eared owl and northern harrier habitat (1,332 permanent, 754 temporary). These losses would be expected to occur along the San Joaquin River and other major waterways in CZ 7.
- *CM7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 623 acres of short-eared owl and northern harrier habitat as part of tidal restoration and 2,479 acres of habitat as part of seasonal floodplain restoration.
- *CM8 Grassland Natural Community Restoration*: Restoration of grassland is expected to be implemented on agricultural lands and would result in the conversion of 1,066 acres of cultivated lands to grassland in CZs 1, 2, 4, 5, 7, 8, and 11. The resulting 2,000 acres of grassland would provide habitat for short-eared owl and northern harrier.
- *CM11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in restored or protected

habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. Habitat management- and enhancement-related activities could short-eared owl and northern harrier nests. If either species were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would be available to minimize these effects.

- *CM18 Conservation Hatcheries*: Implementation of CM18 would remove up to 35 acres of short-eared owl and northern harrier habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1. The loss is expected to occur during the first 10 years of Alternative 9 implementation.
- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect short-eared owl and northern harrier use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7, Mitigation Measure BIO-75, and conservation actions as described below.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged short-eared owl and northern harrier if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to minimize these effects.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 14,639 acres of modeled habitat (12,700 permanent, 1,939 temporary) for short-eared owl and northern harrier in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,887 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration, CM7, Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration*, *CM10 Nontidal Marsh Restoration*, and *CM18 Conservation Hatcheries*—12,752 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of habitat. Using these typical ratios would indicate that 1,887 acres of habitat should be restored and 1,887 acres should be protected to compensate for the CM1 losses of short-eared owl and northern harrier habitat. The near-term effects of other conservation actions would remove 12,752 acres of modeled habitat, and therefore require 12,752 acres of restoration and 12,752 acres of protection of short-eared owl and northern harrier habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, protecting 4,800 acres of managed wetland natural community, protecting 15,400 acres of non-rice cultivated lands, protecting 900 acres of rice or rice equivalent habitat, and restoring 19,150 acres of tidal wetlands (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM4, and CM8 and would occur in the same timeframe as the construction and early restoration losses. The acres of protection and restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and the effects from other near-term restoration actions.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide nesting and foraging habitat for short-eared owl and northern harrier and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) would preserve habitat for short-eared owl and northern harrier (Objective MWNC1.1). Protection and enhancement of managed wetlands to meet this objective would focus on highly degraded areas in order to provide the greatest possible level of enhancement benefit to the managed wetland natural community and associated species. Managed wetland protection and enhancement would be concentrated in Suisun Marsh, which currently supports a high concentration of nesting short-eared owls on Grizzley Island.

The restoration of 19,150 acres of tidal natural communities, including transitional uplands would provide nesting and foraging habitat for short-eared owl and northern harrier. Short-eared owl and northern harrier nest in tidal brackish and freshwater emergent wetland, nontidal freshwater perennial emergent wetland, managed wetland, other natural seasonal wetland, grassland, alkali seasonal wetland, vernal pool complex, and selected cultivated lands, which includes alfalfa, irrigated pasture, and other grain fields. At least 15,400 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1). A minimum of 87% of cultivated lands protected by the late long-term time period would be in alfalfa, irrigated pasture, and other hay crops (Objective SH1.2). This biological objective provides an estimate for the proportion of cultivated lands protected in the near-term time period which would provide suitable nesting and foraging habitat for short-eared owl and northern harrier. These biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

The short-eared owl and the northern harrier are not covered species under the BDCP. For the BDCP to avoid adverse effects on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 406,784 acres of modeled nesting and foraging habitat for short-eared owl and northern harrier. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 49,811 acres of modeled short-eared owl and northern harrier habitat during the term of the Plan (12% of the modeled habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration*, and *CM8 Grassland Natural Community Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, protect 8,100 acres of managed wetland, protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species, and restore at least 65,000 acres of tidal wetlands (Table 3-4 in Chapter 3).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide nesting and foraging habitat for short-eared owl and northern harrier and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) would preserve habitat for short-eared owl and northern harrier (Objective MWNC1.1). Protection and enhancement of managed wetlands to meet this objective would focus on highly degraded areas in order to provide the greatest possible level of enhancement benefit to the managed wetland natural community and associated species. Managed wetland protection and enhancement would be concentrated in Suisun Marsh, which supports a high concentration of nesting short-eared owls on Grizzley Island. At least 1,500 acres of the managed wetlands would be protected and enhanced on Grizzley Island by the late long-term time period. The restoration of 19,150 acres of tidal natural communities, including transitional uplands would provide nesting and foraging habitat for short-eared owl and northern harrier. Short-eared owl and northern harrier nest in open habitats within cultivated lands including alfalfa, irrigated pasture, and other grain fields. A minimum of 87% of the 48,625 acres of cultivated lands protected by the late long-term time period (Objective CLNC1.1) would be managed in alfalfa, irrigated pasture, and other hay crops (Objective SH1.2) which are compatible crop types for these species.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Short-eared owl and northern harrier are not species that are covered under the BDCP. In order for the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that active nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this effect.

NEPA Effects: The loss of short-eared owl and northern harrier habitat and potential direct mortality of these special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection and restoration associated with CM3, CM8, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction period, the effects of short-eared owl and northern harrier habitat loss resulting from Alternative 9 would not be adverse. Short-eared owl and northern harrier are not covered species under the BDCP, and preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75 would be available to address the adverse effect of direct mortality on short-eared owl and northern harrier.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Alternative 9 would remove 14,639 acres of modeled habitat (12,700 permanent, 1,939 temporary) for short-eared owl and northern harrier in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,887 acres), and implementing other conservation measures (*CM2 Yolo*

Bypass Fisheries Enhancement, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration, CM7, Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration*, *CM10 Nontidal Marsh Restoration*, and *CM18 Conservation Hatcheries*—12,752 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of habitat. Using these typical ratios would indicate that 1,887 acres of habitat should be restored and 1,887 acres should be protected to compensate for the CM1 losses of short-eared owl and northern harrier habitat. The near-term effects of other conservation actions would remove 12,752 acres of modeled habitat, and therefore require 12,752 acres of restoration and 12,752 acres of protection of short-eared owl and northern harrier habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, protecting 4,800 acres of managed wetland natural community, protecting 15,400 acres of non-rice cultivated lands, protecting 900 acres of rice or rice equivalent habitat, and restoring 19,150 acres of tidal wetlands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM4, and CM8 and would occur in the same timeframe as the construction and early restoration losses. The acres of protection and restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM and the effects from other near-term restoration actions.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide nesting and foraging habitat for short-eared owl and northern harrier and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) would preserve habitat for short-eared owl and northern harrier (Objective MWNC1.1). Protection and enhancement of managed wetlands to meet this objective would focus on highly degraded areas in order to provide the greatest possible level of enhancement benefit to the managed wetland natural community and associated species. Managed wetland protection and enhancement would be concentrated in Suisun Marsh, which supports a high concentration of nesting short-eared owls on Grizzley Island.

The restoration of 19,150 acres of tidal natural communities, including transitional uplands would provide nesting and foraging habitat for short-eared owl and northern harrier. Short-eared owl and northern harrier nest in tidal brackish and freshwater emergent wetland, nontidal freshwater perennial emergent wetland, managed wetland, other natural seasonal wetland, grassland, alkali seasonal wetland, vernal pool complex, and selected cultivated lands, which includes alfalfa, irrigated pasture, and other grain fields. At least 15,400 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1). A minimum of 87% of cultivated lands protected by the late long-term time period would be in alfalfa, irrigated pasture, and other hay crops (Objective SH1.2). This biological objective provides an estimate for the proportion of cultivated lands protected in the near-term time period which would provide suitable nesting and foraging habitat for short-eared owl and northern harrier. These biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

The short-eared owl and the northern harrier are not covered species under the BDCP. For the BDCP to avoid adverse effects on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. The implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this potential impact to a less-than–significant level.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 406,784 acres of modeled nesting and foraging habitat for short-eared owl and northern harrier. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 49,811 acres of modeled short-eared owl and northern harrier habitat during the term of the Plan (12% of the modeled habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration, and CM8 Grassland Natural Community Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, protect 8,100 acres of managed wetland, protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species, and restore at least 65,000 acres of tidal wetlands (Table 3-4 in Chapter 3).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide nesting and foraging habitat for short-eared owl and northern harrier and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) would preserve habitat for short-eared owl and northern harrier (Objective MWNC1.1). Protection and enhancement of managed wetlands to meet this objective would focus on highly degraded areas in order to provide the greatest possible level of enhancement benefit to the managed wetland natural community and associated species. Managed wetland protection and enhancement would be concentrated in Suisun Marsh, which supports a high concentration of nesting short-eared owls on Grizzley Island. At least 1,500 acres of the managed wetlands would be protected and enhanced on Grizzley Island by the late long-term time period. The restoration of 19,150 acres of tidal natural communities, including transitional uplands would provide nesting and foraging habitat for short-eared owl and northern harrier. Short-eared owl and northern harrier nest in open habitats within cultivated lands including alfalfa, irrigated pasture, and other grain fields. A minimum of 87% of the 48,625 acres of cultivated lands protected by the late long-term time period (Objective CLNC1.1) would be managed in alfalfa, irrigated pasture, and other hay crops (Objective SH1.2) which are compatible crop types for these species.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Short-eared owl and northern harrier are not species that are covered under the BDCP. In order for the BDCP to have a less-than-significant impact on individuals, preconstruction surveys for noncovered avian species would be required to ensure that active nests are detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be reduce the impact to a less-than-significant level.

In the absence of other conservation actions, effects on short-eared owl and northern harrier would represent an adverse effect as a result of habitat modification and potential for direct mortality of special-status species. This impact would be considered significant. Considering these protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7, and Mitigation Measure BIO-75, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of short-eared owl and northern harrier. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on short-eared owl and northern harrier.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-122: Effects on Short-Eared Owl and Northern Harrier Associated with Electrical Transmission Facilities

New transmission lines would increase the risk that short-eared owl and northern harrier could be subject to power line strikes, which could result in injury or mortality of these species. Short-eared owl and northern harrier would be at low risk of bird strike mortality based on their keen eyesight and largely ground-based foraging behavior (BDCP Appendix 5.J, Attachment 5.J-2, *Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). The existing network of transmission lines in the project area currently poses the same small risk for these species, and any incremental risk associated with the new power line corridors would also be expected to be low. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. With the implementation of *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters, which would further reduce any bird strike risk of short-eared owl and northern harrier.

NEPA Effects**:** The construction and presence of new transmission lines would not result in an adverse effect on short-eared owl or northern harrier because the risk of bird strike is considered to be low for both species based on their keen eyesight and behavioral characteristics. New transmission lines would minimally increase the risk for short-eared owl and northern harrier power line strikes. All new transmission lines constructed as a result of the project would be fitted with bird diverters (*AMM20 Greater Sandhill Crane*), which have been shown to reduce avian mortality by 60% and which would further reduce any potential for powerline collisions. Therefore, the construction and operation of transmission lines under Alternative 9 would not result in an adverse effect on short-eared owl or northern harrier.

CEQA Conclusion**:** The construction and presence of new transmission lines would not result in a significant impact on short-eared owl or northern harrier because the risk of bird strike is considered to be low for both species based on their keen eyesight and behavioral characteristics. New transmission lines would minimally increase the risk for short-eared owl and northern harrier power line strikes. All new transmission lines constructed as a result of the project would be fitted with bird diverters (*AMM20 Greater Sandhill Crane*), which have been shown to reduce avian mortality by 60% and which would further reduce any potential for powerline collisions. Therefore, the construction and operation of transmission lines under Alternative 9 would result in a less-than-significant impact on short-eared owl or northern harrier.

Impact BIO-123: Indirect Effects of Plan Implementation on Short-Eared Owl and Northern Harrier

Indirect Construction- and Operation-Related Effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect short-eared owl and northern harrier use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect short-eared owl or northern harrier. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to short-eared owl and northern harrier could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including short-eared owl and northern harrier. Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect short-eared owl and northern harrier, via uptake in lower trophic levels (as described in BDCP Appendix 5.D, *Contaminants*).

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. *CM12 Methylmercury Management* contains provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on short-eared owl and northern harrier.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including short-eared owl and northern harrier. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on short-eared owl and northern harrier.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on short-eared owl and northern harrier from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

***NEPA Effects*:** Noise and visual disturbances from the construction of water conveyance facilities could reduce short-eared owl and northern harrier use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect short-eared owl and northern harrier use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting individuals in addition to AMM1–AMM7. Tidal habitat restoration could result in increased exposure of short-eared owl and northern harrier to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Tidal habitat restoration is unlikely to have an adverse effect on short-eared owl and northern harrier through increased exposure to methylmercury, as these species currently nest and forage in tidal marshes where elevated methylmercury levels exist. However, it is unknown what concentrations of methylmercury are harmful to the species and the potential for increased exposure varies substantially within the study area. Site-specific restoration plans in addition to monitoring and adaptive management, described in CM12 *Methylmercury Management,* would address the uncertainty of methylmercury levels in restored tidal marsh. The site-specific planning phase of marsh restoration would be the appropriate place to assess the potential for risk of methylmercury exposure for short-eared owl and northern harrier, once site specific sampling and other information could be developed.

CEQA Conclusion: Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would have a less-than-significant impact on short-eared owl and northern harrier with the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and AMM1–AMM7. Tidal habitat restoration is unlikely to have a significant impact on short-eared owl and northern harrier through increased exposure to methylmercury, as these species currently nest and forage in tidal marshes where elevated methylmercury levels exist. However, it is unknown what concentrations of methylmercury are harmful to these species. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would better inform potential impacts and address the uncertainty of methylmercury levels in restored tidal marsh in the study area. Tidal habitat restoration could result in increased exposure of short-eared owl and northern harrier to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Therefore, the indirect effects of Alternative 9 implementation would result in a less-than-significant impact on short-eared owl and northern harrier.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-124: Periodic Effects of Inundation on Short-Eared Owl and Northern Harrier as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on approximately 2,926–8,060 acres of modeled short-eared owl and northern harrier habitat (Table 12-9-46).

Based on hypothetical footprints, implementation of *CM5 Seasonally Inundated Floodplain Restoration* could result in the periodic inundation of up to approximately 5,978 acres of modeled habitat (Table 12-9-46), the majority of which would be pasture and other cultivated lands.

Reduced foraging habitat availability may be expected during the fledgling period of the nesting season due to periodic inundation. However, inundation would occur during the nonbreeding season and would not be expected to have an adverse effect on either species.

NEPA Effects: Periodic inundation of floodplains would not result in an adverse effect on short-eared owl and northern harrier because inundation is expected to occur prior to the breeding season.

CEQA Conclusion: Periodic inundation of floodplains would not have a significant impact on short-eared owl and northern harrier because inundation is expected to occur prior to the breeding season.

Redhead and Tule Greater White-Fronted Goose

Impacts, relevant protection and restoration actions, and mitigation requirements under CEQA are discussed for these species in the *General Terrestrial Biology Effects* section under Impacts BIO-178 through BIO-183. Further details of the methods of analysis for waterfowl and shorebirds can be found in the *BDCP Waterfowl and Shorebird Effects Analysis* (Ducks Unlimited 2013).

Mountain Plover

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on mountain plover. Modeled habitat for mountain plover consists of grassland, alkali seasonal wetland, vernal pool complex, alfalfa, grain and hay, pasture, and idle cropland throughout the study area.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of modeled habitat for mountain plover as indicated in Table 12-9-47. Full implementation of Alternative 9 would include the following biological objectives over the term of the BDCP that would benefit the mountain plover (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect at least 8,000 acres of grassland, with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).
- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4, VPNC2.5, GNC2.4, associated with CM11).
- Protect at least 48,625 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species (Objective CLNC1.1, associated with CM3).
- Within the 48,625 acres of protected cultivated lands, protect at least 42,275 acres of cultivated lands as Swainson's hawk foraging habitat with at least 50% in very high-value habitat in CZs 2, 3, 4, 5, 7, 8, 9, and 11 (Objective SH1.2, associated with CM3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species, impacts on mountain plover would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-47. Changes in Mountain Plover Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	Wintering	318	318	1,281	1,281	NA	NA
Total Impacts CM1		**318**	**318**	**1,281**	**1,281**	**NA**	**NA**
CM2–CM18	Wintering	5,450	26,198	376	893	1,158–3,650	3,823
Total Impacts CM2–CM18		**5,450**	**26,198**	**376**	**893**	**1,158–3,650**	**3,823**
TOTAL IMPACTS		**5,768**	**26,516**	**1,657**	**2,174**	**1,158–3,650**	**3,823**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-125: Loss or Conversion of Habitat for and Direct Mortality of Mountain Plover

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 28,690 acres of modeled habitat for mountain plover (25,516 acres of permanent loss and 2,174 of temporary loss, Table 12-9-47). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), riparian restoration (CM7), grassland restoration (CM8), vernal pool and wetland restoration (CM9), nontidal marsh restoration (CM10), and construction of conservation hatcheries (CM18). The majority of habitat loss (20,880 acres) would result from CM4. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, and the construction of recreational trails, signs, and facilities, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate mountain plover modeled wintering habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 1,559 acres of modeled mountain plover habitat (318 acres of permanent loss, 1,281 acres of temporary loss) from CZ 4, 5, 6, and 8. These losses would occur at numerous locations where dredging, construction of operable barriers and canals, and channel enlargement would be undertaken. Other impacts would occur from potential borrow and spoil sites, access roads, barge unloading facilities, and intake and fish screen construction areas. There are no CNDDB occurrences of mountain plover that intersect with the CM1 footprint. However, the study area does overlap with the species' winter range, and there are occurrences west and north of the study area. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Impacts from CM1 would occur within the first 10 years of Alternative 9 implementation.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 1,274 acres of modeled mountain plover wintering habitat (898 acres of permanent loss, 376 acres of temporary loss) in the Yolo Bypass in CZ 2. Impacted habitat would consist primarily of grassland and pasture. Most of the grassland losses would occur at the north end of the bypass below Fremont Weir, along the Toe Drain/Tule Canal, and along the west side channels. Realignment of Putah Creek could also involve excavation and grading in alkali seasonal wetland complex habitat as a new channel is constructed. The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 20,880 acres of modeled mountain plover habitat. The majority of the acres lost would consist of cultivated lands in CZs 1, 2, 4, 5, 6, and/or 7. Grassland losses would likely occur in the vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the upslope fringes of Suisun Marsh, and along narrow bands adjacent to waterways in the South Delta ROA. Tidal restoration would directly impact and fragment grassland just north of Rio Vista in and around French and Prospect Islands, and in an area south of Rio Vista around Threemile Slough. Losses of alkali seasonal wetland complex habitat would likely occur in the south end of the Yolo Bypass and on the northern fringes of Suisun Marsh.

- *CM5 Seasonally Inundated Floodplain Restoration:* Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 1,450 acres of modeled mountain plover habitat (933 permanent, 517 temporary). These losses would be expected after the first 10 years of Alternative 9 implementation along the San Joaquin River and other major waterways in CZ 7.

- *CM7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 370 acres of mountain plover wintering habitat as part of tidal restoration and 1,489 acres of habitat as part of seasonal floodplain restoration.

- *CM8 Grassland Natural Community Restoration* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:* Temporary construction-related disturbance of grassland habitat would result from implementation of CM8 and CM9 in in CZs 1, 2, 4, 5, 7, 8, and 11. However, all areas would be restored after the construction periods. Grassland restoration would be implemented on agricultural lands that also provide wintering habitat for mountain plover and would result in the conversion of 837 acres of cultivated lands to grassland.

- *CM10 Nontidal Marsh Restoration*: Implementation of CM10 would result in the permanent removal of 705 acres of mountain plover habitat.

- *CM11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of mountain plover habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available mountain plover habitat. CM11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. However, approximately 50 acres of grassland habitat would be lost from the construction of trails and facilities.

- *CM18 Conservation Hatcheries:* Implementation of CM18 would remove up to 35 acres of modeled mountain plover habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1.
- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect mountain plover use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7and conservation actions as described below.
- Injury and Direct Mortality: Construction would not be expected to result in direct mortality of mountain plover because foraging individuals would be expected to temporarily avoid the increased noise and activity associated with construction areas.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 7,425 acres (5,768 permanent, 1,657 temporary) of modeled mountain plover wintering habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,599 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—5,826 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 3,198 acres should be protected to compensate for the CM1 losses of 1,599 acres of mountain plover wintering habitat. The near-term effects of other conservation actions would remove 5,826 acres of modeled habitat, and therefore require 11,652 acres of protection of mountain plover habitat using the same typical NEPA and CEQA ratio (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses thereby avoiding adverse effects of habitat loss on mountain plover wintering in the study area. Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand mountain plover wintering habitat and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential wintering habitat for mountain plover (Objective CLNC1.1). Approximately 87% of cultivated lands protected by the late long-term time period would be in alfalfa and pasture crop types (very high- and high-value crop types) for Swainson's hawk (Objective SH1.2) which are also modeled habitat for wintering mountain plover. This biological objective provides an estimate for the high proportion of cultivated lands protected in the near-term time period which would be suitable for mountain plover.

The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on mountain plover, as well as mitigate the near-term effects of the other conservation measures with the consideration that some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would be managed in suitable crop types to compensate for the loss of habitat at a ratio of 2:1. Mitigation Measure BIO-125, *Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat*, would be available to address the adverse effect of habitat loss in the near-term.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

Based on the habitat model, the study area supports approximately 269,411 acres of potential habitat for mountain plover. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 28,690 acres of modeled mountain plover wintering habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration,* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives

ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand habitat for mountain plover and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential wintering habitat for mountain plover (Objective CLNC1.1). Approximately 42,275 acres of cultivated lands protected would be in alfalfa and pasture crop types (very high- and high-value crop types) for Swainson's hawk (Objective SH1.2) which would also provide potential wintering habitat for mountain plover. The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

NEPA Effects: The loss of mountain plover habitat and potential mortality of this special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. However, with habitat protection and restoration associated with CM3, CM8, CM9, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction period, and with implementation of Mitigation Measure BIO-125, *Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat,* the effects of habitat loss and potential for direct mortality on mountain plover under Alternative 9 would not be adverse.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Alternative 9 would remove 7,425 acres (5,768 permanent, 1,657 temporary) of modeled mountain plover wintering habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,599 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—5,826 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 3,198 acres should be protected to compensate for the CM1 losses of 1,599 acres of mountain plover wintering habitat. The near-term effects of other conservation actions would remove 5,826 acres of modeled habitat, and therefore require 11,652 acres of protection of mountain plover habitat using the same typical NEPA and CEQA ratio (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses thereby avoiding significant impacts of habitat loss on mountain plover. Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand wintering habitat for mountain plover and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential wintering habitat for mountain plover (Objective CLNC1.1). Approximately 87% of cultivated lands protected by the late long-term time period would be in alfalfa and pasture crop types (very high- and high-value crop types) for Swainson's hawk (Objective SH1.2) which would also provide potential habitat for mountain plover wintering in the study area. This biological objective provides an estimate for the high proportion of cultivated lands protected in the near-term time period which would provide habitat for mountain plover.

These Plan objectives represent performance standards for considering the effectiveness of conservation actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on mountain plover, as well as mitigate the near-term effects of the other conservation measures with the consideration that some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would be managed in suitable crop types to compensate for the loss of habitat at a ratio of 2:1. The implementation of Mitigation Measure BIO-125, *Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat*, would reduce the impact of habitat loss in the near-term to a less-than-significant level.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 28,690 acres of mountain plover habitat during the term of the Plan (11% of the total habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration,* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand wintering habitat for mountain plover and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential habitat for mountain plover (Objective CLNC1.1). Approximately 42,275 acres of cultivated lands protected would be in alfalfa and pasture crop types (very high- and high-value crop types) for Swainson's hawk (Objective SH1.2) which would also provide habitat for mountain plover.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Considering Alternative 9's protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7 and Mitigation Measure BIO-125, *Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat*, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of mountain plover. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on mountain plover.

Mitigation Measure BIO-125: Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat

DWR will manage and protect sufficient acres of cultivated lands such as pasture, grain and hay crops, or alfalfa to provide habitat for mountain plover such that the total acres of high-value habitat impacted in the near-term timeframe are mitigated at a ratio of 2:1. Additional grassland protection, enhancement, and management may be substituted for the protection of high-value cultivated lands.

Impact BIO-126: Effects on Mountain Plover Associated with Electrical Transmission Facilities

Mountain plovers congregate in flocks during the winter and travel between grasslands and cultivated lands that provide foraging habitat for the species. This flocking behavior puts them at risk of collisions with powerlines. However, plovers exhibit low wing loading and high aspect-ratio wings and as a result can maneuver relatively quickly around an obstacle such as a transmission line. Their wing structure and design allows for rapid flight and quick, evasive actions. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. Plovers are primarily visual foragers and therefore, the risk for collision would be further reduced by *AMM20 Greater Sandhill Crane*, which would require the installation of bird flight diverters on all new transmission lines in the study area.

NEPA Effects: New transmission lines are not expected to have an adverse effect on mountain plover because the probability of bird-powerline strikes is highly unlikely because of plovers' flight behaviors. The implementation of *AMM20 Greater Sandhill Crane* would require the installation of bird flight diverters on all new transmission lines, which would further reduce any potential for mortality. Therefore, the construction and operation of new transmission lines under Alternative 9 would not result in an adverse effect on mountain plover.

CEQA Conclusion: New transmission lines would have a less-than-significant impact on mountain plover because the probability of bird-powerline strikes is highly unlikely because of plovers' flight behaviors. The implementation of *AMM20 Greater Sandhill Crane* would require the installation of bird flight diverters on all new transmission lines, which would further reduce any potential for mortality. Therefore, the construction and operation of new transmission lines under Alternative 9 would result in a less-than-significant impact on mountain plover.

Impact BIO-127: Indirect Effects of Operations and Maintenance of Water Conveyance Facilities on Mountain Plover

Construction- and subsequent maintenance-related noise and visual disturbances could disrupt foraging, and reduce the functions of suitable foraging habitat for mountain plover. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect mountain plover. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7 would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to mountain plover grassland habitat could also have a negative effect on the species. However, AMM1–AMM7 would also ensure that measures would be in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

NEPA Effects: Indirect effects on mountain plover as a result of Alternative 9 implementation could have adverse effects on the species through the modification of habitat. With the With the implementation of AMM1–AMM7, indirect effects as a result of Alternative 9 implementation would not have an adverse effect mountain plover.

CEQA Conclusion: Indirect effects on mountain plover as a result of Alternative 9 implementation could have a significant impact on the species from modification of habitat. With the implementation of AMM1–AMM7, indirect effects as a result of Alternative 9 implementation would have a less-than-significant impact on mountain plover.

Impact BIO-128: Periodic Effects of Inundation on Mountain Plover as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on approximately 1,158–3,650 acres of modeled mountain plover wintering habitat (Table 12-9-47). Based on hypothetical footprints, implementation of *CM5 Seasonally Inundated Floodplain Restoration*, could result in the periodic inundation of up to approximately 3,823 acres of modeled mountain plover habitat (Table 12-9-47).

NEPA Effects: Implementation of CM2 and CM5 would periodically inundate suitable mountain plover foraging habitat. However, effects of periodic inundation would not have an adverse effect on mountain plover because birds would be expected to move to adjacent foraging habitat.

CEQA Conclusion: Implementation of CM2 and CM5 would periodically inundate suitable mountain plover foraging habitat. However, effects of periodic inundation would have a less-than-significant impact on mountain plover because birds would be expected to move to adjacent foraging habitat.

Black Tern

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on black tern. Modeled nesting habitat for black tern in the study area is currently limited to rice in CZ 2.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of modeled habitat for black tern as indicated in Table 12-9-48. Full implementation of Alternative 9 would include the following biological objectives over the term of the BDCP that would benefit the black tern (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect 700 acres of cultivated lands, with at least 500 acres consisting of rice land, to expand upon and buffer newly restored/created nontidal perennial habitat in CZ 2, (Objective GGS2.3, associated with CM3).
- Protect up to 1,700 acres of rice land or equivalent habitat (e.g., perennial wetland) in the Yolo Bypass if this portion meets the criteria specified in CM3, *Reserve Design Requirements by Species*, for giant garter snake. Any remaining acreage (from a total 2,740-acre commitment) will consist of rice land or equivalent-value habitat outside the Yolo Bypass in CZs 1, 2, 4, or 5 (Objective GGS3.1, associated with CM3).
- Restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1, associated with CM4).
- Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities (Objective NFEW/NPANC1.1, associated with CM10).

As explained below, with the restoration and protection of these amounts of habitat, in addition to management activities that would enhance this habitat for the species and implementation of AMM1–AMM7 and Mitigation Measure BIO-75, impacts on black tern would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-48. Changes in Black Tern Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5

CM2–CM18	Nesting	306	490	1	1	791–1,582	0
Total Impacts CM2–CM18		**306**	**490**	**1**	**1**	**791–1,582**	**0**
TOTAL IMPACTS		**306**	**490**	**1**	**1**	**791–1,582**	**0**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-129a: Loss or Conversion of Habitat for and Direct Mortality of Black Tern

Alternative 9 conservation measures would result in the permanent loss of up to 491 acres of modeled nesting habitat for black tern, consisting of freshwater wetlands and rice in CZ 2 (Table 12-9-48). Conservation measures that would result in these losses are Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), grassland restoration (CM8) and nontidal marsh restoration (CM10). Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follows the individual conservation measure discussions.

- *CM2 Yolo Bypass Fisheries Enhancement:* Construction of the Yolo bypass fisheries enhancement would permanently remove 31 acres of modeled black tern habitat in the Yolo Bypass in CZ 2. In addition, 1 acre of habitat would be temporarily removed. The loss is expected to occur during the first 10 years of Alternative 9 implementation.
- *CM4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 199 acres of modeled black tern habitat in CZ 2.
- *CM8 Grassland Natural Community Restoration:* Restoration of grassland is expected to be implemented on agricultural lands and would result in the conversion of 52 acres of rice lands to grassland in CZ 2 by the late-long time period. An estimated 30 acres of impact would occur in the first 10 years.
- *CM10 Nontidal Marsh Restoration:* Implementation of *CM10* would result in the permanent removal of 208 acres of black tern nesting habitat in in CZ 2. An estimated 46 acres would be removed in the first 10 years.

CM11 Natural Communities Enhancement and Management: A variety of habitat management actions that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. Habitat management- and enhancement-related activities could disturb nesting black terns if they were to nest in the vicinity of a worksite. Equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. The potential for these activities to result in direct mortality of black tern would be minimized with the implementation of and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*.

- Operations and Maintenance: Postconstruction operation and maintenance of the restoration infrastructure could result in ongoing but periodic disturbances that could affect black tern nesting adjacent to maintenance areas. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7, Mitigation Measure BIO-75, and conservation actions as described below.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged black tern individuals if they were present in the study area, because they would be expected to avoid contact with construction and other equipment. If black tern were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. These effects would be avoided and minimized with the implementation of Mitigation Measure BIO-75.
- Late season flooding in the Yolo Bypass could result in the loss of rice (nesting habitat for black tern) by precluding the preparation and planting of rice fields. The methods for estimating loss of rice in the bypass and results are provided in BDCP Appendix 5.J, Attachment 5J.E, *Estimation of BDCP Impact on Giant Garter Snake Summer Foraging Habitat in the Yolo Bypass.* This analysis concludes that the estimated loss of rice could be up to 1,662 acres by the late long-term timeframe. This potential impact is further described under Impact BIO-129c below.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. There would be no impacts on black tern nesting habitat resulting from the construction of the water conveyance facilities (CM1). However, there would be a loss of 307 acres of modeled nesting habitat for black tern in the study area in the near-term. These effects would result from implementing *CM2 Yolo Bypass Fisheries Enhancements,*

CM4 Tidal Natural Communities Restoration, CM8 Grassland Natural Community Restoration and *CM10 Nontidal Marsh Restoration.*

The typical NEPA and CEQA project-level mitigation ratio would be 1:1 protection and 1:1 restoration for the loss of black tern habitat. Using this ratio would indicate that 307 acres of rice lands and/or freshwater wetlands should be protected and 307 acres should be restored in CZ 2 to compensate for the losses of black tern nesting habitat.

The BDCP has committed to near-term goals of protecting 200 acres of rice and 700 acres of rice or equivalent habitat and restoring 8,850 acres of tidal freshwater emergent wetland (see Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3 and CM4 and would occur in the same timeframe as the early restoration losses. The BDCP also contains objectives for the giant garter snake to protect at least 500 acres of rice in CZ 2 and to protect up to 1,700 acres of rice land or equivalent habitat in the Yolo Bypass (if this portion meets the criteria specified in CM3, *Reserve Design Requirements by Species* for giant garter snake, Objectives GGS2.3 and GGS 3.1) by the late long-term time period. The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, *Conservation Strategy*) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2).

These objectives would inform the near-term protection actions, and therefore some portion of the 200 acres of rice and 700 acres of rice or equivalent habitat and the 8,850 acres of tidal freshwater emergent wetland would be expected to be restored in CZ 2. However, there is no near-term acreage commitment in the plan that is specific to CZ 2. In order to avoid an adverse effect on black tern from habitat loss, protection and restoration of 307 acres of rice and/or freshwater wetlands would need to occur in CZ 2 in the near-term timeframe. Mitigation Measure BIO-129a, *Compensate for Loss of Black Tern Nesting Habitat*, would be available to address this adverse effect.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, and *AMM6 Disposal and Reuse of Spoils.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Black tern is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of 491 acres of modeled black tern nesting habitat during the term of the Plan. This impact would result from the removal or conversion of rice and freshwater wetlands in CZ 2. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration* to protect 500 acres of rice lands (see Table 3-4 in Chapter 3, *Description of Alternatives*) and up to 1,700 acres of rice lands or equivalent habitat for the giant garter snake (Objective GGS3.1) in CZ 2. The nesting habitat for black tern in the northern part of the study area has largely been reduced to rice lands, and these acres would provide protected nesting habitat for the species. The Plan also includes conservation commitments

through *CM4 Tidal Natural Communities Restoration* to restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, and *AMM6 Disposal and Reuse of Spoils.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Black tern is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this effect.

NEPA Effects**:** The loss of black tern nesting habitat and potential for mortality of this special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection associated with CM3, guided by biological goals and objectives and AMM1–AMM6, which would be in place throughout the construction period, the effects of habitat loss under Alternative 9 would not be adverse under NEPA. Black tern is not a covered species under the BDCP and potential mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this effect.

CEQA Conclusion**:**

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. There would be no impacts on black tern nesting habitat resulting from the construction of the water conveyance facilities (CM1). However, there would be a loss of 307 acres of modeled nesting habitat for black tern in the study area in the near-term. These effects would result from implementing *CM2 Yolo Bypass Fisheries Enhancements, CM4 Tidal Natural Communities Restoration, CM8 Grassland Natural Community Restoration* and *CM10 Nontidal Marsh Restoration.*

The typical NEPA and CEQA project-level mitigation ratio would be 1:1 protection and 1:1 restoration for the loss of black tern nesting habitat. Using this ratio would indicate that 307 acres of rice lands and/or freshwater wetlands should be protected and 307 acres should be restored in CZ 2 to mitigate the losses of black tern nesting habitat.

The BDCP has committed to near-term goals of protecting 200 acres of rice and 700 acres of rice or equivalent habitat habitat and restoring 8,850 acres of tidal freshwater emergent wetland (see Table 3-4 in Chapter 3 *Description of Alternatives*). These conservation actions are associated with CM3 and CM4 and would occur in the same timeframe as the early restoration losses. The BDCP also contains objectives for the giant garter snake to protect at least 500 acres of rice in CZ 2 and to protect up to 1,700 acres of rice land or equivalent habitat in the Yolo Bypass (if this portion meets the criteria specified in CM3, *Reserve Design Requirements by Species* for giant garter snake, Objectives GGS2.3 and GGS 3.1) by the late long-term time period. The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, *Conservation Strategy*) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2).

These objectives would inform the near-term protection actions, and therefore some portion of the 200 acres of rice and 700 acres of rice or equivalent habitat and the 8,850 acres of tidal freshwater emergent wetland would be expected to be restored and protected in CZ 2. However, there is no near-term acreage commitment in the plan that is specific to CZ 2. In order to compensate for black tern habitat loss, the protection and restoration of 307 acres of rice or freshwater wetlands would need to occur in CZ 2 in the near-term timeframe. Mitigation Measure BIO-129a, *Compensate for Loss of Black Tern Nesting Habitat*, would reduce this potential impact to a less-than-significant level.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, and *AMM6 Disposal and Reuse of Spoils.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Black tern is not a covered species under the BDCP. For the BDCP to have a less-than-significant impact on individuals, preconstruction would be required to ensure that nests are detected and avoided. In the absence of other conservation actions, effects on black tern would represent an adverse effect as a result of habitat modification and potential for direct mortality of a special-status species. This impact would be significant. However, the BDCP has committed to habitat protection, restoration, management and enhancement activities described above. As outlined in BDCP Chapter 3, Section 3.4, *Conservation Measures*, natural community restoration and protection are planned so that they keep pace with project impacts. Thus, there would be minimal lag time between impacts and those measures designed to offset those impacts on natural communities and the species that use them. In addition, implementation of AMM1-AMM7, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-129a, *Compensate for Loss of Black Tern Nesting Habitat*, which would require 1:1 protection of habitat in CZ 2 in the near-term time frame, would reduce this potential impact to a less-than-significant level.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of 491 acres of modeled black tern nesting habitat during the term of the Plan. This impact would result from the removal or conversion of rice and freshwater wetlands in CZ 2. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration* to protect 500 acres of rice lands (see Table 3-4 in Chapter 3, *Description of Alternatives*) and up to 1,700 acres of rice lands or equivalent habitat for the giant garter snake (Objective GGS3.1) in CZ 2. The nesting habitat for black tern in the northern part of the study area has largely been reduced to rice lands, and these acres would provide protected nesting habitat for the species. The Plan also includes conservation commitments through *CM4 Tidal Natural Communities Restoration* to restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and*

Countermeasure Plan, and *AMM6 Disposal and Reuse of Spoils.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Black tern is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would identify any nesting terns during preconstruction surveys and ensure that active nests are avoided, which would reduce the potential impact on nesting black tern to a less-than-significant level.

In the absence of other conservation actions, effects on black tern would represent an adverse effect as a result of habitat modification and potential for direct mortality of special-status species. This impact would be significant. Considering these protection provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for habitats lost to construction and restoration activities, loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the alternative would have a less-than-significant impact on black tern.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Mitigation Measure BIO-129a: Compensate for loss of black tern nesting habitat

Because there is no near-term acreage commitment associated with the protection of rice in CZ 2, BDCP proponents must protect rice at a 1:1 ratio for each acre of rice impacted in CZ 2.

Impact BIO-129b: Indirect Effects of Plan Implementation on Black Tern

If black terns were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would avoid the potential for adverse effects of construction-related activities on survival and productivity of nesting black terns. The use of mechanical equipment during restoration activities could cause the accidental release of petroleum or other contaminants that could affect black terns in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including black tern. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy,* for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on black tern.

Because of the uncertainty that exists at this programmatic level of review, there could be an effect on black tern from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

***NEPA Effects*:** Noise and visual disturbances from the construction of conservation components could affect black tern use of modeled habitat adjacent to work areas. Moreover, the use of mechanical equipment for the construction of conservation components could cause the accidental release of petroleum or other contaminants, or the inadvertent discharge of sediment or excess dust adjacent to suitable habitat. AMM1–AMM7, and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting individuals. Tidal habitat restoration could result in increased exposure of black tern to selenium. This effect would be addressed through the implementation of *AMM27 Selenium*

Management, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

***CEQA Conclusion*:** Noise and visual disturbances from the construction of conservation components could affect black tern use of modeled habitat adjacent to work areas. Moreover, the use of mechanical equipment for the construction of conservation components could cause the accidental release of petroleum or other contaminants, or the inadvertent discharge of sediment or excess dust adjacent to suitable habitat which could result in potential mortality of a special-status species. These impacts would be significant. AMM1–AMM7, and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce these impacts to a less-than–significant level. Tidal habitat restoration could result in increased exposure of black tern to selenium, which could result in the mortality of a special-status species. This impact would be significant. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. With AMM27 in place, potential effects of increased exposure of black tern to selenium would be reduced to a less-than-significant impact.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75

Impact BIO-129c: Periodic Effects of Inundation on Black Tern Nesting Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass would inundate 791–1,582 acres of suitable black tern nesting habitat (land currently managed as rice in CZ 2). Inundation would occur during the nonbreeding season but could reduce the availability of nesting habitat during years that flooding extends into the nesting season (past March). Extended inundation of the Yolo Bypass would not be expected to affect black tern nesting habitat. However, if periodic inundation took land out of rice production, this could have an adverse effect on black tern nesting habitat. Late season flooding in the Yolo Bypass could result in the loss of rice (nesting habitat for black tern) by precluding the preparation and planting of rice fields. The methods for estimating loss of rice in the bypass and results are provided in BDCP Appendix 5.J, Attachment 5J.E, *Estimation of BDCP Impact on Giant Garter Snake Summer Foraging Habitat in the Yolo Bypass.* This analysis concludes that the estimated loss of rice could be up to 1,662 acres by the late long-term timeframe. The BDCP has committed to protect, restore and/or create up to 1,700 acres of rice in the Yolo Bypass (Objective GGS3.1). These acres of rice would be protected in areas that are less susceptible to inundation, which would benefit the black tern during years in which the magnitude and duration of inundation were increased.

***NEPA Effects*:** Flooding of the Yolo Bypass is not expected to adversely affect nesting habitat for black tern. However, if flooding were to extend into the nesting season or were to significantly reduce rice production it could also reduce suitable black tern nesting habitat. This potential effect would not be adverse with the creation and/or protection of 1,700 acres of rice in CZ 2 under Objective GGS3.1 in the BDCP.

CEQA Conclusion: Flooding of the Yolo Bypass is not expected to have a significant impact on nesting habitat for black tern. However, if flooding were to extend into the nesting season or were to significantly reduce rice production it could also reduce suitable black tern nesting habitat. This potential impact would be reduced to less than significant by the creation and/or protection of 1,700 acres of rice in CZ 2 under Objective GGS3.1 in the BDCP.

California Horned Lark and Grasshopper Sparrow

The primary impact of concern for grasshopper sparrow and California horned lark would be the loss of breeding habitat in the study area, which consists of grassland, vernal pool complex, and alkali seasonal wetland natural communities and selected cultivated lands including grain and hay crops and pasture. Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of modeled breeding habitat for California horned lark and grasshopper sparrow as indicated in Table 12-9-49. Full implementation of Alternative 9 would include the following biological objectives over the term of the BDCP that would benefit the California horned lark and the grasshopper sparrow (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect at least 8,000 acres of grassland, with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).
- Protect at least 48,625 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species (Objective CLNC1.1, associated with CM3).
- Within the 48,625 acres of protected cultivated lands, protect at least 42,275 acres of cultivated lands as Swainson's hawk foraging habitat with at least 50% in very high-value habitat in CZs 2, 3, 4, 5, 7, 8, 9, and 11 (Objective SH1.2, associated with CM3).
- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4, VPNC2.5, and GNC2.4, associated with CM11).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for these species, and implementation of AMM1–AMM7 and Mitigation Measure BIO-75, impacts on California horned lark and grasshopper sparrow would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-49. Changes in California Horned Lark and Grasshopper Sparrow Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	Breeding	318	318	1,281	1,281	NA	NA
Total Impacts CM1		**318**	**318**	**1,281**	**1,281**	NA	NA
CM2–CM18	Breeding	5,450	26,198	376	893	777–2,423	3,823
Total Impacts CM2–CM18		**5,450**	**26,198**	**376**	**893**	**777–2,423**	**3,823**
TOTAL IMPACTS		**5,768**	**26,516**	**1,657**	**2,174**	**777–2,423**	**3,823**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-130: Loss or Conversion of Habitat for and Direct Mortality of California Horned Lark and Grasshopper Sparrow

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 28,690 acres of modeled breeding habitat for California horned lark and grasshopper sparrow (26,516 acres of permanent loss, 2,174 acres of temporary loss, Table 12-9-49). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), riparian restoration (CM7), grassland restoration (CM8), vernal pool and wetland restoration (CM9), nontidal marsh restoration (CM10), and construction of conservation hatcheries (CM18). The majority of habitat loss (20,880 acres) would result from CM4. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, and the construction of recreational trails, signs, and facilities, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate California horned lark and grasshopper sparrow modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 1,599 acres of potential California horned lark and grasshopper sparrow habitat (318 acres of permanent loss, 1,281 acres of temporary loss) from CZ 4, 5, 6, 7, and 8. These losses would occur at numerous locations where dredging, construction of operable barriers and canals, and channel enlargement would be undertaken. Other impacts would occur from potential borrow and spoil sites, access roads, barge unloading facilities, and intake and fish screen construction areas. Grasshopper sparrows were detected in DHCCP surveys south of Byron Highway in CZ 8 (1 occurrence) and in the Stone Lakes NWR (6 occurrences). However, the CM1 footprint does not overlap with any grasshopper sparrow or California horned lark occurrences. However, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address potential effects on California horned larks and grasshopper sparrows if they were to nest in or adjacent to construction areas. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Impacts from CM1 would occur within the first 10 years of Alternative 9 implementation.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 1,274 acres of modeled California horned lark and grasshopper sparrow habitat (898 acres of permanent loss, 376 acres of temporary loss) in the Yolo Bypass in CZ 2. Impacted habitat would consist primarily of grassland and pasture. Most of the grassland losses would occur at the north end of the bypass below Fremont Weir, along the Toe Drain/Tule Canal, and along the west side channels. Realignment of Putah Creek could also involve excavation and grading in alkali seasonal wetland complex habitat as a new channel is constructed. The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 20,880 acres of modeled California horned lark and grasshopper sparrow habitat. The majority of the acres lost would consist of cultivated lands in CZs 1, 2, 4, 5, 6, and/or 7. Grassland losses would likely occur in the vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the upslope fringes of Suisun Marsh, and along narrow bands adjacent to waterways in the South Delta ROA. Tidal restoration would directly impact and fragment grassland just north of Rio Vista in and around French and Prospect Islands, and in an area south of Rio Vista around Threemile Slough. Losses of alkali seasonal wetland complex habitat would likely occur in the south end of the Yolo Bypass and on the northern fringes of Suisun Marsh.

- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 1,450 acres of modeled California horned lark and grasshopper sparrow nesting habitat (933 permanent, 517 temporary). These losses would be expected after the first 10 years of Alternative 9 implementation along the San Joaquin River and other major waterways in CZ 7.

- *CM7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 370 acres of California horned lark and grasshopper sparrow nesting habitat as part of tidal restoration and 1,489 acres as part of seasonal floodplain restoration.

- *CM8 Grassland Natural Community Restoration* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:* Temporary construction-related disturbance of grassland habitat would result from implementation of CM8 and CM9 in in CZs 1, 2, 4, 5, 7, 8, and 11. However, all areas would be restored after the construction periods. Grassland restoration would be implemented on agricultural lands that also provide nesting habitat for California horned lark and grasshopper sparrow and would result in the conversion of 837 acres of cultivated lands to grassland.

- *CM10 Nontidal Marsh Restoration*: Implementation of CM10 would result in the permanent removal of 705 acres of California horned lark and grasshopper sparrow nesting habitat.
- *CM11 Natural Communities Enhancement and Management:* A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. CM11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. However, approximately 50 acres of grassland habitat would be lost from the construction of trails and facilities.

  Habitat management- and enhancement-related activities could disturb California horned lark and grasshopper sparrow nests. If either species were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these effects.
- *CM18 Conservation Hatcheries:* Implementation of CM18 would remove up to 35 acres of modeled California horned lark and grasshopper sparrow habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1.
- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect California horned lark and grasshopper sparrow use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7, Mitigation Measure BIO-75, and conservation actions as described below.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged California horned lark and grasshopper sparrow if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these effects.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would

provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 7,425 acres (5,768 permanent, 1,657 temporary) of modeled breeding habitat for California horned lark and grasshopper sparrow in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,599 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—5,826 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 3,198 acres should be protected to compensate for the CM1 losses of 1,599 acres of California horned lark and grasshopper sparrow habitat. The near-term effects of other conservation actions would remove 5,826 acres of modeled habitat, and therefore require 11,652 acres of protection of California horned lark and grasshopper sparrow nesting habitat using the same typical NEPA and CEQA ratio (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses thereby avoiding adverse effects of habitat loss on California horned lark and grasshopper sparrow. Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand breeding habitat for California horned lark and grasshopper sparrow and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential nesting habitat for California horned lark and grasshopper sparrow (Objective CLNC1.1). Approximately 87% of cultivated lands protected by the late long-term time period would be in alfalfa and pasture crop types (very high- and high-value crop types) for Swainson's hawk (Objective SH1.2) which would also provide potential nesting habitat for California horned lark and grasshopper sparrow. This biological objective provides an estimate for the high proportion of cultivated lands protected in the near-term time period which would provide nesting habitat for California horned lark and grasshopper sparrow.

The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on California horned lark and grasshopper sparrow, as well as mitigate the near-term effects of the other conservation measures with the consideration that some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would be managed in suitable crop types to compensate for the loss of habitat at a ratio of 2:1. Mitigation Measure BIO-130, *Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat*, would be available to address the adverse effect of habitat loss in the near-term.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

California horned lark and grasshopper sparrow are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 28,690 acres of modeled California horned lark and grasshopper sparrow habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration,* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand breeding habitat for California horned lark and grasshopper sparrow and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential nesting habitat for California horned lark and grasshopper sparrow (Objective CLNC1.1). Approximately 42,275 acres of cultivated lands protected would be in alfalfa and pasture crop types. These are very high- and high-value crop types for Swainson's hawk (Objective SH1.2) and would provide potential nesting habitat for California horned lark and grasshopper sparrow.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. California horned lark and grasshopper sparrow are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

NEPA Effects: The loss of California horned lark and grasshopper sparrow habitat and potential mortality of these special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection and restoration associated with CM3, CM8, CM9, and CM11, guided by biological goals and objectives and AMM1–AMM7, which would be in place throughout the construction period, and with Mitigation Measure BIO-130, *Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat*, the effects of habitat loss under Alternative 9 on California horned lark and grasshopper sparrow would not be adverse under NEPA. California horned lark and grasshopper sparrow are not covered species under the BDCP, and potential mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. Mitigation Measure BIO-75 would be available to address this effect.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Alternative 9 would remove 7,425 acres (5,768 permanent, 1,657 temporary) of modeled breeding habitat for California horned lark and grasshopper sparrow in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,599 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—5,826 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 3,198 acres should be protected to compensate for the CM1 losses of 1,599 acres of California horned lark and grasshopper sparrow habitat. The near-term effects of other conservation actions would remove 5,826 acres of modeled habitat, and therefore require 11,652 acres of protection of California horned lark and grasshopper sparrow nesting habitat using the same typical NEPA and CEQA ratio (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses thereby avoiding significant impacts on California horned lark and grasshopper sparrow. Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand breeding habitat for

California horned lark and grasshopper sparrow and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential nesting habitat for California horned lark and grasshopper sparrow (Objective CLNC1.1). Approximately 87% of cultivated lands protected by the late long-term time period would be in alfalfa and pasture crop types (very high- and high-value crop types) for Swainson's hawk (Objective SH1.2) which would also provide potential nesting habitat for California horned lark and grasshopper sparrow. This biological objective provides an estimate for the high proportion of cultivated lands protected in the near-term time period which would provide nesting habitat for California horned lark and grasshopper sparrow.

The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on California horned lark and grasshopper sparrow, as well as mitigate the near-term effects of the other conservation measures with the consideration that some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would be managed in suitable crop types to compensate for the loss of habitat at a ratio of 2:1. Implementation of Mitigation Measure BIO-130, *Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat*, would reduce the impact of habitat loss in the near-term to a less-than-significant level.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

California horned lark and grasshopper sparrow are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this potential impact to a less-than-significant level.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 28,690 acres of modeled California horned lark and grasshopper sparrow habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration,* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand breeding habitat for California horned lark and grasshopper sparrow and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential nesting habitat for California horned lark and grasshopper sparrow (Objective CLNC1.1). Approximately 42,275 acres of cultivated lands protected would be in alfalfa and pasture crop types (very high- and high-value crop types) for Swainson's hawk (Objective SH1.2) which would also provide potential nesting habitat for California horned lark and grasshopper sparrow. The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. California horned lark and grasshopper sparrow are not covered species under the BDCP. For the BDCP to avoid significant impacts on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Considering Alternative 9's protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7, Mitigation Measure BIO-75, and Mitigation Measure BIO-130, *Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat*, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of California horned lark and grasshopper sparrow. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on California horned lark and grasshopper sparrow.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Mitigation Measure BIO-130: Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat

DWR will manage and protect sufficient acres of cultivated lands such as pasture, grain and hay crops, or alfalfa to provide California horned lark and grasshopper sparrow habitat such that the total acres of habitat impacted in the near-term timeframe are mitigated at a ratio of 2:1 protection. Additional grassland protection, enhancement, and management may be substituted for the protection of cultivated lands.

Impact BIO-131: Effects on California Horned Lark and Grasshopper Sparrow Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes and/or electrocution, which could result in injury or mortality of grasshopper sparrow and California horned lark. The potential for this risk, is considered minimal based on the flight behaviors of each species. Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure. However, this would be expected to have few adverse effects on the grasshopper sparrow and California horned lark local populations.

NEPA Effects: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of grasshopper sparrow and California horned lark. With the implementation of *AMM20 Greater Sandhill Crane*, the effect of new transmission lines on California horned lark and grasshopper sparrow would not be adverse.

CEQA Conclusion: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of grasshopper sparrow and California horned lark. With the incorporation of *AMM20 Greater Sandhill Crane*, new transmission lines would have a less-than-significant impact on grasshopper sparrow and California horned lark.

Impact BIO-132: Indirect Effects of Plan Implementation on Grasshopper Sparrow and California Horned Lark

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect California horned lark and grasshopper sparrow use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect California horned lark or grasshopper sparrow. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to grasshopper sparrow and California horned lark habitat could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

NEPA Effects: Indirect effects on California horned lark and grasshopper sparrow as a result of Alternative 9 implementation could have adverse effects on these species through the modification of habitat and potential direct mortality. California horned lark and grasshopper sparrow are not covered species under the BDCP, and potential mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. In conjunction with AMM1–

AMM7, Mitigation Measure BIO-75 *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

CEQA Conclusion: Indirect effects on grasshopper sparrow and California horned lark as a result of constructing the water conveyance facilities could have a significant impact on these species. The incorporation of AMM1–AMM7 into the BDCP and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-133: Periodic Effects of Inundation on Grasshopper Sparrow and California Horned Lark as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on approximately 1,158–3,650 acres of modeled California horned lark and grasshopper sparrow habitat (Table 12-9-49).

Based on hypothetical footprints, implementation of *CM5 Seasonally Inundated Floodplain Restoration* could result in the periodic inundation of up to approximately 3,823 acres of modeled habitat (Table 12-9-49).

Reduced foraging habitat availability may be expected during the fledgling period of the nesting season due to periodic inundation. However, inundation would occur during the nonbreeding season and would not be expected to have an adverse effect on either species.

NEPA Effects: Periodic inundation of floodplains would not have adverse effects on grasshopper sparrow or California horned lark because inundation is expected to occur prior to the breeding season.

CEQA Conclusion: Periodic inundation of floodplains would not have a significant impact on grasshopper sparrow or California horned lark because inundation is expected to occur prior to the breeding season.

Least Bittern and White-Faced Ibis

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on least bittern and white-faced ibis. Modeled breeding habitat for least bittern and white-faced ibis consists of tidal freshwater and nontidal freshwater emergent wetlands, managed wetlands, and other natural seasonal wetlands in CZs 2, 4, and 11. Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of modeled habitat for least bittern and white-faced ibis as indicated in Table 12-9-50. Full implementation of Alternative 9 would include the following biological objectives over the term of the BDCP that would benefit least bittern and white-faced ibis (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1, associated with CM4).

- Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities (Objective NFEW/NPANC1.1, associated with CM10).
- Protect and enhance at least 8,100 acres of managed wetland, at least 1,500 acres of which are in the Grizzly Island Marsh Complex (Objective MWNC1.1, associated with CM3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for these species, and implementation of AMM1–AMM7, *AMM27 Selenium Management*, and Mitigation Measure BIO-75, impacts on least bittern and white-faced ibis would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-50. Changes in Least Bittern and White-Faced Ibis Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5

Total Impacts CM2–CM18		**5,134**	**13,063**	**45**	**45**	**961–2,672**	**NA**
TOTAL IMPACTS		**5,135**	**13,064**	**45**	**45**	**961–2,672**	**NA**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-134: Loss or Conversion of Habitat for and Direct Mortality of Least Bittern and White-Faced Ibis

Alternative 9 conservation measures would result in the combined permanent and temporary loss and conversion of up to 13,109 acres of modeled habitat for least bittern and white-faced ibis (13,064 acres of permanent loss and conversion and 45 of temporary loss, Table 12-9-50). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), *CM2 Yolo Bypass Fisheries Enhancement*, and *CM4 Tidal Natural Communities Restoration*. Habitat enhancement and management activities (CM11), which would include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate least bittern and white-faced ibis habitat. Each of these individual activities is described below. A summary statement of the combined impacts, NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the permanent loss of 1 acre of modeled least bittern and white-faced ibis habitat from CZ 4. This loss would occur from the fringes of tidal freshwater emergent wetland along channels and island edges that would be impacted from channel dredging activities. The construction footprint for CM1 does not overlap with any occurrences of least bittern or white-faced ibis. The Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Impacts from CM1 would occur within the first 10 years of Alternative 9 implementation.
- *CM2 Yolo Bypass Fisheries Enhancement:* Construction of the Yolo bypass fisheries enhancement would permanently remove 55 acres of modeled least bittern and white-faced ibis habitat in the Yolo Bypass in CZ 2. In addition, 45 acres of habitat would be temporarily removed. The loss is expected to occur during the first 10 years of Alternative 9 implementation.
- *CM4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 13,008 acres of modeled least bittern and white-faced ibis habitat in CZ 2, 4, and 11 by the late long-term time period.
- *CM11 Natural Communities Enhancement and Management:* A variety of habitat management actions included in *CM11 Natural Communities Enhancement and Management* that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of least bittern and white-faced ibis habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available least bittern and white-faced ibis habitat.
- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect least bittern and white-faced ibis use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7described below and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to further reduce potential effects.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of least bittern and white-faced ibis because adults and fledged young would be expected to avoid contact with construction and other equipment. However, if either species were to nest in the construction area, equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these effects.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 5,180 acres of modeled habitat for least bittern and white-faced ibis in the study area in the near-term (5,135 acres of permanent loss, and 45 acres of temporary loss). These effects would result from the construction of the water conveyance facilities (CM1, 1 acre), and the implementation of other conservation measures (Yolo Bypass fisheries enhancement [CM2], and tidal restoration [CM4] 5,179 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 for restoration/creation and 1:1 protection of least bittern and white-faced ibis habitat. Using these ratios would indicate that 1 acre of habitat should be restored and 1 acre of habitat should be protected to compensate for the CM1 losses of 1 acre of least bittern and white-faced ibis habitat. The near-term effects of other conservation actions would remove 5,179 acres of modeled habitat, and therefore require 5,179 acres of restoration and 5,179 acres of protection of least bittern and white-faced ibis habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of restoring 8,850 acres of tidal freshwater emergent wetland and protecting and enhancing 4,800 acres of managed wetland in the Plan Area (Table 3-4 in Chapter 3, *Biological Goals and Objectives*). These conservation actions are associated with CM4 and CM3 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on least bittern and white-faced ibis. The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, *Conservation Strategy*) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The 4,800 acres of managed wetland would be protected and enhanced in CZ 11 and would benefit these species through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 400 acres of nontidal marsh would be created, some of which would provide nesting habitat for least bittern and white-faced ibis. These Plan objectives represent performance standards for considering the effectiveness of restoration and protection actions. The acres of restoration and protection contained in the near-term Plan goals satisfy the typical mitigation that would be applied to the project-level effects of CM1, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan*. All of these AMMs include elements that avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Least bittern and white-faced ibis are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 13,109 acres (13,064 acres of permanent loss, 45 acres of temporary loss) of least bittern and white-faced ibis habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM4 Tidal Natural Communities Restoration* to restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1). In addition, 1,200 acres of nontidal marsh would be created through *CM10 Nontidal Marsh Restoration* and 8,100 acres of managed wetland would be protected and enhanced in CZ 11.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan*. All of these AMMs include elements that avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Least bittern and white-faced ibis are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided.

NEPA Effects: The loss of least bittern and white-faced ibis habitat and potential mortality of these special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. However, with the habitat protection and restoration associated with CM3, CM4, CM6, CM7, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction period, the effects of habitat loss on least bittern and white-faced ibis would not be adverse under Alternative 9. Least bittern and white-faced ibis are not covered species under the BDCP, and the potential for mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. Mitigation Measure BIO-75 would be available to address this effect.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the impacts of construction would be less than significant under CEQA. Alternative 9 would remove 1,580 acres of modeled habitat for least bittern and white-faced ibis in the study area in the near-term (5,135 acres of permanent loss, and 45 acres of temporary loss). These effects would result from the construction of the water conveyance facilities (CM1, 1 acre), and the implementation of other conservation measures (Yolo Bypass fisheries enhancement [CM2], and tidal restoration [CM4] 5,179 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 for restoration/creation and 1:1 protection of least bittern and white-faced ibis habitat. Using these ratios would indicate that 1 acre of habitat should be restored and 1 acre of habitat should be protected to compensate for the CM1 losses of 1 acre of least bittern and white-faced ibis habitat. The near-term effects of other conservation actions would remove 5,179 acres of modeled habitat, and therefore require 5,179 acres of restoration and 5,179 acres of protection of least bittern and white-faced ibis habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal freshwater emergent wetland and 4,800 acres of managed wetland in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM4 and CM3 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on least bittern and white-faced ibis. The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, *Conservation Strategy*) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The 4,800 acres of managed wetland would be protected and enhanced in CZ 11 and would benefit these species through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 400 acres of nontidal marsh would be created, some of which would provide nesting habitat for least bittern and white-faced ibis. These Plan objectives represent performance standards for considering the effectiveness of restoration and protection actions. The acres of restoration and protection contained in the near-term Plan goals satisfy the typical mitigation that would be applied to the project-level effects of CM1, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan*. All of these AMMs include elements that avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS. Least bittern and white-faced ibis are not covered species under the BDCP. For the BDCP to have a less-than-significant impact on individuals, preconstruction surveys would be required to ensure that nests were detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce the potential impact on nesting least bittern and white-faced ibis to a less-than-significant level.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 13,109 acres (13,064 acres of permanent loss, 45 acres of temporary loss) of least bittern and white-faced ibis habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM4 Tidal Natural Communities Restoration* to restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1). In addition, 1,200 acres of nontidal marsh would be created through *CM10 Nontidal Marsh Restoration* and 8,100 acres of managed wetland would be protected and enhanced in CZ 11.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan*. All of these AMMs include elements that avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Least bittern and white-faced ibis are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests were detected and avoided. Implementation of Mitigation Measure BIO-75 would reduce the potential impact on nesting least bittern and white-faced ibis and to a less-than-significant level.

Considering these protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7, and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of least bittern and white-faced ibis. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on least bittern and white-faced ibis.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-135: Effects on Least Bittern and White-Faced Ibis Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of least bittern and white-faced ibis. Waterbirds have a higher susceptibility to collisions than passerines, raptors, and other birds. Bitterns and ibises have a high wing loading/low aspect ratio which limits their maneuverability and make them more vulnerable to collisions rather than more agile species (see BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new project transmission lines would be fitted with flight diverters, which would reduce bird strike risk of least bittern and white-faced ibis.

NEPA Effects: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of least bittern and white-faced ibis. Bitterns and ibises have a high wing loading/low aspect ratio which limits their maneuverability and make them more vulnerable to collisions rather than more agile species. The implementation of *AMM20 Greater*

Sandhill Crane would require the installation of bird flight diverters on all new transmission lines, which could reduce bird strike risk of least bittern and white-faced ibis by 60%. With the installation of bird flight diverters, the construction and operation of new transmission lines under Alternative 9 would not result in an adverse effect on least bittern and white-faced ibis.

CEQA Conclusion: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of least bittern and white-faced ibis. Bitterns and ibises have a high wing loading/low aspect ratio which limits their maneuverability and make them more vulnerable to collisions rather than more agile species. The implementation of *AMM20 Greater Sandhill Crane* would require the installation of bird flight diverters on all new transmission lines, which could reduce bird strike risk of least bittern and white-faced ibis by 60%. With the installation of bird flight diverters, the construction and operation of new transmission lines under Alternative 9 would result in a less-than-significant impact on least bittern and white-faced ibis.

Impact BIO-136: Indirect Effects of Plan Implementation on Least Bittern and White-Faced Ibis

Indirect Construction- and Operation-Related Effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect least bittern and white-faced ibis use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect least bittern or white-faced ibis. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to least bittern and white-faced ibis could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see Chapter 3, *Conservation Strategy*, of the BDCP for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. A detailed review of the methylmercury issues associated with implementation of the BDCP is contained in Appendix 11F, *Substantive BDCP Revisions*. The review includes an overview of the BDCP-related mechanisms that could result in increased mercury in the foodweb, and how exposure to individual species may occur based on feeding habits and where their habitat overlaps with the areas where mercury bioavailability could increase. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect least bittern and white-faced ibis, via uptake in lower trophic levels (as described in Appendix 11F, *Substantive BDCP Revisions*).

Due to the complex and very site-specific factors that determine if mercury becomes mobilized into the foodweb, *CM12 Methylmercury Management* (as revised in Appendix 11F, *Substantive BDCP Revisions*) is included to provide for site-specific evaluation for each restoration project. On a project-specific basis, where high potential for methylmercury production is identified that restoration design and adaptive management cannot fully address while also meeting restoration objectives, alternate restoration areas would be considered. CM12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This conservation measure would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including least bittern and white-faced ibis. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on least bittern and white-faced ibis.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on least bittern and white-faced ibis from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Indirect effects on least bittern and white-faced ibis as a result of constructing the water conveyance facilities could have adverse effects on these species in the absence of other conservation actions. However, the implementation of AMM1–AMM7 would help to reduce this effect. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would also be available to address the adverse indirect effects of construction on active nests. Tidal habitat restoration could result in increased exposure of least bittern and white-faced ibis to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Increased methylmercury associated with natural community and floodplain restoration could indirectly affect least bittern and white-faced ibis, via uptake in lower trophic levels (as described in BDCP Appendix 5.D, *Contaminants*). However, it is unknown what concentrations of methylmercury are harmful to the species, and the potential for increased exposure varies substantially within the study area. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on least bittern and white-faced ibis.

CEQA Conclusion: Indirect effects

of noise and visual disturbance, in addition to the potential for hazardous spills or increased dust on least bittern and white-faced ibis and their habitat as a result of plan implementation would represent a substantial adverse effect in the absence of other conservation actions. This impact would be significant. The incorporation of AMM1–AMM7 into the BDCP and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Tidal habitat restoration could result in increased exposure of least bittern and white-faced ibis to selenium. This effect would be addressed through the implementation of *AMM27 Selenium*

Management, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of least bittern and white-faced ibis to methylmercury in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on least bittern and white-faced ibis.

Indirect effects of plan implementation would represent an adverse effect on least bittern and white-faced ibis in the absence of other conservation measures. This would be a significant impact. With AMM1-7, *AMM27 Selenium Management*, and CM12 in place, and with the implementation of Mitigation Measure BIO-75, indirect effects of plan implementation would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of either species. Therefore, the indirect effects of Alternative 9 plan implementation would have a less-than-significant impact on least bittern and white-faced ibis.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-137: Periodic Effects of Inundation on Least Bittern and White-Faced Ibis as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on approximately 961–2,672 acres of modeled least bittern and white-faced ibis habitat (Table 12-9-50). However, no adverse effects of increased inundation frequency on nesting habitat would be expected because wetland vegetation has persisted under the existing Yolo Bypass flooding regime, and changes to frequency and inundation are within the tolerance of these vegetation types. Inundation would occur in the nonbreeding season and wetlands supporting habitat would not be expected to be affected by flood flows.

NEPA Effects: Periodic inundation of Yolo Bypass would not be expected to have adverse effects on least bittern or white-faced ibis because wetland vegetation has persisted under the existing Yolo Bypass flooding regime, and changes to frequency and inundation are within the tolerance of these vegetation types.

CEQA Conclusion: Periodic inundation of Yolo Bypass would not be expected to have a significant impact on least bittern or white-faced ibis because wetland vegetation has persisted under the existing Yolo Bypass flooding regime, and changes to frequency and inundation are within the tolerance of these vegetation types.

Loggerhead Shrike

Modeled habitat for loggerhead shrike includes both high-value and low-value modeled habitat. High-value habitat includes grassland, vernal pool complex and alkali seasonal wetland natural communities in addition to cultivated lands, including pasture and grain and hay crops. Breeding shrikes require shrubs and tall trees for perching and nest placement, and are generally associated with riparian edge grasslands (Humple 2008) or cultivated lands with associated trees and shrubs. Loggerhead shrike modeled habitat is overestimated because the model does not differentiate between lands with or without associated nesting vegetation. Low-value habitat includes row crops such as truck and berry crops and field crops that are not considered to be valuable habitat for the species but which were included in the model because they may provide foraging opportunities.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of modeled habitat for loggerhead shrike as indicated in Table 12-9-51. Full implementation of Alternative 9 would include the following biological objectives over the term of the BDCP that would benefit loggerhead shrike (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect at least 8,000 acres of grassland, with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).
- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4, VPNC2.5, and GNC2.4, associated with CM11).
- Protect at least 48,625 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species (Objective CLNC1.1, associated with CM3).
- Maintain and protect the small patches of important wildlife habitats that occur in cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3 and CM11).
- Establish 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands at a minimum rate of 400 linear feet per 100 acres (Objective SH2.2, associated with CM11).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for the species, and implementation of AMM1–AMM7 and Mitigation Measure BIO-75, impacts on loggerhead shrike would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-51. Changes in Loggerhead Shrike Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	High-value	318	318	1,281	1,281	NA	NA
	Low-value	55	55	1,231	1,231	NA	NA
Total Impacts CM1		**373**	**373**	**2,512**	**2,512**	**NA**	**NA**
CM2–CM18	High-value	5,450	26,198	376	893	777–2,423	3,823
	Low-value	1,801	17,575	97	624	672–1,996	4,315
Total Impacts CM2–CM18		**7,251**	**43,723**	**474**	**1,517**	**1,830–5,646**	**8,138**
Total High-value		**5,768**	**26,516**	**1,657**	**2,174**		
Total Low-value		**1,856**	**17,630**	**1,328**	**1,855**		
TOTAL IMPACTS		**7,624**	**44,096**	**2,986**	**4,029**		

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-138: Loss or Conversion of Modeled Habitat for and Direct Mortality of Loggerhead Shrike

Alternative 9 conservation measures would result in the combined permanent loss or conversion and temporary loss of up to 48,125 acres of modeled habitat for loggerhead shrike (28,690 acres of which would be high-value habitat, Table 12-9-51). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), channel margin enhancement (CM6), riparian restoration, (CM7), grassland restoration (CM8), vernal pool and wetland restoration (CM9), nontidal marsh restoration (CM10), natural communities enhancement and management (CM11) and construction of conservation hatcheries (CM18). The majority of habitat loss (33,244 acres) would result from CM4. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, and the construction of recreational trails, signs, and facilities, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate loggerhead shrike modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 1,599 acres of high-value loggerhead shrike habitat (318 acres of permanent loss, 1,281 acres of temporary loss). In addition, 1,286 acres of low-value habitat would be removed (55 acres of permanent loss or conversion, 1,231 acres of temporary loss or conversion, Table 12-9-51). These losses would occur at numerous locations where dredging, construction of operable barriers and canals, and channel enlargement would be undertaken. Other impacts would occur from potential borrow and spoil sites, access roads, barge unloading facilities, and intake and fish screen construction areas. Temporarily affected areas (grassland, cultivated lands, and associated shrubs or trees) would be restored within 1 year following completion of construction activities as described *in AMM10 Restoration of Temporarily Affected Natural Communities*.

  Loggerhead shrikes nest in high abundance in shrubs associated with the grasslands to the south and to the west of Clifton Court Forebay. The CM1 construction footprint for the canal that would be constructed south of the Clifton Court Forebay overlaps with two loggerhead shrike occurrences. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address potential effects on nesting loggerhead shrikes. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Construction of the water conveyance facilities would occur in the near-term timeframe.

- *CM2 Yolo Bypass Fisheries Enhancement:* Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 1,274 acres of high-value loggerhead shrike habitat (898 acres of permanent loss, 376 acres of temporary loss) in the Yolo Bypass in CZ 2. In addition, 182 acres of low-value habitat would be removed (85 acres of permanent loss, 97 acres of temporary loss). The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 20,880 acres of high-value loggerhead shrike habitat and 12,364 acres of low-value habitat. The majority of the acres lost would consist of cultivated lands in CZs 1, 2, 4, 5, 6, and/or 7. Grassland losses would likely occur in the vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the upslope fringes of Suisun Marsh, and along narrow bands adjacent to waterways in the South Delta ROA. Tidal restoration would directly impact and fragment grassland just north of Rio Vista in and around French and Prospect Islands, and in an area south of Rio Vista around Threemile Slough. Losses of alkali seasonal wetland complex habitat would likely occur in the south end of the Yolo Bypass and on the northern fringes of Suisun Marsh.

- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 1,450 acres of high-value loggerhead shrike habitat (933 permanent, 517 temporary). These losses would be expected after the first 10 years of Alternative 9 implementation along the San Joaquin River and other major waterways in CZ 7.

- *CM7 Riparian Natural Community Restoration:* Riparian restoration would permanently remove approximately 370 acres of high-value loggerhead shrike habitat as part of tidal restoration and 1,489 acres as part of seasonal floodplain restoration. In addition, 503 acres of low-value habitat would be removed as a part of tidal restoration and 1,971 acres would be removed as part of seasonal floodplain restoration through CM7.

- *CM8 Grassland Natural Community Restoration* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:* Temporary construction-related disturbance of grassland habitat would result from implementation of CM8 and CM9 in in CZs 1, 2, 4, 5, 7, 8, and 11. However, all areas would be restored after the construction periods. Grassland restoration would be implemented on agricultural lands that also provide habitat for loggerhead shrike and would result in the conversion of 1,849 acres of cultivated lands to high-value grassland.

- *CM10 Nontidal Marsh Restoration*: Implementation of CM10 would result in the permanent removal of 705 acres of high-value loggerhead shrike habitat and 735 acres of low-value loggerhead shrike habitat.

- *CM11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. CM11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. However, approximately 50 acres of grassland habitat would be lost from the construction of trails and facilities.

  Habitat management- and enhancement-related activities could disturb loggerhead shrike nests. If the species were to nest in the vicinity of a worksite, equipment operation could destroy nests if shrubs and trees in grasslands or cultivated lands were removed, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these effects.

- *CM18 Conservation Hatcheries*: Implementation of CM18 would remove up to 35 acres of high-value loggerhead shrike habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1. Hatchery construction is expected to occur within the first 10 years of Plan implementation.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect loggerhead shrike use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7, Mitigation Measure BIO-75, and conservation actions as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged loggerhead shrike if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these potential effects.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 7,425 acres (5,768 permanent, 1,657 temporary) of high-value habitat for loggerhead shrike in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,599 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—5,826 acres). In addition, 3,184 acres of low-value habitat would be removed or converted in the near-term (CM1, 1,286 acres; *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—1,898 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 protection of high-value habitat. Using this ratio would indicate that 3,198 acres should be protected to compensate for the loss of high-value habitat from CM1. The near-term effects of other conservation actions would require 11,652 acres of protection to compensate for the loss of high-value shrike habitat using the same typical NEPA and CEQA ratio (2:1 protection for the loss of high-value habitat). The loss of low-value habitat would not require mitigation because a large proportion of the low-value habitat would result from the conversion and enhancement to high-value habitats. In addition, temporary impacts on cultivated lands would be restored relatively quickly after completion of construction.

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would create larger, more expansive patches of high-value habitat for loggerhead shrike and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4).

Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential high-value habitat for loggerhead shrike (Objective CLNC1.1). In addition, there is a commitment in the plan (Objective CLNC1.3) to maintain and protect small patches of trees and shrubs within cultivated lands that would maintain foraging perches and nesting habitat for the species. The establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands would also provide high-value nesting habitat for loggerhead shrike (Objective SH2.2). The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of valley/foothill riparian natural community. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs. *AMM18 Swainson's Hawk* includes a measure to plant large mature trees, including transplanting trees scheduled for removal. Trees would be planted in areas that support high-value Swainson's hawk foraging habitat within or adjacent to conserved cultivated lands, or as a component of the riparian restoration where they are in close proximity to suitable foraging habitat. Locating tree plantings and riparian restoration adjacent to Swainson's hawk foraging habitat would also provide suitable nesting habitat for loggerhead shrike. These Plan objectives represent performance standards for considering the effectiveness of conservation actions.

The combined acres of restoration and protection of 3,660 acres of grassland, vernal pool complex, and alkali seasonal wetland contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 and other near-term effects on loggerhead shrike high-value habitat with the consideration that some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would include suitable high-value crop types for loggerhead shrike. Sufficient acreage of the protected cultivated lands would need to be managed in pasture, alfalfa, or grain and hay crops such that the near-term impacts on high-value habitat were compensated for at a ratio of 2:1. Mitigation Measure BIO-138, *Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat*, would be available to address the adverse effect of near-term high-value habitat loss. With the management and enhancement of cultivated lands including insect prey enhancement through CM3 and CM11, the protection of shrubs and establishment of hedgerows within protected cultivated lands would compensate for any potential effect from the loss of low-value loggerhead shrike foraging habitat.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

The loggerhead shrike is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the combined permanent of and temporary effects on 28,690 acres of high-value habitat and 19,485 acres of low-value loggerhead shrike habitat over the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM7 Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration,* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would create larger, more expansive patches of high-value habitat for loggerhead shrike and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 48,625 acres of potential high-value habitat for loggerhead shrike (Objective CLNC1.1). In addition, there is a commitment in the plan (Objective CLNC1.3) to maintain and protect small patches of trees and shrubs within cultivated lands that would maintain foraging perches and nesting habitat for the species. The establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands would also provide high-value nesting habitat for loggerhead shrike (Objective SH2.2). The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of valley/foothill riparian natural community. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs. *AMM18 Swainson's Hawk* includes a measure to plant large mature trees, including transplanting trees scheduled for removal. Trees would be planted in areas that support high-value Swainson's hawk foraging habitat within or adjacent to conserved cultivated lands, or as a component of the riparian restoration where they are in close proximity to suitable foraging habitat. Locating tree plantings and riparian restoration adjacent to Swainson's hawk foraging habitat would also provide suitable nesting habitat for loggerhead shrike.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. The loggerhead shrike is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this effect.

NEPA Effects: The loss of loggerhead shrike habitat and potential mortality of this special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection and restoration associated with CM3, CM8, CM9, and CM11, guided by biological goals and objectives and by AMM1–AMM6, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM18 Swainson's Hawk*, and with implementation of Mitigation Measure BIO-138, *Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat*, which would be available to guide the near-term protection and management of cultivated lands, the effects of habitat loss on loggerhead shrike under Alternative 9 would not be adverse. Loggerhead shrike is not a covered species under the BDCP, and potential mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this effect.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Alternative 9 would remove 7,425 acres (5,768 permanent, 1,657 temporary) of high-value habitat for loggerhead shrike in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,599 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—5,826 acres). In addition, 3,184 acres of low-value habitat would be removed or converted in the near-term (CM1, 1,286 acres; *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—1,898 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 protection of high-value habitat. Using this ratio would indicate that 3,198 acres should be protected to compensate for the loss of high-value habitat from CM1. The near-term effects of other conservation actions would require 11,652 acres of protection to compensate for the loss of high-value shrike habitat using the same typical NEPA and CEQA ratio (2:1 protection for the loss of high-value habitat). The loss of low-value habitat would not require mitigation because a large proportion of the low-value habitat would result from the conversion and enhancement to high-value habitats. In addition, temporary impacts on cultivated lands would be restored relatively quickly after completion of construction.

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would create larger, more expansive patches of high-value habitat for loggerhead shrike and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential high-value habitat for loggerhead shrike (Objective CLNC1.1). In addition, there is a commitment in the plan (Objective CLNC1.3) to maintain and protect small patches of trees and shrubs within cultivated lands that would maintain foraging perches and nesting habitat for the species. The establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands would also provide high-value nesting habitat for loggerhead shrike (Objective SH2.2). The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of valley/foothill riparian natural community. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs. *AMM18 Swainson's Hawk* includes a measure to plant large mature trees, including transplanting trees scheduled for removal. Trees would be planted in areas that support high-value Swainson's hawk foraging habitat within or adjacent to conserved cultivated lands, or as a component of the riparian restoration where they are in close proximity to suitable foraging habitat. Locating tree plantings and riparian restoration adjacent to Swainson's hawk foraging habitat would also provide suitable nesting habitat for loggerhead shrike. These Plan objectives represent performance standards for considering the effectiveness of conservation actions.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, of the Final EIR/EIS.

In the absence of other conservation actions, the effects on loggerhead shrike habitat would represent an adverse effect as a result of habitat modification and potential direct mortality of a special-status species. This impact would be significant. Loggerhead shrike is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. The combined acres of restoration and protection of 3,660 acres of grassland, vernal pool complex, and alkali seasonal wetland contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 and other near-term effects on loggerhead shrike high-value habitat with the consideration that some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would include suitable high-value crop types for loggerhead shrike. Sufficient acreage of the protected cultivated lands would need to be managed in pasture, alfalfa, or grain and hay crops such that the near-term impacts on high-value habitat were compensated for at a ratio of 2:1. The implementation of Mitigation Measure BIO-138, *Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat*, would reduce the impact of near-term high-value habitat loss to a less-than-significant level.

With the acres of habitat protection and restoration described above, in addition to Mitigation Measure BIO-138, *Compensate for the Near-term Loss of High-Value Loggerhead Shrike Habitat*, Alternative 9 would not result in a substantial adverse effect through loss of high-value habitat. The management and enhancement of cultivated lands including insect prey enhancement through CM3 and CM11, the protection of shrubs and establishment of hedgerows within protected cultivated lands would compensate for any potential substantial impact from the loss of low-value loggerhead shrike foraging habitat. In addition, AMM1–AMM7, and implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would avoid potentially significant impacts on nesting individuals. With these measures in place, Alternative 9 would not result in a substantial adverse effect through habitat modification and would not substantially reduce the number or restrict the range of either species. Therefore, Alternative 9 would have a less-than-significant impact on loggerhead shrike.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the combined permanent of and temporary effects on 28,690 acres of high-value habitat and 19,485 acres of low-value loggerhead shrike habitat over the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM7, Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration,* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would create larger, more expansive patches of high-value habitat for loggerhead shrike and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 48,625 acres of potential high-value habitat for loggerhead shrike (Objective CLNC1.1). In addition, there is a commitment in the plan (Objective CLNC1.3) to maintain and protect small patches of trees and shrubs within cultivated lands that would maintain foraging perches and nesting habitat for the species. The establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands would also provide high-value nesting habitat for loggerhead shrike (Objective SH2.2). The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of valley/foothill riparian natural community. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs. *AMM18 Swainson's Hawk* includes a measure to plant large mature trees, including transplanting trees scheduled for removal. Trees would be planted in areas that support high-value Swainson's hawk foraging habitat within or adjacent to conserved cultivated lands, or as a component of the riparian restoration where they are in close proximity to suitable foraging habitat. Locating tree plantings and riparian restoration adjacent to Swainson's hawk foraging habitat would also provide suitable nesting habitat for loggerhead shrike.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM10 Restoration of Temporarily Affected Natural Communities.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. The loggerhead shrike is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this potential impact to a less-than–significant level.

In the absence of other conservation actions, the effects on loggerhead shrike habitat would represent an adverse effect as a result of habitat modification and potential direct mortality of a special-status species. This impact would be significant. Considering Alternative 9's protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-138, *Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat*, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of loggerhead shrike. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on loggerhead shrike.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Mitigation Measure BIO-138: Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat

Because the BDCP does not include acreage commitments for the protection of crop types in the near-term time period, DWR will manage and protect sufficient acres of cultivated lands such as pasture, grain and hay crops, or alfalfa as high-value loggerhead shrike habitat such that the total acres of high-value habitat impacted in the near-term timeframe are mitigated at a ratio of 2:1. Additional grassland protection, enhancement, and management may be substituted for the protection of high-value cultivated lands.

Impact BIO-139: Effects on Loggerhead Shrike Associated with Electrical Transmission Facilities

Loggerhead shrike's small, relatively maneuverable body, its lack of flocking behavior, and its diurnal foraging behavior contribute to a low risk of collision with the proposed transmission lines. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). For example, Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. As described in *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters, which would substantially reduce any potential for mortality of loggerhead shrike individuals from powerline collisions.

NEPA Effects: Loggerhead shrike's small, relatively maneuverable body, its lack of flocking behavior, and its diurnal foraging behavior contribute to a low risk of collision with the proposed transmission lines In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new transmission lines, which would substantially reduce the risk of bird strike for loggerhead shrike as a result of the project. Therefore, the construction and operation of new transmission lines under Alternative 9 would not result in an adverse effect on loggerhead shrike.

CEQA Conclusion: Loggerhead shrike's small, relatively maneuverable body, its lack of flocking behavior, and its diurnal foraging behavior contribute to a low risk of collision with the proposed transmission lines In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new transmission lines, which would substantially reduce the risk of bird strike for loggerhead shrike as a result of the project. Therefore, the construction and operation of new transmission lines under Alternative 9 would result in a less-than-significant impact on loggerhead shrike.

Impact BIO-140: Indirect Effects of Plan Implementation on Loggerhead Shrike

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect loggerhead shrike use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect loggerhead shrike. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Indirect effects from construction of the new forebay in CZ 8 could result in substantial effects on active loggerhead shrike nests. DHCCP surveys in 2009 detected 10 nest sites south-west of the Clifton Court Forebay (Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*) and the large expanses of grassland in CZ 8 provide high-value nesting habitat for the species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills. The inadvertent discharge of sediment or excessive dust adjacent to loggerhead shrike nesting habitat could also have a negative effect on these species. AMM1–AMM7would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

NEPA Effects: Indirect effects on loggerhead shrike as a result of Alternative 9 implementation could have adverse effects on the species through the modification of habitat and potential for direct mortality. The loggerhead shrike is not a covered species under the BDCP, and the potential for mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. Construction of the new forebay in CZ 8 would have the potential to disrupt nesting loggerhead shrikes in the highly suitable habitat surrounding Clifton Court Forebay and adjacent to work areas. In conjunction with AMM1–AMM7, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

CEQA Conclusion: Indirect effects on loggerhead shrike as a result of Alternative 9 implementation could have a significant impact on the species. Construction of the new forebay in CZ 8 would have the potential to disrupt nesting loggerhead shrikes in the highly suitable habitat surrounding Clifton Court Forebay and adjacent to work areas. The incorporation of AMM1–AMM7 into the BDCP and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-141: Periodic Effects of Inundation on Loggerhead Shrike as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on 1,830–5,646 acres of modeled loggerhead shrike habitat (consisting of approximately 777–2,423 acres of high-value habitat; Table 12-9-51).

Based on hypothetical footprints, implementation of *CM5 Seasonally Inundated Floodplain Restoration* could result in the periodic inundation of up to approximately 8,138 acres of modeled habitat (Table 12-9-51), consisting of 3,823 acres of high-value and 4,315 acres of low-value habitat.

Reduced foraging habitat availability may be expected during the fledgling period of the nesting season due to periodic inundation. However, increased frequency and duration of inundation would occur during the nonbreeding season.

NEPA Effects: Periodic inundation of floodplains would not result in an adverse effect on loggerhead shrike from the modification of habitat. Reduced foraging habitat availability may be expected during the fledgling period of the nesting season due to periodic inundation. However, increased frequency and duration of inundation would occur during the nonbreeding season.

CEQA Conclusion: Periodic inundation of floodplains would result in a less-than-significant impact on loggerhead shrike from the modification of habitat. Reduced foraging habitat availability may be expected during the fledgling period of the nesting season due to periodic inundation. However, increased frequency and duration of inundation would occur during the nonbreeding season.

Song Sparrow "Modesto" Population

The Modesto song sparrow is common and ubiquitous throughout the study area, excluding CZ 11, and modeled habitat for the species includes managed wetlands, tidal freshwater emergent, nontidal freshwater emergent, and valley/foothill riparian vegetation communities.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent removal of Modesto song sparrow habitat in the quantities indicated in Table 12-9-52. Full implementation of Alternative 9 would include the following biological objectives over the term of the BDCP that would benefit Modesto song sparrow (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 5,000 acres of valley/foothill riparian natural community, with at least 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM7).
- Protect at least 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).
- Restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1, associated with CM4).
- Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities (Objective NFEW/NPANC1.1, associated with CM10).
- Create 500 acres of managed wetlands in CZs 3, 4, 5, or 6 (Objectives GSHC1.3 and GSHC1.4, associated with CM10).
- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4, VPNC2.5, and GNC2.4, associated with CM11).
- Maintain and protect the small patches of important wildlife habitats that occur in cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).
- Establish 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands at a minimum rate of 400 linear feet per 100 acres (Objective SH2.2, associated with CM3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to implementation of AMMs and Mitigation Measure BIO-75, impacts on Modesto song sparrow would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-52. Changes in Modesto Song Sparrow Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	Nesting	133	133	418	418	NA	NA
Total Impacts CM1		**133**	**133**	**418**	**418**	**NA**	**NA**
CM2–CM18	Nesting	2,444	3,253	133	169	81–158	284
Total Impacts CM2–CM18		**2,444**	**3,253**	**133**	**169**	**81–158**	**284**
TOTAL IMPACTS		**2,2,577**	**3,386**	**551**	**587**	**81–158**	**284**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-142: Loss or Conversion of Habitat for and Direct Mortality of Modesto Song Sparrow

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 3,973 acres of modeled habitat for Modesto song sparrow (of which 3,386 acres would be a permanent loss and 587 acres would be a temporary loss of habitat, Table 12-9-52). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), and floodplain restoration (CM5). Habitat enhancement and management activities (CM11), which would include ground disturbance and removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate Modesto song sparrow modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 551 acres of modeled Modesto song sparrow habitat (133 acres of permanent loss, 418 acres of temporary loss) from CZ 4, 5, 6, 7, and 8. Most of the permanent loss would occur as wider and deeper channels are dredged in Middle River and Victoria Canal, and as operable barriers and new Sacramento River diversions are constructed in various waterways across the Delta. Temporary losses of habitat would occur primarily along Middle River between Victoria Canal and Mildred Island, where large dredging work areas and operable barrier work areas would be placed. Some of this vegetation may be temporarily removed as dredging progresses, while other areas could remain in place but be temporarily affected by sedimentation and equipment movement associated with dredging. The Modesto song sparrow is ubiquitous throughout the study area. The CM1 construction footprint of permanent impacts overlaps with 63 occurrences of Modesto song sparrow. Permanent impacts include the construction of the canal south of Clifton Court Forebay, channel dredging, instream island dredging, and channel enlargement in Middle River and Victoria Canal, an operable barrier, and a fish screen area. The CM1 footprint of temporary impacts overlaps with 102 occurrences of Modesto song sparrow and the majority of these impacts would be a result of dredging work areas. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address potential effects on nesting Modesto song sparrows. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Construction of the water conveyance facilities would occur in the near-term timeframe.

- *CM2 Yolo Bypass Fisheries Enhancement:* Construction of the Yolo bypass fisheries enhancement would permanently remove 143 acres of modeled Modesto song sparrow habitat in the Yolo Bypass in CZ 2. In addition, 133 acres of habitat would be temporarily removed. These losses would occur in the near-term timeframe and primarily consist of valley/foothill riparian natural community and managed wetland. The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would result in the conversion of an estimated loss of 3,066 acres of modeled Modesto song sparrow habitat by the late long-term timeframe.

- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 80 acres of modeled Modesto song sparrow habitat (44 permanent, 36 temporary). These losses would be expected to occur along the San Joaquin River and other major waterways in CZ 7. The BDCP is expected to restore approximately 5,000 acres of valley/foothill riparian natural community. These lands would be managed as a mosaic of seral stages, age classes, and plant heights, some of which would provide suitable nesting habitat for Modesto song sparrow.

- *CM6 Channel Margin Enhancement:* Channel margin habitat enhancement could result in removal of small amounts of valley/foothill riparian habitat along 20 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur along waterway margins where riparian habitat stringers exist, including levees and channel banks. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs. Some of the restored riparian habitat in the channel margin would be expected to support nesting habitat for Modesto song sparrow.

- *CM11 Natural Communities Enhancement and Management:* A variety of habitat management actions included in *CM11 Natural Communities Enhancement and Management* that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP.

Habitat management- and enhancement-related activities could affect Modesto song sparrow nests. If the individuals were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these effects.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect Modesto song sparrow use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs, and conservation actions as described below.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged Modesto song sparrow if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these effects.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 3,128 acres of modeled habitat (2,557 permanent, 551 temporary) for Modesto song sparrow in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 551 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—2,577 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration/creation and 1:1 protection of habitat. Using these ratios would indicate that 551 acres of suitable habitat should be restored/created and 551 acres should be protected to compensate for the CM1 losses of 551 acres of Modesto song sparrow habitat. The near-term effects of other conservation actions would remove 2,577 acres of modeled habitat, and therefore require 2,577 acres of restoration/creation and 2,577 acres of protection of Modesto song sparrow habitat using the same typical NEPA and CEQA ratios (1:1 for restoration/creation and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of the valley/foothill riparian natural community, restoring 2,000 acres of tidal freshwater emergent wetland, restoring 500 acres of managed wetland, and restoring 400 acres of nontidal marsh in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM4, CM7, and CM10 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on Modesto song sparrow. The majority of the riparian restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*) and would provide suitable Modesto song sparrow nesting habitat. The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The nontidal marsh restoration would occur in CZs2, 4, and/or 5, and the managed wetland restoration would occur in CZs 3, 4, 5, or 6. Both the nontidal marsh and managed wetland restoration are associated with CM10 and would provide nesting habitat for Modesto song sparrow.

The Plan also includes commitments to protect patches of important wildlife habitat on cultivated lands such as trees and shrubs along borders and roadside, riparian corridors, and wetlands (Objective CLNC1.3). In addition, 20- to 30-foot-wide hedgerows would be established along field borders and roadsides, which would provide additional habitat for the species (Objective SH2.2). The management of protected grasslands to increase insect prey through techniques such as the avoidance of use of pesticides (Objectives ASWNC2.4, VPNC2.5, and GNC2.4) would provide further benefits to foraging Modesto song sparrows. These Plan objectives represent performance standards for considering the effectiveness of conservation actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on Modesto song sparrow, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

Modesto song sparrow is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 3,973 acres (3,386 acres of permanent loss, 587 acres of temporary loss) of modeled Modesto song sparrow habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration,* and

CM10 Nontidal Marsh Restoration to protect 750 acres and restore 5,000 acres of the valley/foothill riparian natural community, restore 24,000 acres of tidal freshwater emergent wetland, restore 500 acres of managed wetland, and restore 1,200 acres of nontidal marsh in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). Additional acres of valley/foothill riparian habitat would be restored as a component of channel margin enhancement actions (CM6) along 20 miles of river and slough channels in the Delta, some of which would be expected to support nesting habitat for Modesto song sparrow. Of the 5,000 acres of restored riparian natural communities, a minimum of 3,000 acres of valley/foothill riparian would be restored within the seasonally inundated floodplain, and 1,000 acres would be managed as dense early to mid-successional riparian forest (Objectives VFRNC1.1 and VFRNC1.2). Goals and objectives in the Plan for riparian restoration also include the maintenance and enhancement of structural heterogeneity (Objective VFRNC2.1) which would provide suitable nesting habitat for Modesto song sparrow.

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The nontidal marsh restoration would occur in CZs2, 4, and/or 5, and the managed wetland restoration would occur in CZs 3, 4, 5, or 6. Both the nontidal marsh and managed wetland restoration are associated with CM10 and would provide nesting habitat for Modesto song sparrow.

The Plan includes commitments to protect patches of important wildlife habitat on cultivated lands such as trees and shrubs along borders and roadside, riparian corridors, and wetlands (Objective CLNC1.3). In addition, 20- to 30-foot-wide hedgerows would be established along field borders and roadsides, which would provide additional habitat for the species (Objective SH2.2). The management of protected grasslands to increase insect prey through techniques such as the avoidance of use of pesticides (Objectives ASWNC2.4, VPNC2.5, and GNC2.4) would provide further benefits to foraging Modesto song sparrows. These Plan objectives represent performance standards for considering the effectiveness of conservation actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on Modesto song sparrow, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Modesto song sparrow is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

NEPA Effects: The loss of Modesto song sparrow habitat and potential mortality of this special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection and restoration associated with CM3, CM4, CM6, CM7, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction period, the effects of habitat loss on Modesto song sparrow under Alternative 9 would not be adverse. The Modesto song sparrow is not a covered species under the BDCP, and potential mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. Mitigation Measure BIO-75 would be available to address this effect.

***CEQA Conclusion*:**

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Alternative 9 would remove 3,128 acres of modeled habitat (2,557 permanent, 551 temporary) for Modesto song sparrow in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 551 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—2,577 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration/creation and 1:1 protection of habitat. Using these ratios would indicate that 551 acres of suitable habitat should be restored/created and 551 acres should be protected to compensate for the CM1 losses of 551 acres of Modesto song sparrow habitat. The near-term effects of other conservation actions would remove 2,577 acres of modeled habitat, and therefore require 2,577 acres of restoration/creation and 2,577 acres of protection of Modesto song sparrow habitat using the same typical NEPA and CEQA ratios (1:1 for restoration/creation and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of the valley/foothill riparian natural community, restoring 2,000 acres of tidal freshwater emergent wetland, restoring 500 acres of managed wetland, and restoring 400 acres of nontidal marsh in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM4, CM7, and CM10 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding a significant impact of habitat loss on Modesto song sparrow. The majority of the riparian restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*) and would provide suitable Modesto song sparrow nesting habitat. The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The nontidal marsh restoration would occur in CZs2, 4, and/or 5, and the managed wetland restoration would occur in CZs 3, 4, 5, or 6. Both the nontidal marsh and managed wetland restoration are associated with CM10 and would provide nesting habitat for Modesto song sparrow.

The Plan also includes commitments to protect patches of important wildlife habitat on cultivated lands such as trees and shrubs along borders and roadside, riparian corridors, and wetlands (Objective CLNC1.3). In addition, 20- to 30-foot-wide hedgerows would be established along field borders and roadsides, which would provide additional habitat for the species (Objective SH2.2).

The management of protected grasslands to increase insect prey through techniques such as the avoidance of use of pesticides (Objectives ASWNC2.4, VPNC2.5, and GNC2.4) would provide further benefits to foraging Modesto song sparrows. These Plan objectives represent performance standards for considering the effectiveness of conservation actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on Modesto song sparrow, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Modesto song sparrow is not a covered species under the BDCP. For the BDCP to have a less-than-significant impact on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests were detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 3,973 acres (3,386 acres of permanent loss, 587 acres of temporary loss) of modeled Modesto song sparrow habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration,* and *CM10 Nontidal Marsh Restoration* to protect 750 acres and restore 5,000 acres of the valley/foothill riparian natural community, restore 24,000 acres of tidal freshwater emergent wetland, restore 500 acres of managed wetland, and restore 1,200 acres of nontidal marsh in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). Additional acres of valley/foothill riparian habitat would be restored as a component of channel margin enhancement actions (CM6) along 20 miles of river and slough channels in the Delta, some of which would be expected to support nesting habitat for Modesto song sparrow. Of the 5,000 acres of restored riparian natural communities, a minimum of 3,000 acres of valley/foothill riparian would be restored within the seasonally inundated floodplain, and 1,000 acres would be managed as dense early to mid-successional riparian forest (Objectives VFRNC1.1 and VFRNC1.2). Goals and objectives in the Plan for riparian restoration also include the maintenance and enhancement of structural heterogeneity (Objective VFRNC2.1) which would provide suitable nesting habitat for Modesto song sparrow.

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The nontidal marsh restoration would occur in CZs2, 4, and/or 5, and the managed wetland restoration would occur in CZs 3, 4, 5, or 6. Both the nontidal marsh and managed wetland restoration are associated with CM10 and would provide nesting habitat for Modesto song sparrow.

The Plan includes commitments to protect patches of important wildlife habitat on cultivated lands such as trees and shrubs along borders and roadside, riparian corridors, and wetlands (Objective CLNC1.3). In addition, 20- to 30-foot-wide hedgerows would be established along field borders and roadsides, which would provide additional habitat for the species (Objective SH2.2). The management of protected grasslands to increase insect prey through techniques such as the avoidance of use of pesticides (Objectives ASWNC2.4, VPNC2.5, and GNC2.4) would provide further benefits to foraging Modesto song sparrows. These Plan objectives represent performance standards for considering the effectiveness of conservation actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on Modesto song sparrow, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS. Modesto song sparrow is not a covered species under the BDCP. For the BDCP to minimize direct mortality of individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Considering Alternative 9's protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7 and Mitigation Measure BIO-75, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of Modesto song sparrow. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on Modesto song sparrow.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-143: Effects on Modesto Song Sparrow Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of Modesto song sparrow. Existing lines currently pose this risk for Modesto song sparrow and the incremental increased risk from the construction of new transmission lines is not expected to adversely affect the population.

NEPA Effects: The incremental increased risk of bird-powerline strikes from the construction of new transmission lines would not adversely affect the Modesto song sparrow population.

CEQA Conclusion: The incremental increased risk of bird-powerline strikes from the construction of new transmission lines would have a less-than-significant impact on the Modesto song sparrow population.

Impact BIO-144: Indirect Effects of Plan Implementation on Modesto Song Sparrow

Indirect Construction- and Operation-Related Effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect Modesto song sparrow use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect Modesto song sparrow. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7 including *AMM2 Construction Best Management Practices and Monitoring* would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to Modesto song sparrow could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect Modesto song sparrow, via uptake in lower trophic levels (as described in BDCP Appendix 5.D, *Contaminants*).

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. *CM12 Methylmercury Management* contains provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on Modesto song sparrow.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by

interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009), and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including Modesto song sparrow. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and, therefore, increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 9 restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations are analyzed in Chapter 8, *Water Quality*, which concludes that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on Modesto song sparrow.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on Modesto song sparrow from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Indirect effects on Modesto song sparrow as a result of constructing the Alternative 9 water conveyance facilities could adversely affect individuals in the absence of other conservation actions. The incorporation of AMM1–AMM7 into the BDCP and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would minimize this adverse effect.

The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of Modesto song sparrow to methylmercury. However, it is unknown what concentrations of methylmercury are harmful to the species and the potential for increased exposure varies substantially within the study area. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in *CM12 Methylmercury Management* would address the potential impacts of methylmercury levels in restored tidal marsh in the study area. The site-specific planning phase of marsh restoration would be the appropriate place to assess the potential for risk of methylmercury exposure for Modesto song sparrow, once site specific sampling and other information could be developed.

Tidal habitat restoration could result in increased exposure of Modesto song sparrow to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

CEQA Conclusion: Indirect effects on Modesto song sparrow as a result of constructing the water conveyance facilities could have a significant impact on these species. The incorporation of AMM1–AMM7 into the BDCP and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of Modesto song sparrow to methylmercury. However, it is unknown what concentrations of methylmercury are harmful to the species. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in *CM12 Methylmercury Management* would address the potential impacts of methylmercury levels in restored tidal marsh in the study area.

Tidal habitat restoration could result in increased exposure of Modesto song sparrow to selenium. With implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats, the impact of potential increased exposure to selenium would be less than significant.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-145: Periodic Effects of Inundation on Modesto Song Sparrow as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass (CM2) would inundate 81–158 acres of modeled Modesto song sparrow habitat. However, inundation would occur during the nonbreeding season. Reduced foraging habitat availability would be expected during the fledgling period of the nesting season due to periodic inundation.

Based on hypothetical floodplain restoration, construction of setback levees from seasonally inundated floodplain restoration (CM5) could result in periodic inundation of up to approximately 284 acres of Modesto song sparrow modeled habitat (Table 12-9-52).

The periodic inundation of the Yolo Bypass (CM2) and of seasonal floodplains (CM5) is expected to restore a more natural flood regime in support of wetland and riparian vegetation types that support Modesto song sparrow habitat, but may reduce the availability of nesting habitat during years when flooding extends into the nesting season (past March).

NEPA Effects: Periodic effects of inundation would not result in an adverse effect on Modesto song sparrow because increased frequency and duration of inundation would be expected to restore a more natural flood regime in support of wetland and riparian vegetation types that support Modesto song sparrow habitat.

CEQA Conclusion: Periodic effects of inundation would have a less-than-significant impact on Modesto song sparrow because increased frequency and duration of inundation would be expected to restore a more natural flood regime in support of wetland and riparian vegetation types that support Modesto song sparrow habitat.

Bank Swallow

Bank swallows nest in colonies along rivers, streams, or other water and require fine textured sandy soils in vertical banks to create their burrows. There is little suitable habitat for bank swallow in the study area because most of the erodible banks have been stabilized with of levee revetment. The placement of rock revetment prevents the lateral migration of rivers, removing the natural river process that creates vertical banks through erosion (Bank Swallow Technical Advisory Committee 2013, Stillwater Sciences 2007). An estimated 70–90% of the bank swallow population in California nests along the Sacramento and Feather Rivers upstream of the study area (Bank Swallow Technical Advisory Committee 2013). However, there are three CNDDB records of bank swallow colonies in the study area: two in CZ 2 north of Fremont Weir, and one in CZ 5 on Brannan Island, just west of Twitchell Island.

The closest natural community to represent modeled habitat for bank swallow is valley foothill riparian. Although there are impacts to the valley foothill riparian natural community along the northeast corner of Clifton Court Forebay, at the intermediate forebay, and on Bouldin Island, it is highly unlikely that the habitat in these locations is suitable for bank swallow (alluvial soils that form steep, eroded banks that have not been stabilized with levee revetment). Reusable tunnel material areas are not expected to be colonized by nesting bank swallows, as it is unlikely that the substrate would provide suitable nesting habitat for the species. However, if reusable tunnel material areas were to become suitable for swallows over time, Mitigation Measure BIO-146 *Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized*, would avoid impacts on nesting bank swallows by requiring surveys to be conducted prior to the removal of reusable tunnel material. Construction and restoration associated with Alternative 9 conservation measures would not result in any direct loss of modeled habitat for bank swallow (Table 12-9-53). However, indirect effects of noise and visual disturbance from *CM2 Yolo Bypass Fisheries Enhancement* and *CM4 Tidal Natural Communities Restoration* could impact bank swallow colonies if they are present near work areas. In addition, there is uncertainty with respect to how water flows upstream of the study area would affect bank swallow habitat. As explained below, impacts on bank swallow under Alternative 9 would not be adverse for NEPA purposes and would be less than significant for CEQA purposes with the implementation of mitigation measures to monitor colonies and address the uncertainty of upstream operations on the species.

Table 12-9-53. Changes in Bank Swallow Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-146: Indirect Effects of Implementation of Conservation Components on Bank Swallow

Noise and visual disturbances during restoration activities from *CM2 Yolo Bypass Fisheries Enhancement*, and *CM4 Tidal Natural Communities Restoration* including operation of earthmoving equipment and human activities at work sites, could result in temporary disturbances that cause bank swallow to abandon active nest burrows adjacent to construction areas. Bank swallow colonies with occupied burrows have been recorded in CZ 2 and CZ 5 and construction-related disturbances could result in an adverse effect on individuals. Various activities related to *CM11 Natural Communities Enhancement and Management* could also have indirect impacts on bank swallow.

NEPA Effects: Construction activities associated with habitat restoration could adversely affect bank swallow colonies in the absence of other measures. Noise and visual disturbances could result in adverse effects on bank swallows if active colonies were present within 500 feet of work areas. Mitigation Measure BIO-146, *Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized*, would be available to address this effect.

CEQA Conclusion: Construction activities associated with habitat restoration could result in a significant impact on bank swallow colonies in the absence of other measures. Noise and visual disturbances could result in significant impacts on bank swallows if active colonies were present within 500 feet of work areas. Implementation of Mitigation Measure BIO-146, *Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized*, would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-146: Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized

To the extent practicable, BDCP proponents will not construct conservation components during the bank swallow nesting season (April 1 through August 31). If restoration activities cannot be avoided during nesting season, a qualified biologist will conduct preconstruction surveys to determine if active bank swallow nesting colonies are present within 500 feet of work areas. If no active nesting colonies are present, no further mitigation is required. Reusable tunnel material areas are not expected to be colonized by nesting bank swallows, as it is unlikely that the substrate would provide suitable nesting habitat for the species. However, reusable tunnel material sites could become suitable for swallows over time. Surveys of reusable tunnel material areas that have been present for at least 1 year, allowing the substrate to stabilize, will be conducted prior to the removal of reusable tunnel material.

If active colonies are detected, DWRs will establish a nondisturbance buffer (determined by DWR in consultation with CDFW and the Bank Swallow Technical Advisory Committee) around the colony during the breeding season. In addition, a qualified biologist will monitor any active colony within 500 feet of construction to ensure that construction activities do not affect nest success.

Impact BIO-147: Effects of Upstream Reservoir and Water Conveyance Facilities Operations on Bank Swallow

Bank swallows are a riparian species that have evolved to deal with a dynamic system that changes with annual variation in variables such as rainfall, or late snowpack runoff. The primary threat to the species is loss of nesting habitat from the placement of rock revetment for levee stabilization. Because of this limited available habitat, and the reduction of natural river process, the species is highly sensitive to 1) reductions in winter flows which are necessary to erode banks for habitat creation, and 2) high flows during the breading season. The potential impacts of changes in upstream flows during the breeding season on bank swallows are the flooding of active burrows and destruction of burrows from increased bank sloughing. Bank swallows arrive in California and begin to excavate their burrows in March, and the peak egg-laying occurs during April and May (Bank Swallow Technical Advisory Committee 2013). Therefore, increases in flows after March when the swallows have nested and layed eggs in the burrows could result in the loss of nests. On the Sacramento River, breeding season flows between 14,000 and 30,000 cfs have been associated with localized bank collapses, which resulted in partial or complete colony failure (Stillwater Sciences 2007).

The CALSIM II modeling results of mean monthly flow were analyzed for three flow gauge stations on the Sacramento River (Sacramento River at Keswick, Sacramento River upstream of Red Bluff, Sacramento River at Verona) and two flow gauge stations on the Feather River (Feather River high-flow channel at Thermalito Dam, and Feather River at the confluence with the Sacramento River). Flows were estimated for wet years, above normal years, below normal years, dry years, and critical years. An average also was estimated (see Chapter 5, Section 5.3.1, *Methods for Analysis*, for a description of the model).

On the Sacramento River at the Keswick and Red Bluff gauges, mean monthly flows under Alternative 9 could increase between April and August in average water years based on modeling assumptions (Table 1 in Section 11C.9.1.1 and Table 3 Section 11C.9.1.2 of Appendix 11C, *CALSIM II Model Results Utilized in the Fish Analysis*) which could lead to inundation of active colonies.

However, model outputs indicate that the flows under Existing Conditions and the predicted flows in the late long-term without the project (NAA) show increases in flows during the breeding season (April through August) in these water year types. Similar trends are shown for the Feather River (Table 15 in Section 11C.9.1.8 and Table 17 in Section 11C.9.1.9 of Appendix 11C, *CALSIM II Model Results Utilized in the Fish Analysis*). In addition, at the Keswick flow gauge on the Sacramento River in above normal water years (Table 1 in Section 11C.9.1.1 of Appendix 11C, *CALSIM II Model Results Utilized in the Fish Analysis*) flows are predicted to be greater than 14,000 cfs during the breeding season, which could lead to bank collapse. However, flows of this height are recorded under Existing Conditions at this flow gauge and are also predicted for the late long-term without the project (NAA).

***NEPA Effects*:** High spring flows on the Sacramento and Feather Rivers may already be impacting bank swallow colonies during the breeding season, and predicted flows under Alternative 9 would not differ substantially from those under the No Action Alternative. However, because of the complexity of variables that dictate suitable habitat for the species, there is uncertainty regarding the potential for and magnitude of effects on bank swallow from changes in upstream operations. Soil type, high winter flows, and low spring flows all contribute to successful nesting of bank swallow, and even moderate changes in seasonal flows could have an adverse effect on breeding success for the species. Mitigation Measure BIO-147, *Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area*, would be available to address the uncertainty of potential adverse effects of upstream operations on bank swallow.

***CEQA Conclusion*:** High spring flows on the Sacramento and Feather Rivers may already be impacting bank swallow colonies the breeding season, and predicted flows under Alternative 9 would not differ substantially from those under Existing Conditions. However, because of the complexity of variables that dictate suitable habitat for the species, there is uncertainty regarding the potential for and magnitude of impacts on bank swallow from changes in upstream operations. There are many variables that dictate suitable habitat for the species that cannot be clearly quantified, and seasonal changes in flow could increase or decrease suitable habitat for bank swallow depending on soil type and location of current colonies. Implementation of Mitigation Measure BIO-147, *Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area*, would address this potential significant impact and further determine if additional mitigation is required for bank swallow.

Mitigation Measure BIO-147: Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area

To address the uncertainty of the impact of upstream spring flows on existing bank swallow habitat, DWR will continue to support annual monitoring[1] of existing colonies upstream of the study area. DWR will collect data to be used for quantifying the magnitude of flows that would result in loss of active nest sites or degradation of available nesting habitat, and the extent to which changes in SWP operations attributable solely to the California WaterFix are the cause of such impacts. If DWR determines that changes in SWP operations attributable solely to the

[1] Bank swallow colonies have historically been and are currently monitored by DWR, USFWS, and CDFW in association with the Bank Swallow Technical Advisory Committee, which is a diverse coalition of state and federal agency and nongovernmental organization personnel, created in response to the continued decline of bank swallow populations on the Sacramento River.

California WaterFix have caused loss of active nest sites or degradation of available nesting habitat, replacement habitat will be established at a minimum of 2:1 for the length of bank habitat affected. Replacement habitat will consist of removing bank revetment to create habitat for bank swallow at a location subject to CDFW approval (Bank Swallow Technical Advisory Committee 2013).

Yellow-Headed Blackbird

The habitat model used to assess impacts on yellow-headed blackbird consists of nesting habitat and foraging habitat. Modeled nesting habitat includes tidal freshwater emergent wetland, other natural seasonal wetland, nontidal freshwater perennial emergent wetland, and managed wetland. Modeled foraging habitat for yellow-headed blackbird consists of cultivated lands and noncultivated land cover types known to support abundant insect populations, including corn, pasture, and feedlots.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of yellow-headed blackbird modeled habitat as indicated in Table 12-9-54. Full implementation of Alternative 9 would include the following biological objectives over the term of the BDCP that would benefit yellow-headed blackbird (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1, associated with CM4).
- Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities (Objective NFEW/NPANC1.1, associated with CM10).
- Protect and enhance at least 8,100 acres of managed wetland, at least 1,500 acres of which are in the Grizzly Island Marsh Complex (Objective MWNC1.1, associated with CM3).
- Protect at least 8,000 acres of grassland, with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objective ASWNC1.1, Objective VPNC1.1, associated with CM3).
- Maintain and protect the small patches of important wildlife habitats that occur in cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).
- Protect at least 11,050 acres of high- to very high-value breeding-foraging habitat (Table 12-9-38) in CZs 1, 2, 3, 4, 7, 8, or 11 (Objective TRBL1.3, associated with CM3).
- Increase prey abundance and accessibility for grassland-foraging species (Objective GNC2.4, associated with CM11).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities to enhance habitats for the species, and implementation of AMM1–AMM7, *AMM27 Selenium Management*, and Mitigation Measure BIO-75, impacts on yellow-headed blackbird would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-54. Changes in Yellow-Headed Blackbird Modeled Habitat Associated with Alternative 9

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-148: Loss of Habitat for and Direct Mortality of Yellow-Headed Blackbird

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 43,382 acres of suitable habitat for yellow-headed blackbird (14,189 acres of nesting habitat and 29,193 acres foraging habitat; Table 12-9-54). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), riparian restoration (CM7), grassland restoration (CM8), marsh restoration (CM10), and construction of conservation hatcheries (CM18). Habitat enhancement and management activities (CM11) which include ground disturbance or removal of nonnative vegetation could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate yellow-headed blackbird suitable habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 water conveyance facilities would result in the combined permanent and temporary loss of up to 241 acres of yellow-headed blackbird nesting habitat (72 acres of permanent loss and 169 acres of temporary loss). In addition, 1,615 acres of foraging habitat would be removed (327 acres of permanent loss, 1,288 acres of temporary loss, Table 12-9-54). Impacts from CM1 would occur in the central delta in CZ 4, 5, 6, 7, and 8. Most of the loss of nesting habitat would occur at the channel dredging sites within the Middle River and Victoria Canal. Middle River dredging would occur from Victoria Canal north to Mildred Island, while Victoria Canal dredging would extend from Middle River westward to Old River. Smaller areas would be permanently lost at operable barrier sites adjacent to Middle River and San Joaquin River. impacts on foraging habitat would occur from the construction of the canals in CZ 8 east and south of Clifton Court Forebay and other conveyance structures in CZ 4, 5, 6, 7, and 8. Temporary impacts would primarily occur from borrow and spoil areas and temporary work areas. There are no occurrences of yellow-headed blackbird that overlap with the construction footprint for CM1. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would be available to address potential effects on yellow-headed blackbirds if they were to nest in or adjacent to construction areas. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Impacts from CM1 would occur within the first 10 years of Alternative 9 implementation.

- *CM2 Yolo Bypass Fisheries Enhancement:* Construction of the Yolo bypass fisheries enhancement (CM2) would result in the permanent removal of 29 acres of breeding habitat and 113 acres of nonbreeding habitat for yellow-headed blackbird. In addition, CM2 would result in the temporary loss of 43 acres of breeding habitat for the species. Impacts from CM2 would primarily occur in the near-term timeframe.

- *CM4 Tidal Natural Communities Restoration*: Site preparation and inundation from CM4 would permanently remove or convert an estimated 4,801 acres of breeding habitat. In addition, 3,282 acres of non-breeding habitat would be lost or converted as a result of tidal restoration. However, the resulting 65,000 acres of tidal natural communities would also provide habitat for the species, 24,000 acres of which would be tidal freshwater natural communities providing breeding habitat for yellow-headed blackbird.

- *CM5 Seasonally Inundated Floodplain Restoration/CM7: Riparian Natural Community Restoration:* Construction of setback levees to restore seasonally inundated floodplain and riparian restoration actions (CM5) would permanently and temporarily remove approximately 2,477 acres of suitable yellow-headed blackbird habitat consisting of 2 acres of breeding habitat and 2,475 acres of nonbreeding habitat.

- *CM8 Grassland Natural Community Restoration:* Restoration of grassland is expected to be implemented on agricultural lands and would result in the conversion of 230 acres of yellow-headed blackbird agricultural foraging habitat to grassland foraging habitat in CZs 1, 8, and/or 11. If agricultural lands supporting higher value foraging habitat than the restored grassland were removed, there would be a loss of yellow-headed blackbird foraging habitat value. CM8 would result in the restoration of 2,000 acres of grassland foraging habitat in the Plan Area.

- *CM10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent conversion of 133 acres of cultivated lands foraging habitat to nontidal marsh in CZ 2 and CZ 4. Yellow-headed blackbird nesting habitat may develop along the margins of restored nontidal marsh and restoration would also provide foraging habitat for the species.

- *CM11 Natural Communities Enhancement and Management:* Habitat management- and enhancement-related activities could disturb yellow-headed blackbird nests if they were present near work sites. A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in BDCP-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of yellow-headed blackbird habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, would be expected to have minor effects on available yellow-headed blackbird habitat. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.
- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect yellow-headed blackbird use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and conservation actions as described below.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged yellow-headed blackbird if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment.
- If yellow-headed blackbird were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these adverse effects on yellow-headed blackbird.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 6,100 acres (5,886 acres of permanent loss, 214 acres of temporary loss) of yellow-headed blackbird nesting habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 241 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—5,859 acres). In addition, 7,603 acres (5,939 acres of permanent loss, 1,664 acres of temporary loss) of yellow-headed blackbird foraging habitat would be removed or converted in the near-term (CM1, 1,615acres; *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM10 Nontidal Marsh Restoration*, and *CM18 Conservation Hatcheries*—5,988 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of nesting habitat, and 1:1 protection of foraging habitat. Using these ratios would indicate that 241 acres of nesting habitat should be restored/created and 241 acres should be protected to compensate for the CM1 losses of yellow-headed blackbird nesting habitat. In addition, 1,615 acres of foraging habitat should be protected to compensate for the CM1 losses of yellow-headed blackbird foraging habitat. The near-term effects of other conservation actions would require 5,859 acres each of restoration and protection of breeding habitat and 5,988 acres of protection of foraging habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection of nesting and 1: protection of foraging habitat).

The BDCP has committed to near-term goals of restoring 8,850 acres of tidal freshwater emergent wetland, protecting 4,800 acres of managed wetland, protecting 25 acres and restoring 900 acres of nontidal marsh, protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,600 acres of cultivated lands in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM4, CM8, and CM10 and would occur in the same timeframe as the construction and early restoration losses.

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, *Conservation Strategy*) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The 4,800 acres of managed wetland would be protected and enhanced in CZ 11 and would benefit yellow-headed blackbird through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 900 acres of nontidal marsh would be created, some of which would provide nesting habitat for the species.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide grassland foraging habitat for yellow-headed blackbird. Insect prey availability and abundance would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Within the cultivated lands, important wildlife habitat such as grasslands, ponds, and wetlands would also be protected and maintained as part of the cultivated lands reserve system which would provide additional habitat for yellow-headed blackbird (Objective CLNC1.3).

At least 15,600 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1), much of which would provide foraging habitat for yellow-headed blackbird. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on yellow-headed blackbird habitat, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention*

Plan, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

The yellow-headed blackbird is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

Late Long-Term Timeframe

The study area supports approximately 82,005 acres of modeled nesting habitat and 333,956 acres of modeled foraging habitat for yellow-headed blackbird. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 14,189 acres of potential nesting habitat (17% of the potential nesting habitat in the study area) and the loss or conversion of 29,193 acres of foraging habitat (9% of the foraging habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration, CM8 Grassland Natural Community Restoration,* and *CM10 Nontidal Marsh Restoration* to protect and enhance at least 8,100 acres of managed wetland, restore or create at least 24,000 acres of tidal freshwater emergent wetland, create or restore at least 1,200 acres of nontidal marsh, protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3, *Description of Alternatives*).

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, *Conservation Strategy*) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The managed wetland would be protected and enhanced in CZ 11 and would benefit yellow-headed blackbird through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 1,200 acres of nontidal marsh would be created, some of which would provide nesting habitat for the species.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide grassland foraging habitat for yellow-headed blackbird. Insect prey availability and abundance would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective

SWHA2.2). Within the cultivated lands, important wildlife habitat such as grasslands, ponds, and wetlands would also be protected and maintained as part of the cultivated lands reserve system which would provide additional habitat for yellow-headed blackbird (Objective CLNC1.3). Of the 48,625 acres of cultivated lands that would be protected and enhanced by the late long-term time period (Objective CLNC1.1), 26,300 acres would be managed in moderate to high-value crop types for tricolored blackbird (BDCP Chapter 3, Table 3.3-6). These crop types include pasture, sunflower, alfalfa, and other crop types that would provide high-value foraging habitat for yellow-headed blackbird.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

The yellow-headed blackbird is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

NEPA Effects: The loss of yellow-headed blackbird habitat and potential direct mortality of this special-status species associated with Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection and restoration associated with CM3, CM4, CM8, CM10, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction phase, the effects of habitat loss would not be adverse under Alternative 9. The yellow-headed blackbird is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this effect.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Alternative 9 would remove 6,100 acres (5,886 acres of permanent loss, 214 acres of temporary loss) of yellow-headed blackbird nesting habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 241 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Floodplain Restoration*—5,859 acres). In addition, 7,603 acres (5,939 acres of permanent loss, 1,664 acres of temporary loss) of yellow-headed blackbird foraging habitat would be removed or converted in the near-term (CM1, 1,615 acres; *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal*

Natural Communities Restoration, *CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM10 Nontidal Marsh Restoration*, and *CM18 Conservation Hatcheries*—,988,985 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of nesting habitat, and 1:1 protection of foraging habitat. Using these ratios would indicate that 241 acres of nesting habitat should be restored/created and 241 acres should be protected to compensate for the CM1 losses of yellow-headed blackbird nesting habitat. In addition, 1,615 acres of foraging habitat should be protected to compensate for the CM1 losses of yellow-headed blackbird foraging habitat. The near-term effects of other conservation actions would require 5,859 acres each of restoration and protection of breeding habitat and 5,988 acres of protection of foraging habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection of nesting and 1: protection of foraging habitat).

The BDCP has committed to near-term goals of restoring 8,850 acres of tidal freshwater emergent wetland, protecting 4,800 acres of managed wetland, protecting 25 acres and restoring 900 acres of nontidal marsh, protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,600 acres of cultivated lands in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM4, CM8, and CM10 and would occur in the same timeframe as the construction and early restoration losses.

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, *Conservation Strategy*) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The 4,800 acres of managed wetland would be protected and enhanced in CZ 11 and would benefit yellow-headed blackbird through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 900 acres of nontidal marsh would be created, some of which would provide nesting habitat for the species.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide grassland foraging habitat for yellow-headed blackbird. Insect prey availability and abundance would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Within the cultivated lands, important wildlife habitat such as grasslands, ponds, and wetlands would also be protected and maintained as part of the cultivated lands reserve system which would provide additional habitat for yellow-headed blackbird (Objective CLNC1.3).

At least 15,400 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1), much of which would provide foraging habitat for yellow-headed blackbird. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on yellow-headed blackbird habitat, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

The yellow-headed blackbird is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. The implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce potential impacts on nesting yellow-headed blackbird to a less-than-significant level.

Late Long-Term Timeframe

The study area supports approximately 82,005 acres of modeled nesting habitat and 333,956 acres of modeled foraging habitat for yellow-headed blackbird. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 14,189 acres of potential nesting habitat (17% of the potential nesting habitat in the study area) and the loss or conversion of 29,193 acres of foraging habitat (9% of the foraging habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration*, *CM8 Grassland Natural Community Restoration,* and *CM10 Nontidal Marsh Restoration* to protect and enhance at least 8,100 acres of managed wetland, restore or create at least 24,000 acres of tidal freshwater emergent wetland, create or restore at least 1,200 acres of nontidal marsh, protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3, *Description of Alternatives*).

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, *Conservation Strategy*) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The managed wetland would be protected and enhanced in CZ 11 and would benefit yellow-headed blackbird through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 1,200 acres of nontidal marsh would be created, some of which would provide nesting habitat for the species.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide grassland foraging habitat for yellow-headed blackbird. Insect prey availability and abundance would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Within the cultivated lands, important wildlife habitat such as grasslands, ponds, and wetlands would also be protected and maintained as part of the cultivated lands reserve system which would provide additional habitat for yellow-headed blackbird (Objective CLNC1.3). Of the 48,625 acres of cultivated lands that would be protected and enhanced by the late long-term time period (Objective CLNC1.1), 26,300 acres would be managed in moderate to high-value crop types for tricolored blackbird (BDCP Chapter 3, Table 3.3-6). These crop types include pasture, sunflower, alfalfa, and other crop types that would provide high-value foraging habitat for yellow-headed blackbird.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils,* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. BDCP Appendix 3.C describes the AMMs, which have since been updated and which are provided in Appendix 3B, *Environmental Commitments, AMMs, and CMs*, to the Final EIR/EIS.

The yellow-headed blackbird is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

In the absence of other conservation actions, the effects on yellow-headed blackbird habitat would represent an adverse effect as a result of habitat modification and potential direct mortality of a special-status species. This impact would be significant. Considering Alternative 9's protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts necessary to compensate for habitat lost to construction and restoration activities, and with the implementation of AMM1–AMM7 and Mitigation Measure BIO-75, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of either species. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on yellow-headed blackbird.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-149: Effects on Yellow-Headed Blackbird Associated with Electrical Transmission Facilities

Yellow-headed blackbirds are colonial and have the potential to collide with the proposed transmission lines when migrating in large flocks. However, similar to tricolored blackbird behavior, daily flights associated with foraging likely occur in smaller flocks at heights that are lower than the transmission lines (BDCP Appendix 5.J, Attachment 5.J-2, *Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). For example, Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. As described in *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters, which would reduce the potential for yellow-headed blackbird collision with transmission lines. Transmission line poles and towers also provide perching substrate for raptors, which are predators on yellow-headed blackbird. Although there is potential for transmission lines to result in increased perching opportunities for raptors and result in increased predation pressure on yellow-headed blackbirds, the existing network of transmission lines in the study area currently poses this risk for yellow-headed blackbirds, and any incremental risk associated with the new transmission line corridors would not be expected to affect the study area population. Therefore, it is assumed that the increased risk in predation on yellow-headed blackbird from an increase in raptor perching opportunities would be minimal.

***NEPA Effects*:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of yellow-headed blackbird. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would reduce the potential impact of the construction of new transmission lines on yellow-headed blackbird. The increased risk in predation on yellow-headed blackbird from an increase in raptor perching opportunities would be minimal. Therefore, the construction and operation of new transmission lines under Alternative 9 would not result in an adverse effect on yellow-headed blackbird.

***CEQA Conclusion*:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of yellow-headed blackbird. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would reduce the potential impact of the construction of new transmission lines on yellow-headed blackbird. The increased risk of predation on yellow-headed blackbird from an increase in raptor perching opportunities would be minimal. The construction and operation of new transmission lines under Alternative 9 would not substantially reduce the number or restrict the range of the species and would therefore result in a less-than-significant impact on yellow-headed blackbird.

Impact BIO-150: Indirect Effects of Plan Implementation on Yellow-Headed Blackbird

Indirect Construction- and Operation-Related Effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect yellow-headed blackbird use of suitable habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect yellow-headed blackbird. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect the species in the surrounding habitat.

The inadvertent discharge of sediment or excessive dust adjacent to yellow-headed blackbird habitat could also have a negative effect on the species. Where nests are located above open water, impacts of contamination, dust, and sediment in water could impact fledglings directly, or affect aquatic insect prey, which is important for feeding young. AMM1–AMM7 would minimize the likelihood of spills from occurring and ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including yellow-headed blackbird. Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see Chapter 3, *Conservation Strategy*, of the BDCP for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. A detailed review of the methylmercury issues associated with implementation of the BDCP is contained in Appendix 11F, *Substantive BDCP Revisions*. The review includes an overview of the BDCP-related mechanisms that could result in increased mercury in the foodweb, and how exposure to individual species may occur based on feeding habits and where their habitat overlaps with the areas where mercury bioavailability could increase. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect yellow-headed blackbird, via uptake in lower trophic levels (as described in Appendix 5.D, *Contaminants*, of the BDCP).

Due to the complex and very site-specific factors that determine if mercury becomes mobilized into the foodweb, *CM12 Methylmercury Management* (as revised in Appendix 11F, *Substantive BDCP Revisions*) is included to provide for site-specific evaluation for each restoration project. On a project-specific basis, where high potential for methylmercury production is identified that restoration design and adaptive management cannot fully address while also meeting restoration objectives, alternate restoration areas would be considered. CM12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This conservation measure would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by

interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009), and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including yellow-headed blackbird. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and, therefore, increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 9 restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations are analyzed in Chapter 8, *Water Quality*, which concludes that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on yellow-headed blackbird.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on yellow-headed blackbird from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix 3B, *Environmental Commitments, AMMs, and CMs*). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

***NEPA Effects*:** Noise and visual disturbances from the construction of water conveyance facilities could reduce yellow-headed blackbird use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect yellow-headed blackbird use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting individuals in addition to AMM1–AMM7.

The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of yellow-headed blackbird to methylmercury, in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on yellow-headed blackbird.

Tidal habitat restoration could result in increased exposure of yellow-headed blackbird to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

CEQA Conclusion: In the absence of other conservation actions, noise and visual disturbance, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 9 would represent an adverse effect. This impact would be significant. The implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and AMM1–AMM7, would reduce this impact to a less-than-significant level.

The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of yellow-headed blackbird to methylmercury in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of CM12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on yellow-headed blackbird.

Tidal habitat restoration could result in increased exposure of yellow-headed blackbirdl to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Indirect effects of plan implementation would represent an adverse effect on yellow-headed blackbird in the absence of other conservation measures. This would be a significant impact. With AMM1-7, AMM27, and CM12 in place, and with the implementation of Mitigation Measure BIO-75, indirect effects of plan implementation would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, indirect effects of plan implementation would have a less-than-significant impact on yellow-headed blackbird.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-151: Periodic Effects of Inundation of Yellow-Headed Blackbird Nesting Habitat as a Result of Implementation of Conservation Components
